- **Map.** Maps a source data field selected in the field list on the left of the button to a database column selected in the list on the right. You can map more than one field at a time, but the number of entries selected in both lists must be the same.
- **Unmap.** Removes the mapping for one or more selected database columns. This button is activated when you select a field or database column in the table on the right of the dialog.
- **Add.** Adds one or more source data fields selected in the field list on the left of the button to the list on the right ready for mapping. This button is activated when you select a field in the list on the left and no field with that name exists in the list on the right. Clicking this button maps the selected field to a new database column with the same name. The word <NEW> is displayed after the database column name to indicate that this is a new field.

Merge Rows. You use a key field, such as *Transaction ID*, to merge records with the same value in the key field. This is equivalent to a database "equi-join." Key values must be those of primary keys; that is, they must be unique, and cannot contain null values.

- **Possible keys.** Lists all fields found in all input data sources. Select one or more fields from this list and use the arrow button to add them as key fields for merging records. Any map field with a corresponding mapped database column is available as a key, except that fields added as new database columns (shown with <NEW> after the name) are not available.
- **Keys for merge.** Lists all fields used to merge records from all input data sources based on values of the key fields. To remove a key from the list, select one and use the arrow button to return it to the Possible Keys list. When more than one key field is selected, the option below is enabled.
- **Only include records which exist in database.** Performs a partial join; if the record is in the database and the stream, the mapped fields will be updated.
- **Add records to database.** Performs an outer join; all records in the stream will be merged (if the same record exists in the database) or added (if the record does not yet exist in the database).

To map a source data field to a new database column

1. Click the source field name in the list on the left, under Map Fields.
2. Click the Add button to complete the mapping.

To map a source data field to an existing database column

1. Click the source field name in the list on the left, under Map Fields.
2. Click the column name under Database Column on the right.
3. Click the Map button to complete the mapping.

To remove a mapping

1. In the list on the right, under Field, click the name of the field for which you want to remove the mapping.
2. Click the Unmap button.

To deselect a field in any of the lists

Hold down the CTRL key and click the field name.

-

Database export schema options

On the database export Schema dialog box, you can set options for database export (for databases that support these options), set SQL data types for your fields, specify which fields are primary keys, and customize the `CREATE TABLE` statement generated upon export.

The dialog box has several parts:

- The section at the top (if displayed) contains options for export to a database that supports these options. This section is not displayed if you are not connected to such a database.
- The text field in the center displays the template used to generate the `CREATE TABLE` command, which by default follows the format: `CREATE TABLE <table-name> <(table columns)>`
- The table in the lower portion enables you to specify the SQL data type for each field and to indicate which fields are primary keys as discussed below. The dialog box automatically generates the values of the `<table-name>` and `<(table columns)>` parameters based on the specifications in the table.

Setting database export options

If this section is displayed, you can specify a number of settings for export to the database. The database types that support this feature are as follows.

- SQL Server Enterprise and Developer editions. See the topic [Options for SQL Server](#) for more information.
- Oracle Enterprise or Personal editions. See the topic [Options for Oracle](#) for more information.

Customizing CREATE TABLE statements

Using the text field portion of this dialog box, you can add extra database-specific options to the `CREATE TABLE` statement.

1. Select the Customize CREATE TABLE command check box to activate the text window.
2. Add any database-specific options to the statement. Be sure to retain the text `<table-name>` and `(<table-columns>)` parameters because these are substituted for the real table name and column definitions by IBM® SPSS® Modeler.

Setting SQL data types

By default, IBM SPSS Modeler enables the database server to assign SQL data types automatically. To override the automatic type for a field, find the row corresponding to the field and select the desired type from the drop-down list in the *Type* column of the schema table. You can use Shift-click to select more than one row.

For types that take a length, precision, or scale argument (`BINARY`, `VARBINARY`, `CHAR`, `VARCHAR`, `NUMERIC`, and `NUMBER`), you should specify a length rather than allow the database server to assign an automatic length. For example, specifying a sensible value, such as `VARCHAR(25)`, for length ensures that the storage type in IBM SPSS Modeler will be overwritten if that is your intention. To override the automatic assignment, select *Specify* from the *Type* drop-down list and replace the type definition with the desired SQL type definition statement.

The easiest way to do this is to first select the type that is closest to the desired type definition and then select *Specify* to edit that definition. For example, to set the SQL data type to `VARCHAR(25)`, first set the type to `VARCHAR(length)` from the *Type* drop-down list, and then select *Specify* and replace the text length with the value 25.

Primary keys

If one or more columns in the exported table must have a unique value or combination of values for every row, you can indicate this by selecting the Primary Key check box for each field that applies. Most databases will not allow the table to be modified in a manner that invalidates a primary key constraint and will automatically create an index over the primary key to help enforce this restriction. (Optionally, you can create indexes for other fields in the Indexes dialog box. See the topic [Database Export Index Options](#) for more information.)

- [Options for SQL Server](#)
- [Options for Oracle](#)

Related information

- [Database Export Node](#)
- [Database Node Export Tab](#)
- [Database Export Merge Options](#)
- [Database Export Index Options](#)

Options for SQL Server

Use compression. If selected, creates tables for export with compression.

Compression for. Choose the level of compression.

- Row. Enables row-level compression (for example, the equivalent of `CREATE TABLE MYTABLE (...) WITH (DATA_COMPRESSION = ROW)` ; in SQL).
- Page. Enables page-level compression (for example, `CREATE TABLE MYTABLE (...) WITH (DATA_COMPRESSION = PAGE)` ; in SQL).

Options for Oracle

Oracle settings - Basic option

Use compression. If selected, creates tables for export with compression.

Compression for. Choose the level of compression.

- Default. Enables default compression (for example, `CREATE TABLE MYTABLE (...) COMPRESS` ; in SQL). In this case, it has the same effect as the Basic option.
- Basic. Enables basic compression (for example, `CREATE TABLE MYTABLE (...) COMPRESS BASIC` ; in SQL).

Oracle settings - Advanced option

Use compression. If selected, creates tables for export with compression.

Compression for. Choose the level of compression.

- Default. Enables default compression (for example, `CREATE TABLE MYTABLE (...) COMPRESS`; in SQL). In this case, it has the same effect as the Basic option.
- Basic. Enables basic compression (for example, `CREATE TABLE MYTABLE (...) COMPRESS BASIC`; in SQL).
- OLTP. Enables OLTP compression (for example, `CREATE TABLE MYTABLE (...) COMPRESS FOR OLTP`; in SQL).
- Query Low/High. (Exadata servers only) Enables hybrid columnar compression for query (for example, `CREATE TABLE MYTABLE (...) COMPRESS FOR QUERY LOW`; or `CREATE TABLE MYTABLE (...) COMPRESS FOR QUERY HIGH`; in SQL). Compression for query is useful in data warehousing environments; `HIGH` provides a higher compression ratio than `LOW`.
- Archive Low/High. (Exadata servers only) Enables hybrid columnar compression for archive (for example, `CREATE TABLE MYTABLE (...) COMPRESS FOR ARCHIVE LOW`; or `CREATE TABLE MYTABLE (...) COMPRESS FOR ARCHIVE HIGH`; in SQL). Compression for archive is useful for compressing data that will be stored for long periods of time; `HIGH` provides a higher compression ratio than `LOW`.

Database Export Index Options

The Indexes dialog box enables you to create indexes on database tables exported from IBM® SPSS® Modeler. You can specify the field sets you want to include and customize the `CREATE INDEX` command, as needed.

The dialog box has two parts:

- The text field at the top displays a template that can be used to generate one or more `CREATE INDEX` commands, which by default follows the format:
`CREATE INDEX <index-name> ON <table-name>`
- The table in the lower portion of the dialog box enables you to add specifications for each index you want to create. For each index, specify the index name and the fields or columns to include. The dialog box automatically generates the values of the `<index-name>` and `<table-name>` parameters accordingly.

For example, the generated SQL for a single index on the fields `empid` and `deptid` might look like this:

```
CREATE INDEX MYTABLE_IDX1 ON MYTABLE(EMPID,DEPTID)
```

You can add multiple rows to create multiple indexes. A separate `CREATE INDEX` command is generated for each row.

Customizing the `CREATE INDEX` Command

Optionally, you can customize the `CREATE INDEX` command for all indexes or for a specific index only. This gives you the flexibility to accommodate specific database requirements or options and to apply customizations to all indexes or only specific ones, as needed.

- Select Customize `CREATE INDEX` command at the top of the dialog box to modify the template used for all indexes added subsequently. Note that changes will not automatically apply to indexes that have already been added to the table.
- Select one or more rows in the table and then click Update selected indexes at the top of the dialog box to apply the current customizations to all selected rows.
- Select the Customize check box in each row to modify the command template for that index only.

Note that the values of the `<index-name>` and `<table-name>` parameters are generated automatically by the dialog box based on the table specifications and cannot be edited directly.

BITMAP KEYWORD. If you are using an Oracle database, you can customize the template to create a bitmap index rather than a standard index, as follows:

```
CREATE BITMAP INDEX <index-name> ON <table-name>
```

Bitmap indexes may be useful for indexing columns with a small number of distinct values. The resulting SQL might look this:

```
CREATE BITMAP INDEX MYTABLE_IDX1 ON MYTABLE(COLOR)
```

UNIQUE keyword. Most databases support the `UNIQUE` keyword in the `CREATE INDEX` command. This enforces a uniqueness constraint similar to a primary key constraint on the underlying table.

```
CREATE UNIQUE INDEX <index-name> ON <table-name>
```

Note that for fields actually designated as primary keys, this specification is not necessary. Most databases will automatically create an index for any fields specified as primary key fields within the `CREATE TABLE` command, so explicitly creating indexes on these fields is not necessary. See the topic [Database export schema options](#) for more information.

FILLCODE keyword. Some physical parameters for the index can be fine-tuned. For example, SQL Server enables the user to trade off the index size (after initial creation) against the costs of maintenance as future changes are made to the table.

```
CREATE INDEX MYTABLE_IDX1 ON MYTABLE (EMPID,DEPTID) WITH FILLCODE=20
```

Other Comments

- If an index already exists with the specified name, index creation will fail. Any failures will initially be treated as warnings, allowing subsequent indexes to be created and then re-reported as an error in the message log after all indexes have been attempted.
- For best performance, indexes should be created after data has been loaded into the table. Indexes must contain at least one column.
- Before executing the node, you can preview the generated SQL in the message log.
- For temporary tables written to the database (that is, when node caching is enabled) the options to specify primary keys and indexes are not available. However the system may create indexes on the temporary table as appropriate, depending on how the data is used in downstream nodes. For example, if cached data is subsequently joined by a *DEPT* column, it would make sense to index the cached table on this column.

Indexes and Query Optimization

In some database management systems, once a database table has been created, loaded, and indexed, a further step is required before the optimizer is able to utilize the indexes to speed up query execution on the new table. For example, in Oracle, the cost-based query optimizer requires that a table be analyzed before its indexes can be used in query optimization. The internal ODBC properties file for Oracle (not user-visible) contains an option to make this happen, as follows:

```
# Defines SQL to be executed after a table and any associated indexes
# have been created and populated
table_analysis_sql, 'ANALYZE TABLE <table-name> COMPUTE STATISTICS'
```

This step is executed whenever a table is created in Oracle (regardless of whether primary keys or indexes are defined). If necessary, the ODBC properties file for additional databases can be customized in a similar way - contact Support for assistance.

-

Database export advanced options

When you click the Advanced button from the Database export node dialog box, a new dialog box is displayed in which you can specify technical details for exporting results to a database.

Use batch commit. Select to turn off row-by-row commits to the database.

Batch size. Specifies the number of records to send to the database before committing to memory. Lowering this number provides greater data integrity at the cost of slower transfer speeds. You may want to fine-tune this number for optimal performance with your database.

Use bulk loading. Specifies a method for bulk loading data to the database directly from IBM® SPSS® Modeler. Some experimentation may be required to select which bulk load options are appropriate for a particular scenario.

- Via ODBC. Select to use the ODBC API to execute multiple-row inserts with greater efficiency than normal export to the database. Choose from row-wise or column-wise binding in the options below.
- Via external loader. Select to use a custom bulk loader program specific to your database. Selecting this option activates a variety of options below.

Advanced ODBC Options. These options are available only when Via ODBC is selected. Note that this functionality may not be supported by all ODBC drivers.

- Row-wise. Select row-wise binding to use the `SQLBulkOperations` call for loading data into the database. Row-wise binding typically improves speed compared to the use of parameterized inserts that insert data on a record-by-record basis.
- Column-wise. Select to use column-wise binding for loading data into the database. Column-wise binding improves performance by binding each database column (in a parameterized `INSERT` statement) to an array of *N* values. Executing the `INSERT` statement once causes *N* rows to be inserted into the database. This method can dramatically increase performance.

External Loader Options. When Via external loader is specified, a variety of options are displayed for exporting the dataset to a file and specifying and executing a custom loader program to load the data from that file into the database. IBM SPSS Modeler can interface with external loaders for many popular database systems. Several scripts have been included with the software and are available along with technical documentation under the scripts subdirectory. Note that in order to use this functionality, Python 2.7 must be installed on the same machine as IBM SPSS

Modeler or IBM SPSS Modeler Server, and the `python_exe_path` parameter must be set in the options.cfg file. See the topic [Bulk loader programming](#) for more information.

- Use delimiter. Specifies which delimiter character should be used in the exported file. Select Tab to delimit with tab and Space to delimit with spaces. Select Other to specify another character, such as a comma (,).
- Specify data file. Select to enter the path to use for the data file written during bulk loading. By default, a temporary file is created in the temp directory on the server.
- Specify loader program. Select to specify a bulk loading program. By default, the software searches the scripts subdirectory of the IBM SPSS Modeler installation for a Python script to execute for a given database. Several scripts have been included with the software and are available along with technical documentation under the scripts subdirectory.
- Generate log. Select to generate a log file to the specified directory. The log file contains error information and is useful if the bulk load operation fails.
- Check table size. Select to perform table checking that ensures that the increase in table size corresponds to the number of rows exported from IBM SPSS Modeler.
- Extra loader options. Specifies additional arguments to the loader program. Use double quotes for arguments containing spaces.

Double quotes are included in optional arguments by escaping with a backslash. For example, the option specified as `-comment "This is a \\"comment\\""` includes both the `-comment` flag and the comment itself rendered as `This is a "comment"`.

A single backslash can be included by escaping with another backslash. For example, the option specified as `-specialdir "C:\\\\Test Scripts\\\\"` includes the flag `-specialdir` and the directory rendered as `C:\\Test Scripts\\`.

Bulk loader programming

The Database export node includes options for bulk loading on the Advanced Options dialog box. Bulk loader programs can be used to load data from a text file into a database.

The option Use bulk loading - via external loader configures IBM® SPSS® Modeler to do three things:

- Create any required database tables.
- Export the data to a text file.
- Invoke a bulk loader program to load the data from this file into the database table.

Typically the bulk loader program is not the database load utility itself (for example, Oracle's sqlldr utility) but a small script or program which forms the correct arguments, creates any database-specific auxiliary files (such as a control file) and then invokes the database load utility. The information in the following sections will help you edit an existing bulk loader.

Alternatively you can write your own program for bulk loading. See the topic [Developing bulk loader programs](#) for more information. Note that this is not covered under a standard Technical Support agreement, and you should contact an IBM Services representative for assistance.

Scripts for bulk loading

IBM SPSS Modeler ships with a number of bulk loader programs for different databases that are implemented using Python scripts. When you run a stream containing a Database export node with the Via external loader option selected, IBM SPSS Modeler creates the database table (if required) via ODBC, exports the data to a temporary file on the host running IBM SPSS Modeler Server, then invokes the bulk load script. This script in turn executes utilities provided by the DBMS vendor to upload data from the temporary files to the database.

Notes:

- The IBM SPSS Modeler installation does not include a Python runtime interpreter, so a separate installation of Python is required. See the topic [Database export advanced options](#) for more information.
- Scripts are provided (in the \scripts folder of the IBM SPSS Modeler installation directory) for the databases listed in the following table.
- Currently, the Bulk loader scripts provided by IBM SPSS Modeler don't support LDAP.

Table 1. Bulk loader scripts provided

Database	Script name	Further information
IBM Db2	db2_loader.py	See the topic Bulk loading data to IBM Db2 databases for more information.
IBM Netezza	netezza_loader.py	See the topic Bulk loading data to IBM Netezza databases for more information.
Oracle	oracle_loader.py	See the topic Bulk loading data to Oracle databases for more information.
SQL Server	mssql_loader.py	See the topic Bulk loading data to SQL Server databases for more information.
Teradata	teradata_loader.py	See the topic Bulk loading data to Teradata databases for more information.

- [Bulk loading data to IBM Db2 databases](#)
- [Bulk loading data to IBM Netezza databases](#)
- [Bulk loading data to Oracle databases](#)
- [Bulk loading data to SQL Server databases](#)
- [Bulk loading data to Teradata databases](#)

- [Developing bulk loader programs](#)
- [Testing bulk loader programs](#)

Bulk loading data to IBM Db2 databases

The following points may help you to configure for bulk loading from IBM® SPSS® Modeler to an IBM Db2 database using the External Loader option in the DB Export Advanced Options dialog box.

Ensure that the Db2 command line processor (CLP) utility is installed

The script db2_loader.py invokes the Db2 LOAD command. Ensure that the command line processor (db2 on UNIX, db2cmd on Windows) is installed on the server on which db2_loader.py is to be executed (typically, the host running IBM SPSS Modeler Server).

Check whether the local database alias name is the same as the actual database name

The Db2 local database alias is the name used by Db2 client software to refer to a database in a local or remote Db2 instance. If the local database alias is different from the name of the remote database, supply the extra loader option:

`-alias <local_database_alias>`

For example, the remote database is named STARS on host GALAXY but the Db2 local database alias on the host running IBM SPSS Modeler Server is STARS_GALAXY. Use the extra loader option

`-alias STARS_GALAXY`

Non-ASCII character data encoding

If you are bulk loading data that is not in ASCII format, you should ensure that the codepage variable in the configuration section of db2_loader.py is correctly set up on your system.

Blank strings

Blank strings are exported to the database as NULL values.

Bulk loading data to IBM Netezza databases

The following points may help you to configure for bulk loading from IBM® SPSS® Modeler to an IBM Netezza database using the External Loader option in the DB Export Advanced Options dialog box.

Ensure that the Netezza nzload utility is installed

The script netezza_loader.py invokes the Netezza utility *nzload*. Ensure that *nzload* is installed and correctly configured on the server on which *netezza_loader.py* is to be executed.

Exporting non-ASCII data

If your export contains data that is not in ASCII format, you may need to add `-encoding UTF8` to the Extra loader options field in the DB Export Advanced Options dialog box. This should ensure that non-ASCII data is correctly uploaded.

Date, Time and Timestamp format data

In the stream properties, set the date format to DD-MM-YYYY and the time format to HH:MM:SS.

Blank strings

Blank strings are exported to the database as NULL values.

Different order of columns in stream and target table when inserting data into an existing table

If the order of columns in the stream is different from that in the target table, data values will be inserted into the wrong columns. Use a Field Reorder node to ensure that the order of columns in the stream matches the order in the target table. See the topic [Field Reorder Node](#) for more information.

Tracking nzload progress

When running IBM SPSS Modeler in local mode, add **-sts** to the Extra loader options field in the DB Export Advanced Options dialog box to see status messages every 10000 rows in the command window opened by the *nzload* utility.

Bulk loading data to Oracle databases

The following points may help you to configure for bulk loading from IBM® SPSS® Modeler to an Oracle database using the External Loader option in the DB Export Advanced Options dialog box.

Ensure that the Oracle sqldr utility is installed

The script *oracle_loader.py* invokes the Oracle utility *sqldr*. Note that *sqldr* is not automatically included in Oracle Client. Ensure that *sqldr* is installed on the server on which *oracle_loader.py* is to be executed.

Specify the database SID or service name

If you are exporting data to a non-local Oracle server or your local Oracle server has multiple databases, you will need to specify the following in the Extra loader options field in the DB Export Advanced Options dialog box to pass in the SID or service name:

-database <SID>

Editing the configuration section in *oracle_loader.py*

On UNIX (and optionally, on Windows) systems, edit the configuration section at the start of the *oracle_loader.py* script. Here, values for ORACLE_SID, NLS_LANG, TNS_ADMIN and ORACLE_HOME environment variables can be specified if appropriate, as well as the full path of the *sqldr* utility.

Date, Time and Timestamp format data

In the stream properties, you should normally set the date format to YYYY-MM-DD and the time format to HH:MM:SS.

If you need to use different date and time formats from the above, consult your Oracle documentation and edit the *oracle_loader.py* script file.

Non-ASCII character data encoding

If you are bulk loading data that is not in ASCII format, you should ensure that the environment variable NLS_LANG is correctly set up on your system. This is read by the Oracle loader utility *sqldr*. For example, the correct value for NLS_LANG for Shift-JIS on Windows is Japanese_Japan.JA16SJIS. For more details on NLS_LANG, check your Oracle documentation.

Blank strings

Blank strings are exported to the database as NULL values.

Bulk loading data to SQL Server databases

The following points may help you to configure for bulk loading from IBM® SPSS® Modeler to a SQL Server database using the External Loader option in the DB Export Advanced Options dialog box.

Ensure that the SQL Server bcp.exe utility is installed

The script *mssql_loader.py* invokes the SQL Server utility *bcp.exe*. Ensure that *bcp.exe* is installed on the server where *mssql_loader.py* is to be executed.

Using spaces as delimiter does not work

Avoid choosing space as the delimiter in the DB Export Advanced Options dialog box.

Check table size option recommended

We recommend that you enable the Check table size option in the DB Export Advanced Options dialog box. Failures in the bulk load process are not always detected, and enabling this option performs an extra check that the correct number of rows has been loaded.

Blank strings

Blank strings are exported to the database as NULL values.

Specify the fully qualified SQL server named instance

There may be occasions when SPSS Modeler cannot access SQL Server due to an unqualified hostname and displays the following error:

Error encountered while executing external bulk loader. The log file may provide more details.

To correct this error, add the following string, including the double-quotes, to the Extra loader options field:

"-S mhreboot.spss.com\SQLEXPRESS"

Bulk loading data to Teradata databases

The following points may help you to configure for bulk loading from IBM® SPSS® Modeler to a Teradata database using the External Loader option in the DB Export Advanced Options dialog box.

Ensure that the Teradata fastload utility is installed

The script *teradata_loader.py* invokes the Teradata utility *fastload*. Ensure that *fastload* is installed and correctly configured on the server on which *teradata_loader.py* is to be run.

Data can be bulk loaded only to empty tables

You can only use empty tables as targets for a bulk load. If a target table contains any data prior to the bulk load, the operation will fail.

Date, Time and Timestamp format data

In the stream properties, set the date format to YYYY-MM-DD and the time format to HH:MM:SS.

Blank strings

Blank strings are exported to the database as NULL values.

Teradata process ID (tdpid)

By default, *fastload* exports data to the Teradata system with `tdpid=dbc`. Usually, there will be an entry in the HOSTS file which associates `dbccop1` with the IP address of the Teradata server. To use a different server, specify the following in the Extra loader options field in the DB Export Advanced Options dialog box to pass the `tdpid` of this server:

`-tdpid <id>`

Spaces in table and column names

If table or column names contain spaces, bulk load operation will fail. If possible, rename the table or column names to remove spaces.

Developing bulk loader programs

This topic explains how to develop a bulk loader program that can be run from IBM® SPSS® Modeler to load data from a text file into a database. Note that this is not covered under a standard Technical Support agreement, and you should contact an IBM Services representative for assistance.

Using Python to build bulk loader programs

By default, IBM SPSS Modeler searches for a default bulk loader program based on the database type. See [Table 1](#).

You can use the script *test_loader.py* to assist in developing batch loader programs. See the topic [Testing bulk loader programs](#) for more information.

Objects passed to the bulk loader program

IBM SPSS Modeler writes two files that are passed to the bulk loader program.

- **Data file.** This contains the data to be loaded, in text format.
- **Schema file.** This is an XML file that describes the names and types of the columns, and provides information on how the data file is formatted (for example, what character is used as the delimiter between fields).

In addition, IBM SPSS Modeler passes other information such as table name, user name and password as arguments when invoking the bulk load program.

Note: To signal successful completion to IBM SPSS Modeler, the bulk loader program should delete the schema file.

Arguments passed to the bulk loader program

The arguments passed to the program are listed in the following table.

Table 1. Arguments passed to bulk loader

Argument	Description
<code>schemafile</code>	Path of the schema file.
<code>data_file</code>	Path of the data file.
<code>servername</code>	Name of the DBMS server; may be blank.

Argument	Description
databasename	Name of the database within the DBMS server; may be blank.
username	User name to log into database.
password	Password to log into database.
tablename	Name of the table to load.
ownername	Name of the table owner (also known as schema name).
logfilename	Name of the logfile (if blank, no log file is created).
rowcount	Number of rows in the dataset.

Any options specified in the Extra loader options field on the DB Export Advanced Options dialog box are passed to the bulk loader program after these standard arguments.

Format of the data file

Data is written to the data file in text format, with each field being separated by a delimiter character that is specified on the DB Export Advanced Options dialog box. Here is an example of how a tab-delimited data file might appear.

```
48 F HIGH NORMAL 0.692623 0.055369 drugA
15 M NORMAL HIGH 0.678247 0.040851 drugY
37 M HIGH NORMAL 0.538192 0.069780 drugA
35 F HIGH HIGH 0.635680 0.068481 drugA
```

The file is written in the local encoding used by IBM SPSS Modeler Server (or IBM SPSS Modeler if not connected to IBM SPSS Modeler Server). Some formatting is controlled via the IBM SPSS Modeler stream settings.

Format of the schema file

The schema file is an XML file which describes the data file. Here is an example to accompany the preceding data file.

```
<?xml version="1.0" encoding="UTF-8"?>
<DBSCHEMA version="1.0">
    <table delimiter="\t" commit_every="10000" date_format="YYYY-MM-DD" time_format="HH:MM:SS"
append_existing="false" delete_datafile="false">
        <column name="Age" encoded_name="416765" type="integer"/>
        <column name="Sex" encoded_name="536578" type="char" size="1"/>
        <column name="BP" encoded_name="4250" type="char" size="6"/>
        <column name="Cholesterol" encoded_name="43686F6C65737465726F6C" type="char" size="6"/>
        <column name="Na" encoded_name="4E61" type="real"/>
        <column name="K" encoded_name="4B" type="real"/>
        <column name="Drug" encoded_name="44727567" type="char" size="5"/>
    </table>
</DBSCHEMA>
```

The following two tables list the attributes of the `<table>` and `<column>` elements of the schema file.

Table 2. Attributes of the `<table>` element

Attribute	Description
delimiter	The field delimiter character (TAB is represented as \t).
commit_every	The batch size interval (as on the DB Export Advanced Options dialog box).
date_format	The format used for representing dates.
time_format	The format used for representing times.
append_existing	true if the table to be loaded already contains data; false otherwise.
delete_datafile	true if the bulk load program should delete the data file on completion of loading.

Table 3. Attributes of the `<column>` element

Attribute	Description
name	The column name.
encoded_name	The column name converted to the same encoding as the data file and output as a series of two-digit hexadecimal numbers.
type	The data type of the column: one of integer , real , char , time , date , and datetime .
size	For the char data type, the maximum width of the column in characters.

Testing bulk loader programs

You can test bulk loading using a test script `test_loader.py` included in the `\scripts` folder of the IBM® SPSS® Modeler installation directory. Doing so is useful when trying to develop, debug, or troubleshoot bulk load programs or scripts for use with IBM SPSS Modeler.

To use the test script, proceed as follows.

1. Run the `test_loader.py` script to copy the schema and data files to the files `schema.xml` and `data.txt`, and create a Windows batch file (`test.bat`).
2. Edit the `test.bat` file to select the bulk loader program or script to test.
3. Run `test.bat` from a command shell to test the chosen bulk load program or script.

Note: Running `test.bat` does not actually load data into the database.

Flat File Export Node

The Flat File export node enables you to write data to a delimited text file. This is useful for exporting data that can be read by other analysis or spreadsheet software.

If your data contains geospatial information you can export it as a flat file and, if you generate a Variable File source node for use within the same stream, all storage, measurement, and geospatial metadata is retained in the new source node. However if you export the data and then import it in a different stream, you must take some extra steps to set the geospatial metadata in the new source node. For more information, see the topic [Variable File Node](#).

Note: You cannot write files in the old cache format, because IBM® SPSS® Modeler no longer uses that format for cache files. IBM SPSS Modeler cache files are now saved in IBM SPSS Statistics .sav format, which you can write using a Statistics export node. For more information, see the topic [Statistics Export Node](#).

- [Flat File Export Tab](#)
-

Flat File Export Tab

Export file. Specifies the name of the file. Enter a filename or click the file chooser button to browse to the file's location.

Write mode. If Overwrite is selected, any existing data in the specified file will be overwritten. If Append is selected, output will be added to the end of the existing file, preserving any data it contains.

- Include field names. If this option is selected, field names will be written to the first line of the output file. This option is available only for the Overwrite write mode.

New line after each record. If this option is selected, each record will be written on a new line in the output file.

Field separator. Specifies the character to insert between field values in the generated text file. Options are Comma, Tab, Space, and Other. If you select Other, enter the desired delimiter character(s) in the text box.

Symbol quotes. Specifies the type of quoting to use for values of symbolic fields. Options are None (values are not quoted), Single ('), Double ("), and Other. If you select Other, enter the desired quoting character(s) in the text box.

Encoding. Specifies the text-encoding method used. You can choose between the system default, stream default, or UTF-8.

- The system default is specified in the Windows Control Panel or, if running in distributed mode, on the server computer.
- The stream default is specified in the Stream Properties dialog box.

Decimal symbol. Specifies how decimals should be represented in the data.

- Stream default. The decimal separator defined by the current stream's default setting will be used. This will normally be the decimal separator defined by the computer's locale settings.
- Period (.). The period character will be used as the decimal separator.
- Comma (,). The comma character will be used as the decimal separator.

Generate an import node for this data. Select this option to automatically generate a Variable File source node that will read the exported data file. See the topic [Variable File Node](#) for more information.

Statistics Export Node

The Statistics Export node enables you to export data in IBM® SPSS® Statistics .sav format. IBM SPSS Statistics .sav files can be read by IBM SPSS Statistics Base and other modules. This is also the format used for IBM SPSS Modeler cache files.

Mapping IBM SPSS Modeler field names to IBM SPSS Statistics variable names can sometimes cause errors because IBM SPSS Statistics variable names are limited to 64 characters and cannot include certain characters, such as spaces, dollar signs (\$), and dashes (-). There are two ways to adjust for these restrictions:

- You can rename fields conforming to IBM SPSS Statistics variable name requirements by clicking the Filter tab. See the topic [Renaming or Filtering Fields for IBM SPSS Statistics](#) for more information.
- Choose to export both field names and labels from IBM SPSS Modeler.

Note: IBM SPSS Modeler writes .sav files in Unicode UTF-8 format. IBM SPSS Statistics only supports files in Unicode UTF-8 format from release 16.0 onwards. To prevent the possibility of data corruption .sav files saved with Unicode encoding should not be used in releases of IBM SPSS Statistics prior to 16.0. For more information, see the IBM SPSS Statistics help.

Multiple response sets. Any multiple response sets defined in the stream will automatically be preserved when the file is exported. You can view and edit multiple response sets from any node with a Filter tab. See the topic [Editing Multiple Response Sets](#) for more information.

- [Statistics Export Node - Export Tab](#)
- [Renaming or Filtering Fields for IBM SPSS Statistics](#)
- [Statistics Export Node - Export Tab](#)

Related information

- [Statistics Export Node - Export Tab](#)
- [Statistics File Node](#)
- [Statistics Transform Node](#)
- [Statistics Output Node](#)
- [Statistics Model Node](#)
- [Overview of Output Nodes](#)

Statistics Export Node - Export Tab

Export file Specifies the name of the file. Enter a filename or click the file chooser button to browse to the file's location.

File type Select if the file is to be saved in normal .sav or compressed.zsav format.

Encrypt file with password To protect the file with a password, select this box; you are prompted to enter and confirm the Password in a separate dialog box.

Note: Password protected files can only be opened by SPSS® Modeler version 16 or greater, or by SPSS Statistics version 21 or greater.

Export field names Specifies a method of handling variable names and labels upon export from SPSS Modeler to an SPSS Statistics .sav or .zsav file.

- Names and variable labels Select to export both SPSS Modeler field names and field labels. Names are exported as SPSS Statistics variable names, while labels are exported as SPSS Statistics variable labels.
- Names as variable labels Select to use the SPSS Modeler field names as variable labels in SPSS Statistics. SPSS Modeler allows characters in field names that are invalid in SPSS Statistics variable names. To prevent possibly creating invalid SPSS Statistics names, select Names as variable labels instead, or use the Filter tab to adjust field names.

Launch Application If SPSS Statistics is installed on your computer, you can select this option to invoke the application directly on the saved data file. Options for launching the application must be specified in the Helper Applications dialog box. See the topic [IBM SPSS Statistics Helper Applications](#) for more information. To simply create an SPSS Statistics .sav or .zsav file without opening an external program, deselect this option.

Note: When running SPSS Modeler and SPSS Statistics together in Server (distributed) mode, writing the data out and launching a SPSS Statistics session does not automatically open a SPSS Statistics client showing the data set read into the active data set. The workaround is to manually open the data file in the SPSS Statistics client once it is launched.

Generate an import node for this data Select this option to automatically generate a Statistics File source node that will read the exported data file. See the topic [Statistics File Node](#) for more information.

Related information

- [Statistics Export Node](#)

Renaming or Filtering Fields for IBM SPSS Statistics

Before exporting or deploying data from IBM® SPSS® Modeler to external applications such as IBM SPSS Statistics, it may be necessary to rename or adjust field names. The Statistics Transform, Statistics Output, and Statistics Export dialog boxes contain a Filter tab to facilitate this process.

A basic description of Filter tab functionality is discussed elsewhere. See the topic [Setting filtering options](#) for more information.

To adjust field names to conform to IBM SPSS Statistics naming conventions:

1. On the Filter tab, click the Filter Options Menu toolbar button (the first one on the toolbar).
2. Select Rename For IBM SPSS Statistics.
3. On the Rename For IBM SPSS Statistics dialog, you can choose to replace invalid characters in filenames with either a Hash (#) character or an Underscore (_).

Rename multi response sets. Select this option if you want to adjust the names of multiple response sets, which can be imported into IBM SPSS Modeler using a Statistics File source node. They are used to record data that can have more than one value for each case, such as in survey responses.

 - [Statistics Output Node - Syntax Tab](#)
 - [Statistics Output Node - Output Tab](#)
-

Data Collection Export Node

The Data Collection export node saves data in the format used by Data Collection market research software, based on the Data Collection Data Model. This format distinguishes case data—the actual responses to questions gathered during a survey—from the metadata that describes how the case data is collected and organized. Metadata consists of information such as question texts, variable names and descriptions, multiple-response sets, translations of the various texts, and definitions of the structure of the case data. See the topic [Data Collection Node](#) for more information.

Metadata file. Specifies the name of the questionnaire definition file (.mdd) where the exported metadata will be saved. A default questionnaire is created based on field type information. For example, a nominal (set) field could be represented as a single question with the field description used as the question text and a separate check box for each defined value.

Merge metadata. Specifies whether the metadata will overwrite existing versions or be merged with existing metadata. If the merge option is selected, a new version is created each time the stream is run. This makes it possible to track versions of a questionnaire as it undergoes changes. Each version can be regarded as a snapshot of the metadata used to collect a particular set of case data.

Enable system variables. Specifies whether system variables are included in the exported .mdd file. These include variables such as *Respondent.Serial*, *Respondent.Origin*, and *DataCollection.StartTime*.

Case data settings. Specifies the IBM® SPSS® Statistics data (.sav) file where case data is exported. Note that all the restrictions on variable and value names apply here, so for example you may need to switch to the Filter tab and use the "Rename for IBM SPSS Statistics" option on the Filter options menu to correct invalid characters in field names.

Generate an import node for this data. Select this option to automatically generate a Data Collection source node that will read the exported data file.

Multiple response sets. Any multiple response sets defined in the stream will automatically be preserved when the file is exported. You can view and edit multiple response sets from any node with a Filter tab. See the topic [Editing Multiple Response Sets](#) for more information.

Analytic Server Export node

The Analytic Server Export node enables you to write data from your analysis to an existing Analytic Server data source. This can, for example, be text files on Hadoop Distributed File System (HDFS) or a database.

Typically, a stream with an Analytic Server Export node also begins with Analytic Server Source nodes, and is submitted to the Analytic Server and executed on HDFS. Alternatively, a stream with "local" data sources can end with an Analytic Server Export node in order to upload relatively small datasets (no more than 100,000 records) for use with Analytic Server.

If you want to use your own Analytic Server connection instead of the default connection defined by your administrator, deselect Use default Analytic Server and select your connection.

Data source. Select a data source containing the data you wish to use. A data source contains the files and metadata associated with that source. Click Select to display a list of available data sources. See the topic [Selecting a data source](#) for more information.

If you need to create a new data source or edit an existing one, click Launch Data Source Editor....

Mode. Select Append to add to the existing data source, or Overwrite to replace the contents of the data source.

Generate an Import node for this data. Select to generate a source node for the data as exported to the specified data source. This node is added to the stream canvas.

Note that using multiple Analytic Server connections can be useful in controlling the flow of data. For example, when using the Analytic Server Source and Export nodes, you may want to use different Analytic Server connections in different branches of a stream so that when each branch runs it uses its own Analytic Server and no data will be pulled to the IBM® SPSS® Modeler Server. Note that if a branch contains more than one Analytic Server connection, the data will be pulled from the Analytic Servers to the IBM SPSS Modeler Server.

IBM Cognos export node

The IBM Cognos Export node enables you to export data from an IBM® SPSS® Modeler stream to Cognos Analytics, in UTF-8 format. In this way, Cognos can make use of transformed or scored data from IBM SPSS Modeler. For example, you could use Cognos Report Studio to create a report based on the exported data, including the predictions and confidence values. The report could then be saved on the Cognos server and distributed to Cognos users.

Note: You can export only relational data, not OLAP data.

To export data to Cognos, you need to specify the following:

- Cognos connection - the connection to the Cognos Analytics server
- ODBC connection - the connection to the Cognos data server that the Cognos server uses

Within the Cognos connection you specify a Cognos data source to use. This data source must use the same login as the ODBC data source.

You export the actual stream data to the data server, and the package metadata to the Cognos server.

As with any other export node, you can also use the Publish tab of the node dialog box to publish the stream for deployment using IBM SPSS Modeler Solution Publisher.

Note: The Cognos source node only supports Cognos CQM packages. DQM packages are not supported.

- [Cognos connection](#)
- [ODBC connection](#)

Cognos connection

This is where you specify the connection to the Cognos Analytics server that you want to use for the export. The procedure involves exporting the metadata to a new package on the Cognos server, while the stream data is exported to the Cognos data server.

Connection. Click the Edit button to display a dialog box where you can define the URL and other details of the Cognos server to which you want to export the data. If you are already logged on to a Cognos server through IBM® SPSS® Modeler, you can also edit the details of the current connection. See [Cognos connections](#) for more information.

Data source. The name of the Cognos data source (typically a database) to which you are exporting the data. The drop-down list shows all the Cognos data sources that you can access from the current connection. Click the Refresh button to update the list.

Folder. The path and name of the folder on the Cognos server where the export package is to be created.

Package name. The name of the package in the specified folder that is to contain the exported metadata. This must be a new package with a single query subject; you cannot export to an existing package.

Mode. Specifies how you want to perform the export:

- Publish package now. (default) Performs the export operation as soon as you click Run.
- Export action script. Creates an XML script that you can run later (for example, using Framework Manager) to perform the export. Type the path and file name for the script in the File field, or use the Edit button to specify the name and location of the script file.

Generate an import node for this data. Select to generate a source node for the data as exported to the specified data source and table. When you click Run, this node is added to the stream canvas.

ODBC connection

Here you specify the connection to the Cognos data server (that is, the database) to which the stream data is to be exported.

Note: You must ensure that the data source you specify here points to the same one specified on the Cognos connections panel. You must also ensure that the Cognos connection data source uses the same login as the ODBC data source.

Data source. Shows the selected data source. Enter the name or select it from the drop-down list. If you don't see the desired database in the list, select Add new database connection and locate your database from the Database Connections dialog box. See [Adding a database connection](#) for more information.

Table name. Enter the name of the table to which you want to send the data. If you select the Insert into table option, you can select an existing table in the database by clicking the Select button.

Create table. Select this option to create a new database table or to overwrite an existing database table.

Insert into table. Select this option to insert the data as new rows in an existing database table.

Merge table. (Where available) Select this option to update selected database columns with values from corresponding source data fields. Selecting this option enables the Merge button, which displays a dialog from where you can map source data fields to database columns.

Drop existing table. Select this option to delete any existing table with the same name when creating a new table.

Delete existing rows. Select this option to delete existing rows from the table before exporting, when inserting into a table.

Note: If either of the two options above are selected, you will receive an Overwrite warning message when you execute the node. To suppress the warnings, deselect Warn when a node overwrites a database table on the Notifications tab of the User Options dialog box.

Default string size. Fields you have marked as typeless in an upstream Type node are written to the database as string fields. Specify the size of strings to be used for typeless fields.

Click Schema to open a dialog box where you can set various export options (for databases that support this feature), set SQL data types for your fields, and specify the primary key for purposes of database indexing. See [Database export schema options](#) for more information.

Click Indexes to specify options for indexing the exported table in order to improve database performance. See [Database Export Index Options](#) for more information.

Click Advanced to specify bulk loading and database commit options. See [Database export advanced options](#) for more information.

Quote table and column names. Select options used when sending a **CREATE TABLE** statement to the database. Tables or columns with spaces or nonstandard characters must be quoted.

- As needed. Select to allow IBM® SPSS® Modeler to automatically determine when quoting is needed on an individual basis.
- Always. Select to always enclose table and column names in quotes.
- Never. Select to disable the use of quotes.

Generate an import node for this data. Select to generate a source node for the data as exported to the specified data source and table. When you click Run, this node is added to the stream canvas.

IBM Cognos TM1 Export Node

The IBM Cognos Export node enables you to export data from an SPSS® Modeler stream to Cognos TM1. In this way, Cognos Analytics can make use of transformed or scored data from SPSS Modeler.

Note: You can export only measures, not context dimension data; alternatively, you can add new elements to the cube.

To export data to Cognos Analytics, you need to specify the following:

- The connection to the Cognos TM1 server.
- The Cube into which the data will be exported.
- The mapping from the SPSS data names to the equivalent TM1 dimensions and measures.

Note: The TM1 user needs the following permissions: Write privilege of cubes, Read privilege of dimensions, and Write privilege of dimension elements. In addition, IBM Cognos TM1 10.2 Fix Pack 3, or later, is required before SPSS Modeler can import and export Cognos TM1 data.

Existing streams that were based on previous versions will still function.

Administrator credentials are not required for this node. But if you are still using the old legacy pre-17.1 TM1 node, administrator credentials are still required.

SPSS Modeler only supports working with Cognos TM1 via IntegratedSecurityMode 1, 4, and 5.

As with any other export node, you can also use the Publish tab of the node dialog box to publish the stream for deployment using IBM® SPSS Modeler Solution Publisher.

Note: Before you can use the TM1 Source or Export nodes in SPSS Modeler, you must verify some settings in the tm1s.cfg file; this is the TM1 server configuration file in the root directory of the TM1 server.

- HTTPPortNumber - set a valid port number; typically 1-65535. Note that this is not the port number you subsequently specify in the connection in the node; it is an internal port used by TM1 that is disabled by default. If necessary, contact your TM1 administrator to

- confirm the valid setting for this port.
- UseSSL - if you set this to *True*, HTTPS is used as the transport protocol. In this case you must import the TM1 certification to the SPSS Modeler Server JRE.
 - [Connecting to an IBM Cognos TM1 cube to export data](#)
 - [Mapping IBM Cognos TM1 data for export](#)
-

Connecting to an IBM Cognos TM1 cube to export data

To export data to an IBM Cognos TM1 database, on the Connection tab of the IBM Cognos TM1 dialog box, specify the server connection details and select the associated cube and data details.

Note: Only actual "null" values will be discarded when exporting data to TM1. Zero (0) values will be exported as a valid value. Also note that only fields with a storage type of *string* can be mapped to dimensions on the Mapping tab. Before exporting to TM1, you must use IBM® SPSS® Modeler client to convert non-string data types to string.

Connection Type. Select Admin Server or TM1 Server. Note that the Admin Server has been removed from [Planning Analytics on Cloud](#), so if you have old streams that connect to an old Admin Server, you can modify them to point to Planning Analytics on Cloud instead. If you select Admin Server here, then you must enter the URL for the server (the host name of the REST API) and the name of the server. If you select TM1 Server, proceed to the following sections.

TM1 Server URL. Type the URL of the administration host where the TM1 server you want to connect to is installed. The administration host is defined as a single URL for all TM1 servers. From this URL, all IBM Cognos TM1 servers installed and running on your environment can be discovered and accessed. Click Login. If you have not previously connected to this server you are prompted to enter your User name and Password; alternatively, you can search for previously entered login details that you have saved as a Stored Credential.

Select a TM1 cube to export Displays the name of the cubes within the TM1 server into which you can export data.

To choose the data to export, select the cube and click the right arrow to move the cube into the Export to cube field. When you have selected the cube, use the Mapping tab to map the TM1 dimensions and measures to the relevant SPSS fields or to a fixed value (*Select* operation).

Mapping IBM Cognos TM1 data for export

After you select the TM1 administration host and associated TM1 server and cube, use the Mapping tab of the IBM Cognos TM1 Export dialog box to map TM1 dimensions and measures to SPSS fields or set TM1 dimensions to a fixed value.

Note: Only fields with a storage type of *string* can be mapped to dimensions. Before exporting to TM1, you must use IBM® SPSS® Modeler client to convert non-string data types to string.

Fields Lists the data field names from the SPSS data file that are available for export.

TM1 Dimensions Shows the TM1 cube selected on the Connection tab, along with its regular dimensions, the measure dimension, and the elements of the selected measure dimension. Select the name of the TM1 dimension, or measure, to map to the SPSS data field.

The following options are available on the Mapping tab.

Select a measure dimension From the list of dimensions for the selected cube, select one to be the measure dimension.

When you select a dimension, except the measure dimension, and click *Select*, a dialog is displayed that shows the leaf elements of the selected dimension. You can only select leaf elements. Selected elements are labeled with an S.

Map Maps the selected SPSS data field to the selected TM1 dimension or measure (a regular dimension or a specific measure or element from the measure dimension). Mapped fields are labeled with an M.

Unmap Unmaps the selected SPSS data field from the selected TM1 dimension or measure. Note that you can only unmap a single mapping at a time. The unmapped SPSS data field is moved back to the left column.

Create New Creates a new measure in the TM1 measure dimension. A dialog is displayed in which you enter the new TM1 measure name. This option is only available for measure dimensions, not for regular dimensions.

For more information about TM1, see the IBM Cognos TM1 documentation at http://www-01.ibm.com/support/knowledgecenter/SS9RXT_10.2.2/com.ibm.swg.ba.cognos.ctm1.doc/welcome.html.

SAS Export Node

This feature is available in SPSS® Modeler Professional and SPSS Modeler Premium.

The SAS export node enables you to write data in SAS format to be read into SAS or a SAS-compatible software package. You can export in three SAS file formats: SAS for Windows/OS2, SAS for UNIX, or SAS.

- [SAS Export Node Export Tab](#)

Related information

- [Overview of Output Nodes](#)
- [SAS Export Node Export Tab](#)

SAS Export Node Export Tab

This feature is available in SPSS® Modeler Professional and SPSS Modeler Premium.

Export file. Specify the name of the file. Enter a filename or click the file chooser button to browse to the file's location.

Export. Specify the export file format. Options are SAS for Windows/OS2, SAS for UNIX, or SAS Version 7/8/9.

Export field names. Select options for exporting field names and labels from IBM® SPSS Modeler for use with SAS.

- Names and variable labels. Select to export both IBM SPSS Modeler field names and field labels. Names are exported as SAS variable names, while labels are exported as SAS variable labels.
- Names as variable labels. Select to use the IBM SPSS Modeler field names as variable labels in SAS. IBM SPSS Modeler allows characters in field names that are invalid in SAS variable names. To prevent possibly creating invalid SAS names, select Names and variable labels instead.

Generate an import node for this data. Select this option to automatically generate a SAS source node that will read the exported data file. See the topic [SAS Source Node](#) for more information.

Note: The maximum allowed length of a string is 255 bytes. If a string is more than 255 bytes, it will be truncated when exporting.

Excel Export Node

The Excel export node outputs data in Microsoft Excel .xlsx format. Optionally, you can choose to automatically launch Excel and open the exported file when the node is executed.

- [Excel Node Export Tab](#)

Excel Node Export Tab

File name. Enter a filename or click the file chooser button to browse to the file's location. The default filename is `excelexport.xlsx`.

File type. The Excel .xlsx file format is supported.

Create new file. Creates a new Excel file.

Insert into existing file. Content is replaced beginning at the cell designated by the Start in cell field. Other cells in the spreadsheet are left with their original content.

Include field names. Specifies whether field names should be included in the first row of the worksheet.

Start in cell. The cell location used for the first export record (or first field name if Include field names is checked). Data are filled to the right and down from this initial cell.

Choose worksheet. Specifies the worksheet to which you want to export the data. You can identify the worksheet either by index or by name:

- **By index.** If you are creating a new file, specify a number from 0 to 9 to identify the worksheet to which you want to export, beginning with 0 for the first worksheet, 1 for the second worksheet, and so on. You can use values of 10 or higher only if a worksheet already exists at this position.
- **By name.** If you are creating a new file, specify the name used for the worksheet. If you are inserting into an existing file, the data are inserted into this worksheet if it exists, otherwise a new worksheet with this name is created.

Launch Excel. Specifies whether Excel is automatically launched on the exported file when the node is executed. Note that when running in distributed mode against IBM® SPSS® Modeler Server, the output is saved to the server file system, and Excel is launched on the Client with a copy of the exported file.

Generate an import node for this data. Select this option to automatically generate an Excel source node that will read the exported data file. See the topic [Excel Source node](#) for more information.

Related information

- [Excel Export Node](#)
-

Extension Export node

With the Extension Export node, you can run R or Python for Spark scripts to export data.

- [Extension Export node - Syntax tab](#)
 - [Extension Export node - Console Output tab](#)
-

Extension Export node - Syntax tab

Select your type of syntax – R or Python for Spark. See the following sections for more information. When your syntax is ready, you can click Run to execute the Extension Export node.

R Syntax

R Syntax. You can enter, or paste, custom R scripting syntax for data analysis into this field.

Convert flag fields. Specifies how flag fields are treated. There are two options: Strings to factor, Integers and Reals to double, and Logical values (True, False). If you select Logical values (True, False) the original values of the flag fields are lost. For example, if a field has values Male and Female, these are changed to True and False.

Convert missing values to the R 'not available' value (NA). When selected, any missing values are converted to the R NA value. The value NA is used by R to identify missing values. Some R functions that you use might have an argument that can be used to control how the function behaves when the data contain NA. For example, the function might allow you to choose to automatically exclude records that contain NA. If this option is not selected, any missing values are passed to R unchanged, and might cause errors when your R script is executed.

Convert date/time fields to R classes with special control for time zones. When selected, variables with date or datetime formats are converted to R date/time objects. You must select one of the following options:

- **R POSIXct.** Variables with date or datetime formats are converted to R POSIXct objects.
- **R POSIXlt (list).** Variables with date or datetime formats are converted to R POSIXlt objects.

Note: The POSIX formats are advanced options. Use these options only if your R script specifies that datetime fields are treated in ways that require these formats. The POSIX formats do not apply to variables with time formats.

Python Syntax

Python Syntax. You can enter, or paste, custom Python scripting syntax for data analysis into this field. For more information about Python for Spark, see [Python for Spark](#) and [Scripting with Python for Spark](#).

Extension Export node - Console Output tab

The Console Output tab contains any output that is received when the R script or Python for Spark script on the Syntax tab runs (for example, if using an R script, it shows output received from the R console when the R script in the R Syntax field on the Syntax tab is executed). This output

might include R or Python error messages or warnings that are produced when the R or Python script is executed. The output can be used, primarily, to debug the script. The Console Output tab also contains the script from the R Syntax or Python Syntax field.

Every time the Extension Export script is executed, the content of the Console Output tab is overwritten with the output received from the R console or Python for Spark. The output cannot be edited.

XML Export Node

The XML Export node enables you to output data in XML format, using UTF-8 encoding. You can optionally create an XML source node to read the exported data back into the stream.

XML export file. The full path and file name of the XML file to which you want to export the data.

Use XML schema. Select this check box if you want to use a schema or DTD to control the structure of the exported data. Doing so activates the Map button, described below.

If you do not use a schema or DTD, the following default structure is used for the exported data:

```
<records>
  <record>
    <fieldname1>value</fieldname1>
    <fieldname2>value</fieldname2>
    :
    <fieldnameN>value</fieldnameN>
  </record>
  <record>
    :
    :
  </record>
  :
  :
</records>
```

Spaces in a field name are replaced with underscores; for example, "My Field" becomes `<My_Field>`.

Map. If you have chosen to use an XML schema, this button opens a dialog where you can specify which part of the XML structure should be used to start each new record. See the topic [XML Mapping Records Options](#) for more information.

Mapped fields. Indicates the number of fields that have been mapped.

Generate an import node for this data. Select this option to automatically generate an XML source node that will read the exported data file back into the stream. See the topic [XML Source Node](#) for more information.

- [Writing XML Data](#)
- [XML Mapping Records Options](#)
- [XML Mapping Fields Options](#)
- [XML Mapping Preview](#)

Related information

- [Overview of Output Nodes](#)

Writing XML Data

When an XML element is specified, the field value is placed inside the element tag:

```
<element>value</element>
```

When an attribute is mapped, the field value is placed as the value for the attribute:

```
<element attribute="value">
```

If a field is mapped to an element above the `<records>` element, the field is written only once, and will be a constant for all records. The value for this element will come from the first record.

If a null value is to be written, it is done by specifying empty content. For elements, this is:

```
<element></element>
```

For attributes, it is:

```
<element attribute="">
```

XML Mapping Records Options

The Records tab enables you to specify which part of the XML structure to use to start each new record. In order to map correctly onto a schema, you need to specify the record delimiter.

XML structure. A hierarchical tree showing the structure of the XML schema specified on the previous screen.

Records (XPath expression). To set the record delimiter, select an element in the XML structure and click the right-arrow button. Each time this element is encountered in the source data, a new record is created in the output file.

Note: If you select the root element in the XML structure, only a single record can be written, and all other records are skipped.

XML Mapping Fields Options

The Fields tab is used to map fields in the data set to elements or attributes in the XML structure when a schema file is used.

Field names that match an element or attribute name are automatically mapped as long as the element or attribute name is unique. Thus if there is both an element and an attribute with the name `field1`, there is no automatic mapping. If there is only one item in the structure named `field1`, a field with that name in the stream is automatically mapped.

Fields. The list of fields in the model. Select one or more fields as the source part of the mapping. You can use the buttons at the bottom of the list to select all fields, or all fields with a particular measurement level.

XML structure. Select an element in the XML structure as the map target. To create the mapping, click Map. The mapping is then displayed. The number of fields that have been mapped in this way is displayed below this list.

To remove a mapping, select the item in the XML structure list and click Unmap.

Display attributes. Displays or hides the attributes, if any, of the XML elements in the XML structure.

XML Mapping Preview

On the Preview tab, click Update to see a preview of the XML that will be written.

If the mapping is incorrect, return to the Records or Fields tab to correct the errors and click Update again to see the result.

JSON Export node

Use the JSON export node to output data in JSON format, using UTF-8 encoding. Optionally, you can also create a JSON source node to read the exported data back into the stream.

When SPSS® Modeler writes data to a JSON export file, it performs the following translations.

Table 1. JSON data export translation

SPSS Modeler Data Storage	JSON Value
String	string
Integer	number(int)
Real	number(real)
Date	string
Time	string
Timestamp	string
List	Not supported. Fields of list will be excluded.
Missing values	null

JSON export file. The full path and file name of the JSON file where data will be exported.

JSON string format. Specify the format of the JSON string. Select Records if you want the JSON export node to output a collection of name and value pairs. Or select Values if you only want to export values (no names).

JSON string format. Specify the format of the JSON string. Select Records the JSON export node will output a collection of name and value pairs. Or select Values if you only want to export values (no names).

Generate an import node for this data. Select this option to automatically generate a JSON source node that will read the exported data file back into the stream. For more information, see [JSON Source node](#).

Common Export node tabs

The following options can be specified for all export nodes by clicking the corresponding tab:

- Publish tab. Used to publish results of a stream.
- Annotations tab. Used for all nodes, this tab offers options to rename nodes, supply a custom ToolTip, and store a lengthy annotation.
- [**Publishing streams**](#)

Publishing streams

Publishing streams is done directly from IBM® SPSS® Modeler using any of the standard export nodes: Database, Flat File, Statistics Export, Extension Export, Data Collection Export, SAS Export, Excel, and XML Export nodes. The type of export node determines the format of the results to be written each time the published stream is executed using the IBM SPSS Modeler Solution Publisher Runtime or external application. For example, if you want to write your results to a database each time the published stream is run, use a Database export node.

To publish a stream

1. Open or build a stream in the normal manner and attach an export node at the end.
2. On the Publish tab in the export node, specify a root name for the published files (that is, the file name to which the .pim, .par, and .xml extensions will be appended).
3. Click Publish to publish the stream, or select Publish the stream to automatically publish the stream each time the node is executed.

Published name. Specify the root name for the published image and parameter files.

- The image file (*.pim) provides all of the information needed for the Runtime to execute the published stream exactly as it was at the time of export. If you are confident that you will not need to change any of the settings for the stream (such as the input data source or the output data file), you can deploy the image file only.
- The parameter file (*.par) contains configurable information about data sources, output files, and execution options. If you want to be able to control the input or output of the stream without republishing the stream, you will need the parameter file as well as the image file.
- The metadata file (*.xml) describes the inputs and outputs of the image and their data models. It is designed for use by applications which embed the runtime library and which need to know the structure of the input and output data.

Note: This file is only produced if you select the Publish metadata option.

Publish parameters. If required, you can include stream parameters in the *.par file. You can change these stream parameter values when you execute the image either by editing the *.par file or through the runtime API.

This option enables the Parameters button. The Publish Parameters dialog box is displayed when you click the button.

Choose the parameters you want to include in the published image by selecting the relevant option in the Publish column.

On stream execution. Specifies whether the stream is automatically published when the node is executed.

- Export data. Executes the export node in the standard manner, without publishing the stream. (Basically, the node executes in IBM SPSS Modeler the same way it would if IBM SPSS Modeler Solution Publisher were not available.) If you select this option, the stream will not be published unless you do so explicitly by clicking Publish in the export node dialog box. Alternatively, you can publish the current stream using the Publish tool on the toolbar or by using a script.
- Publish the stream. Publishes the stream for deployment using IBM SPSS Modeler Solution Publisher. Select this option if you want to automatically publish the stream every time it is executed.

Note:

- If you plan to run the published stream with new or updated data, it is important to note that the order of fields in the input file must be the same as the order of fields in the source node input file specified in the published stream.
- When publishing to external applications, consider filtering extraneous fields or renaming fields to conform with input requirements. Both can be accomplished using a Filter node prior to the export node.

IBM® SPSS® Statistics Nodes

- [IBM SPSS Statistics Nodes - Overview](#)
- [Statistics File Node](#)
- [Statistics Transform Node](#)
- [Statistics Model Node](#)
- [Statistics Output Node](#)
- [Statistics Export Node](#)

IBM SPSS Statistics Nodes - Overview

To complement IBM® SPSS® Modeler and its data mining abilities, IBM SPSS Statistics provides you with the ability to carry out further statistical analysis and data management.

If you have a compatible, licensed copy of IBM SPSS Statistics installed, you can connect to it from IBM SPSS Modeler and carry out complex, multistep data manipulation and analysis not otherwise supported by IBM SPSS Modeler. For the advanced user there is also the option to further modify the analysis by using command syntax. See the Release Notes for information on version compatibility.

If available, the IBM SPSS Statistics nodes are shown on a dedicated part of the nodes palette.

Note: We recommend that you instantiate your data in a Type node before using the IBM SPSS Statistics Transform, Model, or Output nodes. This is also a requirement when using the AUTORECODE syntax command.

The IBM SPSS Statistics palette contains the following nodes:

	The Statistics File node reads data from the .sav or .zsav file format used by IBM SPSS Statistics, as well as cache files saved in IBM SPSS Modeler, which also use the same format.
	The Statistics Transform node runs a selection of IBM SPSS Statistics syntax commands against data sources in IBM SPSS Modeler. This node requires a licensed copy of IBM SPSS Statistics.
	The Statistics Model node enables you to analyze and work with your data by running IBM SPSS Statistics procedures that produce PMML. This node requires a licensed copy of IBM SPSS Statistics.
	The Statistics Output node allows you to call an IBM SPSS Statistics procedure to analyze your IBM SPSS Modeler data. A wide variety of IBM SPSS Statistics analytical procedures is available. This node requires a licensed copy of IBM SPSS Statistics.
	The Statistics Export node outputs data in IBM SPSS Statistics .sav or .zsav format. The .sav or .zsav files can be read by IBM SPSS Statistics Base and other products. This is also the format used for cache files in IBM SPSS Modeler.

Note: If your copy of SPSS Statistics is licensed for a single user only and you run a stream with two or more branches, each of which contains an SPSS Statistics node, you may receive a licensing error. This occurs when the SPSS Statistics session for one branch has not terminated before the session for another branch attempts to start. If possible, redesign the stream so that multiple branches with SPSS Statistics nodes do not execute in parallel.

Related information

- [Statistics File Node](#)
- [Statistics Transform Node](#)
- [Statistics Output Node](#)
- [Statistics Model Node](#)
- [Statistics Export Node](#)

Statistics File Node

You can use the Statistics File node to read data directly from a saved IBM® SPSS® Statistics file (.sav or .zsav). This format is now used to replace the cache file from earlier versions of IBM SPSS Modeler. If you would like to import a saved cache file, you should use the IBM SPSS Statistics File node.

Import file. Specify the name of the file. You can enter a filename or click the ellipsis button (...) to select a file. The file path is shown once you have selected a file.

File is password encrypted. Select this box if you know the file is password protected; you are prompted to enter the Password. If the file is password protected, and you do not enter the password, a warning message is displayed if you attempt to change to another tab, refresh the data, preview the node contents, or try to execute a stream containing the node.

Note: Password protected files can only be opened by IBM SPSS Modeler version 16 or greater.

Variable names. Select a method of handling variable names and labels upon import from an IBM SPSS Statistics .sav or .zsav file. Metadata that you choose to include here persists throughout your work in IBM SPSS Modeler and may be exported again for use in IBM SPSS Statistics.

- **Read names and labels.** Select to read both variable names and labels into IBM SPSS Modeler. By default, this option is selected and variable names are displayed in the Type node. Labels may be displayed in charts, model browsers, and other types of output, depending on the options specified in the stream properties dialog box. By default, the display of labels in output is disabled.
- **Read labels as names.** Select to read the descriptive variable labels from the IBM SPSS Statistics .sav or .zsav file rather than the short field names, and use these labels as variable names in IBM SPSS Modeler.

Values. Select a method of handling values and labels upon import from an IBM SPSS Statistics .sav or .zsav file. Metadata that you choose to include here persists throughout your work in IBM SPSS Modeler and may be exported again for use in IBM SPSS Statistics.

- **Read data and labels.** Select to read both actual values and value labels into IBM SPSS Modeler. By default, this option is selected and values themselves are displayed in the Type node. Value labels may be displayed in the Expression Builder, charts, model browsers, and other types of output, depending on the options specified in the stream properties dialog box.
- **Read labels as data.** Select if you want to use the value labels from the .sav or .zsav file rather than the numerical or symbolic codes used to represent the values. For example, selecting this option for data with a gender field whose values of 1 and 2 actually represent *male* and *female*, respectively, will convert the field to a string and import *male* and *female* as the actual values.

It is important to consider missing values in your IBM SPSS Statistics data before selecting this option. For example, if a numeric field uses labels only for missing values (0 = *No Answer*, -99 = *Unknown*), then selecting the option above will import only the value labels *No Answer* and *Unknown* and will convert the field to a string. In such cases, you should import the values themselves and set missing values in a Type node.

Use field format information to determine storage. If this box is cleared, field values that are formatted in the .sav file as integers (i.e., fields specified as Fn.0 in the Variable View in IBM SPSS Statistics) are imported using integer storage. All other field values except strings are imported as real numbers.

If this box is selected (default), all field values except strings are imported as real numbers, whether formatted in the .sav file as integers or not.

Multiple response sets. Any multiple response sets defined in the IBM SPSS Statistics file will automatically be preserved when the file is imported. You can view and edit multiple response sets from any node with a Filter tab. See the topic [Editing Multiple Response Sets](#) for more information.

Statistics Transform Node

The Statistics Transform node enables you to complete data transformations using IBM® SPSS® Statistics command syntax. This makes it possible to complete a number of transformations not supported by IBM SPSS Modeler and allows automation of complex, multistep transformations, including the creation of a number of fields from a single node. It resembles the Statistics Output node, except that the data are returned to IBM SPSS Modeler for further analysis, whereas, in the Output node the data are returned as the requested output objects, such as graphs or tables.

You must have a compatible version of IBM SPSS Statistics installed and licensed on your computer to use this node. See [IBM SPSS Statistics Helper Applications](#) for more information. See the online Release Notes for compatibility information.

If necessary, you can use the Filter tab to filter or rename fields so they conform to IBM SPSS Statistics naming standards. See [Renaming or Filtering Fields for IBM SPSS Statistics](#) for more information.

Syntax Reference. For details about specific IBM SPSS Statistics procedures, see the *IBM SPSS Statistics Command Syntax Reference* guide, included with your copy of the IBM SPSS Statistics software. To view the guide from the Syntax tab, choose the Syntax editor option and click the Launch Statistics Syntax Help button.

Note: Not all IBM SPSS Statistics syntax is supported by this node. See the topic [Allowable Syntax](#) for more information.

Statistics Transform Node - Syntax Tab

IBM® SPSS® Statistics dialog option

If you are unfamiliar with IBM SPSS Statistics syntax for a procedure, the simplest way to create syntax in IBM SPSS Modeler is to choose the IBM SPSS Statistics dialog option, select the dialog box for the procedure, complete the dialog box and click OK. Doing so places the syntax onto the Syntax tab of the IBM SPSS Statistics node you are using in IBM SPSS Modeler. You can then run the stream to obtain the output from the procedure.

IBM SPSS Statistics Syntax editor option

Check. After you have entered your syntax commands in the upper part of the dialog box, use this button to validate your entries. Any incorrect syntax is identified in the bottom part of the dialog box.

To ensure that the checking process does not take too long, when you validate the syntax, it is checked against a representative sample of your data to ensure that the entries are valid instead of checking against the entire dataset.

Related information

- [Statistics Transform Node](#)
- [Allowable Syntax](#)

Allowable Syntax

If you have a lot of legacy syntax from IBM® SPSS® Statistics or are familiar with the data preparation features of IBM SPSS Statistics, you can use the Statistics Transform node to run many of your existing transformations. As a guideline, the node enables you to transform data in predictable ways--for example, by running looped commands or by changing, adding, sorting, filtering, or selecting data.

Examples of the commands that can be carried out are:

- Compute random numbers according to a binomial distribution:

```
COMPUTE newvar = RV.BINOM(10000, 0.1)
```

- Recode a variable into a new variable:

```
RECODE Age (Lowest thru 30=1) (30 thru 50=2) (50 thru Highest=3) INTO AgeRecoded
```

- Replace missing values:

```
RMV Age_1=SMEAN(Age)
```

The IBM SPSS Statistics syntax that is supported by the Statistics Transform node is listed below.

Command Name
ADD VALUE LABELS
APPLY DICTIONARY
AUTORECODE
BREAK
CD
CLEAR MODEL PROGRAMS
CLEAR TIME PROGRAM

Statistics Model Node

The Statistics Model node enables you to analyze and work with your data by running IBM® SPSS® Statistics procedures that produce PMML. The model nuggets you create can then be used in the usual way within IBM SPSS Modeler streams for scoring, and so on.

You must have a compatible version of IBM SPSS Statistics installed and licensed on your computer to use this node. See [IBM SPSS Statistics Helper Applications](#) for more information. See the online Release Notes for compatibility information.

The IBM SPSS Statistics analytical procedures that are available depend on the type of license you have.

Statistics Model Node - Model Tab

Model name. You can generate the model name automatically based on the target or ID field (or model type in cases where no such field is specified) or specify a custom name.

Select a dialog. Click to display a list of available IBM® SPSS® Statistics procedures that you can select and run. The list shows only those procedures that produce PMML and for which you are licensed, and does not include user-written procedures.

1. Click on the required procedure; the relevant IBM SPSS Statistics dialog is displayed.
2. In the IBM SPSS Statistics dialog, enter the details for the procedure.
3. Click OK to return to the Statistics Model node; the IBM SPSS Statistics syntax is displayed in the Model tab.
4. To return to the IBM SPSS Statistics dialog at any time, for example to modify your query, click the IBM SPSS Statistics dialog display button to the right of the procedure selection button.

-

Statistics Model Node - Model Nugget Summary

When you run the Statistics Model node, it executes the associated IBM® SPSS® Statistics procedure and creates a model nugget that you can use in IBM SPSS Modeler streams for scoring.

The Summary tab of the model nugget displays information about the fields, build settings, and model estimation process. Results are presented in a tree view that can be expanded or collapsed by clicking specific items.

The View Model button displays the results in a modified form of the IBM SPSS Statistics Output Viewer. For more information about this viewer, see the IBM SPSS Statistics documentation.

The usual exporting and printing options are available from the File menu. See the topic [Viewing output](#) for more information.

Related information

Statistics Output Node - Syntax Tab

Use this tab to create syntax for the SPSS® Statistics procedure you want to use to analyze your data. Syntax is composed of two parts: a **statement** and associated **options**. The statement specifies the analysis or operation to be performed and the fields to be used. The options specify everything else, including which statistics to display, derived fields to save, and so on.

SPSS Statistics dialog option

If you are unfamiliar with IBM® SPSS Statistics syntax for a procedure, the simplest way to create syntax in IBM SPSS Modeler is to choose the IBM SPSS Statistics dialog option, select the dialog box for the procedure, complete the dialog box and click OK. Doing so places the syntax onto the Syntax tab of the IBM SPSS Statistics node you are using in IBM SPSS Modeler. You can then run the stream to obtain the output from the procedure.

You can optionally generate a Statistics File source node for importing the resulting data. This is useful, for example, if a procedure writes fields such as scores to the active dataset in addition to displaying output.

Note:

- When generating output in languages other than English, it is advisable to specify the language in the syntax.
- The Output Style option is not supported in the Statistics Output node.

To create the syntax

1. Click the Select a dialog button.
2. Choose one of the options:
 - Analyze Lists the contents of the SPSS Statistics Analyze menu; choose the procedure you want to use.
 - Other If shown, lists dialogs created by the Custom Dialog Builder in SPSS Statistics, as well as any other SPSS Statistics dialogs that do not appear on the Analyze menu and for which you have a licence. If there are no applicable dialogs, this option is not shown.

Note: The Automatic Data Preparation dialogs are not shown.

If you have an SPSS Statistics custom dialog that creates new fields, these fields cannot be used in SPSS Modeler because the Statistics Output node is a terminal node.

Optionally check the Generate an import node for the resulting data box to create a Statistics File source node that can be used to import the resulting data into another stream. The node is placed on the screen canvas, with the data contained in the .sav file specified in the File field (default location is the SPSS Modeler installation directory).

Syntax editor option

To save syntax that has been created for a frequently used procedure:

1. Click the File Options button (the first one on the toolbar).
2. Choose Save or Save As from the menu.
3. Save the file as an .sps file.

To use previously created syntax files, replacing the current contents, if any, of the Syntax editor:

1. Click the File Options button (the first one on the toolbar).

2. Choose Open from the menu.
3. Select an .sps file to paste its contents into the Output node Syntax tab.

To insert previously saved syntax without replacing the current contents:

1. Click the File Options button (the first one on the toolbar).
2. Choose Insert from the menu
3. Select an .sps file to paste its contents into the Output node at the point specified by the cursor.

Optionally check the Generate an import node for the resulting data box to create a Statistics File source node that can be used to import the resulting data into another stream. The node is placed on the screen canvas, with the data contained in the .sav file specified in the File field (default location is the SPSS Modeler installation directory).

When you click Run, the results are shown in the SPSS Statistics Output Viewer. For more information about the viewer, see the SPSS Statistics documentation.

Note: Syntax for the following items (and their corresponding SPSS Statistics dialog box options) is not supported. They have no impact on the output.

- **OUTPUT ACTIVATE**
- **OUTPUT CLOSE**
- **OUTPUT DISPLAY**
- **OUTPUT EXPORT**
- **OUTPUT MODIFY**
- **OUTPUT NAME**
- **OUTPUT NEW**
- **OUTPUT OPEN**
- **OUTPUT SAVE**

Statistics Output Node - Output Tab

The Output tab lets you specify the format and location of the output. You can choose to display the results on the screen or send them to one of the available file types.

Output name. Specifies the name of the output produced when the node is executed. Auto chooses a name based on the node that generates the output. Optionally, you can select Custom to specify a different name.

Output to screen (the default). Creates an output object to view online. The output object will appear on the Outputs tab of the manager window when the output node is executed.

Output to file. Saves the output to a file when you run the node. If you choose this option, enter a filename in the Filename field (or navigate to a directory and specify a filename using the File Chooser button) and select a file type.

File type. Choose the type of file to which you want to send the output.

- **HTML document (*.html).** Writes the output in HTML format.
- **IBM® SPSS® Statistics Viewer File (*.spv).** Writes the output in a format that can be read by the IBM SPSS Statistics Output Viewer.
- **IBM SPSS Statistics Web Reports File (*.spw).** Writes the output in IBM SPSS Statistics Web Reports format, which can be published to an IBM SPSS Collaboration and Deployment Services repository and subsequently viewed in a Web browser. See the topic [Publish to Web](#) for more information.

Note: If you select Output to screen the IBM SPSS Statistics OMS directive **VIEWER=NO** has no effect; also, the scripting APIs (*Basic* and *Python SpssClient* module) are not available in IBM SPSS Modeler.

Related information

- [Viewing output](#)
- [Statistics Output Node](#)
- [Statistics Output Node - Syntax Tab](#)
- [Renaming or Filtering Fields for IBM SPSS Statistics](#)

Statistics Export Node

The Statistics Export node enables you to export data in IBM® SPSS® Statistics .sav format. IBM SPSS Statistics .sav files can be read by IBM SPSS Statistics Base and other modules. This is also the format used for IBM SPSS Modeler cache files.

Mapping IBM SPSS Modeler field names to IBM SPSS Statistics variable names can sometimes cause errors because IBM SPSS Statistics variable names are limited to 64 characters and cannot include certain characters, such as spaces, dollar signs (\$), and dashes (-). There are two ways to adjust for these restrictions:

- You can rename fields conforming to IBM SPSS Statistics variable name requirements by clicking the Filter tab. See the topic [Renaming or Filtering Fields for IBM SPSS Statistics](#) for more information.
- Choose to export both field names and labels from IBM SPSS Modeler.

Note: IBM SPSS Modeler writes .sav files in Unicode UTF-8 format. IBM SPSS Statistics only supports files in Unicode UTF-8 format from release 16.0 onwards. To prevent the possibility of data corruption .sav files saved with Unicode encoding should not be used in releases of IBM SPSS Statistics prior to 16.0. For more information, see the IBM SPSS Statistics help.

Multiple response sets. Any multiple response sets defined in the stream will automatically be preserved when the file is exported. You can view and edit multiple response sets from any node with a Filter tab. See the topic [Editing Multiple Response Sets](#) for more information.

- [Statistics Export Node - Export Tab](#)

Related information

- [Statistics Export Node - Export Tab](#)
- [Statistics File Node](#)
- [Statistics Transform Node](#)
- [Statistics Output Node](#)
- [Statistics Model Node](#)
- [Overview of Output Nodes](#)

Statistics Export Node - Export Tab

Export file Specifies the name of the file. Enter a filename or click the file chooser button to browse to the file's location.

File type Select if the file is to be saved in normal .sav or compressed.zsav format.

Encrypt file with password To protect the file with a password, select this box; you are prompted to enter and confirm the Password in a separate dialog box.

Note: Password protected files can only be opened by SPSS® Modeler version 16 or greater, or by SPSS Statistics version 21 or greater.

Export field names Specifies a method of handling variable names and labels upon export from SPSS Modeler to an SPSS Statistics .sav or .zsav file.

- Names and variable labels Select to export both SPSS Modeler field names and field labels. Names are exported as SPSS Statistics variable names, while labels are exported as SPSS Statistics variable labels.
- Names as variable labels Select to use the SPSS Modeler field names as variable labels in SPSS Statistics. SPSS Modeler allows characters in field names that are invalid in SPSS Statistics variable names. To prevent possibly creating invalid SPSS Statistics names, select Names as variable labels instead, or use the Filter tab to adjust field names.

Launch Application If SPSS Statistics is installed on your computer, you can select this option to invoke the application directly on the saved data file. Options for launching the application must be specified in the Helper Applications dialog box. See the topic [IBM SPSS Statistics Helper Applications](#) for more information. To simply create an SPSS Statistics .sav or .zsav file without opening an external program, deselect this option.

Note: When running SPSS Modeler and SPSS Statistics together in Server (distributed) mode, writing the data out and launching a SPSS Statistics session does not automatically open a SPSS Statistics client showing the data set read into the active data set. The workaround is to manually open the data file in the SPSS Statistics client once it is launched.

Generate an import node for this data Select this option to automatically generate a Statistics File source node that will read the exported data file. See the topic [Statistics File Node](#) for more information.

Related information

- [Statistics Export Node](#)

Renaming or Filtering Fields for IBM SPSS Statistics

Before exporting or deploying data from IBM® SPSS® Modeler to external applications such as IBM SPSS Statistics, it may be necessary to rename or adjust field names. The Statistics Transform, Statistics Output, and Statistics Export dialog boxes contain a Filter tab to facilitate this process.

A basic description of Filter tab functionality is discussed elsewhere. See the topic [Setting filtering options](#) for more information.

To adjust field names to conform to IBM SPSS Statistics naming conventions:

1. On the Filter tab, click the Filter Options Menu toolbar button (the first one on the toolbar).
2. Select Rename For IBM SPSS Statistics.
3. On the Rename For IBM SPSS Statistics dialog, you can choose to replace invalid characters in filenames with either a Hash (#) character or an Underscore (_).

Rename multi response sets. Select this option if you want to adjust the names of multiple response sets, which can be imported into IBM SPSS Modeler using a Statistics File source node. They are used to record data that can have more than one value for each case, such as in survey responses.

SuperNodes

- [Overview of SuperNodes](#)
 - [Types of SuperNodes](#)
 - [Creating SuperNodes](#)
 - [Locking SuperNodes](#)
 - [Editing SuperNodes](#)
 - [Saving and loading SuperNodes](#)
-

Overview of SuperNodes

One of the reasons that the IBM® SPSS® Modeler visual programming interface is so easy to learn is that each node has a clearly defined function. However, for complex processing, a long sequence of nodes may be necessary. Eventually, this may clutter the stream canvas and make it difficult to follow stream diagrams. There are two ways to avoid the clutter of a long and complex stream:

- You can split a processing sequence into several streams that feed one into the other. The first stream, for example, creates a data file that the second uses as input. The second creates a file that the third uses as input, and so on. You can manage these multiple streams by saving them in a **project**. A project provides organization for multiple streams and their output. However, a project file contains only a reference to the objects it contains, and you will still have multiple stream files to manage.
- You can create a **SuperNode** as a more streamlined alternative when working with complex stream processes.

SuperNodes group multiple nodes into a single node by encapsulating sections of a data stream. This provides numerous benefits to the data miner:

- Streams are neater and more manageable.
 - Nodes can be combined into a business-specific SuperNode.
 - SuperNodes can be exported to libraries for reuse in multiple data mining projects.
-

Types of SuperNodes

SuperNodes are represented in the data stream by a star icon. The icon is shaded to represent the type of SuperNode and the direction in which the stream must flow to or from it.

There are three types of SuperNodes:

- Source SuperNodes
- Process SuperNodes
- Terminal SuperNodes

- [Source SuperNodes](#)
 - [Process SuperNodes](#)
 - [Terminal SuperNodes](#)
-

Source SuperNodes

Source SuperNodes contain a data source just like a normal source node and can be used anywhere that a normal source node can be used. The left side of a source SuperNode is shaded to indicate that it is "closed" on the left and that data must flow downstream *from* a SuperNode.

Source SuperNodes have only one connection point on the right, showing that data leaves the SuperNode and flows to the stream.

Related information

- [Creating SuperNodes](#)
 - [Types of SuperNodes](#)
-

Process SuperNodes

Process SuperNodes contain only process nodes and are unshaded to show that data can flow both *in* and *out* of this type of SuperNode.

Process SuperNodes have connection points on both the left and right, showing that data enters the SuperNode and leaves to flow back to the stream. Although SuperNodes can contain additional stream fragments and even extra streams, both connection points must flow through a single path connecting the *From Stream* and *To Stream* points.

Note: Process SuperNodes are also sometimes referred to as *Manipulation SuperNodes*.

Related information

 - [Types of SuperNodes](#)
-

Terminal SuperNodes

Terminal SuperNodes contain one or more terminal nodes (plot, table, and so on) and can be used in the same manner as a terminal node. A terminal SuperNode is shaded on the right side to indicate that it is "closed" on the right and that data can flow only *into* a terminal SuperNode.

Terminal SuperNodes have only one connection point on the left, showing that data enters the SuperNode from the stream and terminates inside the SuperNode.

Terminal SuperNodes can also contain scripts that are used to specify the order of execution for all terminal nodes inside the SuperNode. See the topic [SuperNodes and scripting](#) for more information.

Creating SuperNodes

Creating a SuperNode "shrinks" the data stream by encapsulating several nodes into one node. Once you have created or loaded a stream on the canvas, there are several ways to create a SuperNode.

Multiple Selection

The simplest way to create a SuperNode is by selecting all of the nodes that you want to encapsulate:

1. Use the mouse to select multiple nodes on the stream canvas. You can also use Shift-click to select a stream or section of a stream.
Note: Nodes that you select must be from a continuous or forked stream. You cannot select nodes that are not adjacent or connected in some way.
2. Then, using one of the following three methods, encapsulate the selected nodes:
 - Click the SuperNode icon (shaped like a star) on the toolbar.
 - Right-click the SuperNode, and from the context menu choose:
Create SuperNode > From Selection
 - From the SuperNode menu, choose:
Create SuperNode > From Selection

All three of these options encapsulate the nodes into a SuperNode shaded to reflect its type--source, process, or terminal--based on its contents.

Single Selection

You can also create a SuperNode by selecting a single node and using menu options to determine the start and end of the SuperNode or encapsulating everything downstream of the selected node.

1. Click the node that determines the start of encapsulation.
2. From the SuperNode menu, choose:
Create SuperNode > From Here

SuperNodes can also be created more interactively by selecting the start and end of the stream section to encapsulate nodes:

1. Click on the first or last node that you want to include in the SuperNode.
2. From the SuperNode menu, choose:
Create SuperNode > Select...
3. Alternatively, you can use the context menu options by right-clicking the desired node.
4. The cursor becomes a SuperNode icon, indicating that you must select another point in the stream. Move either upstream or downstream to the "other end" of the SuperNode fragment and click on a node. This action will replace all nodes in between with the SuperNode star icon.

Note: Nodes that you select must be from a continuous or forked stream. You cannot select nodes that are not adjacent or connected in some way.

- [Nesting SuperNodes](#)
-

Nesting SuperNodes

SuperNodes can be nested within other SuperNodes. The same rules for each type of SuperNode (source, process, and terminal) apply to nested SuperNodes. For example, a process SuperNode with nesting must have a continuous data flow through all nested SuperNodes in order for it to remain a process SuperNode. If one of the nested SuperNodes is terminal, then data would no longer flow through the hierarchy.

Terminal and source SuperNodes can contain other types of nested SuperNodes, but the same basic rules for creating SuperNodes apply.

Locking SuperNodes

Once you have created a SuperNode, you can lock it with a password to prevent it from being amended. For example, you might do this if you are creating streams, or parts of streams, as fixed-value templates for use by others in your organization who have less experience with setting up IBM® SPSS® Modeler enquiries.

When a SuperNode is locked users can still enter values on the Parameters tab for any parameters that have been defined, and a locked SuperNode can be executed without entering the password.

Note: Locking and unlocking cannot be performed using scripts.

- [Locking and unlocking a SuperNode](#)
- [Editing a locked SuperNode](#)

Locking and unlocking a SuperNode

Warning: Lost passwords cannot be recovered.

You can lock or unlock a SuperNode from any of the three tabs.

1. Click Lock Node.
2. Enter and confirm the password.
3. Click OK.

A password protected SuperNode is identified on the stream canvas by a small padlock symbol to the top-left of the SuperNode icon.

Unlocking a SuperNode

1. To permanently remove the password protection, click Unlock Node. You are prompted for the password.
2. Enter the password and click OK. The SuperNode is no longer password protected and the padlock symbol no longer shows next to the icon in the stream.

For a stream saved in a version of SPSS® Modeler between 16 and 17.0 that contains a locked SuperNode, when opening the stream in a different environment such as in IBM® SPSS Collaboration and Deployment Services or on a Mac when the SPSS Modeler-installed JRE is different, it must first be opened, unlocked, and resaved using version 17.1 or later on the old environment where it was last saved.

Sometimes an incorrect password error will be displayed when unlocking a SuperNode in stream older than version 18. To work around this, reopen and unlock the node using the exact IBM SPSS Modeler version (or a more current version) on the same platform with the same system local settings as when it was last saved. Then open it in version 18 or later, lock the node, and save the stream again.

Editing a locked SuperNode

If you attempt to either define parameters or zoom in to display a locked SuperNode you are prompted to enter the password.

Enter the password and click OK.

You are now able to edit the parameter definitions and zoom in and out as often as you require until you close the stream that the SuperNode is in.

Note that this does not remove the password protection, it only allows you access to work with the SuperNode. See the topic [Locking and unlocking a SuperNode](#) for more information.

Editing SuperNodes

Once you have created a SuperNode, you can examine it more closely by zooming in to it; if the SuperNode is locked, you will be prompted to enter the password. See the topic [Editing a locked SuperNode](#) for more information.

To view the contents of a SuperNode, you can use the zoom-in icon from the IBM® SPSS® Modeler toolbar, or the following method:

1. Right-click a SuperNode.
2. From the context menu, choose Zoom In.

The contents of the selected SuperNode will be displayed in a slightly different IBM SPSS Modeler environment, with connectors showing the flow of data through the stream or stream fragment. At this level on the stream canvas, there are several tasks that you can perform:

- Modify the SuperNode type—source, process, or terminal.
 - Create parameters or edit the values of a parameter. Parameters are used in scripting and CLEM expressions.
 - Specify caching options for the SuperNode and its subnodes.
 - Create or modify a SuperNode script (terminal SuperNodes only).
- [Modifying SuperNode types](#)
 - [Annotating and renaming SuperNodes](#)
 - [SuperNode parameters](#)
 - [SuperNodes and caching](#)
 - [SuperNodes and scripting](#)

Modifying SuperNode types

In some circumstances, it is useful to alter the type of a SuperNode. This option is available only when you are zoomed in to a SuperNode, and it applies only to the SuperNode at that level. The three types of SuperNodes are explained in the following table.

Table 1. Types of SuperNode

Type of SuperNode	Description
Source SuperNode	One connection going out
Process SuperNode	Two connections: one coming in and one going out
Terminal SuperNode	One connection coming in

To change the type of a SuperNode

1. Be sure that you are zoomed in to the SuperNode.
2. From the SuperNode menu, choose SuperNode Type, and then choose the type.

Annotating and renaming SuperNodes

You can rename a SuperNode as it appears in the stream, and write annotations used in a project or report. To access these properties:

- Right-click a SuperNode (zoomed out) and choose Rename and Annotate.
- Alternatively, from the SuperNode menu, choose Rename and Annotate. This option is available in both zoomed-in and zoomed-out modes.

In both cases, a dialog box opens with the Annotations tab selected. Use the options here to customize the name displayed on the stream canvas and provide documentation regarding SuperNode operations.

Using Comments with SuperNodes

If you create a SuperNode from a commented node or nugget, you must include the comment in the selection to create the SuperNode if you want the comment to appear in the SuperNode. If you omit the comment from the selection, the comment will remain on the stream when the SuperNode is created.

When you expand a SuperNode that included comments, the comments are reinstated to where they were before the SuperNode was created.

When you expand a SuperNode that included commented objects, but the comments were not included in the SuperNode, the objects are reinstated to where they were, but the comments are not reattached.

SuperNode parameters

In IBM® SPSS® Modeler, you have the ability to set user-defined variables, such as **Minvalue**, whose values can be specified when used in scripting or CLEM expressions. These variables are called **parameters**. You can set parameters for streams, sessions, and SuperNodes. Any parameters set for a SuperNode are available when building CLEM expressions in that SuperNode or any nested nodes. Parameters set for nested SuperNodes are not available to their parent SuperNode.

There are two steps to creating and setting parameters for SuperNodes:

1. Define parameters for the SuperNode.
2. Then, specify the value for each parameter of the SuperNode.

These parameters can then be used in CLEM expressions for any encapsulated nodes.

- [Defining SuperNode Parameters](#)
- [Setting Values for SuperNode Parameters](#)
- [Using SuperNode Parameters to Access Node Properties](#)

Defining SuperNode Parameters

Parameters for a SuperNode can be defined in both zoomed-out and zoomed-in modes. The parameters defined apply to all encapsulated nodes. To define the parameters of a SuperNode, you first need to access the Parameters tab of the SuperNode dialog box. Use one of the following methods to open the dialog box:

- Double-click a SuperNode in the stream.
- From the SuperNode menu, choose Set Parameters.
- Alternatively, when zoomed in to a SuperNode, choose Set Parameters from the context menu.

Once you have opened the dialog box, the Parameters tab is visible with any previously defined parameters.

To Define a New Parameter

Click the Define Parameters button to open the dialog box.

Name. Parameter names are listed here. You can create a new parameter by entering a name in this field. For example, to create a parameter for the minimum temperature, you could type `minvalue`. Do not include the `$P-` prefix that denotes a parameter in CLEM expressions. This name is also used for display in the CLEM Expression Builder.

Long name. Lists the descriptive name for each parameter created.

Storage. Select a storage type from the list. Storage indicates how the data values are stored in the parameter. For example, when working with values containing leading zeros that you want to preserve (such as 008), you should select String as the storage type. Otherwise, the zeros will be stripped from the value. Available storage types are string, integer, real, time, date, and timestamp. For date parameters, note that values must be specified using ISO standard notation as shown in the next paragraph.

Value. Lists the current value for each parameter. Adjust the parameter as required. Note that for date parameters, values must be specified in ISO standard notation (that is, `YYYY-MM-DD`). Dates specified in other formats are not accepted.

Type (optional). If you plan to deploy the stream to an external application, select a measurement level from the list. Otherwise, it is advisable to leave the *Type* column as is. If you want to specify value constraints for the parameter, such as upper and lower bounds for a numeric range, select Specify from the list.

Note that long name, storage, and type options can be set for parameters through the user interface only. These options cannot be set using scripts.

Click the arrows at the right to move the selected parameter further up or down the list of available parameters. Use the delete button (marked with an *X*) to remove the selected parameter.

Setting Values for SuperNode Parameters

Once you have defined parameters for a SuperNode, you can specify values using the parameters in a CLEM expression or script.

To Specify the Parameters of a SuperNode

1. Double-click the SuperNode icon to open the SuperNode dialog box.
2. Alternatively, from the SuperNode menu, choose Set Parameters.
3. Click the Parameters tab. *Note:* The fields in this dialog box are the fields defined by clicking the Define Parameters button on this tab.
4. Enter a value in the text box for each parameter that you have created. For example, you can set the value `minvalue` to a particular threshold of interest. This parameter can then be used in numerous operations, such as selecting records above or below this threshold for further exploration.

Using SuperNode Parameters to Access Node Properties

SuperNode parameters can also be used to define node properties (also known as **slot parameters**) for encapsulated nodes. For example, suppose you want to specify that a SuperNode train an encapsulated Neural Net node for a certain length of time using a random sample of the data available. Using parameters, you can specify values for the length of time and percentage sample.

Suppose your example SuperNode contains a Sample node called *Sample* and a Neural Net node called *Train*. You can use the node dialog boxes to specify the Sample node's **Sample** setting as Random % and the Neural Net node's **Stop on** setting to Time. Once these options are specified, you can access the node properties with parameters and specify specific values for the SuperNode. In the SuperNode dialog box, click Define Parameters and create the parameters shown in the following table.

Table 1. Parameters to create

Parameter	Value	Long name
Train.time	5	Time to train (minutes)
Sample.random	10	Percentage random sample

Note: The parameter names, such as *Sample.random*, use correct syntax for referring to node properties, where *Sample* represents the name of the node and *random* is a node property.

Once you have defined these parameters, you can easily modify values for the two Sample and Neural Net node properties without reopening each dialog box. Instead, simply select Set Parameters from the SuperNode menu to access the Parameters tab of the SuperNode dialog box, where you can specify new values for Random % and Time. This is particularly useful when exploring the data during numerous iterations of model building.

SuperNodes and caching

From within a SuperNode, all nodes except terminal nodes can be cached. Caching is controlled by right-clicking a node and choosing one of several options from the Cache context menu. This menu option is available both from outside a SuperNode and for the nodes encapsulated within a SuperNode.

There are several guidelines for SuperNode caches:

- If any of the nodes encapsulated in a SuperNode have caching enabled, the SuperNode will also.
- Disabling the cache on a SuperNode disables the cache for *all* encapsulated nodes.
- Enabling caching on a SuperNode actually enables the cache on the last cacheable subnode. In other words, if the last subnode is a Select node, the cache will be enabled for that Select node. If the last subnode is a terminal node (which does not allow caching), the next node upstream that supports caching will be enabled.
- Once you have set caches for the subnodes of a SuperNode, any activities upstream from the cached node, such as adding or editing nodes, will flush the caches.

SuperNodes and scripting

You can use the SPSS® Modeler scripting language to write simple programs that manipulate and execute the contents of a terminal SuperNode. For instance, you might want to specify the order of execution for a complex stream. As an example, if a SuperNode contains a Set Globals node that needs to be executed before a Plot node, you can create a script that executes the Set Globals node first. Values calculated by this node, such as the average or standard deviation, can then be used when the Plot node is executed.

The Script tab of the SuperNode dialog box is available only for terminal SuperNodes.

To open the Scripting dialog box for a Terminal SuperNode:

- Right-click the SuperNode canvas and choose SuperNode Script.
- Alternatively, in both zoomed-in and zoomed-out modes, you can choose SuperNode Script from the SuperNode menu.

Note: SuperNode scripts are executed only with the stream and SuperNode when you have selected Run this script in the dialog box. Specific options for scripting and its use within SPSS Modeler are discussed in the *Scripting and Automation Guide*, which is available as a PDF file as part of your product download.

Saving and loading SuperNodes

One of the advantages of SuperNodes is that they can be saved and reused in other streams. When saving and loading SuperNodes, note that they use an .slb extension.

To save a SuperNode

1. Zoom in on the SuperNode.
2. From the SuperNode menu, choose Save SuperNode.
3. Specify a filename and directory in the dialog box.
4. Select whether to add the saved SuperNode to the current project.
5. Click Save.

To load a SuperNode

1. From the Insert menu in the IBM® SPSS® Modeler window, choose SuperNode.
2. Select a SuperNode file (.slb) from the current directory or browse to a different one.
3. Click Load.

Note: Imported SuperNodes have the default values for all of their parameters. To change the parameters, double-click a SuperNode on the stream canvas.

Modeling Overview

-

Overview of modeling nodes

IBM® SPSS® Modeler offers a variety of modeling methods taken from machine learning, artificial intelligence, and statistics. The methods available on the Modeling palette allow you to derive new information from your data and to develop predictive models. Each method has certain strengths and is best suited for particular types of problems.

The *IBM SPSS Modeler Applications Guide* provides examples for many of these methods, along with a general introduction to the modeling process. This guide is available as an online tutorial, and also in PDF format. [More information](#).

Modeling methods are divided into these categories:

- Supervised
- Association
- Segmentation

Supervised Models

Supervised models use the values of one or more **input** fields to predict the value of one or more output, or **target**, fields. Some examples of these techniques are: decision trees (C&R Tree, QUEST, CHAID and C5.0 algorithms), regression (linear, logistic, generalized linear, and Cox regression algorithms), neural networks, support vector machines, and Bayesian networks.

Supervised models help organizations to predict a known result, such as whether a customer will buy or leave or whether a transaction fits a known pattern of fraud. Modeling techniques include machine learning, rule induction, subgroup identification, statistical methods, and multiple model generation.

Supervised nodes

	The Auto Classifier node creates and compares a number of different models for binary outcomes (yes or no, churn or do not churn, and so on), allowing you to choose the best approach for a given analysis. A number of modeling algorithms are supported, making it possible to select the methods you want to use, the specific options for each, and the criteria for comparing the results. The node generates a set of models based on the specified options and ranks the best candidates according to the criteria you specify.
	The Auto Numeric node estimates and compares models for continuous numeric range outcomes using a number of different methods. The node works in the same manner as the Auto Classifier node, allowing you to choose the algorithms to use and to experiment with multiple combinations of options in a single modeling pass. Supported algorithms include neural networks, C&R Tree, CHAID, linear regression, generalized linear regression, and support vector machines (SVM). Models can be compared based on correlation, relative error, or number of variables used.

	The Classification and Regression (C&R) Tree node generates a decision tree that allows you to predict or classify future observations. The method uses recursive partitioning to split the training records into segments by minimizing the impurity at each step, where a node in the tree is considered “pure” if 100% of cases in the node fall into a specific category of the target field. Target and input fields can be numeric ranges or categorical (nominal, ordinal, or flags); all splits are binary (only two subgroups).
	The QUEST node provides a binary classification method for building decision trees, designed to reduce the processing time required for large C&R Tree analyses while also reducing the tendency found in classification tree methods to favor inputs that allow more splits. Input fields can be numeric ranges (continuous), but the target field must be categorical. All splits are binary.
	The CHAID node generates decision trees using chi-square statistics to identify optimal splits. Unlike the C&R Tree and QUEST nodes, CHAID can generate nonbinary trees, meaning that some splits have more than two branches. Target and input fields can be numeric range (continuous) or categorical. Exhaustive CHAID is a modification of CHAID that does a more thorough job of examining all possible splits but takes longer to compute.
	The C5.0 node builds either a decision tree or a rule set. The model works by splitting the sample based on the field that provides the maximum information gain at each level. The target field must be categorical. Multiple splits into more than two subgroups are allowed.
	The Decision List node identifies subgroups, or segments, that show a higher or lower likelihood of a given binary outcome relative to the overall population. For example, you might look for customers who are unlikely to churn or are most likely to respond favorably to a campaign. You can incorporate your business knowledge into the model by adding your own custom segments and previewing alternative models side by side to compare the results. Decision List models consist of a list of rules in which each rule has a condition and an outcome. Rules are applied in order, and the first rule that matches determines the outcome.
	Linear regression models predict a continuous target based on linear relationships between the target and one or more predictors.
	The PCA/Factor node provides powerful data-reduction techniques to reduce the complexity of your data. Principal components analysis (PCA) finds linear combinations of the input fields that do the best job of capturing the variance in the entire set of fields, where the components are orthogonal (perpendicular) to each other. Factor analysis attempts to identify underlying factors that explain the pattern of correlations within a set of observed fields. For both approaches, the goal is to find a small number of derived fields that effectively summarizes the information in the original set of fields.
	The Feature Selection node screens input fields for removal based on a set of criteria (such as the percentage of missing values); it then ranks the importance of remaining inputs relative to a specified target. For example, given a data set with hundreds of potential inputs, which are most likely to be useful in modeling patient outcomes?
	Discriminant analysis makes more stringent assumptions than logistic regression but can be a valuable alternative or supplement to a logistic regression analysis when those assumptions are met.
	Logistic regression is a statistical technique for classifying records based on values of input fields. It is analogous to linear regression but takes a categorical target field instead of a numeric range.
	The Generalized Linear model expands the general linear model so that the dependent variable is linearly related to the factors and covariates through a specified link function. Moreover, the model allows for the dependent variable to have a non-normal distribution. It covers the functionality of a wide number of statistical models, including linear regression, logistic regression, loglinear models for count data, and interval-censored survival models.
	A generalized linear mixed model (GLMM) extends the linear model so that the target can have a non-normal distribution, is linearly related to the factors and covariates via a specified link function, and so that the observations can be correlated. Generalized linear mixed models cover a wide variety of models, from simple linear regression to complex multilevel models for non-normal longitudinal data.
	The Cox regression node enables you to build a survival model for time-to-event data in the presence of censored records. The model produces a survival function that predicts the probability that the event of interest has occurred at a given time (t) for given values of the input variables.
	The Support Vector Machine (SVM) node enables you to classify data into one of two groups without overfitting. SVM works well with wide data sets, such as those with a very large number of input fields.
	The Bayesian Network node enables you to build a probability model by combining observed and recorded evidence with real-world knowledge to establish the likelihood of occurrences. The node focuses on Tree Augmented Naïve Bayes (TAN) and Markov Blanket networks that are primarily used for classification.
	The Self-Learning Response Model (SLRM) node enables you to build a model in which a single new case, or small number of new cases, can be used to reestimate the model without having to retrain the model using all data.
	The Time Series node estimates exponential smoothing, univariate Autoregressive Integrated Moving Average (ARIMA), and multivariate ARIMA (or transfer function) models for time series data and produces forecasts of future performance. This Time Series node is similar to the previous Time Series node that was deprecated in SPSS Modeler version 18. However, this newer Time Series node is designed to harness the power of IBM SPSS Analytic Server to process big data, and display the resulting model in the output viewer that was added in SPSS Modeler version 17.
	The k -Nearest Neighbor (KNN) node associates a new case with the category or value of the k objects nearest to it in the predictor space, where k is an integer. Similar cases are near each other and dissimilar cases are distant from each other.

The Spatio-Temporal Prediction (STP) node uses data that contains location data, input fields for prediction (predictors), a time field, and a target field. Each location has numerous rows in the data that represent the values of each predictor at each time of measurement. After the data is analyzed, it can be used to predict target values at any location within the shape data that is used in the analysis.

Association Models

Association models find patterns in your data where one or more entities (such as events, purchases, or attributes) are associated with one or more other entities. The models construct rule sets that define these relationships. Here the fields within the data can act as both inputs and targets. You could find these associations manually, but association rule algorithms do so much more quickly, and can explore more complex patterns. Apriori and Carma models are examples of the use of such algorithms. One other type of association model is a sequence detection model, which finds sequential patterns in time-structured data.

Association models are most useful when predicting multiple outcomes—for example, customers who bought product X also bought Y and Z. Association models associate a particular conclusion (such as the decision to buy something) with a set of conditions. The advantage of association rule algorithms over the more standard decision tree algorithms (C5.0 and C&RT) is that associations can exist between any of the attributes. A decision tree algorithm will build rules with only a single conclusion, whereas association algorithms attempt to find many rules, each of which may have a different conclusion.

Association nodes

	The Apriori node extracts a set of rules from the data, pulling out the rules with the highest information content. Apriori offers five different methods of selecting rules and uses a sophisticated indexing scheme to process large data sets efficiently. For large problems, Apriori is generally faster to train; it has no arbitrary limit on the number of rules that can be retained, and it can handle rules with up to 32 preconditions. Apriori requires that input and output fields all be categorical but delivers better performance because it is optimized for this type of data.
	The CARMA model extracts a set of rules from the data without requiring you to specify input or target fields. In contrast to Apriori the CARMA node offers build settings for rule support (support for both antecedent and consequent) rather than just antecedent support. This means that the rules generated can be used for a wider variety of applications—for example, to find a list of products or services (antecedents) whose consequent is the item that you want to promote this holiday season.
	The Sequence node discovers association rules in sequential or time-oriented data. A sequence is a list of item sets that tends to occur in a predictable order. For example, a customer who purchases a razor and aftershave lotion may purchase shaving cream the next time he shops. The Sequence node is based on the CARMA association rules algorithm, which uses an efficient two-pass method for finding sequences.
	The Association Rules Node is similar to the Apriori Node; however, unlike Apriori, the Association Rules Node can process list data. In addition, the Association Rules Node can be used with IBM SPSS Analytic Server to process big data and take advantage of faster parallel processing.

Segmentation Models

Segmentation models divide the data into segments, or clusters, of records that have similar patterns of input fields. As they are only interested in the input fields, segmentation models have no concept of output or target fields. Examples of segmentation models are Kohonen networks, K-Means clustering, two-step clustering and anomaly detection.

Segmentation models (also known as "clustering models") are useful in cases where the specific result is unknown (for example, when identifying new patterns of fraud, or when identifying groups of interest in your customer base). Clustering models focus on identifying groups of similar records and labeling the records according to the group to which they belong. This is done without the benefit of prior knowledge about the groups and their characteristics, and it distinguishes clustering models from the other modeling techniques in that there is no predefined output or target field for the model to predict. There are no right or wrong answers for these models. Their value is determined by their ability to capture interesting groupings in the data and provide useful descriptions of those groupings. Clustering models are often used to create clusters or segments that are then used as inputs in subsequent analyses (for example, by segmenting potential customers into homogeneous subgroups).

Segmentation nodes

	The Auto Cluster node estimates and compares clustering models, which identify groups of records that have similar characteristics. The node works in the same manner as other automated modeling nodes, allowing you to experiment with multiple combinations of options in a single modeling pass. Models can be compared using basic measures with which to attempt to filter and rank the usefulness of the cluster models, and provide a measure based on the importance of particular fields.
	The K-Means node clusters the data set into distinct groups (or clusters). The method defines a fixed number of clusters, iteratively assigns records to clusters, and adjusts the cluster centers until further refinement can no longer improve the model. Instead of trying to predict an outcome, k-means uses a process known as unsupervised learning to uncover patterns in the set of input fields.
	The Kohonen node generates a type of neural network that can be used to cluster the data set into distinct groups. When the network is fully trained, records that are similar should be close together on the output map, while records that are different will be far apart. You can look at the number of observations captured by each unit in the model nugget to identify the strong units. This may give you a sense of the appropriate number of clusters.
	The TwoStep node uses a two-step clustering method. The first step makes a single pass through the data to compress the raw input data into a manageable set of subclusters. The second step uses a hierarchical clustering method to progressively

	merge the subclusters into larger and larger clusters. TwoStep has the advantage of automatically estimating the optimal number of clusters for the training data. It can handle mixed field types and large data sets efficiently.
	The Anomaly Detection node identifies unusual cases, or outliers, that do not conform to patterns of "normal" data. With this node, it is possible to identify outliers even if they do not fit any previously known patterns and even if you are not exactly sure what you are looking for.

Note: KNN, SVM, GENLin, Cox, SLRM, and Bayes Net nodes are part of the Extension Classification Module in SPSS Modeler and are supported under the Modeler Premium license.

In-Database Mining Models

IBM SPSS Modeler supports integration with data mining and modeling tools that are available from database vendors, including Oracle Data Miner and Microsoft Analysis Services. You can build, score, and store models inside the database—all from within the IBM SPSS Modeler application. For full details, see the *IBM SPSS Modeler In-Database Mining Guide*.

IBM SPSS Statistics Models

If you have a copy of IBM SPSS Statistics installed and licensed on your computer, you can access and run certain IBM SPSS Statistics routines from within IBM SPSS Modeler to build and score models.

Building Split Models

Split modeling enables you to use a single stream to build separate models for each possible value of a flag, nominal, or continuous input field, with the resulting models all being accessible from a single model nugget. The possible values for the input fields could have very different effects on the model. With split modeling, you can easily build the best-fitting model for each possible field value in a single execution of the stream.

Note that interactive modeling sessions cannot use splitting. With interactive modeling you specify each model individually, so there would be no advantage in using splitting, which builds multiple models automatically.

Split modeling works by designating a particular input field as a split field. You can do this by setting the field role to Split in the Type specification.

You can designate only fields with a measurement level of Flag, Nominal, Ordinal, or Continuous as split fields.

You can assign more than one input field as a split field. In this case, however, the number of models created can be greatly increased. A model is built for each possible combination of the values of the selected split fields. For example, if three input fields, each having three possible values, are designated as split fields, this will result in the creation of 27 different models.

Even after you assign one or more fields as split fields, you can still choose whether to create split models or a single model, by means of a check box setting on the modeling node dialog.

If split fields are defined but the check box is not selected, only a single model is generated. Likewise if the check box is selected but no split field is defined, splitting is ignored and a single model is generated.

When you run the stream, separate models are built behind the scenes for each possible value of the split field or fields, but only a single model nugget is placed in the models palette and the stream canvas. A split-model nugget is denoted by the split symbol; this is two gray rectangles overlaid on the nugget image.

When you browse the split-model nugget, you see a list of all the separate models that have been built.

You can investigate an individual model from a list by double-clicking its nugget icon in the viewer. Doing so opens a standard browser window for the individual model. When the nugget is on the canvas, double-clicking a graph thumbnail opens the full-size graph. See the topic [Split Model Viewer](#) for more information.

Once a model has been created as a split model, you cannot remove the split processing from it, nor can you undo splitting further downstream from a split-modeling node or nugget.

Example. A national retailer wants to estimate sales by product category at each of its stores around the country. Using split modeling, they designate the Store field of their input data as a split field, enabling them to build separate models for each category at each store in a single operation. They can then use the resulting information to control stock levels much more accurately than they could with only a single model.

- [Splitting and Partitioning](#)
- [Modeling nodes supporting split models](#)
- [Features Affected by Splitting](#)

Splitting and Partitioning

Splitting has some features in common with partitioning, but the two are used in very different ways.

Partitioning divides the dataset randomly into either two or three parts: training, testing and (optionally) validation, and is used to test the performance of a single model.

Splitting divides the dataset into as many parts as there are possible values for a split field, and is used to build multiple models.

Partitioning and splitting operate completely independently of each other. You can choose either, both or neither in a modeling node.

Modeling nodes supporting split models

A number of modeling nodes can create split models. The exceptions are Auto Cluster, PCA/Factor, Feature Selection, SLM, Random Trees, Tree-AS, Linear-AS, LSVM, the association models (Apriori, Carma and Sequence), the clustering models (K-Means, Kohonen, Two Step and Anomaly), Statistics models, and the nodes used for in-database modeling.

The modeling nodes that support split modeling are:

	C&R Tree		Bayes Net		Linear
	QUEST		GenLin		GLMM
	CHAID		KNN		STP
	C5.0		Cox		One-Class SVM
	Neural Net		Auto Classifier		XGBoost Tree
	Decision List		Auto Numeric		XGBoost Linear
	Regression		Logistic		HDBSCAN
	Discriminant		SVM		Time Series

Features Affected by Splitting

The use of split models affects a number of IBM® SPSS® Modeler features in various ways. This section provides guidance on using split models with other nodes in a stream.

Record Ops nodes

When you use split models in a stream that contains a Sample node, stratify records by the split field to achieve an even sampling of records. This option is available when you choose *Complex* as the sample method.

If the stream contains a Balance node, balancing applies to the overall set of input records, not to the subset of records inside a split.

When aggregating records by means of an Aggregate node, set the split fields to be key fields if you want to calculate aggregates for each split.

Field Ops nodes

The Type node is where you specify which field or fields to use as split fields.

Note: While the Ensemble node is used to combine two or more model nuggets, it cannot be used to reverse the action of splitting, as the split models are contained inside a single model nugget.

Modeling nodes

Split models do not support the calculation of predictor importance (the relative importance of the predictor input fields in estimating the model). Predictor importance settings are ignored when building split models.

Note: Adjusted propensity score settings are ignored when using a split model.

The KNN (nearest neighbor) node supports split models only if it is set to predict a target field. The alternative setting (only identify nearest neighbors) does not create a model. If the option Automatically select k is chosen, each of the split models might have a different number of nearest neighbors. Thus the overall model has a number of generated columns equal to the largest number of nearest neighbors that are found across all the split models. For those split models where the number of nearest neighbors is less than this maximum, there is a corresponding number of columns filled with `$null` values. See the topic [KNN node](#) for more information.

Database Modeling nodes

The in-database modeling nodes do not support split models.

Model nuggets

Export to PMML from a split model nugget is not possible, as the nugget contains multiple models and PMML does not support such a packaging. Export to text or HTML is possible.

Modeling Node Fields Options

All modeling nodes have a Fields tab, where you can specify the fields to be used in building the model.

Before you can build a model, you need to specify which fields you want to use as targets and as inputs. With a few exceptions, all modeling nodes will use field information from an upstream Type node. If you are using a Type node to select input and target fields, you don't need to change anything on this tab. (Exceptions include the Sequence node and the Text Extraction node, which require that field settings be specified in the modeling node.)

Use type node settings. This option tells the node to use field information from an upstream Type node. This is the default.

Use custom settings. This option tells the node to use field information specified here instead of that given in any upstream Type node(s). After selecting this option, specify the fields below as required.

Note: Not all fields are displayed for all nodes.

- **Use transactional format (Apriori, CARMA, MS Association Rules and Oracle Apriori nodes only).** Select this check box if the source data is in **transactional format**. Records in this format have two fields, one for an ID and one for content. Each record represents a single transaction or item, and associated items are linked by having the same ID. Deselect this box if the data is in **tabular format**, in which items are represented by separate flags, where each flag field represents the presence or absence of a specific item and each record represents a complete set of associated items. See the topic [Tabular versus Transactional Data](#) for more information.
 - ID. For transactional data, select an ID field from the list. Numeric or symbolic fields can be used as the ID field. Each unique value of this field should indicate a specific unit of analysis. For example, in a market basket application, each ID might represent a single customer. For a Web log analysis application, each ID might represent a computer (by IP address) or a user (by login data).
 - IDs are contiguous. (Apriori and CARMA nodes only) If your data are presorted so that all records with the same ID are grouped together in the data stream, select this option to speed up processing. If your data are not presorted (or you are not sure), leave this option unselected and the node will sort the data automatically.
Note: If your data are not sorted and you select this option, you may get invalid results in your model.
 - Content. Specify the content field(s) for the model. These fields contain the items of interest in association modeling. You can specify multiple flag fields (if data are in tabular format) or a single nominal field (if data are in transactional format).
- **Target.** For models that require one or more target fields, select the target field or fields. This is similar to setting the field role to *Target* in a Type node.
- **Evaluation.** (For Auto Cluster models only.) No target is specified for cluster models; however, you can select an evaluation field to identify its level of importance. In addition, you can evaluate how well the clusters differentiate values of this field, which in turn indicates whether the clusters can be used to predict this field. *Note* The evaluation field must be a string with more than one value.
 - Inputs. Select the input field or fields. This is similar to setting the field role to *Input* in a Type node.
 - Partition. This field allows you to specify a field used to partition the data into separate samples for the training, testing, and validation stages of model building. By using one sample to generate the model and a different sample to test it, you can get a good indication of how well the model will generalize to larger datasets that are similar to the current data. If multiple partition fields have been defined by using Type or Partition nodes, a single partition field must be selected on the Fields tab in each modeling node that uses partitioning. (If only one partition is present, it is automatically used whenever partitioning is enabled.) Also note that to apply the selected partition in your analysis, partitioning must also be enabled in the Model Options tab for the node. (Deselecting this option makes it possible to disable partitioning without changing field settings.)

- **Splits.** For split models, select the split field or fields. This is similar to setting the field role to *Split* in a Type node. You can designate only fields with a measurement level of Flag, Nominal, Ordinal or Continuous as split fields. Fields chosen as split fields cannot be used as target, input, partition, frequency or weight fields. See the topic [Building Split Models](#) for more information.
- **Use frequency field.** This option enables you to select a field as a frequency weight. Use this if the records in your training data represent more than one unit each--for example, if you are using aggregated data. The field values should be the number of units represented by each record. See the topic [Using Frequency and Weight Fields](#) for more information.

Note: If you see the error message Metadata (on input/output fields) not valid, ensure that you have specified all fields that are required, such as the frequency field.

- **Use weight field.** This option enables you to select a field as a case weight. Case weights are used to account for differences in variance across levels of the output field. See the topic [Using Frequency and Weight Fields](#) for more information.
- **Consequents.** For rule induction nodes (Apriori), select the fields to be used as consequents in the resulting rule set. (This corresponds to fields with role *Target* or *Both* in a Type node.)
- **Antecedents.** For rule induction nodes (Apriori), select the fields to be used as antecedents in the resulting rule set. (This corresponds to fields with role *Input* or *Both* in a Type node.)

Some models have a Fields tab that differs from those described in this section.

- See the topic [Sequence Node Fields Options](#) for more information.
- See the topic [CARMA Node Fields Options](#) for more information.
- [Using Frequency and Weight Fields](#)

Related information

- [Overview of modeling nodes](#)

Using Frequency and Weight Fields

Frequency and weight fields are used to give extra importance to some records over others, for example, because you know that one section of the population is under-represented in the training data (weight) or because one record represents a number of identical cases (frequency).

- Values for a frequency field should be positive integers. Records with a negative or zero frequency weight are excluded from the analysis. Non-integer frequency weights are rounded to the nearest integer.
- Case weight values should be positive but need not be integer values. Records with a negative or zero case weight are excluded from the analysis.

Scoring Frequency and Weight Fields

Frequency and weight fields are used in training models, but are not used in scoring, because the score for each record is based on its characteristics regardless of how many cases it represents. For example, suppose you have the data in the following table.

Table 1. Data example

Married	Responded
Yes	Yes
Yes	Yes
Yes	Yes
Yes	No
No	Yes
No	No
No	No

Based on this, you conclude that three out of four married people respond to the promotion, and two out of three unmarried people didn't respond. So you will score any new records accordingly, as shown in the following table.

Table 2. Scored records example

Married	\$-Responded	\$RP-Responded
Yes	Yes	0.75 (three/four)
No	No	0.67 (two/three)

Alternatively, you could store your training data more compactly, using a frequency field, as shown in the following table.

Table 3. Scored records alternative example

Married	Responded	Frequency
---------	-----------	-----------

Married	Responded	Frequency
Yes	Yes	3
Yes	No	1
No	Yes	1
No	No	2

Since this represents exactly the same dataset, you will build the same model and predict responses based solely on marital status. If you have ten married people in your scoring data, you will predict Yes for each of them regardless of whether they are presented as ten separate records, or one with a frequency value of 10. Weight, although generally not an integer, can be thought of as similarly indicating the importance of a record. This is why frequency and weight fields are not used when scoring records.

Evaluating and Comparing Models

Some model types support frequency fields, some support weight fields, and some support both. But in all cases where they apply, they are used only for model building and are not considered when evaluating models using an Evaluation node or Analysis node, or when ranking models using most of the methods supported by the Auto Classifier and Auto Numeric nodes.

- When comparing models (using evaluation charts, for example), frequency and weight values will be ignored. This enables a level comparison between models that use these fields and models that don't, but means that for an accurate evaluation, a dataset that accurately represents the population without relying on a frequency or weight field must be used. In practical terms, you can do this by making sure that models are evaluated using a testing sample in which the value of the frequency or weight field is always null or 1. (This restriction only applies when evaluating models; if frequency or weight values were always 1 for both training and testing samples, there would be no reason to use these fields in the first place.)
- If using Auto Classifier, frequency can be taken into account if ranking models based on Profit, so this method is recommended in that case.
- If necessary, you can split the data into training and testing samples using a Partition node.

-

Modeling Node Analyze Options

Many modeling nodes include an Analyze tab that enables you to obtain predictor importance information along with raw and adjusted propensity scores.

Model Evaluation

Calculate predictor importance. For models that produce an appropriate measure of importance, you can display a chart that indicates the relative importance of each predictor in estimating the model. Typically you will want to focus your modeling efforts on the predictors that matter most, and consider dropping or ignoring those that matter least. Note that predictor importance may take longer to calculate for some models, particularly when working with large datasets, and is off by default for some models as a result. Predictor importance is not available for decision list models. See [Predictor Importance](#) for more information.

Propensity Scores

Propensity scores can be enabled in the modeling node, and on the Settings tab in the model nugget. This functionality is available only when the selected target is a flag field. See the topic [Propensity Scores](#) for more information.

Calculate raw propensity scores. Raw propensity scores are derived from the model based on the training data only. If the model predicts the true value (will respond), then the propensity is the same as P, where P is the probability of the prediction. If the model predicts the false value, then the propensity is calculated as $(1 - P)$.

- If you choose this option when building the model, propensity scores will be enabled in the model nugget by default. However, you can always choose to enable raw propensity scores in the model nugget whether or not you select them in the modeling node.
- When scoring the model, raw propensity scores will be added in a field with the letters *RP* appended to the standard prefix. For example, if the predictions are in a field named *\$R-churn*, the name of the propensity score field will be *\$RRP-churn*.

Calculate adjusted propensity scores. Raw propensities are based purely on estimates given by the model, which may be overfitted, leading to over-optimistic estimates of propensity. Adjusted propensities attempt to compensate by looking at how the model performs on the test or validation partitions and adjusting the propensities to give a better estimate accordingly.

- This setting requires that a valid partition field is present in the stream.
- Unlike raw confidence scores, adjusted propensity scores must be calculated when building the model; otherwise, they will not be available when scoring the model nugget.
- When scoring the model, adjusted propensity scores will be added in a field with the letters *AP* appended to the standard prefix. For example, if the predictions are in a field named *\$R-churn*, the name of the propensity score field will be *\$RAP-churn*. Adjusted propensity scores are not available for logistic regression models.

- When calculating the adjusted propensity scores, the test or validation partition used for the calculation must not have been balanced. To avoid this, be sure the Only balance training data option is selected in any upstream Balance nodes. In addition, if a complex sample has been taken upstream this will invalidate the adjusted propensity scores.
- Adjusted propensity scores are not available for "boosted" tree and rule set models. See the topic [Boosted C5.0 Models](#) for more information.

Based on. For adjusted propensity scores to be computed, a partition field must be present in the stream. You can specify whether to use the testing or validation partition for this computation. For best results, the testing or validation partition should include at least as many records as the partition used to train the original model.

- [Propensity Scores](#)

Related information

- [Overview of modeling nodes](#)
-

Propensity Scores

For models that return a *yes* or *no* prediction, you can request propensity scores in addition to the standard prediction and confidence values. Propensity scores indicate the likelihood of a particular outcome or response. The following table contains an example.

Table 1. Propensity scores

Customer	Propensity to respond
Joe Smith	35%
Jane Smith	15%

Propensity scores are available only for models with flag targets, and indicate the likelihood of the *True* value defined for the field, as specified in a source or Type node.

Propensity Scores Versus Confidence Scores

Propensity scores differ from confidence scores, which apply to the current prediction, whether *yes* or *no*. In cases where the prediction is *no*, for example, a high confidence actually means a high likelihood *not* to respond. Propensity scores sidestep this limitation to enable easier comparison across all records. For example, a *no* prediction with a confidence of 0.85 translates to a raw propensity of 0.15 (or 1 minus 0.85).

Table 2. Confidence scores

Customer	Prediction	Confidence
Joe Smith	Will respond	.35
Jane Smith	Won't respond	.85

Obtaining Propensity Scores

- Propensity scores can be enabled on the Analyze tab in the modeling node or on the Settings tab in the model nugget. This functionality is available only when the selected target is a flag field. See the topic [Modeling Node Analyze Options](#) for more information.
- Propensity scores may also be calculated by the Ensemble node, depending on the ensemble method used.

Calculating Adjusted Propensity Scores

Adjusted propensity scores are calculated as part of the process of building the model, and will not be available otherwise. Once the model is built, it is then scored using data from the test or validation partition, and a new model to deliver adjusted propensity scores is constructed by analyzing the original model's performance on that partition. Depending on the type of model, one of two methods may be used to calculate the adjusted propensity scores.

- For rule set and tree models, adjusted propensity scores are generated by recalculating the frequency of each category at each tree node (for tree models) or the support and confidence of each rule (for rule set models). This results in a new rule set or tree model which is stored with the original model, to be used whenever adjusted propensity scores are requested. Each time the original model is applied to new data, the new model can subsequently be applied to the raw propensity scores to generate the adjusted scores.
- For other models, records produced by scoring the original model on the test or validation partition are then binned by their raw propensity score. Next, a neural network model is trained that defines a non-linear function that maps from the mean raw propensity in each bin to the mean observed propensity in the same bin. As noted earlier for tree models, the resulting neural net model is stored with the original model, and can be applied to the raw propensity scores whenever adjusted propensity scores are requested.

Caution regarding missing values in the testing partition. Handling of missing input values in the testing/validation partition varies by model (see individual model scoring algorithms for details). The C5 model cannot compute adjusted propensities when there are missing inputs.

Misclassification Costs

In some contexts, certain kinds of errors are more costly than others. For example, it may be more costly to classify a high-risk credit applicant as low risk (one kind of error) than it is to classify a low-risk applicant as high risk (a different kind of error). Misclassification costs allow you to specify the relative importance of different kinds of prediction errors.

Misclassification costs are basically weights applied to specific outcomes. These weights are factored into the model and may actually change the prediction (as a way of protecting against costly mistakes).

With the exception of C5.0 models, misclassification costs are not applied when scoring a model and are not taken into account when ranking or comparing models using an Auto Classifier node, evaluation chart, or Analysis node. A model that includes costs may not produce fewer errors than one that doesn't and may not rank any higher in terms of overall accuracy, but it is likely to perform better in practical terms because it has a built-in bias in favor of less expensive errors.

The cost matrix shows the cost for each possible combination of predicted category and actual category. By default, all misclassification costs are set to 1.0. To enter custom cost values, select Use misclassification costs and enter your custom values into the cost matrix.

To change a misclassification cost, select the cell corresponding to the desired combination of predicted and actual values, delete the existing contents of the cell, and enter the desired cost for the cell. Costs are not automatically symmetrical. For example, if you set the cost of misclassifying A as B to be 2.0, the cost of misclassifying B as A will still have the default value of 1.0 unless you explicitly change it as well.

Note: Only the Decision Trees model allows costs to be specified at build time.

Model Nuggets

Figure 1. Model nugget

A model nugget is a container for a model, that is, the set of rules, formulas or equations that represent the results of your model building operations in SPSS® Modeler. The main purpose of a nugget is for scoring data to generate predictions, or to enable further analysis of the model properties. Opening a model nugget on the screen enables you to see various details about the model, such as the relative importance of the input fields in creating the model. To view the predictions, you need to attach and execute a further process or output node. See the topic [Using Model Nuggets in Streams](#) for more information.

Figure 2. Model link from modeling node to model nugget

When you successfully execute a modeling node, a corresponding model nugget is placed on the stream canvas, where it is represented by a gold, diamond-shaped icon (hence the name "nugget"). On the stream canvas, the nugget is shown with a connection (solid line) to the nearest suitable node before the modeling node, and a link (dotted line) to the modeling node itself.

The nugget is also placed in the Models palette in the upper right corner of the IBM® SPSS Modeler window. From either location, nuggets can be selected and browsed to view details of the model.

Nuggets are always placed in the Models palette when a modeling node is successfully executed. You can set a user option to control whether the nugget is additionally placed on the stream canvas.

The following topics provide information on using model nuggets in IBM SPSS Modeler. For an in-depth understanding of the algorithms used, see the *IBM SPSS Modeler Algorithms Guide*, available as a PDF file as part of your product download.

Model Links

Figure 1. Model link from modeling node to model nugget

By default, a nugget is shown on the canvas with a link to the modeling node that created it. This is especially useful in complex streams with several nuggets, enabling you to identify the nugget that will be updated by each modeling node. Each link contains a symbol to indicate whether the model is replaced when the modeling node is executed. See the topic [Replacing a model](#) for more information.

- [Defining and Removing Model Links](#)
- [Copying and Pasting Model Links](#)
- [Model Links and SuperNodes](#)

Defining and Removing Model Links

You can define and remove links manually on the canvas. When you are defining a new link, the cursor changes to the link cursor.

Figure 1. Link cursor

Defining a new link (context menu)

1. Right-click on the modeling node from which you want the link to start.
2. Choose Define Model Link from the context menu.
3. Click the nugget where you want the link to end.

Defining a new link (main menu)

1. Click the modeling node from which you want the link to start.
2. From the main menu, choose:
Edit > Node > Define Model Link
3. Click the nugget where you want the link to end.

Removing an existing link (context menu)

1. Right-click on the nugget at the end of the link.
2. Choose Remove Model Link from the context menu.

Alternatively:

1. Right-click on the symbol in the middle of the link.
2. Choose Remove Link from the context menu.

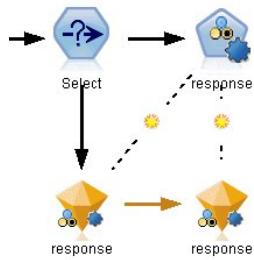

Removing an existing link (main menu)

1. Click the modeling node or nugget from which you want to remove the link.
2. From the main menu, choose:
Edit > Node > Remove Model Link

Copying and Pasting Model Links

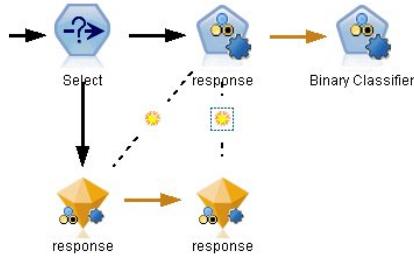

If you copy a linked nugget, without its modeling node, and paste it into the same stream, the nugget is pasted with a link to the modeling node. The new link has the same model replacement status (see [Replacing a model](#)) as the original link.

Figure 1. Copying and pasting a linked nugget

If you copy and paste a nugget together with its linked modeling node, the link is retained whether the objects are pasted into the same stream or a new stream.

Figure 2. Copying and pasting a linked nugget

Note: If you copy a linked nugget, without its modeling node, and paste the nugget into a new stream (or into a SuperNode that does not contain the modeling node), the link is broken and only the nugget is pasted.

Model Links and SuperNodes

If you define a SuperNode to include either the modeling node or the model nugget of a linked model (but not both), the link is broken. Expanding the SuperNode does not restore the link; you can only do this by undoing creation of the SuperNode.

Replacing a model

You can choose whether to replace (that is, update) an existing nugget on re-execution of the modeling node that created the nugget. If you turn off the replacement option, a new nugget is created when you re-execute the modeling node.

Each link from modeling node to nugget contains a symbol to indicate whether the model is replaced when the modeling node is re-executed.

Figure 1. Model link with model replacement turned on

The link is initially shown with model replacement turned on, depicted by the small sunburst symbol in the link. In this state, re-executing the modeling node at one end of the link simply updates the nugget at the other end.

Figure 2. Model link with model replacement turned off

If model replacement is turned off, the link symbol is replaced by a gray dot. In this state, re-executing the modeling node at one end of the link adds a new, updated version of the nugget to the canvas.

In either case, in the Models palette the existing nugget is updated or a new nugget is added, depending on the setting of the Replace previous model system option.

Order of execution

When you execute a stream with multiple branches containing model nuggets, the stream is first evaluated to make sure that a branch with model replacement turned on is executed before any branch that uses the resulting model nugget.

If your requirements are more complex, you can set the order of execution manually through scripting.

Changing the model replacement setting

1. Right-click the symbol on the link.
2. Choose Turn On(Off) Model Replacement as desired.

Note: The model replacement setting on a model link overrides the setting on the Notifications tab of the User Options dialog (Tools > Options > User Options).

The models palette

The models palette (on the Models tab in the managers window) enables you to use, examine, and modify model nuggets in various ways.

Figure 1. Models palette

Right-clicking a model nugget in the models palette opens a context menu with the following options:

- Add To Stream. Adds the model nugget to the currently active stream. If there is a selected node in the stream, the model nugget will be connected to the selected node when such a connection is possible, or otherwise to the nearest possible node. The nugget is displayed with a link to the modeling node that created the model, if that node is still in the stream.
- Browse. Opens the model browser for the nugget.
- Rename and Annotate. Allows you to rename the model nugget and/or modify the annotation for the nugget.
- Generate Modeling Node. If you have a model nugget that you want to modify or update and the stream used to create the model is not available, you can use this option to recreate a modeling node with the same options used to create the original model.
- Save Model, Save Model As. Saves the model nugget to an external generated model (.gm) binary file.
- Store Model. Stores the model nugget in IBM® SPSS® Collaboration and Deployment Services Repository.
- Export PMML. Exports the model nugget as predictive model markup language (PMML), which can be used for scoring new data outside of IBM SPSS Modeler. Export PMML is available for all generated model nodes.
- Add to Project. Saves the model nugget and adds it to the current project. On the Classes tab, the nugget will be added to the Generated Models folder. On the CRISP-DM tab, it will be added to the default project phase.
- Delete. Deletes the model nugget from the palette.

Right-clicking an unoccupied area in the models palette opens a context menu with the following options:

- Open Model. Loads a model nugget previously created in IBM SPSS Modeler.
- Retrieve Model. Retrieves a stored model from an IBM SPSS Collaboration and Deployment Services repository.
- Load Palette. Loads a saved models palette from an external file.
- Retrieve Palette. Retrieves a stored models palette from an IBM SPSS Collaboration and Deployment Services repository.
- Save Palette. Saves the entire contents of the models palette to an external generated models palette (.gen) file.
- Store Palette. Stores the entire contents of the models palette in an IBM SPSS Collaboration and Deployment Services repository.
- Clear Palette. Deletes all nuggets from the palette.
- Add Palette To Project. Saves the models palette and adds it to the current project. On the Classes tab, the nugget will be added to the Generated Models folder. On the CRISP-DM tab, it will be added to the default project phase.
- Import PMML. Loads a model from an external file. You can open, browse, and score PMML models created by IBM SPSS Statistics or other applications that support this format. See the topic [Importing and exporting models as PMML](#) for more information.

Browsing model nuggets

The model nugget browsers enable you to examine and use the results of your models. From the browser, you can save, print, or export the generated model, examine the model summary, and view or edit annotations for the model. For some types of model nugget, you can also generate new nodes, such as Filter nodes or Rule Set nodes. For some models, you can also view model parameters, such as rules or cluster centers. For some types of models (tree-based models and cluster models), you can view a graphical representation of the structure of the model. Controls for using the model nugget browsers are described below.

Menus

File menu. All model nuggets have a File menu, containing some subset of the following options:

- Save Node. Saves the model nugget to a node (.nod) file.
- Store Node. Stores the model nugget in an IBM® SPSS® Collaboration and Deployment Services repository.
- Header and Footer. Allows you to edit the page header and footer for printing from the nugget.
- Page Setup. Allows you to change the page setup for printing from the nugget.
- Print Preview. Displays a preview of how the nugget will look when printed. Select the information you want to preview from the submenu.
- Print. Prints the contents of the nugget. Select the information you want to print from the submenu.
- Print View. Prints the current view or all views.
- Export Text. Exports the contents of the nugget to a text file. Select the information you want to export from the submenu.
- Export HTML. Exports the contents of the nugget to an HTML file. Select the information you want to export from the submenu.
- Export PMML. Exports the model as predictive model markup language (PMML), which can be used with other PMML-compatible software. See the topic [Importing and exporting models as PMML](#) for more information.
- Export SQL. Exports the model as structured query language (SQL), which can be edited and used with other databases.
Note: SQL Export is available only from the following models: C5, C&RT, CHAID, QUEST, Linear Regression, Logistic Regression, Neural Net, PCA/Factor, and Decision List models.
- Publish for Server Scoring Adapter. Publishes the model to a database that has a scoring adapter installed, enabling model scoring to be performed within the database. See the topic [Publishing models for a scoring adapter](#) for more information.

Generate menu. Most model nuggets also have a Generate menu, enabling you to generate new nodes based on the model nugget. The options available from this menu will depend on the type of model you are browsing. See the specific model nugget type for details about what you can generate from a particular model.

View menu. On the Model tab of a nugget, this menu enables you to display or hide the various visualization toolbars that are available in the current mode. To make the full set of toolbars available, select Edit Mode (the paintbrush icon) from the General toolbar.

Preview button. Some model nuggets have a Preview button, which enables you to see a sample of the model data, including the extra fields created by the modeling process. The default number of rows displayed is 10; however, you can change this in the stream properties.

Add to Current Project button. Saves the model nugget and adds it to the current project. On the Classes tab, the nugget will be added to the Generated Models folder. On the CRISP-DM tab, it will be added to the default project phase.

Model Nugget Summary / Information

The Summary tab or Information view for a model nugget displays information about the fields, build settings, and model estimation process. Results are presented in a tree view that can be expanded or collapsed by clicking specific items.

Analysis. Displays information about the model. Specific details vary by model type, and are covered in the section for each model nugget. In addition, if you execute an Analysis node that is attached to this modeling node, information from that analysis is also displayed in this section.

Fields. Lists the fields that are used as the target and the inputs in building the model. For split models, also lists the fields that determined the splits.

Note: In the Information view for neural networks, linear, and other models with either boosting or bagging modes, the icon that is shown is the same (nominal icon), regardless of whether the type is a flag, nominal, or ordinal.

Build Settings / Options. Contains information about the settings that are used in building the model.

Training Summary. Shows the type of model, the stream that is used to create it, the user who created it, when it was built, and the elapsed time for building the model. Note that the elapsed time for building the model is only available on the Summary tab, not the Information view.

Related information

- [Browsing model nuggets](#)
- [Predictor Importance](#)
- [Using Model Nuggets in Streams](#)

Predictor Importance

Typically, you will want to focus your modeling efforts on the predictor fields that matter most and consider dropping or ignoring those that matter least. The predictor importance chart helps you do this by indicating the relative importance of each predictor in estimating the model. Since the values are relative, the sum of the values for all predictors on the display is 1.0. Predictor importance does not relate to model accuracy. It just relates to the importance of each predictor in making a prediction, not whether or not the prediction is accurate.

Predictor importance is available for models that produce an appropriate statistical measure of importance, including neural networks, decision trees (C&R Tree, C5.0, CHAID, and QUEST), Bayesian networks, discriminant, SVM, and SLM models, linear and logistic regression, generalized linear, and nearest neighbor (KNN) models. For most of these models, predictor importance can be enabled on the Analyze tab in the modeling node. See the topic [Modeling Node Analyze Options](#) for more information. For KNN models, see [Neighbors](#).

Note: Predictor importance is not supported for split models. Predictor importance settings are ignored when building split models. See the topic [Building Split Models](#) for more information.

Calculating predictor importance may take significantly longer than model building, particularly when using large datasets. It takes longer to calculate for SVM and logistic regression than for other models, and is disabled for these models by default. If using a dataset with a large number of predictors, initial screening using a Feature Selection node may give faster results (see below).

- Predictor importance is calculated from the test partition, if available. Otherwise the training data is used.
- For SLM models, predictor importance is available but is computed by the SLM algorithm. See the topic [SLM Model Nuggets](#) for more information.
- You can use IBM® SPSS® Modeler's graph tools to interact, edit, and save the graph.
- Optionally, you can generate a Filter node based on the information in the predictor importance chart. See the topic [Filtering Variables Based on Importance](#) for more information.

Predictor Importance and Feature Selection

The predictor importance chart displayed in a model nugget may seem to give results similar to the Feature Selection node in some cases. While feature selection ranks each input field based on the strength of its relationship to the specified target, independent of other inputs, the predictor importance chart indicates the relative importance of each input for *this* particular model. Thus feature selection will be more conservative in screening inputs. For example, if *job title* and *job category* are both strongly related to salary, then feature selection would indicate that both are important. But in modeling, interactions and correlations are also taken into consideration. Thus you might find that only one of two inputs is used if both duplicate much of the same information. In practice, feature selection is most useful for preliminary screening, particularly when dealing with large datasets with large numbers of variables, and predictor importance is more useful in fine-tuning the model.

Predictor Importance Differences Between Single Models and Automated Modeling Nodes

Depending on whether you are creating a single model from an individual node, or using an automated modelling node to produce results, you may see slight differences in the predictor importance. Such differences in implementation are due to some engineering restrictions.

For example, with single classifiers such as CHAID the calculation applies a stopping rule and uses probability values when computing importance values. In contrast, the Auto Classifier does not use a stopping rule and uses predicted labels directly in the calculation. These differences can mean that if you produce a single model using Auto Classifier, the importance value can be considered as a rough estimation, compared with that computed for a single classifier. To obtain the most accurate predictor importance values we suggest using a single node instead of the automated modelling nodes.

Filtering Variables Based on Importance

Optionally, you can generate a Filter node based on the information in the predictor importance chart.

Mark the predictors you want to include on the chart, if applicable, and from the menus choose:

Generate...>[Filter Node \(Predictor Importance\)](#)

OR

...Field Selection (Predictor Importance)

Top number of variables. Includes or excludes the most important predictors up to the specified number.

Importance greater than. Includes or excludes all predictors with relative importance greater than the specified value.

Ensemble Viewer

- [Models for ensembles](#)
-

Models for ensembles

The model for an ensemble provides information about the component models in the ensemble and the performance of the ensemble as a whole.

The main (view-independent) toolbar allows you to choose whether to use the ensemble or a reference model for scoring. If the ensemble is used for scoring you can also select the combining rule. These changes do not require model re-execution; however, these choices are saved to the model (nugget) for scoring and/or downstream model evaluation. They also affect PMML exported from the ensemble viewer.

Combining Rule. When scoring an ensemble, this is the rule used to combine the predicted values from the base models to compute the ensemble score value.

- Ensemble predicted values for **categorical** targets can be combined using voting, highest probability, or highest mean probability. **Voting** selects the category that has the highest probability most often across the base models. **Highest probability** selects the category that achieves the single highest probability across all base models. **Highest mean probability** selects the category with the highest value when the category probabilities are averaged across base models.
- Ensemble predicted values for **continuous** targets can be combined using the mean or median of the predicted values from the base models.

The default is taken from the specifications made during model building. Changing the combining rule recomputes the model accuracy and updates all views of model accuracy. The Predictor Importance chart also updates. This control is disabled if the reference model is selected for scoring.

Show All Combining rules. When selected, results for all available combining rules are shown in the model quality chart. The Component Model Accuracy chart is also updated to show reference lines for each voting method.

 - [Automatic Data Preparation \(ensemble viewer\)](#)
-

Model Summary (ensemble viewer)

The Model Summary view is a snapshot, at-a-glance summary of the ensemble quality and diversity.

Quality. The chart displays the accuracy of the final model, compared to a reference model and a naive model. Accuracy is presented in larger is better format; the "best" model will have the highest accuracy. For a categorical target, accuracy is simply the percentage of records for which the predicted value matches the observed value. For a continuous target, accuracy is 1 minus the ratio of the mean absolute error in prediction (the average of the absolute values of the predicted values minus the observed values) to the range of predicted values (the maximum predicted value minus the minimum predicted value).

For bagging ensembles, the reference model is a standard model built on the whole training partition. For boosted ensembles, the reference model is the first component model.

The naive model represents the accuracy if no model were built, and assigns all records to the modal category. The naive model is not computed for continuous targets.

Diversity. The chart displays the "diversity of opinion" among the component models used to build the ensemble, presented in larger is more diverse format. It is a measure of how much predictions vary across the base models. Diversity is not available for boosted ensemble models, nor is it shown for continuous targets.

Predictor Importance (ensemble viewer)

Typically, you will want to focus your modeling efforts on the predictor fields that matter most and consider dropping or ignoring those that matter least. The predictor importance chart helps you do this by indicating the relative importance of each predictor in estimating the model. Since the values are relative, the sum of the values for all predictors on the display is 1.0. Predictor importance does not relate to model accuracy. It just relates to the importance of each predictor in making a prediction, not whether or not the prediction is accurate.

Predictor importance is not available for all ensemble models. The predictor set may vary across component models, but importance can be computed for predictors used in at least one component model.

Predictor Frequency (ensemble viewer)

The predictor set can vary across component models due to the choice of modeling method or predictor selection. The Predictor Frequency plot is a dot plot that shows the distribution of predictors across component models in the ensemble. Each dot represents one or more component models containing the predictor. Predictors are plotted on the y-axis, and are sorted in descending order of frequency; thus the topmost predictor is the one that is used in the greatest number of component models and the bottommost one is the one that was used in the fewest. The top 10 predictors are shown.

Predictors that appear most frequently are typically the most important. This plot is not useful for methods in which the predictor set cannot vary across component models.

Component Model Accuracy (ensemble viewer)

The chart is a dot plot of predictive accuracy for component models. Each dot represents one or more component models with the level of accuracy plotted on the y-axis. Hover over any dot to obtain information on the corresponding individual component model.

Reference lines. The plot displays color coded lines for the ensemble as well as the reference model and naïve models. A checkmark appears next to the line corresponding to the model that will be used for scoring.

Interactivity. The chart updates if you change the combining rule.

Boosted ensembles. A line chart is displayed for boosted ensembles.

Component Model Details (ensemble viewer)

The table displays information on component models, listed by row. By default, component models are sorted in ascending model number order. You can sort the rows in ascending or descending order by the values of any column.

Model. A number representing the sequential order in which the component model was created.

Accuracy. Overall accuracy formatted as a percentage.

Method. The modeling method.

Predictors. The number of predictors used in the component model.

Model Size. Model size depends on the modeling method: for trees, it is the number of nodes in the tree; for linear models, it is the number of coefficients; for neural networks, it is the number of synapses.

Records. The weighted number of input records in the training sample.

Automatic Data Preparation (ensemble viewer)

This view shows information about which fields were excluded and how transformed fields were derived in the automatic data preparation (ADP) step. For each field that was transformed or excluded, the table lists the field name, its role in the analysis, and the action taken by the ADP step. Fields are sorted by ascending alphabetical order of field names.

The action Trim outliers, if shown, indicates that values of continuous predictors that lie beyond a cutoff value (3 standard deviations from the mean) have been set to the cutoff value.

Model Nuggets for Split Models

The model nugget for a split model provides access to all the separate models created by the splits.

A split-model nugget contains:

- a list of all the split models created, together with a set of statistics about each model
- information about the overall model

From the list of split models, you can open up individual models to examine them further.

- [Split Model Viewer](#)

Split Model Viewer

The Model tab lists all the models contained in the nugget, and provides statistics in various forms about the split models. It has two general forms, depending on the modeling node.

Sort by. Use this list to choose the order in which the models are listed. You can sort the list based on the values of any of the display columns, in ascending or descending order. Alternatively, click on a column heading to sort the list by that column. Default is descending order of overall accuracy.

Show/hide columns menu. Click this button to display a menu from where you can choose individual columns to show or hide.

View. If you are using partitioning, you can choose to view the results for either the training data or the testing data.

For each split, the details shown are as follows:

Graph. A thumbnail indicating the data distribution for this model. When the nugget is on the canvas, double-click the thumbnail to open the full-size graph.

Model. An icon of the model type. Double-click the icon to open the model nugget for this particular split.

Split fields. The fields designated in the modeling node as split fields, with their various possible values.

No. Records in Split. The number of records involved in this particular split.

No. Fields Used. Ranks split models based on the number of input fields used.

Overall Accuracy (%). The percentage of records that is correctly predicted by the split model relative to the total number of records in that split.

Split. The column heading shows the field(s) used to create splits, and the cells are the split values. Double-click any split to open a Model Viewer for the model built for that split.

Accuracy. Overall accuracy formatted as a percentage.

Model Size. Model size depends on the modeling method: for trees, it is the number of nodes in the tree; for linear models, it is the number of coefficients; for neural networks, it is the number of synapses.

Records. The weighted number of input records in the training sample.

Using Model Nuggets in Streams

Model nuggets are placed in streams to enable you to score new data and generate new nodes. **Scoring** data enables you to use the information gained from model building to create predictions for new records. To see the results of scoring, you need to attach a terminal node (that is, a processing or output node) to the nugget and execute the terminal node.

For some models, model nuggets can also give you additional information about the quality of the prediction, such as confidence values or distances from cluster centers. Generating new nodes enables you to easily create new nodes based on the structure of the generated model. For example, most models that perform input field selection enable you to generate Filter nodes that will pass only input fields that the model identified as important.

Note: There can be small differences in the scores assigned to a given case by a given model when executed in different versions of IBM® SPSS® Modeler. This is usually a result of enhancements to the software between versions.

To Use a Model Nugget for Scoring Data

1. Connect the model nugget to a data source or stream that will pass data to it.
2. Add or connect one or more processing or output nodes (such as a Table or Analysis node) to the model nugget.
3. Execute one of the nodes downstream from the model nugget.

Note: You cannot use the Unrefined Rule node for scoring data. To score data based on an association rule model, use the Unrefined Rule node to generate a Rule Set nugget, and use the Rule Set nugget for scoring. See the topic [Generating a Rule Set from an Association Model Nugget](#) for more information.

To Use a Model Nugget for Generating Processing Nodes

1. On the palette, browse the model, or, on the stream canvas, edit the model.
2. Select the desired node type from the Generate menu of the model nugget browser window. The options available will vary, depending on the type of model nugget. See the specific model nugget type for details about what you can generate from a particular model.

Regenerating a modeling node

If you have a model nugget that you want to modify or update and the stream used to create the model is not available, you can regenerate a modeling node with the same options used to create the original model.

To rebuild a model, right-click on the model in the models palette and choose Generate Modeling Node.

Alternatively, when browsing any model, choose Generate Modeling Node from the Generate menu.

The regenerated modeling node should be functionally identical to the one used to create the original model in most cases.

- For Decision Tree models, additional settings specified during the interactive session may also be stored with the node, and the Use tree directives option will be enabled in the regenerated modeling node.
 - For Decision List models, the Use saved interactive session information option will be enabled. See the topic [Decision List Model Options](#) for more information.
 - For Time Series models, the Continue estimation using existing model(s) option is enabled, which enables you to regenerate the previous model with current data. See the topic [Time Series Model Options](#) for more information.
-

Importing and exporting models as PMML

PMML, or predictive model markup language, is an XML format for describing data mining and statistical models, including inputs to the models, transformations used to prepare data for data mining, and the parameters that define the models themselves. IBM® SPSS® Modeler can import and export PMML, making it possible to share models with other applications that support this format, such as IBM SPSS Statistics.

For more information about PMML, see the Data Mining Group website (<http://www.dmg.org>).

To export a model

PMML export is supported for most of the model types generated in IBM SPSS Modeler. See the topic [Model types supporting PMML](#) for more information.

1. Right-click a model nugget on the models palette. (Alternatively, double-click a model nugget on the canvas and select the File menu.)
2. On the menu, click Export PMML.
3. In the Export (or Save) dialog box, specify a target directory and a unique name for the model.

Note:

You can change options for PMML export in the User Options dialog box. On the main menu, click:

Tools > Options > User Options

and click the PMML tab.

See the topic [Setting PMML Export Options](#) for more information.

To import a model saved as PMML

Models exported as PMML from IBM SPSS Modeler or another application can be imported into the models palette. See the topic [Model types supporting PMML](#) for more information.

1. In the models palette, right-click the palette and select Import PMML from the menu.
2. Select the file to import and specify options for variable labels as required.
3. Click Open.

Use variable labels if present in model. The PMML may specify both variable names and variable labels (such as Referrer ID for *RefID*) for variables in the data dictionary. Select this option to use variable labels if they are present in the originally exported PMML.

If you have selected the variable label option but there are no variable labels in the PMML, the variable names are used as normal.

- [Model types supporting PMML](#)
-

Model types supporting PMML

PMML Export

IBM SPSS Modeler models. The following models created in IBM® SPSS® Modeler can be exported as PMML 4.3:

- C&R Tree
- QUEST
- CHAID
- Neural Net
- C5.0
- Logistic Regression
- Genlin
- SVM
- Apriori
- Carma
- K-Means
- Kohonen
- TwoStep
- TwoStep-AS
- GLMM (PMML is exported for all GLMM models, but the PMML has only fixed effects)
- Decision List
- Cox
- Sequence (scoring for Sequence PMML models is not supported)
- Random Trees
- Tree-AS
- Linear
- Linear-AS
- Regression
- Logistic
- GLE
- LSVM
- KNN
- Association Rules

Database native models. For models generated using database-native algorithms, PMML export is not available. Models created using Analysis Services from Microsoft or Oracle Data Miner cannot be exported.

PMML Import

IBM SPSS Modeler can import and score PMML models generated by current versions of all IBM SPSS Statistics products, including models exported from IBM SPSS Modeler as well as model or transformation PMML generated by IBM SPSS Statistics 17.0 or later. Essentially, this means any PMML that the scoring engine can score, with the following exceptions:

- Apriori, CARMA, Anomaly Detection, Sequence, and Association Rules models cannot be imported.

- PMML models may not be browsed after importing into IBM SPSS Modeler even though they can be used in scoring. (Note that this includes models that were exported from IBM SPSS Modeler to begin with. To avoid this limitation, export the model as a generated model file [*.gm] rather than PMML.)
- Limited validation occurs on import, but full validation is performed on attempting to score the model. Thus it is possible for import to succeed but scoring to fail or produce incorrect results.

Note: For third party PMML imported into IBM SPSS Modeler, IBM SPSS Modeler will attempt to score valid PMML that can be recognized and scored. But it is not guaranteed that all PMML will score or that it will score in the same way as the application that generated it.

Publishing models for a scoring adapter

You can publish models to a database server that has a scoring adapter installed. A scoring adapter enables model scoring to be performed within the database by using the user-defined function (UDF) capabilities of the database. Performing scoring in the database avoids the need to extract the data before scoring. Publishing to a scoring adapter also generates some example SQL to execute the UDF.

To publish a scoring adapter

1. Double-click the model nugget to open it.
2. From the model nugget menu, choose:
File > Publish for Server Scoring Adapter
3. Fill in the relevant fields on the dialog box and click OK.

Database connection. The connection details for the database you want to use for the model.

Publish ID. (Db2 for z/OS databases only) An identifier for the model. If you rebuild the same model and use the same publish ID, the generated SQL remains the same, so it is possible to rebuild a model without having to change the application that uses the SQL previously generated. (For other databases the generated SQL is unique to the model.)

Generate Example SQL. If selected, generates the example SQL into the file specified in the File field.

Unrefined Models

An unrefined model contains information extracted from the data but is not designed for generating predictions directly. This means that it cannot be added to streams. Unrefined models are displayed as “diamonds in the rough” on the generated models palette.

Figure 1. Unrefined model icon

To see information about the unrefined rule model, right-click the model and choose Browse from the context menu. Like other models generated in IBM® SPSS® Modeler, the various tabs provide summary and rule information about the model created.

Generating nodes. The Generate menu enables you to create new nodes based on the rules.

- **Select Node.** Generates a Select node to select records to which the currently selected rule applies. This option is disabled if no rule is selected.
- **Rule set.** Generates a Rule Set node to predict values for a single target field. See the topic [Generating a Rule Set from an Association Model Nugget](#) for more information.

Cluster Models Model Tab

The Model tab for cluster models (TwoStep, K-Means, and Kohonen) contains detailed information about the clusters defined by the model.

When you first browse a cluster model nugget, the Model tab results are collapsed. To see the results of interest, use the expander control to the left of the item to unfold it, or click the Expand All button to show all results. To hide the results when finished viewing them, use the expander control to collapse the specific results that you want to hide, or click the Collapse All button to collapse all results.

Clusters. Clusters are labeled and the number of records assigned to each cluster is shown. Each cluster is described by its center, which can be thought of as the **prototype** for the cluster. The details available for the clusters depend on the type of cluster model. Select the specific type of cluster model below for more information.

Generated Rule Set/Decision Tree Model Tab

On the generated Rule Set node Model tab, you will see a list of rules extracted from the data by the algorithm. The format of the rules depends on the type of model generated. Select the specific model type below for details.

Screening Models

- [Screening Fields and Records](#)
 - [Feature Selection node](#)
 - [Feature Selection Model Nuggets](#)
 - [Anomaly Detection Node](#)
 - [Anomaly Detection Model Nuggets](#)
-

Screening Fields and Records

Several modeling nodes can be used during the preliminary stages of an analysis in order to locate fields and records that are most likely to be of interest in modeling. You can use the Feature Selection node to screen and rank fields by importance and the Anomaly Detection node to locate unusual records that do not conform to the known patterns of "normal" data.

	The Feature Selection node screens input fields for removal based on a set of criteria (such as the percentage of missing values); it then ranks the importance of remaining inputs relative to a specified target. For example, given a data set with hundreds of potential inputs, which are most likely to be useful in modeling patient outcomes?
	The Anomaly Detection node identifies unusual cases, or outliers, that do not conform to patterns of "normal" data. With this node, it is possible to identify outliers even if they do not fit any previously known patterns and even if you are not exactly sure what you are looking for.

Note that anomaly detection identifies unusual records or cases through cluster analysis based on the set of fields selected in the model without regard for any specific target (dependent) field and regardless of whether those fields are relevant to the pattern you are trying to predict. For this reason, you may want to use anomaly detection in combination with feature selection or another technique for screening and ranking fields. For example, you can use feature selection to identify the most important fields relative to a specific target and then use anomaly detection to locate the records that are the most unusual with respect to those fields. (An alternative approach would be to build a decision tree model and then examine any misclassified records as potential anomalies. However, this method would be more difficult to replicate or automate on a large scale.)

-

Feature Selection node

Data mining problems may involve hundreds, or even thousands, of fields that can potentially be used as inputs. As a result, a great deal of time and effort may be spent examining which fields or variables to include in the model. To narrow down the choices, the Feature Selection algorithm can be used to identify the fields that are most important for a given analysis. For example, if you are trying to predict patient outcomes based on a number of factors, which factors are the most likely to be important?

Feature selection consists of three steps:

- Screening. Removes unimportant and problematic inputs and records, or cases such as input fields with too many missing values or with too much or too little variation to be useful.
- Ranking. Sorts remaining inputs and assigns ranks based on importance.
- Selecting. Identifies the subset of features to use in subsequent models—for example, by preserving only the most important inputs and filtering or excluding all others.

In an age where many organizations are overloaded with too much data, the benefits of feature selection in simplifying and speeding the modeling process can be substantial. By focusing attention quickly on the fields that matter most, you can reduce the amount of computation required; more easily locate small but important relationships that might otherwise be overlooked; and, ultimately, obtain simpler, more accurate, and more easily explainable models. By reducing the number of fields used in the model, you may find that you can reduce scoring times as well as the amount of data collected in future iterations.

Example. A telephone company has a data warehouse containing information about responses to a special promotion by 5,000 of the company's customers. The data includes a large number of fields containing customers' ages, employment, income, and telephone usage statistics. Three target fields show whether or not the customer responded to each of three offers. The company wants to use this data to help predict which customers are most likely to respond to similar offers in the future.

Requirements. A single target field (one with its role set to *Target*), along with multiple input fields that you want to screen or rank relative to the target. Both target and input fields can have a measurement level of *Continuous* (numeric range) or *Categorical*.

- [Feature Selection Model Settings](#)
 - [Feature Selection Options](#)
-

Feature Selection Model Settings

The settings on the Model tab include standard model options along with settings that enable you to fine-tune the criteria for screening input fields.

Model name. You can generate the model name automatically based on the target or ID field (or model type in cases where no such field is specified) or specify a custom name.

Screening Input Fields

Screening involves removing inputs or cases that do not add any useful information with respect to the input/target relationship. Screening options are based on attributes of the field in question without respect to predictive power relative to the selected target field. Screened fields are excluded from the computations used to rank inputs and optionally can be filtered or removed from the data used in modeling.

Fields can be screened based on the following criteria:

- **Maximum percentage of missing values.** Screens fields with too many missing values, expressed as a percentage of the total number of records. Fields with a large percentage of missing values provide little predictive information.
- **Maximum percentage of records in a single category.** Screens fields that have too many records falling into the same category relative to the total number of records. For example, if 95% of the customers in the database drive the same type of car, including this information is not useful in distinguishing one customer from the next. Any fields that exceed the specified maximum are screened. This option applies to categorical fields only.
- **Maximum number of categories as a percentage of records.** Screens fields with too many categories relative to the total number of records. If a high percentage of the categories contains only a single case, the field may be of limited use. For example, if every customer

wears a different hat, this information is unlikely to be useful in modeling patterns of behavior. This option applies to categorical fields only.

- **Minimum coefficient of variation.** Screens fields with a coefficient of variance less than or equal to the specified minimum. This measure is the ratio of the input field standard deviation to the mean of the input field. If this value is near zero, there is not much variability in the values for the variable. This option applies to continuous (numeric range) fields only.
- **Minimum standard deviation.** Screens fields with standard deviation less than or equal to the specified minimum. This option applies to continuous (numeric range) fields only.

Records with missing data. Records or cases that have missing values for the target field, or missing values for all inputs, are automatically excluded from all computations used in the rankings.

Related information

 - [Feature Selection Model Results](#)
 - [Selecting Fields by Importance](#)
 - [Generating a Filter from a Feature Selection Model](#)
-

Feature Selection Options

The Options tab allows you to specify the default settings for selecting or excluding input fields in the model nugget. You can then add the model to a stream to select a subset of fields for use in subsequent model-building efforts. Alternatively, you can override these settings by selecting or deselecting additional fields in the model browser after generating the model. However, the default settings make it possible to apply the model nugget without further changes, which may be particularly useful for scripting purposes.

See the topic [Feature Selection Model Results](#) for more information.

The following options are available:

All fields ranked. Selects fields based on their ranking as *important*, *marginal*, or *unimportant*. You can edit the label for each ranking as well as the cutoff values used to assign records to one rank or another.

Top number of fields. Selects the top n fields based on importance.

Importance greater than. Selects all fields with importance greater than the specified value.

The target field is always preserved regardless of the selection.

Importance Ranking Options

All categorical. When all inputs and the target are categorical, importance can be ranked based on any of four measures:

- **Pearson chi-square.** Tests for independence of the target and the input without indicating the strength or direction of any existing relationship.
- **Likelihood-ratio chi-square.** Similar to Pearson's chi-square but also tests for target-input independence.
- **Cramer's V.** A measure of association based on Pearson's chi-square statistic. Values range from 0, which indicates no association, to 1, which indicates perfect association.
- **Lambda.** A measure of association reflecting the proportional reduction in error when the variable is used to predict the target value. A value of 1 indicates that the input field perfectly predicts the target, while a value of 0 means the input provides no useful information about the target.

Some categorical. When some—but not all—inputs are categorical and the target is also categorical, importance can be ranked based on either the Pearson or likelihood-ratio chi-square. (Cramer's V and lambda are not available unless all inputs are categorical.)

Categorical versus continuous. When ranking a categorical input against a continuous target or vice versa (one or the other is categorical but not both), the F statistic is used.

Both continuous. When ranking a continuous input against a continuous target, the t statistic based on the correlation coefficient is used.

Feature Selection Model Nuggets

Feature Selection model nuggets display the importance of each input relative to a selected target, as ranked by the Feature Selection node. Any fields that were screened out prior to the ranking are also listed. See the topic [Feature Selection node](#) for more information.

When you run a stream containing a Feature Selection model nugget, the model acts as a filter that preserves only selected inputs, as indicated by the current selection on the Model tab. For example, you could select all fields ranked as important (one of the default options) or manually select a subset of fields on the Model tab. The target field is also preserved regardless of the selection. All other fields are excluded.

Filtering is based on the field name only; for example, if you select *age* and *income*, any field that matches either of these names will be preserved. The model does not update field rankings based on new data; it simply filters fields based on the selected names. For this reason, care should be used in applying the model to new or updated data. When in doubt, regenerating the model is recommended.

-

Feature Selection Model Results

The Model tab for a Feature Selection model nugget displays the rank and importance of all inputs in the upper pane and enables you to select fields for filtering by using the check boxes in the column on the left. When you run the stream, only the selected fields are preserved; the other fields are discarded. The default selections are based on the options specified in the model-building node, but you can select or deselect additional fields as needed.

The lower pane lists inputs that have been excluded from the rankings based on the percentage of missing values or on other criteria specified in the modeling node. As with the ranked fields, you can choose to include or discard these fields by using the check boxes in the column on the left. See the topic [Feature Selection Model Settings](#) for more information.

- To sort the list by rank, field name, importance, or any of the other displayed columns, click on the column header. Or, to use the toolbar, select the desired item from the Sort By list, and use the up and down arrows to change the direction of the sort.
- You can use the toolbar to check or uncheck all fields and to access the Check Fields dialog box, which enables you to select fields by rank or importance. You can also press the Shift and Ctrl keys while clicking on fields to extend the selection and use the spacebar to toggle on or off a group of selected fields. See the topic [Selecting Fields by Importance](#) for more information.
- The threshold values for ranking inputs as important, marginal, or unimportant are displayed in the legend below the table. These values are specified in the modeling node. See the topic [Feature Selection Options](#) for more information.

Selecting Fields by Importance

When scoring data using a Feature Selection model nugget, all fields selected from the list of ranked or screened fields--as indicated by the check boxes in the column on the left--will be preserved. Other fields will be discarded. To change the selection, you can use the toolbar to

access the Check Fields dialog box, which enables you to select fields by rank or importance.

All fields marked. Selects all fields marked as important, marginal, or unimportant.

Top number of fields. Allows you to select the top n fields based on importance.

Importance greater than. Selects all fields with importance greater than the specified threshold.

Generating a Filter from a Feature Selection Model

Based on the results of a Feature Selection model, you can use the Generate Filter from Feature dialog box to generate one or more Filter nodes that include or exclude subsets of fields based on importance relative to the specified target. While the model nugget can also be used as a filter, this gives you the flexibility to experiment with different subsets of fields without copying or modifying the model. The target field is always preserved by the filter regardless of whether include or exclude is selected.

Include/Exclude. You can choose to include or exclude fields—for example, to include the top 10 fields or exclude all fields marked as unimportant.

Selected fields. Includes or excludes all fields currently selected in the table.

All fields marked. Selects all fields marked as important, marginal, or unimportant.

Top number of fields. Allows you to select the top n fields based on importance.

Importance greater than. Selects all fields with importance greater than the specified threshold.

Anomaly Detection Node

Anomaly detection models are used to identify outliers, or unusual cases, in the data. Unlike other modeling methods that store rules about unusual cases, anomaly detection models store information on what normal behavior looks like. This makes it possible to identify outliers even if they do not conform to any known pattern, and it can be particularly useful in applications, such as fraud detection, where new patterns may constantly be emerging. Anomaly detection is an unsupervised method, which means that it does not require a training dataset containing known cases of fraud to use as a starting point.

While traditional methods of identifying outliers generally look at one or two variables at a time, anomaly detection can examine large numbers of fields to identify clusters or peer groups into which similar records fall. Each record can then be compared to others in its peer group to identify possible anomalies. The further away a case is from the normal center, the more likely it is to be unusual. For example, the algorithm might lump records into three distinct clusters and flag those that fall far from the center of any one cluster.

Each record is assigned an anomaly index, which is the ratio of the group deviation index to its average over the cluster that the case belongs to. The larger the value of this index, the more deviation the case has than the average. Under the usual circumstance, cases with anomaly index values less than 1 or even 1.5 would not be considered as anomalies, because the deviation is just about the same or a bit more than the average. However, cases with an index value greater than 2 could be good anomaly candidates because the deviation is at least twice the average.

Anomaly detection is an exploratory method designed for quick detection of unusual cases or records that should be candidates for further analysis. These should be regarded as *suspected anomalies*, which, on closer examination, may or may not turn out to be real. You may find that a record is perfectly valid but choose to screen it from the data for purposes of model building. Alternatively, if the algorithm repeatedly turns up false anomalies, this may point to an error or artifact in the data collection process.

Note that anomaly detection identifies unusual records or cases through cluster analysis based on the set of fields selected in the model without regard for any specific target (dependent) field and regardless of whether those fields are relevant to the pattern you are trying to predict. For this reason, you may want to use anomaly detection in combination with feature selection or another technique for screening and ranking fields. For example, you can use feature selection to identify the most important fields relative to a specific target and then use anomaly detection to locate the records that are the most unusual with respect to those fields. (An alternative approach would be to build a decision tree model and then examine any misclassified records as potential anomalies. However, this method would be more difficult to replicate or automate on a large scale.)

Example. In screening agricultural development grants for possible cases of fraud, anomaly detection can be used to discover deviations from the norm, highlighting those records that are abnormal and worthy of further investigation. You are particularly interested in grant applications that seem to claim too much (or too little) money for the type and size of farm.

Requirements. One or more input fields. Note that only fields with a role set to Input using a source or Type node can be used as inputs. Target fields (role set to Target or Both) are ignored.

Strengths. By flagging cases that do *not* conform to a known set of rules rather than those that do, Anomaly Detection models can identify unusual cases even when they don't follow previously known patterns. When used in combination with feature selection, anomaly detection makes it possible to screen large amounts of data to identify the records of greatest interest relatively quickly.

- [Anomaly Detection Model Options](#)
- [Anomaly Detection Expert Options](#)

Anomaly Detection Model Options

Model name. You can generate the model name automatically based on the target or ID field (or model type in cases where no such field is specified) or specify a custom name.

Determine cutoff value for anomaly based on. Specifies the method used to determine the cutoff value for flagging anomalies. The following options are available:

- **Minimum anomaly index level.** Specifies the minimum cutoff value for flagging anomalies. Records that meet or exceed this threshold are flagged.
- **Percentage of most anomalous records in the training data.** Automatically sets the threshold at a level that flags the specified percentage of records in the training data. The resulting cutoff is included as a parameter in the model. Note that this option determines how the cutoff value is set, *not* the actual percentage of records to be flagged during scoring. Actual scoring results may vary depending on the data.
- **Number of most anomalous records in the training data.** Automatically sets the threshold at a level that flags the specified number of records in the training data. The resulting threshold is included as a parameter in the model. Note that this option determines how the cutoff value is set, *not* the specific number of records to be flagged during scoring. Actual scoring results may vary depending on the data.

Note: Regardless of how the cutoff value is determined, it does not affect the underlying anomaly index value reported for each record. It simply specifies the threshold for flagging records as anomalous when estimating or scoring the model. If you later want to examine a larger or smaller number of records, you can use a Select node to identify a subset of records based on the anomaly index value (`$O-AnomalyIndex > x`).

Number of anomaly fields to report. Specifies the number of fields to report as an indication of why a particular record is flagged as an anomaly. The most anomalous fields are reported, defined as those that show the greatest deviation from the field norm for the cluster to which the record is assigned.

Anomaly Detection Expert Options

To specify options for missing values and other settings, set the mode to Expert on the Expert tab.

Adjustment coefficient. Value used to balance the relative weight given to continuous (numeric range) and categorical fields in calculating the distance. Larger values increase the influence of continuous fields. This must be a nonzero value.

Automatically calculate number of peer groups. Anomaly detection can be used to rapidly analyze a large number of possible solutions to choose the optimal number of peer groups for the training data. You can broaden or narrow the range by setting the minimum and maximum number of peer groups. Larger values will enable the system to explore a broader range of possible solutions; however, the cost is increased processing time.

Specify number of peer groups. If you know how many clusters to include in your model, select this option and enter the number of peer groups. Selecting this option will generally result in improved performance.

Noise level and ratio. These settings determine how outliers are treated during two-stage clustering. In the first stage, a cluster feature (CF) tree is used to condense the data from a very large number of individual records to a manageable number of clusters. The tree is built based on similarity measures, and when a node of the tree gets too many records in it, it splits into child nodes. In the second stage, hierarchical clustering commences on the terminal nodes of the CF tree. Noise handling is turned on in the first data pass, and it is off in the second data pass. The cases in the noise cluster from the first data pass are assigned to the regular clusters in the second data pass.

- **Noise level.** Specify a value between 0 and 0.5. This setting is relevant only if the CF tree fills during the growth phase, meaning that it cannot accept any more cases in a leaf node and that no leaf node can be split.
If the CF tree fills and the noise level is set to 0, the threshold will be increased and the CF tree regrown with all cases. After final clustering, values that cannot be assigned to a cluster are labeled outliers. The outlier cluster is given an identification number of -1. The outlier cluster is not included in the count of the number of clusters; that is, if you specify n clusters and noise handling, the algorithm will output n clusters and one noise cluster. In practical terms, increasing this value gives the algorithm more latitude to fit unusual records into the tree rather than assign them to a separate outlier cluster.

If the CF tree fills and the noise level is greater than 0, the CF tree will be regrown after placing any data in sparse leaves into their own noise leaf. A leaf is considered sparse if the ratio of the number of cases in the sparse leaf to the number of cases in the largest leaf is less than the noise level. After the tree is grown, the outliers will be placed in the CF tree if possible. If not, the outliers are discarded for the second phase of clustering.

- **Noise ratio.** Specifies the portion of memory allocated for the component that should be used for noise buffering. This value ranges between 0.0 and 0.5. If inserting a specific case into a leaf of the tree would yield tightness less than the threshold, the leaf is not split. If the tightness exceeds the threshold, the leaf is split, adding another small cluster to the CF tree. In practical terms, increasing this setting may cause the algorithm to gravitate more quickly toward a simpler tree.

Impute missing values. For continuous fields, substitutes the field mean in place of any missing values. For categorical fields, missing categories are combined and treated as a valid category. If this option is deselected, any records with missing values are excluded from the analysis.

Anomaly Detection Model Nuggets

Anomaly Detection model nuggets contain all of the information captured by the Anomaly Detection model as well as information about the training data and estimation process.

When you run a stream containing an Anomaly Detection model nugget, a number of new fields are added to the stream, as determined by the selections made on the Settings tab in the model nugget. See the topic [Anomaly Detection Model Settings](#) for more information. New field names are based on the model name, prefaced by $\$O$, as summarized in the following table.

Table 1. New field name generation

Field name	Description
$\$O\text{-Anomaly}$	Flag field indicating whether or not the record is anomalous.
$\$O\text{-AnomalyIndex}$	The anomaly index value for the record.
$\$O\text{-PeerGroup}$	Specifies the peer group to which the record is assigned.
$\$O\text{-Field-}n$	Name of the n th most anomalous field in terms of deviation from the cluster norm.
$\$O\text{-FieldImpact-}n$	Variable deviation index for the field. This value measures the deviation from the field norm for the cluster to which the record is assigned.

Optionally, you can suppress scores for non-anomalous records to make the results easier to read. See the topic [Anomaly Detection Model Settings](#) for more information.

- [Anomaly Detection model details](#)
- [Anomaly Detection Model Summary](#)
- [Anomaly Detection Model Settings](#)

Anomaly Detection model details

The Model tab for a generated Anomaly Detection model displays information about the peer groups in the model.

Note that the peer group sizes and statistics reported are estimates based on the training data and may differ slightly from actual scoring results even if run on the same data.

The Residual of the unreported reasons is 1 minus the sum of the mean anomaly index values for each of the anomaly columns for the records that are identified as anomalies. This percentage can serve as an indication of how much of the anomaly is explained by the fields that are

reported. This might guide you in determining how many anomaly fields to report.

Anomaly Detection Model Summary

The Summary tab for an Anomaly Detection model nugget displays information about the fields, build settings, and estimation process. The number of peer groups is also shown, along with the cutoff value used to flag records as anomalous.

Anomaly Detection Model Settings

Use the Settings tab to specify options for scoring the model nugget.

Indicate anomalous records with Specifies how anomalous records are treated in the output.

- Flag and index Creates a flag field that is set to *True* for all records that exceed the cutoff value included in the model. The anomaly index is also reported for each record in a separate field. See the topic [Anomaly Detection Model Options](#) for more information.
- Flag only Creates a flag field but without reporting the anomaly index for each record.
- Index only Reports the anomaly index without creating a flag field.

Number of anomaly fields to report Specifies the number of fields to report as an indication of why a particular record is flagged as an anomaly. The most anomalous fields are reported, defined as those that show the greatest deviation from the field norm for the cluster to which the record is assigned.

Discard records Select this option to discard all Non anomalous records from the stream, making it easier to focus on potential anomalies in any downstream nodes. Alternatively, you can choose to discard all Anomalous records in order to limit the subsequent analysis to those records that are not flagged as potential anomalies based on the model.

Note: Due to slight differences in rounding, the actual number of records flagged during scoring may not be identical to those flagged while training the model even if run on the same data.

Generate SQL for this model When using data from a database, SQL code can be pushed back to the database for execution, providing superior performance for many operations.

Select one of the following options to specify how SQL generation is performed.

- Default: Score using Server Scoring Adapter (if installed) otherwise in process If connected to a database with a scoring adapter installed, generates SQL using the scoring adapter and associated user defined functions (UDF) and scores your model within the database. When no scoring adapter is available, this option fetches your data back from the database and scores it in SPSS® Modeler.
- Score outside of the Database If selected, this option fetches your data back from the database and scores it in SPSS Modeler.

Automated Modeling Nodes

The automated modeling nodes estimate and compare a number of different modeling methods, enabling you to try out a variety of approaches in a single modeling run. You can select the modeling algorithms to use, and the specific options for each, including combinations that would otherwise be mutually-exclusive. For example, rather than choose between the quick, dynamic, or prune methods for a Neural Net, you can try them all. The node explores every possible combination of options, ranks each candidate model based on the measure you specify, and saves the best for use in scoring or further analysis.

You can choose from three automated modeling nodes, depending on the needs of your analysis:

	The Auto Classifier node creates and compares a number of different models for binary outcomes (yes or no, churn or do not churn, and so on), allowing you to choose the best approach for a given analysis. A number of modeling algorithms are supported, making it possible to select the methods you want to use, the specific options for each, and the criteria for comparing the results. The node generates a set of models based on the specified options and ranks the best candidates according to the criteria you specify.
	The Auto Numeric node estimates and compares models for continuous numeric range outcomes using a number of different methods. The node works in the same manner as the Auto Classifier node, allowing you to choose the algorithms to use and to experiment with multiple combinations of options in a single modeling pass. Supported algorithms include neural networks, C&R Tree, CHAID, linear regression, generalized linear regression, and support vector machines (SVM). Models can be compared based on correlation, relative error, or number of variables used.
	The Auto Cluster node estimates and compares clustering models, which identify groups of records that have similar characteristics. The node works in the same manner as other automated modeling nodes, allowing you to experiment with multiple combinations of options in a single modeling pass. Models can be compared using basic measures with which to

attempt to filter and rank the usefulness of the cluster models, and provide a measure based on the importance of particular fields.

The best models are saved in a single composite model nugget, enabling you to browse and compare them, and to choose which models to use in scoring.

- For binary, nominal, and numeric targets only you can select multiple scoring models and combine the scores in a single model ensemble. By combining predictions from multiple models, limitations in individual models may be avoided, often resulting in a higher overall accuracy than can be gained from any one of the models.
- Optionally, you can choose to drill down into the results and generate modeling nodes or model nuggets for any of the individual models you want to use or explore further.

Models and Execution Time

Depending on the dataset and the number of models, automated modeling nodes may take hours or even longer to execute. When selecting options, pay attention to the number of models being produced. When practical, you may want to schedule modeling runs during nights or weekends when system resources are less likely to be in demand.

- If necessary, a Partition or Sample node can be used to reduce the number of records included in the initial training pass. Once you have narrowed the choices to a few candidate models, the full dataset can be restored.
 - To reduce the number of input fields, use Feature Selection. See the topic [Feature Selection node](#) for more information. Alternatively, you can use your initial modeling runs to identify fields and options that are worth exploring further. For example, if your best-performing models all seem to use the same three fields, this is a strong indication that those fields are worth keeping.
 - Optionally, you can limit the amount of time spent estimating any one model and specify the evaluation measures used to screen and rank models.
- [Automated Modeling Node Algorithm Settings](#)
 - [Automated Modeling Node Stopping Rules](#)
 - [Execution Feedback](#)
 - [Auto Classifier node](#)
 - [Auto Numeric node](#)
 - [Auto Cluster node](#)
 - [Automated Model Nuggets](#)

Automated Modeling Node Algorithm Settings

For each model type, you can use the default settings, or you can choose options for each model type. The specific options are similar to those available in the separate modeling nodes, with the difference that rather than choosing one setting or another, you can choose as many as you want to apply in most cases. For example, if comparing Neural Net models, you can choose several different training methods, and try each method with and without a random seed. All possible combinations of the selected options will be used, making it very easy to generate many different models in a single pass. Use care, however, as choosing multiple settings can cause the number of models to multiply very quickly.

To choose options for each model type

1. On the automated modeling node, select the Expert tab.
2. Click in the Model parameters column for the model type.
3. From the drop-down menu, choose Specify.
4. On the Algorithm settings dialog, select options from the Options column.

Note: Further options are available on the Expert tab of the Algorithm settings dialog.

Automated Modeling Node Stopping Rules

Stopping rules specified for automated modeling nodes relate to the overall node execution, not the stopping of individual models built by the node.

Restrict overall execution time. (Neural Network, K-Means, Kohonen, TwoStep, SVM, KNN, Bayes Net and C&R Tree models only) Stops execution after a specified number of hours. All models generated up to that point will be included in the model nugget, but no further models will be produced.

Stop as soon as valid models are produced. Stops execution when a model passes all criteria specified on the Discard tab (for the Auto Classifier or Auto Cluster node) or the Model tab (for the Auto Numeric node). See the topic [Auto Classifier Node Discard Options](#) for more information. See the topic [Auto Cluster Node Discard Options](#) for more information.

Execution Feedback

In addition to displaying the standard Execution Feedback dialog box if the stream takes longer than three seconds to execute, IBM® SPSS® Modeler displays information about the number of models involved.

Auto Classifier node

The Auto Classifier node estimates and compares models for either nominal (set) or binary (yes/no) targets, using a number of different methods, enabling you to try out a variety of approaches in a single modeling run. You can select the algorithms to use, and experiment with multiple combinations of options. For example, rather than choose between Radial Basis Function, polynomial, sigmoid, or linear methods for an SVM, you can try them all. The node explores every possible combination of options, ranks each candidate model based on the measure you specify, and saves the best models for use in scoring or further analysis. For more information, see [Automated Modeling Nodes](#).

Example

A retail company has historical data tracking the offers made to specific customers in past campaigns. The company now wants to achieve more profitable results by matching the right offer to each customer.

Requirements

A target field with a measurement level of either *Nominal* or *Flag* (with the role set to Target), and at least one input field (with the role set to Input). For a flag field, the *True* value defined for the target is assumed to represent a hit when calculating profits, lift, and related statistics. Input fields can have a measurement level of *Continuous* or *Categorical*, with the limitation that some inputs may not be appropriate for some model types. For example, ordinal fields used as inputs in C&R Tree, CHAID, and QUEST models must have numeric storage (not string), and will be ignored by these models if specified otherwise. Similarly, continuous input fields can be binned in some cases. The requirements are the same as when using the individual modeling nodes; for example a Bayes Net model works the same whether generated from the Bayes Net node or the Auto Classifier node.

Frequency and weight fields

Frequency and weight are used to give extra importance to some records over others because, for example, the user knows that the build dataset under-represents a section of the parent population (Weight) or because one record represents a number of identical cases (Frequency). If specified, a frequency field can be used by C&R Tree, CHAID, QUEST, Decision List, and Bayes Net models. A weight field can be used by C&RT, CHAID, and C5.0 models. Other model types will ignore these fields and build the models anyway. Frequency and weight fields are used only for model building, and are not considered when evaluating or scoring models. For more information, see [Using Frequency and Weight Fields](#).

Prefixes

If you attach a table node to the nugget for the Auto Classifier Node, there are several new variables in the table with names that begin with a \$ prefix.

The names of the fields that are generated during scoring are based on the target field, but with a standard prefix. Different model types use different sets of prefixes.

For example, the prefixes \$G, \$R, \$C are used as the prefix for predictions that are generated by the Generalized Linear model, CHAID model, and C5.0 model, respectively. \$X is typically generated by using an ensemble, and \$XR, \$XS, and \$XF are used as prefixes in cases where the target field is a Continuous, Categorical, or Flag field, respectively.

\$..C prefixes are used for prediction confidence of a Categorical, or Flag target; for example, \$XFC is used as a prefix for ensemble Flag prediction confidence. \$RC and \$CC are the prefixes for a single prediction of confidence for a CHAID model and C5.0 model respectively.

Supported Model Types

Supported model types include Neural Net, C&R Tree, QUEST, CHAID, C5.0, Logistic Regression, Decision List, Bayes Net, Discriminant, Nearest Neighbor, SVM, XGBoost Tree, and XGBoost-AS. See the topic [Auto Classifier Node Expert Options](#) for more information.

Continuous machine learning

An inconvenience with modeling is models getting outdated due to changes to your data over time. This is commonly referred to as *model drift* or *concept drift*. To help overcome model drift effectively, SPSS Modeler provides continuous automated machine learning. This feature is available for Auto Classifier node and Auto Numeric node model nuggets. For more information, see [Continuous machine learning](#).

- [Auto Classifier node model options](#)
 - [Auto Classifier Node Expert Options](#)
 - [Auto Classifier Node Discard Options](#)
 - [Auto Classifier node settings](#)
-

Auto Classifier node model options

The Model tab of the Auto Classifier node enables you to specify the number of models to be created, along with the criteria used to compare models.

Model name. You can generate the model name automatically based on the target or ID field (or model type in cases where no such field is specified) or specify a custom name.

Use partitioned data. If a partition field is defined, this option ensures that data from only the training partition is used to build the model.

Cross-validate. Cross-validation gives the model a dataset of *known data* on which to run training (a training dataset), and a dataset of *unknown data* to test the model against (validation dataset or testing set). The goal of cross-validation is to test the model's ability to predict new data that was not used in estimating it, in order to flag problems like overfitting or selection bias.

Create split models. Builds a separate model for each possible value of input fields that are specified as split fields. See [Building Split Models](#) for more information.

Rank models by. Specifies the criteria used to compare and rank models. Options include overall accuracy, area under the ROC curve, profit, lift, and number of fields. Note that all of these measures will be available in the summary report regardless of which is selected here.

Note: For a nominal (set) target, ranking is restricted to either Overall Accuracy or Number of Fields.

When calculating profits, lift, and related statistics, the *True* value defined for the target field is assumed to represent a hit.

- Overall accuracy. The percentage of records that is correctly predicted by the model relative to the total number of records.
- Area under the ROC curve. The ROC curve provides an index for the performance of a model. The further the curve lies above the reference line, the more accurate the test.
- Profit (Cumulative). The sum of profits across cumulative percentiles (sorted in terms of confidence for the prediction), as computed based on the specified cost, revenue, and weight criteria. Typically, the profit starts near 0 for the top percentile, increases steadily, and then decreases. For a good model, profits will show a well-defined peak, which is reported along with the percentile where it occurs. For a model that provides no information, the profit curve will be relatively straight and may be increasing, decreasing, or level, depending on the cost/revenue structure that applies.

- Lift (Cumulative). The ratio of hits in cumulative quantiles relative to the overall sample (where quantiles are sorted in terms of confidence for the prediction). For example, a lift value of 3 for the top quantile indicates a hit rate three times as high as for the sample overall. For a good model, lift should start well above 1.0 for the top quantiles and then drop off sharply toward 1.0 for the lower quantiles. For a model that provides no information, the lift will hover around 1.0.
- Number of fields. Ranks models based on the number of input fields used.

Rank models using. If a partition is in use, you can specify whether ranks are based on the training dataset or the testing set. With large datasets, use of a partition for preliminary screening of models may greatly improve performance.

Number of models to use. Specifies the maximum number of models to be listed in the model nugget produced by the node. The top-ranking models are listed according to the specified ranking criterion. Note that increasing this limit may slow performance. The maximum allowable value is 100.

Calculate predictor importance. For models that produce an appropriate measure of importance, you can display a chart that indicates the relative importance of each predictor in estimating the model. Typically you will want to focus your modeling efforts on the predictors that matter most, and consider dropping or ignoring those that matter least. Note that predictor importance may extend the time needed to calculate some models, and is not recommended if you simply want a broad comparison across many different models. It is more useful once you have narrowed your analysis to a handful of models that you want to explore in greater detail. See [Predictor Importance](#) for more information.

Profit Criteria. Only for flag targets. Profit equals the revenue for each record minus the cost for the record. Profits for a quantile are simply the sum of profits for all records in the quantile. Profits are assumed to apply only to hits, but costs apply to all records.

- Costs. Specify the cost associated with each record. You can select Fixed or Variable costs. For fixed costs, specify the cost value. For variable costs, click the Field Chooser button to select a field as the cost field. (Costs is not available for ROC charts.)
- Revenue. Specify the revenue associated with each record that represents a hit. You can select Fixed or Variable costs. For fixed revenue, specify the revenue value. For variable revenue, click the Field Chooser button to select a field as the revenue field. (Revenue is not available for ROC charts.)
- Weight. If the records in your data represent more than one unit, you can use frequency weights to adjust the results. Specify the weight associated with each record, using Fixed or Variable weights. For fixed weights, specify the weight value (the number of units per record). For variable weights, click the Field Chooser button to select a field as the weight field. (Weight is not available for ROC charts.)

Lift Criteria. Only for flag targets. Specifies the percentile to use for lift calculations. Note that you can also change this value when comparing the results. See the topic [Automated Model Nuggets](#) for more information.

Auto Classifier Node Expert Options

The Expert tab of the Auto Classifier node enables you to apply a partition (if available), select the algorithms to use, and specify stopping rules.

Select models. By default, all models are selected to be built; however, if you have Analytic Server, you can choose to restrict the models to those that can run on Analytic Server and preset them so that they either build split models or are ready to process very large data sets.

Note: Local building of Analytic Server models within the Auto Classifier node is not supported.

Models used. Use the check boxes in the column on the left to select the model types (algorithms) to include in the comparison. The more types you select, the more models will be created and the longer the processing time will be.

Model type. Lists the available algorithms (see below).

Model parameters. For each model type, you can use the default settings or select Specify to choose options for each model type. The specific options are similar to those available in the separate modeling nodes, with the difference that multiple options or combinations can be selected. For example, if comparing Neural Net models, rather than choosing one of the six training methods, you can choose all of them to train six models in a single pass.

Number of models. Lists the number of models produced for each algorithm based on current settings. When combining options, the number of models can quickly add up, so paying close attention to this number is strongly recommended, particularly when using large datasets.

Restrict maximum time spent building a single model. (K-Means, Kohonen, TwoStep, SVM, KNN, Bayes Net and Decision List models only) Sets a maximum time limit for any one model. For example, if a particular model requires an unexpectedly long time to train because of some complex interaction, you probably don't want it to hold up your entire modeling run.

Note: If the target is a nominal (set) field, the Decision List option is unavailable.

Supported Algorithms

	The Support Vector Machine (SVM) node enables you to classify data into one of two groups without overfitting. SVM works well with wide data sets, such as those with a very large number of input fields.
	The <i>k</i> -Nearest Neighbor (KNN) node associates a new case with the category or value of the <i>k</i> objects nearest to it in the predictor space, where <i>k</i> is an integer. Similar cases are near each other and dissimilar cases are distant from each other.

	Discriminant analysis makes more stringent assumptions than logistic regression but can be a valuable alternative or supplement to a logistic regression analysis when those assumptions are met.
	The Bayesian Network node enables you to build a probability model by combining observed and recorded evidence with real-world knowledge to establish the likelihood of occurrences. The node focuses on Tree Augmented Naïve Bayes (TAN) and Markov Blanket networks that are primarily used for classification.
	The Decision List node identifies subgroups, or segments, that show a higher or lower likelihood of a given binary outcome relative to the overall population. For example, you might look for customers who are unlikely to churn or are most likely to respond favorably to a campaign. You can incorporate your business knowledge into the model by adding your own custom segments and previewing alternative models side by side to compare the results. Decision List models consist of a list of rules in which each rule has a condition and an outcome. Rules are applied in order, and the first rule that matches determines the outcome.
	Logistic regression is a statistical technique for classifying records based on values of input fields. It is analogous to linear regression but takes a categorical target field instead of a numeric range.
	The CHAID node generates decision trees using chi-square statistics to identify optimal splits. Unlike the C&R Tree and QUEST nodes, CHAID can generate nonbinary trees, meaning that some splits have more than two branches. Target and input fields can be numeric range (continuous) or categorical. Exhaustive CHAID is a modification of CHAID that does a more thorough job of examining all possible splits but takes longer to compute.
	The QUEST node provides a binary classification method for building decision trees, designed to reduce the processing time required for large C&R Tree analyses while also reducing the tendency found in classification tree methods to favor inputs that allow more splits. Input fields can be numeric ranges (continuous), but the target field must be categorical. All splits are binary.
	The Classification and Regression (C&R) Tree node generates a decision tree that allows you to predict or classify future observations. The method uses recursive partitioning to split the training records into segments by minimizing the impurity at each step, where a node in the tree is considered “pure” if 100% of cases in the node fall into a specific category of the target field. Target and input fields can be numeric ranges or categorical (nominal, ordinal, or flags); all splits are binary (only two subgroups).
	The C5.0 node builds either a decision tree or a rule set. The model works by splitting the sample based on the field that provides the maximum information gain at each level. The target field must be categorical. Multiple splits into more than two subgroups are allowed.
	The Neural Net node uses a simplified model of the way the human brain processes information. It works by simulating a large number of interconnected simple processing units that resemble abstract versions of neurons. Neural networks are powerful general function estimators and require minimal statistical or mathematical knowledge to train or apply.
	Linear regression models predict a continuous target based on linear relationships between the target and one or more predictors.
	The Linear Support Vector Machine (LSVM) node enables you to classify data into one of two groups without overfitting. LSVM is linear and works well with wide data sets, such as those with a very large number of records.
	The Random Trees node is similar to the existing C&RT node; however, the Random Trees node is designed to process big data to create a single tree and displays the resulting model in the output viewer that was added in SPSS® Modeler version 17. The Random Trees tree node generates a decision tree that you use to predict or classify future observations. The method uses recursive partitioning to split the training records into segments by minimizing the impurity at each step, where a node in the tree is considered <i>pure</i> if 100% of cases in the node fall into a specific category of the target field. Target and input fields can be numeric ranges or categorical (nominal, ordinal, or flags); all splits are binary (only two subgroups).
	The Tree-AS node is similar to the existing CHAID node; however, the Tree-AS node is designed to process big data to create a single tree and displays the resulting model in the output viewer that was added in SPSS Modeler version 17. The node generates a decision tree by using chi-square statistics (CHAID) to identify optimal splits. This use of CHAID can generate nonbinary trees, meaning that some splits have more than two branches. Target and input fields can be numeric range (continuous) or categorical. Exhaustive CHAID is a modification of CHAID that does a more thorough job of examining all possible splits but takes longer to compute.
	XGBoost Tree® is an advanced implementation of a gradient boosting algorithm with a tree model as the base model. Boosting algorithms iteratively learn weak classifiers and then add them to a final strong classifier. XGBoost Tree is very flexible and provides many parameters that can be overwhelming to most users, so the XGBoost Tree node in SPSS Modeler exposes the core features and commonly used parameters. The node is implemented in Python.
	XGBoost® is an advanced implementation of a gradient boosting algorithm. Boosting algorithms iteratively learn weak classifiers and then add them to a final strong classifier. XGBoost is very flexible and provides many parameters that can be overwhelming to most users, so the XGBoost-AS node in SPSS Modeler exposes the core features and commonly used parameters. The XGBoost-AS node is implemented in Spark.

Note: If you select Tree-AS to run on Analytic Server, it will fail to build a model when there is a Partition node upstream. In this case, to make Auto Classifier work with other modeling nodes on Analytic Server, deselect the Tree-AS model type.

Auto Classifier Node Discard Options

The Discard tab of the Auto Classifier node enables you to automatically discard models that do not meet certain criteria. These models will not be listed in the summary report.

You can specify a minimum threshold for overall accuracy and a maximum threshold for the number of variables used in the model. In addition, for flag targets, you can specify a minimum threshold for lift, profit, and area under the curve; lift and profit are determined as specified on the Model tab. See the topic [Auto Classifier node model options](#) for more information.

Optionally, you can configure the node to stop execution the first time a model is generated that meets all specified criteria. See the topic [Automated Modeling Node Stopping Rules](#) for more information.

Auto Classifier node settings

On the Auto Classifier node's Settings tab, you can preconfigure the score-time options that are available on the nugget.

Filter out fields generated by ensembled models. Removes from the output all of the additional fields generated by the individual models that feed into the Ensemble node. Select this check box if you are interested only in the combined score from all of the input models. Ensure that this option is deselected if, for example, you want to use an Analysis node or Evaluation node to compare the accuracy of the combined score with that of each of the individual input models.

Tip: *Continuous machine learning* settings are also available for the Auto Classifier node and the Auto Numeric node. For details, see [Continuous machine learning](#).

Auto Numeric node

The Auto Numeric node estimates and compares models for continuous numeric range outcomes using a number of different methods, enabling you to try out a variety of approaches in a single modeling run. You can select the algorithms to use, and experiment with multiple combinations of options. For example, you could predict housing values using neural net, linear regression, C&RT, and CHAID models to see which performs best, and you could try out different combinations of stepwise, forward, and backward regression methods. The node explores every possible combination of options, ranks each candidate model based on the measure you specify, and saves the best for use in scoring or further analysis. See the topic [Automated Modeling Nodes](#) for more information.

Example

A municipality wants to more accurately estimate real estate taxes and to adjust values for specific properties as needed without having to inspect every property. Using the Auto Numeric node, the analyst can generate and compare a number of models that predict property values based on building type, neighborhood, size, and other known factors.

Requirements

A single target field (with the role set to Target), and at least one input field (with the role set to Input). The target must be a continuous (numeric range) field, such as *age* or *income*. Input fields can be continuous or categorical, with the limitation that some inputs may not be appropriate for some model types. For example, C&R Tree models can use categorical string fields as inputs, while linear regression models cannot use these fields and will ignore them if specified. The requirements are the same as when using the individual modeling nodes. For example, a CHAID model works the same whether generated from the CHAID node or the Auto Numeric node.

Frequency and weight fields

Frequency and weight are used to give extra importance to some records over others because, for example, the user knows that the build dataset under-represents a section of the parent population (Weight) or because one record represents a number of identical cases (Frequency). If specified, a frequency field can be used by C&R Tree and CHAID algorithms. A weight field can be used by C&RT, CHAID, Regression, and GenLin algorithms. Other model types will ignore these fields and build the models anyway. Frequency and weight fields are used only for model building and are not considered when evaluating or scoring models. See the topic [Using Frequency and Weight Fields](#) for more information.

Prefixes

If you attach a table node to the nugget for the Auto Numeric Node, there are several new variables in the table with names that begin with a \$ prefix.

The names of the fields that are generated during scoring are based on the target field, but with a standard prefix. Different model types use different sets of prefixes.

For example, the prefixes \$G, \$R, \$C are used as the prefix for predictions that are generated by the Generalized Linear model, CHAID model, and C5.0 model, respectively. \$X is typically generated by using an ensemble, and \$XR, \$XS, and \$XF are used as prefixes in cases where the target field is a Continuous, Categorical, or Flag field, respectively.

\$..E prefixes are used for the prediction confidence of a Continuous target; for example, \$XRE is used as a prefix for ensemble Continuous prediction confidence. \$GE is the prefix for a single prediction of confidence for a Generalized Linear model.

Supported model types

Supported model types include Neural Net, C&R Tree, CHAID, Regression, GenLin, Nearest Neighbor, SVM, XGBoost Linear, GLE, and XGBoost-AS. For more information, see [Auto Numeric Node Expert Options](#).

Continuous machine learning

An inconvenience with modeling is models getting outdated due to changes to your data over time. This is commonly referred to as *model drift* or *concept drift*. To help overcome model drift effectively, SPSS Modeler provides continuous automated machine learning. This feature is available for Auto Classifier node and Auto Numeric node model nuggets. For more information, see [Continuous machine learning](#).

- [Auto Numeric node model options](#)
 - [Auto Numeric Node Expert Options](#)
 - [Auto Numeric node settings](#)
-

Auto Numeric node model options

The Model tab of the Auto Numeric node enables you to specify the number of models to be saved, along with the criteria used to compare models.

Model name. You can generate the model name automatically based on the target or ID field (or model type in cases where no such field is specified) or specify a custom name.

Use partitioned data. If a partition field is defined, this option ensures that data from only the training partition is used to build the model.

Cross-validate. Cross-validation gives the model a dataset of *known data* on which to run training (a training dataset), and a dataset of *unknown data* to test the model against (validation dataset or testing set). The goal of cross-validation is to test the model's ability to predict new data that was not used in estimating it, in order to flag problems like overfitting or selection bias.

Create split models. Builds a separate model for each possible value of input fields that are specified as split fields. See [Building Split Models](#) for more information.

Rank models by. Specifies the criteria used to compare models.

- Correlation. The Pearson Correlation between the observed value for each record and the value predicted by the model. The correlation is a measure of linear association between two variables, with values closer to 1 indicating a stronger relationship. (Correlation values range between -1, for a perfect negative relationship, and +1 for a perfect positive relationship. A value of 0 indicates no linear relationship, while a model with a negative correlation would rank lowest of all.)
- Number of fields. The number of fields used as predictors in the model. Choosing models that use fewer fields may streamline data preparation and improve performance in some cases.
- Relative error. The relative error is the ratio of the variance of the observed values from those predicted by the model to the variance of the observed values from the mean. In practical terms, it compares how well the model performs relative to a **null** or **intercept** model that simply returns the mean value of the target field as the prediction. For a good model, this value should be less than 1, indicating that the model is more accurate than the null model. A model with a relative error greater than 1 is less accurate than the null model and is therefore not useful. For linear regression models, the relative error is equal to the square of the correlation and adds no new information. For nonlinear models, the relative error is unrelated to the correlation and provides an additional measure for assessing model performance.

Rank models using. If a partition is in use, you can specify whether ranks are based on the training partition or the testing partition. With large datasets, use of a partition for preliminary screening of models may greatly improve performance.

Number of models to use. Specifies the maximum number of models to be shown in the model nugget produced by the node. The top-ranking models are listed according to the specified ranking criterion. Increasing this limit will enable you to compare results for more models but may slow performance. The maximum allowable value is 100.

Calculate predictor importance. For models that produce an appropriate measure of importance, you can display a chart that indicates the relative importance of each predictor in estimating the model. Typically you will want to focus your modeling efforts on the predictors that matter most, and consider dropping or ignoring those that matter least. Note that predictor importance may extend the time needed to calculate some

models, and is not recommended if you simply want a broad comparison across many different models. It is more useful once you have narrowed your analysis to a handful of models that you want to explore in greater detail. See [Predictor Importance](#) for more information.

Do not keep models if. Specifies threshold values for correlation, relative error, and number of fields used. Models that fail to meet any of these criteria will be discarded and will not be listed in the summary report.

- Correlation less than. The minimum correlation (in terms of absolute value) for a model to be included in the summary report.
- Number of fields used is greater than. The maximum number of fields to be used by any model to be included.
- Relative error is greater than. The maximum relative error for any model to be included.

Optionally, you can configure the node to stop execution the first time a model is generated that meets all specified criteria. See the topic [Automated Modeling Node Stopping Rules](#) for more information.

Auto Numeric Node Expert Options

The Expert tab of the Auto Numeric node enables you to select the algorithms and options to use and to specify stopping rules.

Select models. By default, all models are selected to be built; however, if you have Analytic Server, you can choose to restrict the models to those that can run on Analytic Server and preset them so that they either build split models or are ready to process very large data sets.

Note: Local building of Analytic Server models within the Auto Numeric node is not supported.

Models used. Use the check boxes in the column on the left to select the model types (algorithms) to include in the comparison. The more types you select, the more models will be created and the longer the processing time will be.

Model type. Lists the available algorithms (see below).

Model parameters. For each model type, you can use the default settings or select Specify to choose options for each model type. The specific options are similar to those available in the separate modeling nodes, with the difference that multiple options or combinations can be selected. For example, if comparing Neural Net models, rather than choosing one of the six training methods, you can choose all of them to train six models in a single pass.

Number of models. Lists the number of models produced for each algorithm based on current settings. When combining options, the number of models can quickly add up, so paying close attention to this number is strongly recommended, particularly when using large datasets.

Restrict maximum time spent building a single model. (K-Means, Kohonen, TwoStep, SVM, KNN, Bayes Net and Decision List models only) Sets a maximum time limit for any one model. For example, if a particular model requires an unexpectedly long time to train because of some complex interaction, you probably don't want it to hold up your entire modeling run.

Supported algorithms

	The Neural Net node uses a simplified model of the way the human brain processes information. It works by simulating a large number of interconnected simple processing units that resemble abstract versions of neurons. Neural networks are powerful general function estimators and require minimal statistical or mathematical knowledge to train or apply.
	The Classification and Regression (C&R) Tree node generates a decision tree that allows you to predict or classify future observations. The method uses recursive partitioning to split the training records into segments by minimizing the impurity at each step, where a node in the tree is considered "pure" if 100% of cases in the node fall into a specific category of the target field. Target and input fields can be numeric ranges or categorical (nominal, ordinal, or flags); all splits are binary (only two subgroups).
	The CHAID node generates decision trees using chi-square statistics to identify optimal splits. Unlike the C&R Tree and QUEST nodes, CHAID can generate nonbinary trees, meaning that some splits have more than two branches. Target and input fields can be numeric range (continuous) or categorical. Exhaustive CHAID is a modification of CHAID that does a more thorough job of examining all possible splits but takes longer to compute.
	Linear regression is a common statistical technique for summarizing data and making predictions by fitting a straight line or surface that minimizes the discrepancies between predicted and actual output values.
	The Generalized Linear model expands the general linear model so that the dependent variable is linearly related to the factors and covariates through a specified link function. Moreover, the model allows for the dependent variable to have a non-normal distribution. It covers the functionality of a wide number of statistical models, including linear regression, logistic regression, loglinear models for count data, and interval-censored survival models.
	The k -Nearest Neighbor (KNN) node associates a new case with the category or value of the k objects nearest to it in the predictor space, where k is an integer. Similar cases are near each other and dissimilar cases are distant from each other.
	The Support Vector Machine (SVM) node enables you to classify data into one of two groups without overfitting. SVM works well with wide data sets, such as those with a very large number of input fields.
	Linear regression models predict a continuous target based on linear relationships between the target and one or more predictors.

	The Linear Support Vector Machine (LSVM) node enables you to classify data into one of two groups without overfitting. LSVM is linear and works well with wide data sets, such as those with a very large number of records.
	The Random Trees node is similar to the existing C&RT node; however, the Random Trees node is designed to process big data to create a single tree and displays the resulting model in the output viewer that was added in SPSS® Modeler version 17. The Random Trees tree node generates a decision tree that you use to predict or classify future observations. The method uses recursive partitioning to split the training records into segments by minimizing the impurity at each step, where a node in the tree is considered <i>pure</i> if 100% of cases in the node fall into a specific category of the target field. Target and input fields can be numeric ranges or categorical (nominal, ordinal, or flags); all splits are binary (only two subgroups).
	The Tree-AS node is similar to the existing CHAID node; however, the Tree-AS node is designed to process big data to create a single tree and displays the resulting model in the output viewer that was added in SPSS Modeler version 17. The node generates a decision tree by using chi-square statistics (CHAID) to identify optimal splits. This use of CHAID can generate nonbinary trees, meaning that some splits have more than two branches. Target and input fields can be numeric range (continuous) or categorical. Exhaustive CHAID is a modification of CHAID that does a more thorough job of examining all possible splits but takes longer to compute.
	XGBoost Linear® is an advanced implementation of a gradient boosting algorithm with a linear model as the base model. Boosting algorithms iteratively learn weak classifiers and then add them to a final strong classifier. The XGBoost Linear node in SPSS Modeler is implemented in Python.
	A GLE extends the linear model so that the target can have a non-normal distribution, is linearly related to the factors and covariates via a specified link function, and so that the observations can be correlated. Generalized linear mixed models cover a wide variety of models, from simple linear regression to complex multilevel models for non-normal longitudinal data.
	XGBoost® is an advanced implementation of a gradient boosting algorithm. Boosting algorithms iteratively learn weak classifiers and then add them to a final strong classifier. XGBoost is very flexible and provides many parameters that can be overwhelming to most users, so the XGBoost-AS node in SPSS Modeler exposes the core features and commonly used parameters. The XGBoost-AS node is implemented in Spark.

Auto Numeric node settings

The Settings tab of the Auto Numeric node enables you to preconfigure the score-time options that are available on the nugget.

Filter out fields generated by ensembled models. Removes from the output all of the additional fields generated by the individual models that feed into the Ensemble node. Select this check box if you are interested only in the combined score from all of the input models. Ensure that this option is deselected if, for example, you want to use an Analysis node or Evaluation node to compare the accuracy of the combined score with that of each of the individual input models.

Calculate standard error. For a continuous (numeric range) target, a standard error calculation is run by default to calculate the difference between the measured or estimated values and the true values; and to show how close those estimates matched.

Tip: *Continuous machine learning* settings are also available for the Auto Classifier node and the Auto Numeric node. For details, see [Continuous machine learning](#).

Auto Cluster node

The Auto Cluster node estimates and compares clustering models that identify groups of records with similar characteristics. The node works in the same manner as other automated modeling nodes, enabling you to experiment with multiple combinations of options in a single modeling pass. Models can be compared using basic measures with which to attempt to filter and rank the usefulness of the cluster models, and provide a measure based on the importance of particular fields.

Clustering models are often used to identify groups that can be used as inputs in subsequent analyses. For example you may want to target groups of customers based on demographic characteristics such as income, or based on the services they have bought in the past. This can be done without prior knowledge about the groups and their characteristics -- you may not know how many groups to look for, or what features to use in defining them. Clustering models are often referred to as unsupervised learning models, since they do not use a target field, and do not return a specific prediction that can be evaluated as true or false. The value of a clustering model is determined by its ability to capture interesting groupings in the data and provide useful descriptions of those groupings. See [Clustering models](#) for more information.

Requirements. One or more fields that define characteristics of interest. Cluster models do not use target fields in the same manner as other models, because they do not make specific predictions that can be assessed as true or false. Instead they are used to identify groups of cases that may be related. For example you cannot use a cluster model to predict whether a given customer will churn or respond to an offer. But you can use a cluster model to assign customers to groups based on their tendency to do those things. Weight and frequency fields are not used.

Evaluation fields. While no target is used, you can optionally specify one or more evaluation fields to be used in comparing models. The usefulness of a cluster model may be evaluated by measuring how well (or badly) the clusters differentiate these fields.

Supported model types

Supported model types include TwoStep, K-Means, Kohonen, One-Class SVM, and K-Means-AS.

- [Auto Cluster Node Model Options](#)
 - [Auto Cluster Node Expert Options](#)
 - [Auto Cluster Node Discard Options](#)
-

Auto Cluster Node Model Options

The Model tab of the Auto Cluster node enables you to specify the number of models to be saved, along with the criteria used to compare models.

Model name. You can generate the model name automatically based on the target or ID field (or model type in cases where no such field is specified) or specify a custom name.

Use partitioned data. If a partition field is defined, this option ensures that data from only the training partition is used to build the model.

Rank models by. Specifies the criteria used to compare and rank models.

- **Silhouette.** An index measuring both cluster cohesion and separation. See *Silhouette Ranking Measure* below for more information.
- **Number of clusters.** The number of clusters in the model.
- **Size of smallest cluster.** The smallest cluster size.
- **Size of largest cluster.** The largest cluster size.
- **Smallest / largest cluster.** The ratio of the size of the smallest cluster to the largest cluster.
- **Importance.** The importance of the Evaluation field on the Fields tab. Note that this can only be calculated if an Evaluation field has been specified.

Rank models using. If a partition is in use, you can specify whether ranks are based on the training dataset or the testing set. With large datasets, use of a partition for preliminary screening of models may greatly improve performance.

Number of models to keep. Specifies the maximum number of models to be listed in the nugget produced by the node. The top-ranking models are listed according to the specified ranking criterion. Note that increasing this limit may slow performance. The maximum allowable value is 100.

Silhouette Ranking Measure

The default ranking measure, Silhouette, has a default value of 0 because a value of less than 0 (i.e. negative) indicates that the average distance between a case and points in its assigned cluster is greater than the minimum average distance to points in another cluster. Therefore, models with a negative Silhouette can safely be discarded.

The ranking measure is actually a modified silhouette coefficient, which combines the concepts of cluster cohesion (favoring models which contain tightly cohesive clusters) and cluster separation (favoring models which contain highly separated clusters). The average Silhouette coefficient is simply the average over all cases of the following calculation for each individual case:

$$(B - A) / \max(A, B)$$

where A is the distance from the case to the centroid of the cluster which the case belongs to; and B is the minimal distance from the case to the centroid of every other cluster.

The Silhouette coefficient (and its average) range between -1 (indicating a very poor model) and 1 (indicating an excellent model). The average can be conducted on the level of total cases (which produces total Silhouette) or the level of clusters (which produces cluster Silhouette). Distances may be calculated using Euclidean distances.

Auto Cluster Node Expert Options

The Expert tab of the Auto Cluster node enables you to apply a partition (if available), select the algorithms to use, and specify stopping rules.

Select models. By default, all models are selected to be built; however, if you have Analytic Server, you can choose to restrict the models to those that can run on Analytic Server and preset them so that they either build split models or are ready to process very large data sets.

Note: Local building of Analytic Server models within the Auto Cluster node is not supported.

Models used. Use the check boxes in the column on the left to select the model types (algorithms) to include in the comparison. The more types you select, the more models will be created and the longer the processing time will be.

Model type. Lists the available algorithms (see below).

Model parameters. For each model type, you can use the default settings or select Specify to choose options for each model type. The specific options are similar to those available in the separate modeling nodes, with the difference that multiple options or combinations can be selected. For example, if comparing Neural Net models, rather than choosing one of the six training methods, you can choose all of them to train six models in a single pass.

Number of models. Lists the number of models produced for each algorithm based on current settings. When combining options, the number of models can quickly add up, so paying close attention to this number is strongly recommended, particularly when using large datasets.

Restrict maximum time spent building a single model. (K-Means, Kohonen, TwoStep, SVM, KNN, Bayes Net and Decision List models only) Sets a maximum time limit for any one model. For example, if a particular model requires an unexpectedly long time to train because of some complex interaction, you probably don't want it to hold up your entire modeling run.

Supported algorithms

	The K-Means node clusters the data set into distinct groups (or clusters). The method defines a fixed number of clusters, iteratively assigns records to clusters, and adjusts the cluster centers until further refinement can no longer improve the model. Instead of trying to predict an outcome, k-means uses a process known as unsupervised learning to uncover patterns in the set of input fields.
	The Kohonen node generates a type of neural network that can be used to cluster the data set into distinct groups. When the network is fully trained, records that are similar should be close together on the output map, while records that are different will be far apart. You can look at the number of observations captured by each unit in the model nugget to identify the strong units. This may give you a sense of the appropriate number of clusters.
	The TwoStep node uses a two-step clustering method. The first step makes a single pass through the data to compress the raw input data into a manageable set of subclusters. The second step uses a hierarchical clustering method to progressively merge the subclusters into larger and larger clusters. TwoStep has the advantage of automatically estimating the optimal number of clusters for the training data. It can handle mixed field types and large data sets efficiently.

Auto Cluster Node Discard Options

The Discard tab of the Auto Cluster node enables you to automatically discard models that do not meet certain criteria. These models will not be listed on the model nugget.

You can specify the minimum silhouette value, cluster numbers, cluster sizes, and the importance of the evaluation field used in the model. Silhouette and the number and size of clusters are determined as specified in the modeling node. See the topic [Auto Cluster Node Model Options](#) for more information.

Optionally, you can configure the node to stop execution the first time a model is generated that meets all specified criteria. See the topic [Automated Modeling Node Stopping Rules](#) for more information.

Automated Model Nuggets

When an automated modeling node is executed, the node estimates candidate models for every possible combination of options, ranks each candidate model based on the measure you specify, and saves the best models in a composite automated model nugget. This model nugget

actually contains a set of one or more models generated by the node, which can be individually browsed or selected for use in scoring. The model type and build time are listed for each model, along with a number of other measures as appropriate for the type of model. You can sort the table on any of these columns to quickly identify the most interesting models.

- To browse any of the individual model nuggets, double-click the nugget icon. From there you can then generate a modeling node for that model to the stream canvas, or a copy of the model nugget to the models palette.
- Thumbnail graphs give a quick visual assessment for each model type, as summarized below. You can double-click on a thumbnail to generate a full-sized graph. The full-sized plot shows up to 1000 points and will be based on a sample if the dataset contains more. (For scatterplots only, the graph is regenerated each time it is displayed, so any changes in the upstream data—such as updating of a random sample or partition if Set Random Seed is not selected—may be reflected each time the scatterplot is redrawn.)
- Use the toolbar to show or hide specific columns on the Model tab or to change the column used to sort the table. (You can also change the sort by clicking on the column headers.)
- Use the Delete button to permanently remove any unused models.
- To reorder columns, click on a column header and drag the column to the desired location.
- If a partition is in use, you can choose to view results for the training or testing partition as applicable.

The specific columns depend on the type of models being compared, as detailed below.

Binary Targets

- For binary models, the thumbnail graph shows the distribution of actual values, overlaid with the predicted values, to give a quick visual indication of how many records were correctly predicted in each category.
- Ranking criteria match the options in the Auto Classifier modeling node. See the topic [Auto Classifier node model options](#) for more information.
- For the maximum profit, the percentile in which the maximum occurs is also reported.
- For cumulative lift, you can change the selected percentile using the toolbar.

Nominal Targets

- For nominal (set) models, the thumbnail graph shows the distribution of actual values, overlaid with the predicted values, to give a quick visual indication of how many records were correctly predicted in each category.
- Ranking criteria match the options in the Auto Classifier modeling node. See the topic [Auto Classifier node model options](#) for more information.

Continuous Targets

- For continuous (numeric range) models, the graph plots predicted against observed values for each model, providing a quick visual indication of the correlation between them. For a good model, points should tend to cluster along the diagonal rather than be scattered randomly across the graph.
- Ranking criteria match the options in the Auto Numeric modeling node. See the topic [Auto Numeric node model options](#) for more information.

Cluster Targets

- For cluster models, the graph plots counts against clusters for each model, providing a quick visual indication of cluster distribution.
- Ranking criteria match the options in the Auto Cluster modeling node. See the topic [Auto Cluster Node Model Options](#) for more information.

Selecting Models for Scoring

The Use? column enables you to select the models to use in scoring.

- For binary, nominal, and numeric targets, you can select multiple scoring models and combine the scores in the single, ensembled model nugget. By combining predictions from multiple models, limitations in individual models may be avoided, often resulting in a higher overall accuracy than can be gained from any one of the models.
 - For cluster models, only one scoring model can be selected at a time. By default, the top ranked one is selected first.

Generating Nodes and Models

You can generate a copy of the composite automated model nugget, or the automated modeling node from which it was built. For example, this may be useful if you do not have the original stream from which the automated model nugget was built. Alternatively, you can generate a nugget or modeling node for any of the individual models listed in the automated model nugget.

Automated Modeling Nugget

From the Generate menu, select Model to Palette to add the automated model nugget to the Models palette. The generated model can be saved or used as is without rerunning the stream.

Alternatively, you can select Generate Modeling Node from the Generate menu to add the modeling node to the stream canvas. This node can be used to reestimate the selected models without repeating the entire modeling run.

Individual Modeling Nugget

1. In the Model menu, double-click on the individual nugget you require. A copy of that nugget opens in a new dialog.
2. From the Generate menu in the new dialog, select Model to Palette to add the individual modeling nugget to the Models palette.
3. Alternatively, you can select Generate Modeling Node from the Generate menu in the new dialog to add the individual modeling node to the stream canvas.

-

Generating Evaluation Charts

For binary models only, you can generate evaluation charts that offer a visual way to assess and compare the performance of each model. Evaluation charts are not available for models generated by the Auto Numeric or Auto Cluster nodes.

1. Under the Use? column in the Auto Classifier automated model nugget, select the models that you want to evaluate.
2. From the Generate menu, choose Evaluation Chart(s). The Evaluation Chart dialog box is displayed.
3. Select the chart type and other options as desired.

Evaluation Graphs

On the Model tab of the automated model nugget you can drill down to display individual graphs for each of the models shown. For Auto Classifier and Auto Numeric nuggets, the Graph tab displays both a graph and predictor importance that reflect the results of all the models combined. See the topic [Predictor Importance](#) for more information.

For Auto Classifier a distribution graph is shown, whereas a multiplot (also known as a scatterplot) is shown for Auto Numeric.

Automated Model Nugget Summary

The Summary tab of the automated model nugget lists the fields used along with the build settings for each model, the total time elapsed to build all models, and the model ranking criterion used.

Continuous machine learning

As a result of IBM research, and inspired by natural selection in biology, *continuous machine learning* is available for the Auto Classifier node and the Auto Numeric node.

An inconvenience with modeling is models getting outdated due to changes to your data over time. This is commonly referred to as *model drift* or *concept drift*. To help overcome model drift effectively, SPSS Modeler provides continuous automated machine learning.

What is model drift? When you build a model based on historical data, it can become stagnant. In many cases, new data is always coming in—new variations, new patterns, new trends, etc.—that the old historical data doesn't capture. To solve this problem, IBM was inspired by the

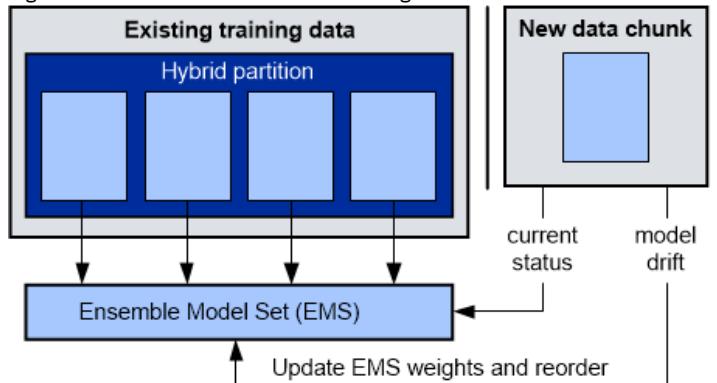

famous phenomenon in biology called the natural selection of species. Think of models as species and think of data as nature. Just as nature selects species, we should let data select the model. There's one big difference between models and species: species can evolve, but models are static once they've been built.

There are two preconditions for species to evolve; the first is gene mutation, and the second is population. Now, from a modeling perspective, to satisfy the first precondition (gene mutation), we should introduce new data changes into the existing model. To satisfy the second precondition (population), we should use a number of models rather than just one. What can represent a number of models? An Ensemble Model Set (EMS)!

The following figure illustrates how an EMS can evolve. The upper left portion of the figure represents historical data with hybrid partitions. The hybrid partitions ensure a rich initial EMS. The upper right portion of the figure represents a new chunk of data that becomes available, with vertical bars on each side. The left vertical bar represents current status, and the right vertical bar represents the status when there's a risk of model drift. In each new round of continuous machine learning, two steps are performed to evolve your model and avoid model drift.

First, you construct an ensemble model set (EMS) using existing training data. After that, when a new chunk of data becomes available, new models are built against that new data and added to the EMS as component models. The weights of existing component models in the EMS are reevaluated using the new data. As a result of this reevaluation, component models having higher weights are selected for the current prediction, and component models having lower weights may be deleted from the EMS. This process refreshes the EMS for both model weights and model instances, thus evolving in a flexible and efficient way to address the inevitable changes to your data over time.

Figure 1. Continuous auto machine learning

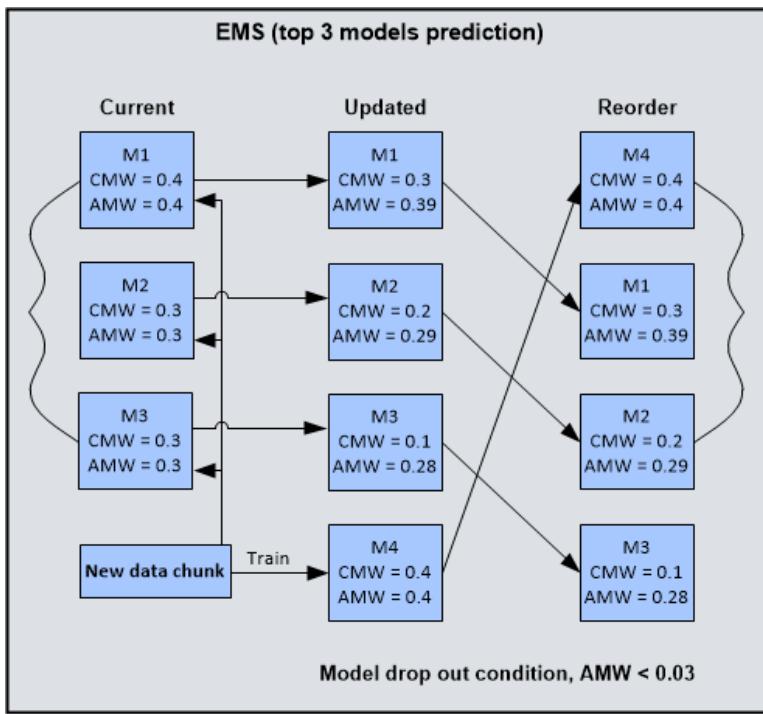

The ensemble model set (EMS) is a generated auto model nugget, and there's a refresh link between the auto modeling node and the generated auto model nugget that defines the refresh relationship between them. When you enable continuous auto machine learning, new data assets are continuously fed to auto modeling nodes to generate new component models. The model nugget is updated instead of replaced.

The following figure provides an example of the internal structure of an EMS in a continuous machine learning scenario. Only the top three component models are selected for the current prediction. For each component model (labeled as M1, M2, and M3), two kinds of weights are maintained. Current Model Weight (CMW) describes how a component model performs with a new chunk of data, and Accumulated Model Weight (AMW) describes the comprehensive performance of a component model against recent chunks of data. AMW is calculated iteratively via CMW and previous values of itself, and there's a hyper parameter beta to balance between them. The formula to calculate AMW is called *exponential moving average*.

When a new chunk of data becomes available, first SPSS Modeler uses it to build a few new component models. In this example figure, model four (M4) is built with CMW and AMW calculated during the initial model building process. Then SPSS Modeler uses the new chunk of data to reevaluate measures of existing component models (M1, M2, and M3) and update their CMW and AMW based on the reevaluation results. Finally, SPSS Modeler might reorder the component models based on CMW or AMW and select the top three component models accordingly.

In this figure, CMW is described using normalized value (sum = 1) and AMW is calculated based on CMW. In SPSS Modeler, the absolute value (equal to evaluation-weighted measure selected - for example, accuracy) is chosen to represent CMW and AMW for simplicity.

Figure 2. EMS structure

Note that there are two types of weights defined for each EMS component model as shown below, both of which could be used for selecting top N models and component model drop out:

- *Current Model Weight (CMW)* is computed via evaluation against the new data chunk (for example, evaluation accuracy on the new data chunk).
- *Accumulated Model Weight (AMW)* is computed via combining both CMW and existing AMW (for example, exponentially weighted moving average (EWMA)).

Exponential moving average formula for calculating AMW:

$$AMW = \beta * AMW + (1 - \beta) * CMW, \quad \text{suggested } \beta > 0.9$$

In SPSS Modeler, after running an Auto Classifier node to generate a model nugget, the following model options are available for continuous machine learning:

- Enable continuous auto machine learning during model refresh. Select this option to enable continuous machine learning. Keep in mind that consistent metadata (data model) must be used to train the continuous auto model. If you select this option, the other options below are enabled.
- Enable automatic model weights reevaluation. This option controls whether evaluation measures (accuracy, for example) are computed and updated during model refresh. If you select this option, an automatic evaluation process will run after the EMS (during model refresh). This is because it's usually necessary to reevaluate existing component models using new data to reflect the current state of your data. Then the weights of the EMS component models are assigned according to reevaluation results, and the weights are used to decide the proportion a component model contributes to the final ensemble prediction. This option is selected by default.

Figure 3. Model settings

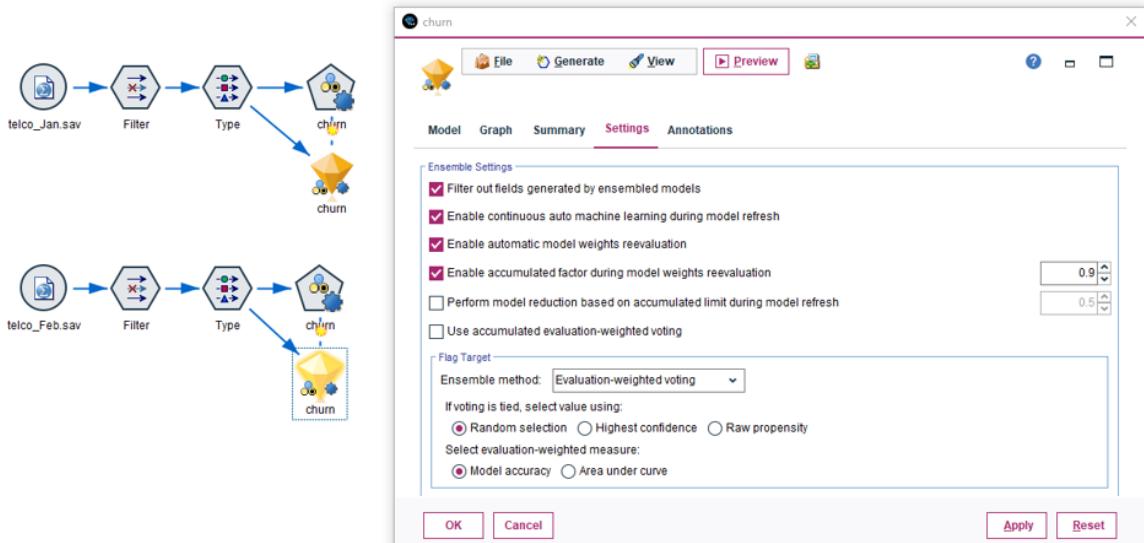

Figure 4. Flag target

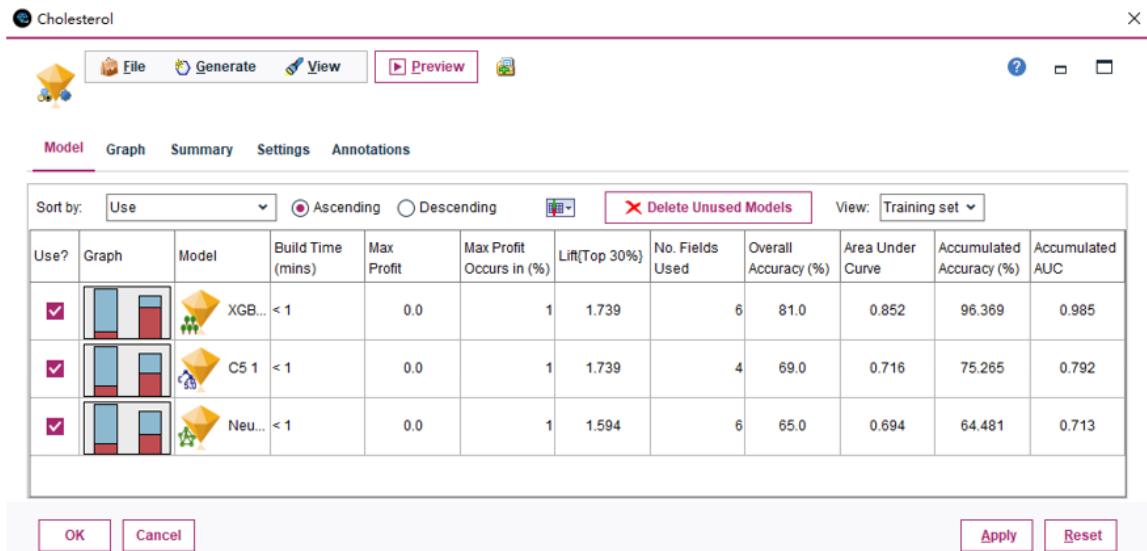

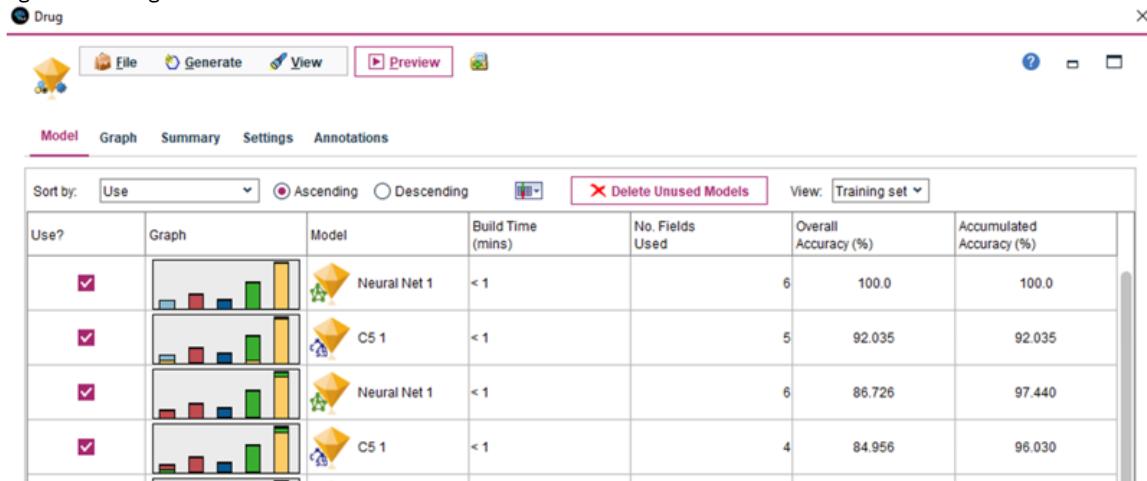

Figure 5. Set target

Following are the supported CMW and AMW for the Auto Classifier node:

Table 1. Supported CMW and AMW

Target type	CMW	AMW
flag target	Overall Accuracy Area Under Curve	Accumulated Accuracy Accumulated AUC
set target	Overall Accuracy	Accumulated Accuracy

The following three options are related to AMW, which is used to evaluate how a component model performs during recent data chunk periods:

- Enable accumulated factor during model weights reevaluation. If you select this option, AMW computation will be enabled during model weights reevaluation. AMW represents the comprehensive performance of an EMS component model during recent data chunk periods, related to the accumulated factor β defined in the AMW formula above, which you can adjust in the node properties. When this option isn't selected, only CMW will be computed. This option is selected by default.
- Perform model reduction based on accumulated limit during model refresh. Select this option if you want component models with an AMW value below the specified limit to be removed from the auto model EMS during model refresh. This can be helpful in discarding component models that are useless to prevent the auto model EMS from becoming too heavy. The accumulated limit value evaluation is related to the weighted measure used when Evaluation-weighted voting is selected as the ensemble method. See below.

Figure 6. Targets

Flag Target

Ensemble method: Evaluation-weighted voting

If voting is tied, select value using:

- Random selection
- Highest confidence
- Raw propensity

Select evaluation-weighted measure:

- Model Accuracy
- Area under curve

Set Target

Ensemble method: Confidence-weighted voting

If voting is tied, select value using:

- Random selection
- Highest confidence

Note that if you select Model Accuracy for the evaluation-weighted measure, models with an accumulated accuracy below the specified limit will be deleted. And if you select Area under curve for the evaluation-weighted measure, models with an accumulated AUC below the specified limit will be deleted.

By default, Model Accuracy is used for the evaluation-weighted measure for the Auto Classifier node, and there's an optional AUC ROC measure in the case of flag targets.

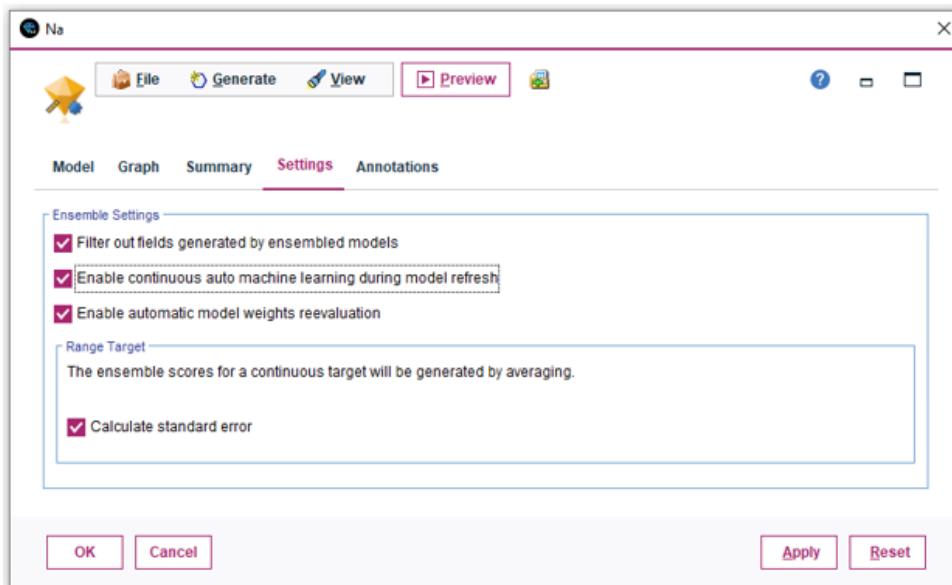

- Use accumulated evaluation-weighted voting. Select this option if you want AMW to be used for the current scoring/prediction. Otherwise, CMW will be used by default. This option is enabled when Evaluation-weighted voting is selected for the ensemble method. Note that for flag targets, by selecting this option, if you select Model Accuracy for the evaluation-weighted measure, then Accumulated Accuracy will be used as the AMW to perform the current scoring. Or if you select Area under curve for the evaluation-weighted measure, then Accumulated AUC will be used as the AMW to perform the current scoring. If you don't select this option and you select Model Accuracy for the evaluation-weighted measure, then Overall Accuracy will be used as the CMW to perform the current scoring. If you select Area under curve, Area under curve will be used as the CMW to perform the current scoring.

For set targets, if you select this Use accumulated evaluation-weighted voting option, then Accumulated Accuracy will be used as the AMW to perform the current scoring. Otherwise, Overall Accuracy will be used as the CMW to perform the current scoring.

With continuous auto machine learning, the auto model nugget is evolving all the time by rebuilding the auto model, which ensures that you get the most updated version reflecting the current state of your data. SPSS Modeler provides the flexibility for different top N component models in the EMS to be selected according to their current weights, which keeps pace with varying data during different periods.

Note: The Auto Numeric node is a much simpler case, providing a subset of the options in the Auto Classifier node.

Figure 7. Auto Numeric node

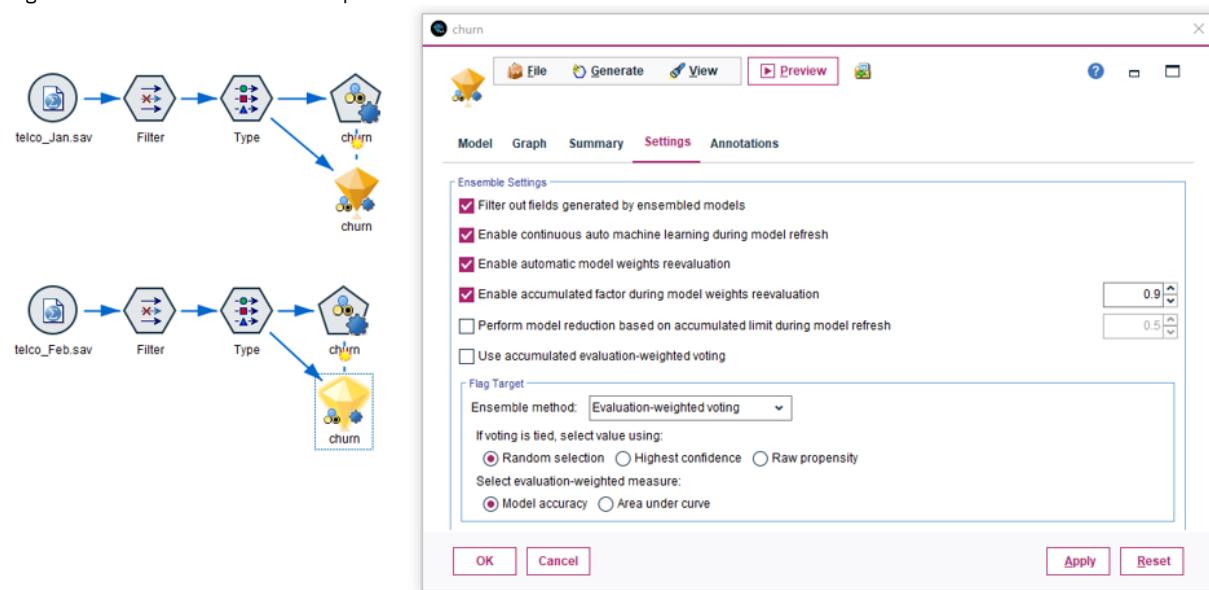

Example

In this example, continuous machine learning is used in the telecommunications industry to predict behavior and retain customers.

In the following flow, the data asset includes information about customers who left within the last month (**Churn** column). Since new data will be available every month, this scenario is suitable for continuous machine learning. In this example, January (**Jan**) data is used to construct an initial auto model, and then February (**Feb**) data is used to enhance the auto model via continuous machine learning.

Figure 8. Telecommunications example

In the upper branch of the flow, after the Data Asset node, there's a Filter node to filter out some unimportant fields. At the end of the branch, there's a terminal Auto Classifier modeling node. Under the node's expert settings, we select the algorithms we want to use for the training process. In this example, we select three algorithms: Logistic Regression, Bayesian Network, and Neural Network. Then we run the flow to generate an auto model nugget.

Now let's have a look at what's inside the auto model nugget. We can see it contains three component models for the three algorithms we selected. For each component model, there are several evaluation measures generated (such as accuracy and area under curve). These evaluation measures describe how a component model performs against training data (the January data set). You can select which component models to use in the current ensemble prediction.

Figure 9. Evaluations measures

OK Cancel Apply Reset

In the upper branch of the flow, after the Data Asset node, there's a Filter node to filter out some unimportant fields. At the end of the branch, there's a terminal Auto Classifier modeling node. Under the node's expert settings, we select the algorithms we want to use for the training process. In this example, we select three algorithms: Logistic Regression, Bayesian Network, and Neural Network. Then we run the flow to generate an auto model nugget.

You may see accumulated evaluation measures, also. These accumulated measures are for continuous machine learning, as they describe how a component model performs with recent data changes, so that you're aware of the model's comprehensive performance over a period of time. As this is our initial auto model, we see that the initial values for the accumulated measures are the same as related current measures. By default, evaluation measures are calculated against training data, so there could be some degree of overfitting. To avoid this, the Auto Classifier node provides a build option that calculates more stable evaluation measures via cross validation.

Next, let's look at how the final ensemble prediction is generated. If we open an auto model's properties, under Ensemble Flag Targets, the training target churn field is a yes/no flag target. Under Ensemble Set Targets (for set target fields that contain more than two values), there's an Ensemble method drop-down. Several options are available in the drop-down (for example, Majority voting means each component model holds one ticket to vote, and Confidence-weighted voting means the confidence field of each component model's prediction is used as the voting weight—with higher confidence having more influence on the final ensemble prediction). Similarly, to enable better support for continuous machine learning, Evaluation-weighted voting is available so that the component model's evaluation measure (for example, model accuracy or area under curve) will be used as the voting weight. In the case of a flag target, there's also an option to select a specific evaluation measure as the voting weight when Evaluation-weighted voting is used. In the case of a set target, only Accuracy is currently supported.

Figure 10. Set and flag targets

Under the Ensemble Common settings is where you turn on continuous machine learning. Then we can use the February data to see what's happening. We might select two different algorithms to distinguish between the existing component model algorithms. Then after rebuilding the flow and viewing the auto model's content, we see that two new component models are added (C5 and C&RT). We also notice that the evaluation measures for the existing component models have been recalculated. Both CMW measures and AMW measures are different than before. We can now compare them to the corresponding measures in the original auto model.

Figure 11. Evaluation measures

Use?	Graph	Model	Build Time (mins)	Max Profit Occurs in (%)	Lift(Top 30%)	No. Fields Used	Overall Accuracy (%)	Area Under Curve	Accumulated Accuracy (%)	Accumulated AUC	
✓	[Bar Chart]	Bayesian N...	< 1	0.0	1	2.115	10	78.4	0.85	78.4	0.85
✓	[Bar Chart]	Logistic regres...	< 1	0.0	1	2.0	10	75.6	0.805	75.6	0.805
✓	[Bar Chart]	Neural Net 1	< 1	0.0	1	1.908	10	74.8	0.801	74.8	0.801
✓	[Bar Chart]	Neural Net 1	< 1	0.0	1	1.862	10	73.4	0.769	78.62	0.789
✓	[Bar Chart]	Logistic regres...	< 1	0.0	1	1.816	10	73.4	0.758	78.44	0.791
✓	[Bar Chart]	Bayesian N...	< 1	0.0	1	1.77	10	73.4	0.718	79.88	0.838

Now what? With the enhanced auto model, we can select a prioritized evaluation measure and get top-N component models ordered by that measure. Then we can use the top-N component models to participate in the final ensemble prediction for incoming predictive analytics requests. And if Evaluation-weighted voting is selected for the Ensemble method, we can use accumulated measures as voting weights by simply selecting the option Use accumulated evaluation-weighted voting under the Ensemble Common settings. If deselected, CMW measures will be used by default in evaluation-weighted voting.

With continuous machine learning, the auto model is evolving all the time as it is continuously rebuilding against new chunks of data, ensuring that your model is the most up-to-date version that reflects the current status of the data. This allows for the flexibility to select different top-N component models in the EMS according to their current or accumulated evaluation measures, to keep pace with varying data during different periods.

Decision Trees

- [C&R Tree, CHAID, QUEST, C5.0, and Apriori rule set model nuggets](#)

Decision Tree Models

Use decision tree models to develop classification systems that predict or classify future observations based on a set of decision rules. If you have data divided into classes that interest you (for example, high- versus low-risk loans, subscribers versus nonsubscribers, voters versus nonvoters, or types of bacteria), you can use your data to build rules that you can use to classify old or new cases with maximum accuracy. For example, you might build a tree that classifies credit risk or purchase intent based on age and other factors.

This approach, sometimes known as *rule induction*, has several advantages. First, the reasoning process behind the model is clearly evident when browsing the tree. This is in contrast to other *black box* modeling techniques in which the internal logic can be difficult to work out.

Second, the process automatically includes in its rule only the attributes that really matter in making a decision. Attributes that do not contribute to the accuracy of the tree are ignored. This can yield very useful information about the data and can be used to reduce the data to relevant fields before training another learning technique, such as a neural net.

Decision tree model nuggets can be converted into a collection of if-then rules (a *rule set*), which in many cases show the information in a more comprehensible form. The decision-tree presentation is useful when you want to see how attributes in the data can *split*, or *partition*, the population into subsets relevant to the problem. The Tree-AS node output is different from the other Decision tree nodes because it includes a list of rules directly in the nugget without having to create a rule set. The rule set presentation is useful if you want to see how particular groups of items relate to a specific conclusion. For example, the following rule provides a *profile* for a group of cars that is worth buying:

```
IF tested = 'yes'  
AND mileage = 'low'  
THEN -> 'BUY'.
```

Tree-building algorithms

Several algorithms are available for performing classification and segmentation analysis. These algorithms all perform basically the same thing, they examine all of the fields of your dataset to find the one that gives the best classification or prediction by splitting the data into subgroups. The process is applied recursively, splitting subgroups into smaller and smaller units until the tree is finished (as defined by certain stopping criteria). The target and input fields used in tree building can be continuous (numeric range) or categorical, depending on the algorithm used. If a continuous target is used, a regression tree is generated; if a categorical target is used, a classification tree is generated.

	The Classification and Regression (C&R) Tree node generates a decision tree that allows you to predict or classify future observations. The method uses recursive partitioning to split the training records into segments by minimizing the impurity at each step, where a node in the tree is considered “pure” if 100% of cases in the node fall into a specific category of the target field. Target and input fields can be numeric ranges or categorical (nominal, ordinal, or flags); all splits are binary (only two subgroups).
	The CHAID node generates decision trees using chi-square statistics to identify optimal splits. Unlike the C&R Tree and QUEST nodes, CHAID can generate nonbinary trees, meaning that some splits have more than two branches. Target and input fields can be numeric range (continuous) or categorical. Exhaustive CHAID is a modification of CHAID that does a more thorough job of examining all possible splits but takes longer to compute.
	The QUEST node provides a binary classification method for building decision trees, designed to reduce the processing time required for large C&R Tree analyses while also reducing the tendency found in classification tree methods to favor inputs that allow more splits. Input fields can be numeric ranges (continuous), but the target field must be categorical. All splits are binary.
	The C5.0 node builds either a decision tree or a rule set. The model works by splitting the sample based on the field that

	provides the maximum information gain at each level. The target field must be categorical. Multiple splits into more than two subgroups are allowed.
	The Tree-AS node is similar to the existing CHAID node; however, the Tree-AS node is designed to process big data to create a single tree and displays the resulting model in the output viewer that was added in SPSS® Modeler version 17. The node generates a decision tree by using chi-square statistics (CHAID) to identify optimal splits. This use of CHAID can generate nonbinary trees, meaning that some splits have more than two branches. Target and input fields can be numeric range (continuous) or categorical. Exhaustive CHAID is a modification of CHAID that does a more thorough job of examining all possible splits but takes longer to compute.
	The Random Trees node is similar to the existing C&RT node; however, the Random Trees node is designed to process big data to create a single tree and displays the resulting model in the output viewer that was added in SPSS Modeler version 17. The Random Trees tree node generates a decision tree that you use to predict or classify future observations. The method uses recursive partitioning to split the training records into segments by minimizing the impurity at each step, where a node in the tree is considered <i>pure</i> if 100% of cases in the node fall into a specific category of the target field. Target and input fields can be numeric ranges or categorical (nominal, ordinal, or flags); all splits are binary (only two subgroups).

General uses of tree-based analysis

The following are some general uses of tree-based analysis:

Segmentation: Identify persons who are likely to be members of a particular class.

Stratification: Assign cases into one of several categories, such as high-, medium-, and low-risk groups.

Prediction: Create rules and use them to predict future events. Prediction can also mean attempts to relate predictive attributes to values of a continuous variable.

Data reduction and variable screening: Select a useful subset of predictors from a large set of variables for use in building a formal parametric model.

Interaction identification: Identify relationships that pertain only to specific subgroups and specify these in a formal parametric model.

Category merging and banding continuous variables: Recode group predictor categories and continuous variables with minimal loss of information.

The Interactive Tree Builder

You can generate a tree model automatically, where the algorithm decides the best split at each level, or you can use the interactive tree builder to take control, applying your business knowledge to refine or simplify the tree before saving the model nugget.

1. Create a stream and add one of the decision tree nodes C&R Tree, CHAID, or QUEST.
Note: Interactive tree building is not supported for either Tree-AS or C5.0 trees.
2. Open the node and, on the Fields tab, select target and predictor fields and specify additional model options as needed. For specific instructions, see the documentation for each tree-building node.
3. On the Objectives panel of the Build Options tab, select Launch interactive session.
4. Click Run to launch the tree builder.

The current tree is displayed, starting with the root node. You can edit and prune the tree level-by-level and access gains, risks, and related information before generating one or more models.

Comments

- With the C&R Tree, CHAID, and QUEST nodes, any ordinal fields used in the model must have numeric storage (not string). If necessary, the Reclassify node can be used to convert them.
- Optionally, you can use a partition field to separate the data into training and test samples.
- As an alternative to using the tree builder, you can also generate a model directly from the modeling node as with other IBM® SPSS® Modeler models. See the topic [Building a Tree Model Directly](#) for more information.

Growing and Pruning the Tree

To launch the tree builder, execute a stream containing a C&R Tree, QUEST, or CHAID node, making sure the Launch interactive session option is selected on the Objectives panel of the Build Options tab.

The Viewer tab in the tree builder enables you to view the current tree, starting with the root node.

1. To grow the tree, from the menus choose:

Tree > Grow Tree

The system builds the tree by recursively splitting each branch until one or more stopping criteria are met. At each split, the best predictor is automatically selected based on the modeling method used.

2. Alternatively, select Grow Tree One Level to add a single level.
3. To add a branch below a specific node, select the node and select Grow Branch.
4. To choose the predictor used for a split, select the desired node and select Grow Branch with Custom Split. See the topic [Defining Custom Splits](#) for more information.
5. To prune a branch, select a node and select Remove Branch to clear up the selected node.
6. To remove the bottom level from the tree, select Remove One Level.
7. For C&R Tree and QUEST trees only, select Grow Tree and Prune to prune based on a cost-complexity algorithm that adjusts the risk estimate based on the number of terminal nodes, typically resulting in a simpler tree. See the topic [C&R Tree Node](#) for more information.

Reading Split Rules on the Viewer Tab

When viewing split rules on the Viewer tab, square brackets mean that the adjacent value is included in the range whereas parentheses indicate that the adjacent value is excluded from the range. The expression (23,37] therefore means from 23 exclusive to 37 inclusive; that is, from just above 23 to 37. On the Model tab, the same condition would be displayed as:

Age > 23 and Age <= 37

Interrupting tree growth. To interrupt a tree-growing operation (if it is taking longer than expected, for example), click the Stop Execution button on the toolbar.

Figure 1. Stop Execution button

The button is enabled only during tree growth. It stops the current growing operation at its current point, leaving any nodes that have already been added, without saving changes or closing the window. The tree builder remains open, enabling you to generate a model, update directives, or export output in the appropriate format, as needed.

Defining Custom Splits

The Define Split dialog box enables you to select the predictor and specify conditions for each split.

1. In the tree builder, select a node on the Viewer tab, and from the menus choose:
Tree > Grow Branch with Custom Split
2. Select the desired predictor from the drop-down list, or click on the Predictors button to view details of each predictor. See the topic [Viewing Predictor Details](#) for more information.
3. You can accept the default conditions for each split or select Custom to specify conditions for the split as appropriate.
 - For continuous (numeric range) predictors, you can use the Edit Range Values fields to specify the range of values that fall into each new node.
 - For categorical predictors, you can use the Edit Set Values or Edit Ordinal Values fields to specify the specific values (or range of values in case of an ordinal predictor) that map to each new node.
4. Select Grow to regrow the branch using the selected predictor.

The tree can generally be split using any predictor, regardless of stopping rules. The only exceptions are when the node is pure (meaning that 100% of cases fall into the same target class, thus there is nothing left to split) or the chosen predictor is constant (there is nothing to split against).

Missing values into. For CHAID trees only, if missing values are available for a given predictor, you have the option when defining a custom split to assign them to a specific child node. (With C&R Tree and QUEST, missing values are handled using surrogates as defined in the algorithm. See the topic [Split Details and Surrogates](#) for more information.)

Viewing Predictor Details

The Select Predictor dialog box displays statistics on available predictors (or "competitors" as they are sometimes called) that can be used for the current split.

- For CHAID and exhaustive CHAID, the chi-square statistic is listed for each categorical predictor; if a predictor is a numeric range, the F statistic is shown. The chi-square statistic is a measure of how independent the target field is from the splitting field. A high chi-square statistic generally relates to a lower probability, meaning that there is less chance that the two fields are independent—an indication that the split is a good one. Degrees of freedom are also included because these take into account the fact that it is easier for a three-way split to have a large statistic and small probability than it is for a two-way split.

- For C&R Tree and QUEST, the improvement for each predictor is displayed. The greater the improvement, the greater the reduction in impurity between the parent and child nodes if that predictor is used. (A pure node is one in which all cases fall into a single target category; the lower the impurity across the tree, the better the model fits the data.) In other words, a high improvement figure generally indicates a useful split for this type of tree. The impurity measure used is specified in the tree-building node.

Split Details and Surrogates

You can select any node on the Viewer tab and select the split information button on the right side of the toolbar to view details about the split for that node. The split rule used is displayed, along with relevant statistics. For C&R Tree categorical trees, improvement and association are displayed. The association is a measure of correspondence between a surrogate and the primary split field, with the “best” surrogate generally being the one that most closely mimics the split field. For C&R Tree and QUEST, any surrogates used in place of the primary predictor are also listed.

To edit the split for the selected node, you can click the icon on the left side of the surrogates panel to open the Define Split dialog box. (As a shortcut, you can select a surrogate from the list before clicking the icon to select it as the primary split field.)

Surrogates. Where applicable, any surrogates for the primary split field are shown for the selected node. Surrogates are alternate fields used if the primary predictor value is missing for a given record. The maximum number of surrogates allowed for a given split is specified in the tree-building node, but the actual number depends on the training data. In general, the more missing data, the more surrogates are likely to be used. For other decision tree models, this tab is empty.

Note: To be included in the model, surrogates must be identified during the training phase. If the training sample has no missing values, then no surrogates will be identified, and any records with missing values encountered during testing or scoring will automatically fall into the child node with the largest number of records. If missing values are expected during testing or scoring, be sure that values are missing from the training sample, as well. Surrogates are not available for CHAID trees.

Although surrogates are not used for CHAID trees, when defining a custom split you have the option to assign them to a specific child node. See the topic [Defining Custom Splits](#) for more information.

Customizing the Tree View

The Viewer tab in the tree builder displays the current tree. By default, all branches in the tree are expanded, but you can expand and collapse branches and customize other settings as needed.

- Click the minus sign (-) at the bottom right corner of a parent node to hide all of its child nodes. Click the plus sign (+) at the bottom right corner of a parent node to display its child nodes.
- Use the View menu or the toolbar to change the orientation of the tree (top-down, left-to-right, or right-to-left).
- Click the "Display field and value labels" button on the main toolbar to show or hide field and value labels.
- Use the magnifying glass buttons to zoom the view in or out, or click the tree map button on the right side of the toolbar to view a diagram of the complete tree.
- If a partition field is in use, you can swap the tree view between training and testing partitions (View > Partition). When the testing sample is displayed, the tree can be viewed but not edited. (The current partition is displayed in the status bar in the lower right corner of the window.)
- Click the split information button (the "i" button on the far right of the toolbar) to view details on the current split. See the topic [Split Details and Surrogates](#) for more information.
- Display statistics, graphs, or both within each node (see below).

Displaying Statistics and Graphs

Node statistics. For a categorical target field, the table in each node shows the number and percentage of records in each category and the percentage of the entire sample that the node represents. For a continuous (numeric range) target field, the table shows the mean, standard deviation, number of records, and predicted value of the target field.

Node graphs. For a categorical target field, the graph is a bar chart of percentages in each category of the target field. Preceding each row in the table is a color swatch that corresponds to the color that represents each of the target field categories in the graphs for the node. For a continuous (numeric range) target field, the graph shows a histogram of the target field for records in the node.

Gains

The Gains tab displays statistics for all terminal nodes in the tree. Gains provide a measure of how far the mean or proportion at a given node differs from the overall mean. Generally speaking, the greater this difference, the more useful the tree is as a tool for making decisions. For example, an index or "lift" value of 148% for a node indicates that records in the node are about one-and-a-half times as likely to fall under the target category as for the dataset as a whole.

For C&R Tree and QUEST nodes where an overfit prevention set is specified, two sets of statistics are displayed:

- tree growing set - the training sample with the overfit prevention set removed
- overfit prevention set

For other C&R Tree and QUEST interactive trees, and for all CHAID interactive trees, only the tree growing set statistics are displayed.

The Gains tab enables you to:

- Display node-by-node, cumulative, or quantile statistics.
- Display gains or profits.
- Swap the view between tables and charts.
- Select the target category (categorical targets only).
- Sort the table in ascending or descending order based on the index percentage. If statistics for multiple partitions are displayed, sorts are always applied on the training sample rather than on the testing sample.

In general, selections made in the gains table will be updated in the tree view and vice versa. For example, if you select a row in the table, the corresponding node will be selected in the tree.

Classification Gains

For classification trees (those with a categorical target variable), the gain index percentage tells you how much greater the proportion of a given target category at each node differs from the overall proportion.

Node-by-Node Statistics

In this view, the table displays one row for each terminal node. For example, if the overall response to your direct mail campaign was 10% but 20% of the records that fall into node X responded positively, the index percentage for the node would be 200%, indicating that respondents in this group are twice as likely to buy relative to the overall population.

For C&R Tree and QUEST nodes where an overfit prevention set is specified, two sets of statistics are displayed:

- tree growing set - the training sample with the overfit prevention set removed
- overfit prevention set

For other C&R Tree and QUEST interactive trees, and for all CHAID interactive trees, only the tree growing set statistics are displayed.

Nodes. The ID of the current node (as displayed on the Viewer tab).

Node: n. The total number of records in that node.

Node (%). The percentage of all records in the dataset that fall into this node.

Gain: n. The number of records with the selected target category that fall into this node. In other words, of all the records in the dataset that fall under the target category, how many are in this node?

Gain (%). The percentage of all records in the target category, across the entire dataset, that fall into this node.

Response (%). The percentage of records in the current node that fall under the target category. Responses in this context are sometimes referred to as "hits."

Index (%). The response percentage for the current node expressed as a percentage of the response percentage for the entire dataset. For example, an index value of 300% indicates that records in this node are three times as likely to fall under the target category as for the dataset as a whole.

Cumulative Statistics

In the cumulative view, the table displays one node per row, but statistics are cumulative, sorted in ascending or descending order by index percentage. For example if a descending sort is applied, the node with the highest index percentage is listed first, and statistics in the rows that follow are cumulative for that row and above.

The cumulative index percentage decreases row-by-row as nodes with lower and lower response percentages are added. The cumulative index for the final row is always 100% because at this point the entire dataset is included.

Quantiles

In this view, each row in the table represents a quantile rather than a node. The quantiles are either quartiles, quintiles (fifths), deciles (tenths), vigintiles (twentieths), or percentiles (hundredths). Multiple nodes can be listed in a single quantile if more than one node is needed to make up that percentage (for example, if quartiles are displayed but the top two nodes contain fewer than 50% of all cases). The rest of the table is cumulative and can be interpreted in the same manner as the cumulative view.

-

Classification Profits and ROI

For classification trees, gains statistics can also be displayed in terms of profit and ROI (return on investment). The Define Profits dialog box enables you to specify revenue and expenses for each category.

1. On the Gains tab, click the Profit button (labeled \$/\$) on the toolbar to access the dialog box.
2. Enter revenue and expense values for each category of the target field.

For example, if it costs you \$0.48 to mail an offer to each customer and the revenue from a positive response is \$9.95 for a three-month subscription, then each *no* response costs you \$0.48 and each *yes* earns you \$9.47 (calculated as 9.95–0.48).

In the gains table, **profit** is calculated as the sum of revenues minus expenditures for each of the records at a terminal node. **ROI** is total profit divided by total expenditure at a node.

Comments

- Profit values affect only average profit and ROI values displayed in the gains table, as a way of viewing statistics in terms more applicable to your bottom line. They do not affect the basic tree model structure. Profits should not be confused with misclassification costs, which are specified in the tree-building node and are factored into the model as a way of protecting against costly mistakes.
- Profit specifications are not persisted between one interactive tree-building session and the next.

- [Classification Gains](#)
- [Classification Profits and ROI](#)
- [Gains Charts](#)
- [Gains-Based Selection](#)
- [Risks](#)

Gains Charts

Charts can be displayed on the Gains tab as an alternative to tables.

1. On the Gains tab, select the Quantiles icon (third from left on the toolbar). (Charts are not available for node-by-node or cumulative statistics.)
2. Select the Charts icon.
3. Select the displayed units (percentiles, deciles, and so on) from the drop-down list as desired.
4. Select Gains, Response, or Lift to change the displayed measure.

Gains Chart

The gains chart plots the values in the *Gains (%)* column from the table. Gains are defined as the proportion of hits in each increment relative to the total number of hits in the tree, using the equation:

$$(\text{hits in increment} / \text{total number of hits}) \times 100\%$$

The chart effectively illustrates how widely you need to cast the net to capture a given percentage of all the hits in the tree. The diagonal line plots the expected response for the entire sample, if the model were not used. In this case, the response rate would be constant, since one person is just as likely to respond as another. To double your yield, you would need to ask twice as many people. The curved line indicates how much you can improve your response by including only those who rank in the higher percentiles based on gain. For example, including the top 50% might net you more than 70% of the positive responses. The steeper the curve, the higher the gain.

Lift Chart

The lift chart plots the values in the *Index (%)* column in the table. This chart compares the percentage of records in each increment that are hits with the overall percentage of hits in the training dataset, using the equation:

$$(\text{hits in increment} / \text{records in increment}) / (\text{total number of hits} / \text{total number of records})$$

Response Chart

The response chart plots the values in the *Response (%)* column of the table. The response is a percentage of records in the increment that are hits, using the equation:

$$(\text{responses in increment} / \text{records in increment}) \times 100\%$$

- [Risks](#)

Gains-Based Selection

The Gains-Based Selection dialog box enables you to automatically select terminal nodes with the best (or worst) gains based on a specified rule or threshold. You can then generate a Select node based on the selection.

1. On the Gains tab, select the node-by-node or cumulative view and select the target category on which you want to base the selection. (Selections are based on the current table display and are not available for quantiles.)
2. On the Gains tab, from the menus choose:
Edit...>Select Terminal Nodes...>Gains-Based Selection

Select only. You can select matching nodes or nonmatching nodes—for example, to select *all but* the top 100 records.

Match by gains information. Matches nodes based on gain statistics for the current target category, including:

- Nodes where the gain, response, or lift (index) matches a specified threshold—for example, response greater than or equal to 50%.
 - The top *n* nodes based on the gain for the target category.
 - The top nodes up to a specified number of records.
 - The top nodes up to a specified percentage of training data.
3. Click OK to update the selection on the Viewer tab.
 4. To create a new Select node based on the current selection on the Viewer tab, choose Select Node from the Generate menu. See the topic [Generating Filter and Select Nodes](#) for more information.

Note: Since you are actually selecting nodes rather than records or percentages, a perfect match with the selection criterion may not always be achieved. The system selects complete nodes *up to* the specified level. For example, if you select the top 12 cases and you have 10 in the first node and two in the second node, only the first node will be selected.

Risks

Risks tell you the chances of misclassification at any level. The Risks tab displays a point risk estimate and (for categorical outputs) a misclassification table.

- For numeric predictions, the risk is a pooled estimate of the variance at each of the terminal nodes.
- For categorical predictions, the risk is the proportion of cases incorrectly classified, adjusted for any priors or misclassification costs.

Saving Tree Models and Results

You can save or export the results of your interactive tree-building sessions in a number of ways, including:

- Generate a model based on the current tree (Generate > Generate model).
- Save the directives used to grow the current tree. The next time the tree-building node is executed, the current tree will automatically be regrown, including any custom splits that you have defined.
- Export model, gain, and risk information. See the topic [Exporting Model, Gain, and Risk Information](#) for more information.

From either the tree builder or a tree model nugget, you can:

- Generate a Filter or Select node based on the current tree. See [Generating Filter and Select Nodes](#) for more information.
- Generate a Rule Set nugget that represents the tree structure as a set of rules defining the terminal branches of the tree. See [Generating a Rule Set from a Decision Tree](#) for more information.
- In addition, for tree model nuggets only, you can export the model in PMML format. See [The models palette](#) for more information. If the model includes any custom splits, this information is not preserved in the exported PMML. (The split is preserved, but the fact that it is custom rather than chosen by the algorithm is not.)
- Generate a graph based on a selected part of the current tree. Note that this only works for a nugget when it is attached to other nodes in a stream. See [Generating Graphs](#) for more information.

Note: The interactive tree itself cannot be saved. To avoid losing your work, generate a model and/or update tree directives before closing the tree builder window.

Generating a Model from the Tree Builder

To generate a model based on the current tree, from the tree builder menus choose:

Generate...> Model

In the Generate New Model dialog box you can choose from the following options:

Model name. You can specify a custom name or generate the name automatically based on the name of the modeling node.

Create node on. You can add the node on the Canvas, GM Palette, or Both.

Include tree directives. To include the directives from the current tree in the generated model, select this box. This enables you to regenerate the tree, if required. See the topic [Tree-Growing Directives](#) for more information.

Tree-Growing Directives

For C&R Tree, CHAID, and QUEST models, tree directives specify conditions for growing the tree, one level at a time. Directives are applied each time the interactive tree builder is launched from the node.

- Directives are most safely used as a way to regenerate a tree created during a previous interactive session. See the topic [Updating Tree Directives](#) for more information. You can also edit directives manually, but this should be done with care.

- Directives are highly specific to the structure of the tree they describe. Thus, any change to the underlying data or modeling options may cause a previously valid set of directives to fail. For example, if the CHAID algorithm changes a two-way split to a three-way split based on updated data, any directives based on the previous two-way split would fail.

Note: If you choose to generate a model directly (without using the tree builder), any tree directives are ignored.

Editing Directives

1. To view or edit saved directives, open the tree-building node and select the Objective panel of the Build Options tab.
2. Select Launch interactive session to enable the controls, select Use tree directives, and click Directives.

Directive Syntax

Directives specify conditions for growing the tree, starting with the root node. For example to grow the tree one level:

```
Grow Node Index 0 Children 1 2
```

Since no predictor is specified, the algorithm chooses the best split.

Note that the first split must always be on the root node (**Index 0**) and the index values for both children must be specified (1 and 2 in this case). It is invalid to specify **Grow Node Index 2 Children 3 4** unless you first grew the root that created Node 2.

To grow the tree:

```
Grow Tree
```

To grow and prune the tree (C&R Tree only):

```
Grow And Prune Tree
```

To specify a custom split for a continuous predictor:

```
Grow Node Index 0 Children 1 2 Spliton
  ("EDUCATE", Interval ( NegativeInfinity, 12.5)
   Interval ( 12.5, Infinity ))
```

To split on a nominal predictor with two values:

```
Grow Node Index 2 Children 3 4 Spliton
  ("GENDER", Group( "0.0" )Group( "1.0" ))
```

To split on a nominal predictor with multiple values:

```
Grow Node Index 6 Children 7 8 Spliton
  ("ORGs", Group( "2.0","4.0" )
   Group( "0.0","1.0","3.0","6.0" ))
```

To split on an ordinal predictor:

```
Grow Node Index 4 Children 5 6 Spliton
  ("CHILDS", Interval ( NegativeInfinity, 1.0)
   Interval ( 1.0, Infinity ))
```

Note: When specifying custom splits, field names and values (**EDUCATE**, **GENDER**, **CHILDS**, etc.) are case sensitive.

Directives for CHAID Trees

Directives for CHAID trees are particularly sensitive to changes in the data or model because--unlike C&R Tree and QUEST--they are not constrained to use binary splits. For example, the following syntax looks perfectly valid but would fail if the algorithm splits the root node into more than two children:

```
Grow Node Index 0 Children 1 2
Grow Node Index 1 Children 3 4
```

With CHAID, it is possible that Node 0 will have 3 or 4 children, which would cause the second line of syntax to fail.

Using Directives in Scripts

Directives can also be embedded in scripts using triple quotation marks.

Updating Tree Directives

To preserve your work from an interactive tree-building session, you can save the directives used to generate the current tree. Unlike saving a model nugget, which cannot be edited further, this enables you to regenerate the tree in its current state for further editing.

To update directives, from the tree builder menus choose:

File>Update Directives

Directives are saved in the modeling node used to create the tree (either C&R Tree, QUEST, or CHAID) and can be used to regenerate the current tree. See the topic [Tree-Growing Directives](#) for more information.

Exporting Model, Gain, and Risk Information

From the tree builder, you can export model, gain, and risk statistics in text, HTML, or image formats as appropriate.

1. In the tree builder window, select the tab or view that you want to export.
2. From the menus choose:
File>Export
3. Select Text, HTML, or Graph as appropriate, and select the specific items you want to export from the submenu.

Where applicable, the export is based on current selections.

Exporting Text or HTML formats. You can export gain or risk statistics for the training or testing partition (if defined). The export is based on the current selections on the Gains tab—for example, you can choose node-by-node, cumulative, or quantile statistics.

Exporting graphics. You can export the current tree as displayed on the Viewer tab or export gains charts for the training or testing partition (if defined). Available formats include .JPEG, .PNG, and .BMP. For gains, the export is based on current selections on the Gains tab (available only when a chart is displayed).

Generating Filter and Select Nodes

In the tree builder window, or when browsing a decision tree model nugget, from the menus choose:

Generate > Filter Node

or

> Select Node

Filter Node. Generates a node that filters any fields not used by the current tree. This is a quick way to pare down the dataset to include only those fields that are selected as important by the algorithm. If there is a Type node upstream from this decision tree node, any fields with the role *Target* are passed on by the Filter model nugget.

Select Node. Generates a node that selects all records that fall into the current node. This option requires that one or more tree branches be selected on the Viewer tab.

The model nugget is placed on the stream canvas.

Generating a Rule Set from a Decision Tree

You can generate a Rule Set model nugget that represents the tree structure as a set of rules that define the terminal branches of the tree. Rule sets can often retain most of the important information from a full decision tree but with a less complex model. The most important difference is that with a rule set, more than one rule might apply for any particular record or no rules at all might apply. For example, you might see all of the rules that predict a *no* outcome followed by all of the rules that predict *yes*. If multiple rules apply, each rule gets a weighted "vote" based on the confidence that is associated with that rule, and the final prediction is decided by combining the weighted votes of all of the rules that apply to the record in question. If no rule applies, a default prediction is assigned to the record.

Note: When you score a rule set you might notice differences in scoring compared to scoring against the tree; this is because each terminal branch in a tree is scored independently. One area where this difference might become noticeable is when there are missing values in your data. Rule sets can be generated only from trees with categorical target fields (no regression trees).

In the tree builder window, or when you browse a decision tree model nugget, from the menus choose:

Generate > Rule Set

Rule set name Specify the name of the new Rule Set model nugget.

Create node on Controls the location of the new Rule Set model nugget. Select Canvas, GM Palette, or Both.

Minimum instances Specify the minimum number of instances (number of records to which the rule applies) to preserve in the Rule Set model nugget. Rules with support less than the specified value are not included in the new rule set.

Minimum confidence Specify the minimum confidence for rules to be preserved in the Rule Set model nugget. Rules with confidence less than the specified value are not included in the new rule set.

Building a Tree Model Directly

As an alternative to using the interactive tree builder, you can build a decision tree model directly from the node when the stream is run. This is consistent with most other model-building nodes. For C5.0 tree and Tree-AS models, which are not supported by the interactive tree builder, this is the only method that can be used.

1. Create a stream and add one of the decision tree nodes—C&R Tree, CHAID, QUEST, C5.0, or Tree-AS.
2. For C&R Tree, QUEST or CHAID, on the Objective panel of the Build Options tab, choose one of the main objectives. If you choose Build a single tree, ensure that Mode is set to Generate model.
For C5.0, on the Model tab, set Output type to Decision tree.
For Tree-AS, on the Basics panel of the Build Options tab, select the Tree growing algorithm type.
3. Select target and predictor fields and specify additional model options, as needed. For specific instructions, see the documentation for each tree-building node.
4. Run the stream to generate the model.

Comments about tree building

- When generating trees using this method, tree-growing directives are ignored.
- Whether interactive or direct, both methods of creating decision trees ultimately generate similar models. It's just a question of how much control you want along the way.

Decision Tree Nodes

The Decision Tree nodes in IBM® SPSS® Modeler provide access to the following tree-building algorithms:

- C&R Tree
- QUEST
- CHAID
- C5.0
- Tree-AS
- Random Trees

See the topic [Decision Tree Models](#) for more information.

The algorithms are similar in that they can all construct a decision tree by recursively splitting the data into smaller and smaller subgroups. However, there are some important differences.

Input fields. The input fields (predictors) can be any of the following types (measurement levels): continuous, categorical, flag, nominal or ordinal.

Target fields. Only one target field can be specified. For C&R Tree, CHAID, Tree-AS, and Random Trees, the target can be continuous, categorical, flag, nominal or ordinal. For QUEST it can be categorical, flag or nominal. For C5.0 the target can be flag, nominal or ordinal.

Type of split. C&R Tree, QUEST, and Random Trees support only binary splits (that is, each node of the tree can be split into no more than two branches). By contrast, CHAID, C5.0, and Tree-AS support splitting into more than two branches at a time.

Method used for splitting. The algorithms differ in the criteria used to decide the splits. When C&R Tree predicts a categorical output, a dispersion measure is used (by default the Gini coefficient, though you can change this). For continuous targets, the least squared deviation method is used. CHAID and Tree-AS use a chi-square test; QUEST uses a chi-square test for categorical predictors, and analysis of variance for continuous inputs. For C5.0 an information theory measure is used, the information gain ratio.

Missing value handling. All algorithms allow missing values for the predictor fields, though they use different methods to handle them. C&R Tree and QUEST use substitute prediction fields, where needed, to advance a record with missing values through the tree during training. CHAID makes the missing values a separate category and enables them to be used in tree building. C5.0 uses a fractioning method, which passes a fractional part of a record down each branch of the tree from a node where the split is based on a field with a missing value.

Pruning. C&R Tree, QUEST and C5.0 offer the option to grow the tree fully and then prune it back by removing bottom-level splits that do not contribute significantly to the accuracy of the tree. However, all of the decision tree algorithms allow you to control the minimum subgroup size, which helps avoid branches with few data records.

Interactive tree building. C&R Tree, QUEST and CHAID provide an option to launch an interactive session. This enables you to build your tree one level at a time, edit the splits, and prune the tree before you create the model. C5.0, Tree-AS, and Random Trees do not have an interactive option.

Prior probabilities. C&R Tree and QUEST support the specification of prior probabilities for categories when predicting a categorical target field. Prior probabilities are estimates of the overall relative frequency for each target category in the population from which the training data are drawn. In other words, they are the probability estimates that you would make for each possible target value prior to knowing anything about predictor values. CHAID, C5.0, Tree-AS, and Random Trees do not support specifying prior probabilities.

Rule sets. Not available for Tree-AS or Random Trees. For models with categorical target fields, the decision tree nodes provide the option to create the model in the form of a rule set, which can sometimes be easier to interpret than a complex decision tree. For C&R Tree, QUEST and CHAID you can generate a rule set from an interactive session; for C5.0 you can specify this option on the modeling node. In addition, all decision tree models enable you to generate a rule set from the model nugget. See the topic [Generating a Rule Set from a Decision Tree](#) for more information.

- [C&R Tree Node](#)
- [CHAID Node](#)
- [QUEST Node](#)
- [Decision Tree Node Fields Options](#)
- [Decision Tree Node Build Options](#)
- [Decision Tree Node Model Options](#)

C&R Tree Node

The Classification and Regression (C&R) Tree node is a tree-based classification and prediction method. Similar to C5.0, this method uses recursive partitioning to split the training records into segments with similar output field values. The C&R Tree node starts by examining the input fields to find the best split, measured by the reduction in an impurity index that results from the split. The split defines two subgroups, each of which is subsequently split into two more subgroups, and so on, until one of the stopping criteria is triggered. All splits are binary (only two subgroups).

Pruning

C&R Trees give you the option to first grow the tree and then prune based on a cost-complexity algorithm that adjusts the risk estimate based on the number of terminal nodes. This method, which enables the tree to grow large before pruning based on more complex criteria, may result in smaller trees with better cross-validation properties. Increasing the number of terminal nodes generally reduces the risk for the current (training) data, but the actual risk may be higher when the model is generalized to unseen data. In an extreme case, suppose you have a separate terminal node for each record in the training set. The risk estimate would be 0%, since every record falls into its own node, but the risk of misclassification for unseen (testing) data would almost certainly be greater than 0. The cost-complexity measure attempts to compensate for this.

Example. A cable TV company has commissioned a marketing study to determine which customers would buy a subscription to an interactive news service via cable. Using the data from the study, you can create a stream in which the target field is the intent to buy the subscription and the predictor fields include age, sex, education, income category, hours spent watching television each day, and number of children. By applying a C&R Tree node to the stream, you will be able to predict and classify the responses to get the highest response rate for your campaign.

Requirements. To train a C&R Tree model, you need one or more *Input* fields and exactly one *Target* field. Target and input fields can be continuous (numeric range) or categorical. Fields set to *Both* or *None* are ignored. Fields used in the model must have their types fully

instantiated, and any ordinal (ordered set) fields used in the model must have numeric storage (not string). If necessary, the Reclassify node can be used to convert them.

Strengths. C&R Tree models are quite robust in the presence of problems such as missing data and large numbers of fields. They usually do not require long training times to estimate. In addition, C&R Tree models tend to be easier to understand than some other model types--the rules derived from the model have a very straightforward interpretation. Unlike C5.0, C&R Tree can accommodate continuous as well as categorical output fields.

CHAID Node

CHAID, or Chi-squared Automatic Interaction Detection, is a classification method for building decision trees by using chi-square statistics to identify optimal splits.

CHAID first examines the crosstabulations between each of the input fields and the outcome, and tests for significance using a chi-square independence test. If more than one of these relations is statistically significant, CHAID will select the input field that is the most significant (smallest p value). If an input has more than two categories, these are compared, and categories that show no differences in the outcome are collapsed together. This is done by successively joining the pair of categories showing the least significant difference. This category-merging process stops when all remaining categories differ at the specified testing level. For nominal input fields, any categories can be merged; for an ordinal set, only contiguous categories can be merged.

Exhaustive CHAID is a modification of CHAID that does a more thorough job of examining all possible splits for each predictor but takes longer to compute.

Requirements. Target and input fields can be continuous or categorical; nodes can be split into two or more subgroups at each level. Any ordinal fields used in the model must have numeric storage (not string). If necessary, the Reclassify node can be used to convert them.

Strengths. Unlike the C&R Tree and QUEST nodes, CHAID can generate nonbinary trees, meaning that some splits have more than two branches. It therefore tends to create a wider tree than the binary growing methods. CHAID works for all types of inputs, and it accepts both case weights and frequency variables.

QUEST Node

QUEST—or Quick, Unbiased, Efficient Statistical Tree—is a binary classification method for building decision trees. A major motivation in its development was to reduce the processing time required for large C&R Tree analyses with either many variables or many cases. A second goal of QUEST was to reduce the tendency found in classification tree methods to favor inputs that allow more splits, that is, continuous (numeric range) input fields or those with many categories.

- QUEST uses a sequence of rules, based on significance tests, to evaluate the input fields at a node. For selection purposes, as little as a single test may need to be performed on each input at a node. Unlike C&R Tree, all splits are not examined, and unlike C&R Tree and CHAID, category combinations are not tested when evaluating an input field for selection. This speeds the analysis.
- Splits are determined by running quadratic discriminant analysis using the selected input on groups formed by the target categories. This method again results in a speed improvement over exhaustive search (C&R Tree) to determine the optimal split.

Requirements. Input fields can be continuous (numeric ranges), but the target field must be categorical. All splits are binary. Weight fields cannot be used. Any ordinal (ordered set) fields used in the model must have numeric storage (not string). If necessary, the Reclassify node can be used to convert them.

Strengths. Like CHAID, but unlike C&R Tree, QUEST uses statistical tests to decide whether or not an input field is used. It also separates the issues of input selection and splitting, applying different criteria to each. This contrasts with CHAID, in which the statistical test result that determines variable selection also produces the split. Similarly, C&R Tree employs the impurity-change measure to both select the input field and to determine the split.

Decision Tree Node Fields Options

On the Fields tab, you choose whether you want to use the field role settings already defined in upstream nodes, or make the field assignments manually.

Use predefined roles This option uses the role settings (targets, predictors and so on) from an upstream Type node (or the Types tab of an upstream source node).

Use custom field assignments. To manually assign targets, predictors and other roles, select this option.

Fields. Use the arrow buttons to assign items manually from this list to the various role fields on the right of the screen. The icons indicate the valid measurement levels for each role field.

To select all the fields in the list, click the All button, or click an individual measurement level button to select all fields with that measurement level.

Target. Select one field as the target for the prediction.

Predictors (Inputs). Choose one or more fields as inputs for the prediction.

Analysis Weight. (CHAID, C&RT, and Trees-AS only) To use a field as a case weight, specify the field here. Case weights are used to account for differences in variance across levels of the output field. See the topic [Using Frequency and Weight Fields](#) for more information.

Decision Tree Node Build Options

The Build Options tab is where you set all the options for building the model. You can, of course, just click the Run button to build a model with all the default options, but normally you will want to customize the build for your own purposes.

The tab contains several different panes on which you set the customizations that are specific to your model.

- [C&R Tree and QUEST Nodes - Costs & Priors](#)
- [CHAID Node - Costs](#)
- [C&R Tree Node - Advanced](#)
- [QUEST Node - Advanced](#)
- [CHAID Node - Advanced](#)

Decision Tree Nodes - Objectives

For the C&R Tree, QUEST, and CHAID nodes, in the Objectives pane on the Build Options tab, you can choose whether to build a new model or update an existing one. You also set the main objective of the node: to build a standard model, to build one with enhanced accuracy or stability, or to build one for use with very large datasets.

What do you want to do?

Build new model. (Default) Creates a completely new model each time you run a stream containing this modeling node.

Continue training existing model. By default, a completely new model is created each time a modeling node is executed. If this option is selected, training continues with the last model successfully produced by the node. This makes it possible to update or refresh an existing model without having to access the original data and may result in significantly faster performance since *only* the new or updated records are fed into the stream. Details on the previous model are stored with the modeling node, making it possible to use this option even if the previous model nugget is no longer available in the stream or Models palette.

Note: This option is activated only if you select Build a single tree (for C&R Tree, CHAID, and QUEST), Create a standard model (for Neural Net and Linear), or Create a model for very large datasets as the objective.

What is your main objective?

- Build a single tree. Creates a single, standard decision tree model. Standard models are generally easier to interpret, and can be faster to score, than models built using the other objective options.

Note: Continue training existing model is only supported with Build a single tree split models, and you must be connected to Analytic Server.

Mode. Specifies the method used to build the model. Generate model creates a model automatically when the stream is run. Launch interactive session opens the tree builder, which enables you to build your tree one level at a time, edit splits, and prune as desired before

creating the model nugget.

Use tree directives. Select this option to specify directives to apply when generating an interactive tree from the node. For example, you can specify the first- and second-level splits, and these would automatically be applied when the tree builder is launched. You can also save directives from an interactive tree-building session in order to re-create the tree at a future date. See the topic [Updating Tree Directives](#) for more information.

- Enhance model accuracy (boosting). Choose this option if you want to use a special method, known as **boosting**, to improve the model accuracy rate. Boosting works by building multiple models in a sequence. The first model is built in the usual way. Then, a second model is built in such a way that it focuses on the records that were misclassified by the first model. Then a third model is built to focus on the second model's errors, and so on. Finally, cases are classified by applying the whole set of models to them, using a weighted voting procedure to combine the separate predictions into one overall prediction. Boosting can significantly improve the accuracy of a decision tree model, but it also requires longer training.
- Enhance model stability (bagging). Choose this option if you want to use a special method, known as **bagging** (bootstrap aggregating), to improve the stability of the model and to avoid overfitting. This option creates multiple models and combines them, in order to obtain more reliable predictions. Models obtained using this option can take longer to build and score than standard models.
- Create a model for very large datasets. Choose this option when working with datasets that are too large to build a model using any of the other objective options. This option divides the data into smaller data blocks and builds a model on each block. The most accurate models are then automatically selected and combined into a single model nugget. You can perform incremental model updating if you select the Continue training existing model option on this screen. The Continue training existing model option is only supported with Create a model for very large datasets models, and you don't need to connect to Analytic Server. But a model for very large datasets can't be created with splits.

Note: This option for very large datasets requires a connection to IBM® SPSS® Modeler Server.

Decision Tree Nodes - Basics

Specify the basic options about how the decision tree is to be built.

Tree growing algorithm (CHAID and Tree-AS only) Choose the type of CHAID algorithm you want to use. Exhaustive CHAID is a modification of CHAID that does a more thorough job of examining all possible splits for each predictor but takes longer to compute.

Maximum tree depth Specify the maximum number of levels below the root node (the number of times the sample will be split recursively). The default is 5; choose Custom and enter a value to specify a different number of levels.

Pruning (C&RT and QUEST only)

Prune tree to avoid overfitting Pruning consists of removing bottom-level splits that do not contribute significantly to the accuracy of the tree. Pruning can help simplify the tree, making it easier to interpret and, in some cases, improving generalization. If you want the full tree without pruning, leave this option deselected.

- Set maximum difference in risk (in Standard Errors) Enables you to specify a more liberal pruning rule. The standard error rule enables the algorithm to select the simplest tree whose risk estimate is close to (but possibly greater than) that of the subtree with the smallest risk. The value indicates the size of the allowable difference in the risk estimate between the pruned tree and the tree with the smallest risk in terms of the risk estimate. For example, if you specify 2, a tree whose risk estimate is $(2 \times \text{standard error})$ larger than that of the full tree could be selected.

Maximum surrogates. Surrogates are a method for dealing with missing values. For each split in the tree, the algorithm identifies the input fields that are most similar to the selected split field. Those fields are the *surrogates* for that split. When a record must be classified but has a missing value for a split field, its value on a surrogate field can be used to make the split. Increasing this setting will allow more flexibility to handle missing values but may also lead to increased memory usage and longer training times.

Decision Tree Nodes - Stopping Rules

These options control how the tree is constructed. Stopping rules determine when to stop splitting specific branches of the tree. Set the minimum branch sizes to prevent splits that would create very small subgroups. Minimum records in parent branch prevents a split if the number of records in the node to be split (the *parent*) is less than the specified value. Minimum records in child branch prevents a split if the number of records in any branch created by the split (the *child*) would be less than the specified value.

- Use percentage Specify sizes in terms of percentage of overall training data.
- Use absolute value Specify sizes as the absolute numbers of records.

Decision Tree Nodes - Ensembles

These settings determine the behavior of ensembling that occurs when boosting, bagging, or very large datasets are requested in Objectives. Options that do not apply to the selected objective are ignored.

Bagging and Very Large Datasets. When scoring an ensemble, this is the rule used to combine the predicted values from the base models to compute the ensemble score value.

- Default combining rule for categorical targets. Ensemble predicted values for categorical targets can be combined using voting, highest probability, or highest mean probability. **Voting** selects the category that has the highest probability most often across the base models. **Highest probability** selects the category that achieves the single highest probability across all base models. **Highest mean probability** selects the category with the highest value when the category probabilities are averaged across base models.
- Default combining rule for continuous targets. Ensemble predicted values for continuous targets can be combined using the mean or median of the predicted values from the base models.

Note that when the objective is to enhance model accuracy, the combining rule selections are ignored. Boosting always uses a weighted majority vote to score categorical targets and a weighted median to score continuous targets.

Boosting and Bagging. Specify the number of base models to build when the objective is to enhance model accuracy or stability; for bagging, this is the number of bootstrap samples. It should be a positive integer.

C&R Tree and QUEST Nodes - Costs & Priors

Misclassification Costs

In some contexts, certain kinds of errors are more costly than others. For example, it may be more costly to classify a high-risk credit applicant as low risk (one kind of error) than it is to classify a low-risk applicant as high risk (a different kind of error). Misclassification costs allow you to specify the relative importance of different kinds of prediction errors.

Misclassification costs are basically weights applied to specific outcomes. These weights are factored into the model and may actually change the prediction (as a way of protecting against costly mistakes).

With the exception of C5.0 models, misclassification costs are not applied when scoring a model and are not taken into account when ranking or comparing models using an Auto Classifier node, evaluation chart, or Analysis node. A model that includes costs may not produce fewer errors than one that doesn't and may not rank any higher in terms of overall accuracy, but it is likely to perform better in practical terms because it has a built-in bias in favor of *less expensive* errors.

The cost matrix shows the cost for each possible combination of predicted category and actual category. By default, all misclassification costs are set to 1.0. To enter custom cost values, select Use misclassification costs and enter your custom values into the cost matrix.

To change a misclassification cost, select the cell corresponding to the desired combination of predicted and actual values, delete the existing contents of the cell, and enter the desired cost for the cell. Costs are not automatically symmetrical. For example, if you set the cost of misclassifying A as B to be 2.0, the cost of misclassifying B as A will still have the default value of 1.0 unless you explicitly change it as well.

Priors

These options allow you to specify prior probabilities for categories when predicting a categorical target field. **Prior probabilities** are estimates of the overall relative frequency for each target category in the population from which the training data are drawn. In other words, they are the probability estimates that you would make for each possible target value *prior* to knowing anything about predictor values. There are three methods of setting priors:

- Based on training data. This is the default. Prior probabilities are based on the relative frequencies of the categories in the training data.
- Equal for all classes. Prior probabilities for all categories are defined as $1/k$, where k is the number of target categories.
- Custom. You can specify your own prior probabilities. Starting values for prior probabilities are set as equal for all classes. You can adjust the probabilities for individual categories to user-defined values. To adjust a specific category's probability, select the probability cell in the table corresponding to the desired category, delete the contents of the cell, and enter the desired value.

The prior probabilities for all categories should sum to 1.0 (the **probability constraint**). If they do not sum to 1.0, a warning is displayed, with an option to automatically normalize the values. This automatic adjustment preserves the proportions across categories while enforcing the probability constraint. You can perform this adjustment at any time by clicking the Normalize button. To reset the table to equal values for all categories, click the Equalize button.

Adjust priors using misclassification costs. This option enables you to adjust the priors, based on misclassification costs (specified on the Costs tab). This enables you to incorporate cost information directly into the tree-growing process for trees that use the Twoing impurity measure. (When this option is not selected, cost information is used only in classifying records and calculating risk estimates for trees based on the Twoing measure.)

CHAID Node - Costs

In some contexts, certain kinds of errors are more costly than others. For example, it may be more costly to classify a high-risk credit applicant as low risk (one kind of error) than it is to classify a low-risk applicant as high risk (a different kind of error). Misclassification costs allow you to specify the relative importance of different kinds of prediction errors.

Misclassification costs are basically weights applied to specific outcomes. These weights are factored into the model and may actually change the prediction (as a way of protecting against costly mistakes).

With the exception of C5.0 models, misclassification costs are not applied when scoring a model and are not taken into account when ranking or comparing models using an Auto Classifier node, evaluation chart, or Analysis node. A model that includes costs may not produce fewer errors than one that doesn't and may not rank any higher in terms of overall accuracy, but it is likely to perform better in practical terms because it has a built-in bias in favor of *less expensive* errors.

The cost matrix shows the cost for each possible combination of predicted category and actual category. By default, all misclassification costs are set to 1.0. To enter custom cost values, select Use misclassification costs and enter your custom values into the cost matrix.

To change a misclassification cost, select the cell corresponding to the desired combination of predicted and actual values, delete the existing contents of the cell, and enter the desired cost for the cell. Costs are not automatically symmetrical. For example, if you set the cost of misclassifying A as B to be 2.0, the cost of misclassifying B as A will still have the default value of 1.0 unless you explicitly change it as well.

C&R Tree Node - Advanced

The advanced options enable you to fine-tune the tree-building process.

Minimum change in impurity. Specify the minimum change in impurity to create a new split in the tree. **Impurity** refers to the extent to which subgroups defined by the tree have a wide range of output field values within each group. For categorical targets, a node is considered “pure” if 100% of cases in the node fall into a specific category of the target field. The goal of tree building is to create subgroups with similar output values--in other words, to minimize the impurity within each node. If the best split for a branch reduces the impurity by less than the specified amount, the split will not be made.

Impurity measure for categorical targets. For categorical target fields, specify the method used to measure the impurity of the tree. (For continuous targets, this option is ignored, and the **least squared deviation** impurity measure is always used.)

- Gini is a general impurity measure based on probabilities of category membership for the branch.
- Twoing is an impurity measure that emphasizes the binary split and is more likely to lead to approximately equal-sized branches from a split.
- Ordered adds the additional constraint that only contiguous target classes can be grouped together, as is applicable only with ordinal targets. If this option is selected for a nominal target, the standard twoing measure is used by default.

Overfit prevention set. The algorithm internally separates records into a model building set and an overfit prevention set, which is an independent set of data records used to track errors during training in order to prevent the method from modeling chance variation in the data. Specify a percentage of records. The default is 30.

Replicate results. Setting a random seed enables you to replicate analyses. Specify an integer or click Generate, which will create a pseudo-random integer between 1 and 2147483647, inclusive.

QUEST Node - Advanced

The advanced options enable you to fine-tune the tree-building process.

Significance level for splitting. Specifies the significance level (alpha) for splitting nodes. The value must be between 0 and 1. Lower values tend to produce trees with fewer nodes.

Overfit prevention set. The algorithm internally separates records into a model building set and an overfit prevention set, which is an independent set of data records used to track errors during training in order to prevent the method from modeling chance variation in the data. Specify a percentage of records. The default is 30.

Replicate results. Setting a random seed enables you to replicate analyses. Specify an integer or click Generate, which will create a pseudo-random integer between 1 and 2147483647, inclusive.

CHAID Node - Advanced

The advanced options enable you to fine-tune the tree-building process.

Significance level for splitting. Specifies the significance level (alpha) for splitting nodes. The value must be between 0 and 1. Lower values tend to produce trees with fewer nodes.

Significance level for merging. Specifies the significance level (alpha) for merging categories. The value must be greater than 0 and less than or equal to 1. To prevent any merging of categories, specify a value of 1. For continuous targets, this means the number of categories for the variable in the final tree matches the specified number of intervals. This option is not available for Exhaustive CHAID.

Adjust significance values using Bonferroni method. Adjusts significance values when testing the various category combinations of a predictor. Values are adjusted based on the number of tests, which directly relates to the number of categories and measurement level of a predictor. This is generally desirable because it better controls the false-positive error rate. Disabling this option will increase the power of your analysis to find true differences, but at the cost of an increased false-positive rate. In particular, disabling this option may be recommended for small samples.

Allow resplitting of merged categories within a node. The CHAID algorithm attempts to merge categories in order to produce the simplest tree that describes the model. If selected, this option enables merged categories to be resplit if that results in a better solution.

Chi-square for categorical targets. For categorical targets, you can specify the method used to calculate the chi-square statistic.

- **Pearson.** This method provides faster calculations but should be used with caution on small samples.
- **Likelihood ratio.** This method is more robust than Pearson but takes longer to calculate. For small samples, this is the preferred method. For continuous targets, this method is always used.

Minimum change in expected cell frequencies. When estimating cell frequencies (for both the nominal model and the row effects ordinal model), an iterative procedure (epsilon) is used to converge on the optimal estimate used in the chi-square test for a specific split. Epsilon determines how much change must occur for iterations to continue; if the change from the last iteration is smaller than the specified value, iterations stop. If you are having problems with the algorithm not converging, you can increase this value or increase the maximum number of iterations until convergence occurs.

Maximum iterations for convergence. Specifies the maximum number of iterations before stopping, whether convergence has taken place or not.

Overfit prevention set. (This option is only available when using the interactive tree builder.) The algorithm internally separates records into a model building set and an overfit prevention set, which is an independent set of data records used to track errors during training in order to prevent the method from modeling chance variation in the data. Specify a percentage of records. The default is 30.

Replicate results. Setting a random seed enables you to replicate analyses. Specify an integer or click Generate, which will create a pseudo-random integer between 1 and 2147483647, inclusive.

Decision Tree Node Model Options

On the Model Options tab, you can choose whether to specify a name for the model, or generate a name automatically. You can also choose to obtain predictor importance information, as well as raw and adjusted propensity scores for flag targets.

Model name. You can generate the model name automatically based on the target or ID field (or model type in cases where no such field is specified) or specify a custom name.

Model Evaluation

Calculate predictor importance. For models that produce an appropriate measure of importance, you can display a chart that indicates the relative importance of each predictor in estimating the model. Typically you will want to focus your modeling efforts on the predictors that matter most, and consider dropping or ignoring those that matter least. Note that predictor importance may take longer to calculate for some models, particularly when working with large datasets, and is off by default for some models as a result. Predictor importance is not available for decision list models. See [Predictor Importance](#) for more information.

Propensity Scores

Propensity scores can be enabled in the modeling node, and on the Settings tab in the model nugget. This functionality is available only when the selected target is a flag field. See the topic [Propensity Scores](#) for more information.

Calculate raw propensity scores. Raw propensity scores are derived from the model based on the training data only. If the model predicts the true value (will respond), then the propensity is the same as P, where P is the probability of the prediction. If the model predicts the false value, then the propensity is calculated as $(1 - P)$.

- If you choose this option when building the model, propensity scores will be enabled in the model nugget by default. However, you can always choose to enable raw propensity scores in the model nugget whether or not you select them in the modeling node.
- When scoring the model, raw propensity scores will be added in a field with the letters *RP* appended to the standard prefix. For example, if the predictions are in a field named *\$R-churn*, the name of the propensity score field will be *\$RRP-churn*.

Calculate adjusted propensity scores. Raw propensities are based purely on estimates given by the model, which may be overfitted, leading to over-optimistic estimates of propensity. Adjusted propensities attempt to compensate by looking at how the model performs on the test or validation partitions and adjusting the propensities to give a better estimate accordingly.

- This setting requires that a valid partition field is present in the stream.
- Unlike raw confidence scores, adjusted propensity scores must be calculated when building the model; otherwise, they will not be available when scoring the model nugget.
- When scoring the model, adjusted propensity scores will be added in a field with the letters *AP* appended to the standard prefix. For example, if the predictions are in a field named *\$R-churn*, the name of the propensity score field will be *\$RAP-churn*. Adjusted propensity scores are not available for logistic regression models.
- When calculating the adjusted propensity scores, the test or validation partition used for the calculation must not have been balanced. To avoid this, be sure the Only balance training data option is selected in any upstream Balance nodes. In addition, if a complex sample has been taken upstream this will invalidate the adjusted propensity scores.
- Adjusted propensity scores are not available for "boosted" tree and rule set models. See the topic [Boosted C5.0 Models](#) for more information.

Based on. For adjusted propensity scores to be computed, a partition field must be present in the stream. You can specify whether to use the testing or validation partition for this computation. For best results, the testing or validation partition should include at least as many records as the partition used to train the original model.

C5.0 Node

This feature is available in SPSS® Modeler Professional and SPSS Modeler Premium.

This node uses the C5.0 algorithm to build either a **decision tree** or a **rule set**. A C5.0 model works by splitting the sample based on the field that provides the maximum **information gain**. Each subsample defined by the first split is then split again, usually based on a different field, and the process repeats until the subsamples cannot be split any further. Finally, the lowest-level splits are reexamined, and those that do not contribute significantly to the value of the model are removed or **pruned**.

Note: The C5.0 node can predict only a categorical target. When analyzing data with categorical (nominal or ordinal) fields, the node is more likely to group categories together than versions of C5.0 prior to release 11.0.

C5.0 can produce two kinds of models. A **decision tree** is a straightforward description of the splits found by the algorithm. Each terminal (or "leaf") node describes a particular subset of the training data, and each case in the training data belongs to exactly one terminal node in the tree. In other words, exactly one prediction is possible for any particular data record presented to a decision tree.

In contrast, a **rule set** is a set of rules that tries to make predictions for individual records. Rule sets are derived from decision trees and, in a way, represent a simplified or distilled version of the information found in the decision tree. Rule sets can often retain most of the important information from a full decision tree but with a less complex model. Because of the way rule sets work, they do not have the same properties as decision trees. The most important difference is that with a rule set, more than one rule may apply for any particular record, or no rules at all may apply. If multiple rules apply, each rule gets a weighted "vote" based on the confidence associated with that rule, and the final prediction is decided by combining the weighted votes of all of the rules that apply to the record in question. If no rule applies, a default prediction is assigned to the record.

Example. A medical researcher has collected data about a set of patients, all of whom suffered from the same illness. During their course of treatment, each patient responded to one of five medications. You can use a C5.0 model, in conjunction with other nodes, to help find out which drug might be appropriate for a future patient with the same illness.

Requirements. To train a C5.0 model, there must be one categorical (i.e., nominal or ordinal) *Target* field, and one or more *Input* fields of any type. Fields set to *Both* or *None* are ignored. Fields used in the model must have their types fully instantiated. A weight field can also be specified.

Strengths. C5.0 models are quite robust in the presence of problems such as missing data and large numbers of input fields. They usually do not require long training times to estimate. In addition, C5.0 models tend to be easier to understand than some other model types, since the rules derived from the model have a very straightforward interpretation. C5.0 also offers the powerful **boosting** method to increase accuracy of classification.

Note: C5.0 model building speed may benefit from enabling parallel processing.

C5.0 Node Model Options

This feature is available in SPSS® Modeler Professional and SPSS Modeler Premium.

Model name. Specify the name of the model to be produced.

- **Auto.** With this option selected, the model name will be generated automatically, based on the target field name(s). This is the default.
- **Custom.** Select this option to specify your own name for the model nugget that will be created by this node.

Use partitioned data. If a partition field is defined, this option ensures that data from only the training partition is used to build the model.

Create split models. Builds a separate model for each possible value of input fields that are specified as split fields. See [Building Split Models](#) for more information.

Output type. Specify here whether you want the resulting model nugget to be a Decision tree or a Rule set.

Group symbolics. If this option is selected, C5.0 will attempt to combine symbolic values that have similar patterns with respect to the output field. If this option is not selected, C5.0 will create a child node for every value of the symbolic field used to split the parent node. For example, if C5.0 splits on a *COLOR* field (with values *RED*, *GREEN*, and *BLUE*), it will create a three-way split by default. However, if this option is selected, and the records where *COLOR = RED* are very similar to records where *COLOR = BLUE*, it will create a two-way split, with the *GREENs* in one group and the *BLUES* and *REDS* together in the other.

Use boosting. The C5.0 algorithm has a special method for improving its accuracy rate, called **boosting**. It works by building multiple models in a sequence. The first model is built in the usual way. Then, a second model is built in such a way that it focuses on the records that were misclassified by the first model. Then a third model is built to focus on the second model's errors, and so on. Finally, cases are classified by applying the whole set of models to them, using a weighted voting procedure to combine the separate predictions into one overall prediction. Boosting can significantly improve the accuracy of a C5.0 model, but it also requires longer training. The Number of trials option enables you to control how many models are used for the boosted model.

Cross-validate. If this option is selected, C5.0 will use a set of models built on subsets of the training data to estimate the accuracy of a model built on the full dataset. This is useful if your dataset is too small to split into traditional training and testing sets. The cross-validation models are discarded after the accuracy estimate is calculated. You can specify the **number of folds**, or the number of models used for cross-validation. Note that in previous versions of IBM® SPSS Modeler, building the model and cross-validating it were two separate operations. In the current version, no separate model-building step is required. Model building and cross-validation are performed at the same time.

Mode. For Simple training, most of the C5.0 parameters are set automatically. Expert training allows more direct control over the training parameters.

Simple Mode Options

Favor. By default, C5.0 will try to produce the most accurate tree possible. In some instances, this can lead to overfitting, which can result in poor performance when the model is applied to new data. Select Generality to use algorithm settings that are less susceptible to this problem.

Note: Models built with the Generality option selected are not guaranteed to generalize better than other models. When generality is a critical issue, always validate your model against a held-out test sample.

Expected noise (%). Specify the expected proportion of noisy or erroneous data in the training set.

Expert Mode Options

Pruning severity. Determines the extent to which the decision tree or rule set will be pruned. Increase this value to obtain a smaller, more concise tree. Decrease it to obtain a more accurate tree. This setting affects local pruning only (see "Use global pruning" below).

Minimum records per child branch. The size of subgroups can be used to limit the number of splits in any branch of the tree. A branch of the tree will be split only if two or more of the resulting subbranches would contain at least this many records from the training set. The default value is 2. Increase this value to help prevent **overtraining** with noisy data.

Use global pruning. Trees are pruned in two stages: First, a local pruning stage, which examines subtrees and collapses branches to increase the accuracy of the model. Second, a global pruning stage considers the tree as a whole, and weak subtrees may be collapsed. Global pruning is performed by default. To omit the global pruning stage, deselect this option.

Winnow attributes. If this option is selected, C5.0 will examine the usefulness of the predictors before starting to build the model. Predictors that are found to be irrelevant are then excluded from the model-building process. This option can be helpful for models with many predictor fields and can help prevent overfitting.

Note: C5.0 model building speed may benefit from enabling parallel processing.

Tree-AS node

The Tree-AS node can be used with data in a distributed environment. In this node you can choose to build decision trees using either a CHAID or Exhaustive CHAID model.

CHAID, or Chi-squared Automatic Interaction Detection, is a classification method for building decision trees by using chi-square statistics to identify optimal splits.

CHAID first examines the crosstabulations between each of the input fields and the outcome, and tests for significance using a chi-square independence test. If more than one of these relations is statistically significant, CHAID will select the input field that is the most significant (smallest p value). If an input has more than two categories, these are compared, and categories that show no differences in the outcome are collapsed together. This is done by successively joining the pair of categories showing the least significant difference. This category-merging process stops when all remaining categories differ at the specified testing level. For nominal input fields, any categories can be merged; for an ordinal set, only contiguous categories can be merged.

Exhaustive CHAID is a modification of CHAID that does a more thorough job of examining all possible splits for each predictor but takes longer to compute.

Requirements. Target and input fields can be continuous or categorical; nodes can be split into two or more subgroups at each level. Any ordinal fields used in the model must have numeric storage (not string). If necessary, use the Reclassify node to convert them.

Strengths. CHAID can generate nonbinary trees, meaning that some splits have more than two branches. It therefore tends to create a wider tree than the binary growing methods. CHAID works for all types of inputs, and it accepts both case weights and frequency variables.

 - [Tree-AS node model options](#)
 - [Tree-AS model nugget](#)
-

Tree-AS node fields options

On the Fields tab, you choose whether you want to use the field role settings already defined in upstream nodes, or make the field assignments manually.

Use predefined roles This option uses the role settings (targets, predictors and so on) from an upstream Type node (or the Types tab of an upstream source node).

Use custom field assignments. To manually assign targets, predictors and other roles, select this option.

Fields. Use the arrow buttons to assign items manually from this list to the various role fields on the right of the screen. The icons indicate the valid measurement levels for each role field.

To select all the fields in the list, click the All button, or click an individual measurement level button to select all fields with that measurement level.

Target. Select one field as the target for the prediction.

Predictors Select one or more fields as inputs for the prediction.

Analysis Weight To use a field as a case weight, specify the field here. Case weights are used to account for differences in variance across levels of the output field. For more information, see [Using Frequency and Weight Fields](#).

Tree-AS node build options

The Build Options tab is where you set all the options for building the model. You can, of course, just click the Run button to build a model with all the default options, but normally you will want to customize the build for your own purposes.

The tab contains several different panes on which you set the customizations that are specific to your model.

- [Tree-AS node - basics](#)
 - [Tree-AS node - growing](#)
 - [Tree-AS node - stopping rules](#)
 - [Tree-AS node - costs](#)
-

Tree-AS node - basics

Specify the basic options about how the decision tree is to be built.

Tree growing algorithm Select the type of CHAID algorithm you want to use. Exhaustive CHAID is a modification of CHAID that does a more thorough job of examining all possible splits for each predictor but takes longer to compute.

Maximum tree depth Specify the maximum number of levels below the root node (the number of times the sample is split recursively); the default is 5. The maximum number of levels (also referred to as *nodes*) is 50,000.

Binning If you use continuous data, you must bin the inputs. You can do this in a preceding node; however, the Tree-AS node automatically bins any continuous inputs. If you use the Tree-AS node to automatically bin the data, select the Number of bins into which the inputs are to be divided. Data is divided into bins with equal frequency; the available options are 2, 4, 5, 10, 20, 25, 50, or 100.

Tree-AS node - growing

Use the growing options to fine-tune the tree-building process.

Record threshold for switching from p-values to effect sizes Specify the number of records at which the model will switch from using the P-values settings to the Effect size settings when building the tree. The default is 1,000,000.

Significance level for splitting Specify the significance level (alpha) for splitting nodes. The value must be between 0.01 and 0.99. Lower values tend to produce trees with fewer nodes.

Significance level for merging Specify the significance level (alpha) for merging categories. The value must be between 0.01 and 0.99. This option is not available for Exhaustive CHAID.

Adjust significance values using Bonferroni method Adjust significance values when you are testing the various category combinations of a predictor. Values are adjusted based on the number of tests, which directly relates to the number of categories and measurement level of a predictor. This is generally desirable because it better controls the false-positive error rate. Disabling this option increases the power of your analysis to find true differences, but at the cost of an increased false-positive rate. In particular, disabling this option may be recommended for small samples.

Effect size threshold (continuous targets only) Set the effect size threshold to be used when splitting nodes and merging categories; when using a continuous target. The value must be between 0.01 and 0.99.

Effect size threshold (categorical targets only) Set the effect size threshold to be used when splitting nodes and merging categories; when using a categorical target. The value must be between 0.01 and 0.99.

Allow resplitting of merged categories within a node The CHAID algorithm attempts to merge categories in order to produce the simplest tree that describes the model. If selected, this option enables merged categories to be resplit if that results in a better solution.

Significance level for grouping leaf nodes Specify the significance level that determines how groups of leaf nodes are formed or how unusual leaf nodes are identified.

Chi-square for categorical targets For categorical targets, you can specify the method used to calculate the chi-square statistic.

- Pearson This method provides faster calculations but should be used with caution on small samples.
- Likelihood ratio This method is more robust than Pearson but takes longer to calculate. For small samples, this is the preferred method. For continuous targets, this method is always used.

Tree-AS node - stopping rules

These options control how the tree is constructed. Stopping rules determine when to stop splitting specific branches of the tree. Set the minimum branch sizes to prevent splits that would create very small subgroups. Minimum records in parent branch prevents a split if the number of records in the node to be split (the *parent*) is less than the specified value. Minimum records in child branch prevents a split if the number of records in any branch created by the split (the *child*) would be less than the specified value.

- Use percentage Specify sizes in terms of percentage of overall training data.
- Use absolute value Specify sizes as the absolute numbers of records.

Minimum change in expected cell frequencies When estimating cell frequencies (for both the nominal model and the row effects ordinal model), an iterative procedure (epsilon) is used to converge on the optimal estimate used in the chi-square test for a specific split. Epsilon determines how much change must occur for iterations to continue; if the change from the last iteration is smaller than the specified value, iterations stop. If you are having problems with the algorithm not converging, you can increase this value or increase the maximum number of iterations until convergence occurs.

Maximum iterations for convergence Specifies the maximum number of iterations before stopping, whether convergence has taken place or not.

Tree-AS node - costs

In some contexts, certain kinds of errors are more costly than others. For example, it may be more costly to classify a high-risk credit applicant as low risk (one kind of error) than it is to classify a low-risk applicant as high risk (a different kind of error). Misclassification costs allow you to specify the relative importance of different kinds of prediction errors.

Misclassification costs are basically weights applied to specific outcomes. These weights are factored into the model and may actually change the prediction (as a way of protecting against costly mistakes).

A model that includes costs might not produce fewer errors than one that doesn't, and might not rank any higher in terms of overall accuracy, but it is likely to perform better in practical terms because it has a built-in bias in favor of less expensive errors.

The cost matrix shows the cost for each possible combination of predicted category and actual category. By default, all misclassification costs are set to 1.0. To enter custom cost values, select Use misclassification costs and enter your custom values into the cost matrix.

To change a misclassification cost, select the cell corresponding to the desired combination of predicted and actual values, delete the existing contents of the cell, and enter the desired cost for the cell. Costs are not automatically symmetrical. For example, if you set the cost of misclassifying A as B to be 2.0, the cost of misclassifying B as A will still have the default value of 1.0 unless you explicitly change it as well.

For ordinal targets only, you can select the Default cost increase for ordinal target and set default values in the costs matrix. The available options are described in the following list.

- No increase - A default value of 1.0 for every correct prediction.
- Linear - Each successive incorrect prediction increases the cost by 1.
- Square - Each successive incorrect prediction is the square of the linear value. In this case, the values might be: 1, 4, 9, and so on.
- Custom - If you manually edit any values in the table, the drop-down option automatically changes to Custom. If you change the drop-down selection to any of the other options your edited values are replaced with the values for the selected option.

Tree-AS node model options

On the Model Options tab, you can choose whether to specify a name for the model, or generate a name automatically. You can also choose to calculate confidence values and add an identifying ID during scoring of the model.

Model name. You can generate the model name automatically based on the target or ID field (or model type in cases where no such field is specified) or specify a custom name.

Calculate confidences To add a confidence field when the model is scored, select this check box.

Rule identifier To add a field when the model is scored that contains the ID of the leaf node a record was assigned to, select this check box.

Tree-AS model nugget

- [Tree-AS model nugget output](#)
- [Tree-AS model nugget settings](#)

Tree-AS model nugget output

After you create a Tree-AS model, the following information is available in the Output viewer.

Model Information table

The Model Information table provides key information about the model. The table identifies some high-level model settings, such as:

- The algorithm type used; either CHAID or Exhaustive CHAID.
- The name of the target field selected in either the Type node or the Tree-AS node Fields tab.
- The names of the fields selected as predictors in either the Type node or the Tree-AS node Fields tab.
- The number of records in the data. If you build a model with a frequency weight, this value is the weighted, valid count which represents the records on which the tree is based.
- The number of *leaf nodes* in the generated tree.
- The number of levels in the tree; that is, the tree depth.

Predictor Importance

The Predictor Importance graph shows the importance of the top 10 inputs (predictors) in the model as a bar chart.

If there are more than 10 fields in the chart, you can change the selection of predictors that are included in the chart by using the slider beneath the chart. The indicator marks on the slider are a fixed width, and each mark on the slider represents 10 fields. You can move the indicator marks along the slider to display the next or previous 10 fields, ordered by predictor importance.

You can double-click the chart to open a separate dialog box in which you can edit the graph settings. For example, you can amend items such as the size of the graph, and the size and color of the fonts used. When you close this separate editing dialog box, the changes are applied to the chart that is displayed in the Output tab.

Top Decision Rules table

By default, this interactive table displays the statistics of the rules for the top five leaf nodes in the output, based on the percentage of total records that are contained within the leaf node.

You can double-click the table to open a separate dialog box in which you can edit the rule information that is shown in the table. The information that is displayed, and the options that are available in the dialog box, depend on the data type of the target; such as, categorical, or continuous.

The following rule information is shown in the table:

- Rule ID
- The details of how the rule is applied and made up
- Record count for each rule. If you build a model with a frequency weight, this value is the weighted, valid count which represents the records on which the tree is based.
- Record percentage for each rule

In addition, for a continuous target, an extra column in the table shows the Mean value for each rule.

You can alter the rule table layout using the following Table contents options:

- Top decision rules The top five decision rules are sorted by the percentage of total records contained within the leaf nodes.
- All rules The table contains all of the leaf nodes produced by the model but only shows 20 rules per page. When you select this layout, you can search for a rule by using the additional options of Find rule by ID and Page.

In addition, for a categorical target, you can alter the rule table layout using the Top rules by category option. The top five decision rules are sorted by the percentage of total records for a Target category that you select.

If you change the layout of the rules table, you can copy the modified rules table back to the Output viewer by clicking the Copy to Viewer button at the upper-left of the dialog box.

Tree-AS model nugget settings

On the Settings tab for a Tree-AS model nugget, you specify options for confidences and for SQL generation during model scoring. This tab is available only after the model nugget is added to a stream.

Calculate confidences To include confidences in scoring operations, select this check box. When you score models in the database, excluding confidences means that you can generate more efficient SQL. For regression trees, confidences are not assigned.

Rule identifier To add a field in the scoring output that indicates the ID for the terminal node to which each record is assigned, select this check box.

Generate SQL for this model When using data from a database, SQL code can be pushed back to the database for execution, providing superior performance for many operations.

Select one of the following options to specify how SQL is generated:

- Default: Score using Server Scoring Adapter (if installed) otherwise in process If connected to a database with a scoring adapter installed, generates SQL by using the scoring adapter and associated user-defined functions (UDF) and scores your model within the database. When no scoring adapter is available, this option fetches your data back from the database and scores it in SPSS® Modeler.
- Score outside of the Database If selected, this option fetches your data back from the database and scores it in SPSS Modeler.

Random Trees node

The Random Trees node can be used with data in a distributed environment. In this node, you build an ensemble model that consists of multiple decision trees.

The Random Trees node is a tree-based classification and prediction method that is built on Classification and Regression Tree methodology. As with C&R Tree, this prediction method uses recursive partitioning to split the training records into segments with similar output field values. The node starts by examining the input fields available to it to find the best split, which is measured by the reduction in an impurity index that results from the split. The split defines two subgroups, each of which is then split into two more subgroups, and so on, until one of the stopping criteria is triggered. All splits are binary (only two subgroups).

The Random Trees node uses bootstrap sampling with replacement to generate sample data. The sample data is used to grow a tree model. During tree growth, Random Trees will not sample the data again. Instead, it randomly selects part of the predictors and uses the best one to split a tree node. This process is repeated when splitting each tree node. This is the basic idea of growing a tree in random forest.

Random Trees uses C&R Tree-like trees. Since such trees are binary, each field for splitting results in two branches. For a categorical field with multiple categories, the categories are grouped into two groups based on the inner splitting criterion. Each tree grows to the largest extent possible (there is no pruning). In scoring, Random Trees combines individual tree scores by majority voting (for classification) or average (for regression).

Random Trees differ from C&R Trees as follows:

- Random Trees nodes randomly select a specified number of predictors and uses the best one from the selection to split a node. In contrast, C&R Tree finds the best one from all predictors.
- Each tree in Random Trees grows fully until each leaf node typically contains a single record. So the tree depth could be very large. But standard C&R Tree uses different stopping rules for tree growth, which usually leads to a much shallower tree.

Random Trees adds two features compared to C&R Tree:

- The first feature is *bagging*, where replicas of the training dataset are created by sampling with replacement from the original dataset. This action creates bootstrap samples that are of equal size to the original dataset, after which a *component model* is built on each replica. Together these component models form an ensemble model.
- The second feature is that, at each split of the tree, only a sampling of the input fields is considered for the impurity measure.

Requirements. To train a Random Trees model, you need one or more *Input* fields and one *Target* field. Target and input fields can be continuous (numeric range) or categorical. Fields that are set to either *Both* or *None* are ignored. Fields that are used in the model must have their types fully instantiated, and any ordinal (ordered set) fields that are used in the model must have numeric storage (not string). If necessary, the Reclassify node can be used to convert them.

Strengths. Random Trees models are robust when you are dealing with large data sets and numbers of fields. Due to the use of bagging and field sampling, they are much less prone to overfitting and thus the results that are seen in testing are more likely to be repeated when you use new data.

- [Random Trees node fields options](#)
- [Random Trees node build options](#)
- [Random Trees node model options](#)
- [Random Trees model nugget](#)

Random Trees node fields options

On the Fields tab, you choose whether you want to use the field role settings already defined in upstream nodes, or make the field assignments manually.

Use predefined roles This option uses the role settings (targets, predictors and so on) from an upstream Type node (or the Types tab of an upstream source node).

Use custom field assignments. To manually assign targets, predictors and other roles, select this option.

Fields. Use the arrow buttons to assign items manually from this list to the various role fields on the right of the screen. The icons indicate the valid measurement levels for each role field.

To select all the fields in the list, click the All button, or click an individual measurement level button to select all fields with that measurement level.

Target. Select one field as the target for the prediction.

Predictors Select one or more fields as inputs for the prediction.

Analysis Weight To use a field as a case weight, specify the field here. Case weights are used to account for differences in variance across levels of the output field. For more information, see [Using Frequency and Weight Fields](#).

Random Trees node build options

The Build Options tab is where you set all the options for building the model. You can, of course, just click the Run button to build a model with all the default options, but normally you will want to customize the build for your own purposes.

The tab contains several different panes on which you set the customizations that are specific to your model.

- [Random Trees node - basics](#)
- [Random Trees node - costs](#)
- [Random Trees node - advanced](#)

Random Trees node - basics

Specify basic options for how to build the decision tree.

Number of models to build. Specify the maximum number of trees that the node can build.

Sample size. By default, the size of the bootstrap sample is equal to the original training data. When dealing with large datasets, reducing the sample size can increase performance. It is a ratio from 0 to 1. For example, set the sample size to **0 . 6** to reduce it to 60% of the original training data size.

Handle imbalanced data. If the model's target is a flag outcome (for example, purchase or do not purchase) and the ratio of the desired outcome to non-desired is very small, the data is imbalanced and the bootstrap sampling that is conducted by the model could affect model accuracy. To improve accuracy select this check box; the model then captures a larger proportion of the desired outcome and generates a better model.

Use weighted sampling for variable selection. By default, variables for each leaf node are randomly selected with the same probability. To apply weighting to variables and improve the selection process, select this check box. The weight is calculated by the Random Trees node itself. The more important fields (with higher weight) are more likely to be selected as predictors.

Maximum number of nodes. Specify the maximum number of leaf nodes that are allowed in individual trees. If the number would be exceeded on the next split, tree growth is stopped before the split occurs.

Maximum tree depth. Specify the maximum number of levels *leaf nodes* below the root node; that is, the number of times the sample is split recursively).

Minimum child node size. Specify the minimum number of records that must be contained in a child node after the parent node is split. If a child node would contain fewer records than you enter, the parent node will not be split.

Specify number of predictors to use for splitting. If you are building split models, set the minimum number of predictors to be used to build each split. This prevents the split from creating excessively small subgroups. If you don't select this option, the default value is **[sqrt(M)]** for classification and **[M/3]** for regression, where **M** is the total number of predictor variables. If this option is selected, the specified number of predictors will be used.

Note: The number of predictors for splitting cannot be greater than the total number of predictors in the data.

Stop building when accuracy can no longer be improved. Random Trees uses a particular procedure for deciding when to stop training.

Specifically, if the improvement of the current ensemble accuracy is smaller than a specified threshold, then it will stop adding new trees. This could result in a model with fewer trees than the value you specified for the Number of models to build option.

Random Trees node - costs

In some contexts, certain kinds of errors are more costly than others. For example, it may be more costly to classify a high-risk credit applicant as low risk (one kind of error) than it is to classify a low-risk applicant as high risk (a different kind of error). Misclassification costs allow you to specify the relative importance of different kinds of prediction errors.

Misclassification costs are basically weights applied to specific outcomes. These weights are factored into the model and may actually change the prediction (as a way of protecting against costly mistakes).

A model that includes costs might not produce fewer errors than one that doesn't, and might not rank any higher in terms of overall accuracy, but it is likely to perform better in practical terms because it has a built-in bias in favor of less expensive errors.

The cost matrix shows the cost for each possible combination of predicted category and actual category. By default, all misclassification costs are set to 1.0. To enter custom cost values, select Use misclassification costs and enter your custom values into the cost matrix.

To change a misclassification cost, select the cell corresponding to the desired combination of predicted and actual values, delete the existing contents of the cell, and enter the desired cost for the cell. Costs are not automatically symmetrical. For example, if you set the cost of

misclassifying *A* as *B* to be 2.0, the cost of misclassifying *B* as *A* will still have the default value of 1.0 unless you explicitly change it as well.

For ordinal targets only, you can select the Default cost increase for ordinal target and set default values in the costs matrix. The available options are described in the following list.

- No increase - A default value of 1.0 for every incorrect prediction.
 - Linear - Each successive incorrect prediction increases the cost by 1.
 - Square - Each successive incorrect prediction is the square of the linear value. In this case, the values might be: 1, 4, 9, and so on.
 - Custom - If you manually edit any values in the table, the drop-down option automatically changes to Custom. If you change the drop-down selection to any of the other options your edited values are replaced with the values for the selected option.
-

Random Trees node - advanced

Specify advanced options for how to build the decision tree.

Maximum percentage of missing values. Specify the maximum percentage of missing values allowed in any input. If the percentage exceeds this number, the input is excluded from model building.

Exclude fields with a single category majority over. Specify the maximum percentage of records that a single category can have within a field. If any category value represents a higher percentage of records than specified, the entire field is excluded from model building.

Maximum number of field categories. Specify the maximum number of categories that can be contained within a field. If the number of categories exceeds this number, the field is excluded from model building.

Minimum field variation. If the coefficient of variation of a continuous field is smaller than the value you specify here (in other words, the field is nearly constant), then field is excluded from model building.

Number of bins. Specify the number of equal frequency bins to be used for continuous inputs. The available options are: 2, 4, 5, 10, 20, 25, 50, or 100.

Number of interesting rules to report. Specify the number of rules to report (minimum of 1, maximum of 1000, with a default of 50).

Random Trees node model options

On the Model Options tab, you can choose whether to specify a name for the model, or generate a name automatically. You can also choose to calculate the importance of the predictors during scoring of the model.

Model name. You can generate the model name automatically based on the target or ID field (or model type in cases where no such field is specified) or specify a custom name.

Random Trees model nugget

- [Random Trees model nugget output](#)
 - [Random Trees model nugget settings](#)
-

Random Trees model nugget output

After you create a Random Trees model, the following information is available in the Output viewer:

Model information table

The Model information table provides key information about the model. The table always includes the following high-level model settings:

- The name of the target field that is selected in either the Type node or the Random Trees node Fields tab.
- The model building method - Random Trees.
- The number of predictors input into the model.

The additional details that are shown in the table depend on whether you build a classification or regression model, and if the model is built to handle imbalanced data:

- Classification model (default settings)
 - Model accuracy
 - Misclassification rule
- Classification model (Handle imbalanced data selected)
 - Gmean
 - True positive rate, which is subdivided into classes.
- Regression model
 - Root mean squared error
 - Relative error
 - Variance explained

Records Summary

The summary shows how many records were used to fit the model, and how many were excluded. Both the number of records and the percentage of the whole number are shown. If the model was built to include frequency weight, the unweighted number of records that are included and excluded is also shown.

Predictor Importance

The Predictor Importance graph shows the importance of the top 10 inputs (predictors) in the model as a bar chart.

If there are more than 10 fields in the chart, you can change the selection of predictors that are included in the chart by using the slider beneath the chart. The indicator marks on the slider are a fixed width, and each mark on the slider represents 10 fields. You can move the indicator marks along the slider to display the next or previous 10 fields, ordered by predictor importance.

You can double-click the chart to open a separate dialog box in which you can edit the graph size. When you close this separate editing dialog box, the changes are applied to the chart that is displayed in the Output tab.

Top Decision Rules table

By default, this interactive table displays the statistics of the top rules, which are sorted by interestingness.

You can double-click the table to open a separate dialog box in which you can edit the rule information that is shown in the table. The information that is displayed, and the options that are available in the dialog box, depend on the data type of the target; such as, categorical, or continuous.

The following rule information is shown in the table:

- The details of how the rule is applied and made up
- If the results are in the most frequent category
- Rule accuracy
- Trees accuracy
- Interestingness index

The interestingness index is calculated by using the following formula:

$$I_{Index}(t) = P(A(t)) * P(B(t)) * (P(B(t)|A(t)) + P(\bar{B}(t)|\bar{A}(t)))$$

In this formula:

- $P(A(t))$ is the trees accuracy
- $P(B(t))$ is the rule accuracy
- $P(B(t)|A(t))$ represents correct predictions by both the trees and the node
- The remaining piece of the formula represents incorrect predictions by both the trees and the node.

You can alter the rule table layout by using the following Table contents options:

- Top decision rules The top five decision rules, which are sorted by the interestingness index.
- All rules The table contains all of the rules that are produced by the model but shows only 20 rules per page. When you select this layout, you can search for a rule by using the additional options of Find rule by ID and Page.

In addition, for a categorical target, you can alter the rule table layout by using the Top rules by category option. The top five decision rules are sorted by the percentage of total records for a Target category that you select.

Note: For categorical targets, the table is only available when Handle imbalanced data is not selected in the Basics tab of the Build Options. If you change the layout of the rules table, you can copy the modified rules table back to the Output viewer by clicking the Copy to Viewer button at the upper left of the dialog box.

Confusion Matrix

For classification models, the confusion matrix shows the number of predicted results versus the actual observed results, including the proportion of correct predictions.

Note: The confusion matrix is not available for regression models, nor when Handle imbalanced data is selected in the Basics tab of the Build Options.

Random Trees model nugget settings

On the Settings tab for a Random Trees model nugget, you specify options for confidences and for SQL generation during model scoring. This tab is available only after the model nugget is added to a stream.

Calculate confidences To include confidences in scoring operations, select this check box. When you score models in the database, excluding confidences means that you can generate more efficient SQL. For regression trees, confidences are not assigned.

Generate SQL for this model When using data from a database, SQL code can be pushed back to the database for execution, providing superior performance for many operations.

Select one of the following options to specify how SQL is generated:

- **Default:** Score using Server Scoring Adapter (if installed) otherwise in process If connected to a database with a scoring adapter installed, generates SQL by using the scoring adapter and associated user-defined functions (UDF) and scores your model within the database. When no scoring adapter is available, this option fetches your data back from the database and scores it in SPSS® Modeler.
- **Score outside of the Database** If selected, this option fetches your data back from the database and scores it in SPSS Modeler.

C&R Tree, CHAID, QUEST, and C5.0 decision tree model nuggets

Decision tree model nuggets represent the tree structures for predicting a particular output field discovered by one of the decision tree modeling nodes (C&R Tree, CHAID, QUEST or C5.0). Tree models can be generated directly from the tree-building node, or indirectly from the interactive tree builder. See the topic [The Interactive Tree Builder](#) for more information.

In the model nugget, different options are available depending on the objective specified on the modeling node:

- [single tree model nuggets](#)
- [model nuggets for boosting, bagging and very large datasets](#)

Scoring Tree Models

When you run a stream containing a tree model nugget, the specific result depends on the type of tree.

- For classification trees (categorical target), two new fields, containing the predicted value and the confidence for each record, are added to the data. The prediction is based on the most frequent category for the terminal node to which the record is assigned; if a majority of respondents in a given node is yes, the prediction for all records assigned to that node is yes.
- For regression trees, only predicted values are generated; confidences are not assigned.
- Optionally, for CHAID, QUEST, and C&R Tree models, an additional field can be added that indicates the ID for the node to which each record is assigned.

The new field names are derived from the model name by adding prefixes. For C&R Tree, CHAID, and QUEST, the prefixes are \$R- for the prediction field, \$RC- for the confidence field, and \$RI- for the node identifier field. For C5.0 trees, the prefixes are \$C- for the prediction field and \$CC- for the confidence field. If multiple tree model nodes are present, the new field names will include numbers in the prefix to distinguish them if necessary—for example, \$R1- and \$RC1-, and \$R2-.

Working with Tree Model Nuggets

You can save or export information related to the model in a number of ways.

Note: Many of these options are also available from the tree builder window. From either the tree builder or a tree model nugget, you can:

- Generate a Filter or Select node based on the current tree. See [Generating Filter and Select Nodes](#) for more information.
- Generate a Rule Set nugget that represents the tree structure as a set of rules defining the terminal branches of the tree. See [Generating a Rule Set from a Decision Tree](#) for more information.
- In addition, for tree model nuggets only, you can export the model in PMML format. See [The models palette](#) for more information. If the model includes any custom splits, this information is not preserved in the exported PMML. (The split is preserved, but the fact that it is custom rather than chosen by the algorithm is not.)
- Generate a graph based on a selected part of the current tree. Note that this only works for a nugget when it is attached to other nodes in a stream. See [Generating Graphs](#) for more information.

- For boosted C5.0 models only, you can choose Single Decision Tree (Canvas) or Single Decision Tree (GM Palette) to create a new single rule set derived from the currently selected rule. See the topic [Boosted C5.0 Models](#) for more information.

Note: Although the Build Rule node was replaced by the C&R Tree node, decision tree nodes in existing streams that were originally created using a Build Rule node will still function properly.

Single Tree Model Nuggets

If you select Build a single tree as the main objective on the modeling node, the resulting model nugget contains the following tabs.

Table 1. Tabs on single tree nugget

Tab	Description	Further Information
Model	Displays the rules that define the model.	See the topic Decision Tree Model Rules for more information.
Viewer	Displays the tree view of the model.	See the topic Decision Tree Model Viewer for more information.
Summary	Displays information about the fields, build settings, and model estimation process.	See the topic Model Nugget Summary/Information for more information.
Settings	Enables you to specify options for confidences and for SQL generation during model scoring.	See the topic Decision Tree/Rule Set model nugget settings for more information.
Annotation	Enables you to add descriptive annotations, specify a custom name, add tooltip text and specify search keywords for the model.	

- [Decision Tree Model Rules](#)
- [Decision Tree Model Viewer](#)
- [Decision Tree/Rule Set model nugget settings](#)
- [Boosted C5.0 Models](#)
- [Generating Graphs](#)

Decision Tree Model Rules

The Model tab for a decision tree nugget displays the rules that define the model. Optionally, a graph of predictor importance and a third panel with information about history, frequencies, and surrogates can also be displayed.

Note: If you select the Create a model for very large datasets option on the CHAID node Build Options tab (Objective panel), the Model tab displays the tree rule details only.

Tree Rules

The left pane displays a list of conditions defining the partitioning of data discovered by the algorithm—essentially a series of rules that can be used to assign individual records to child nodes based on the values of different predictors.

Decision trees work by recursively partitioning the data based on input field values. The data partitions are called *branches*. The initial branch (sometimes called the *root*) encompasses all data records. The root is split into subsets, or *child branches*, based on the value of a particular

input field. Each child branch can be further split into sub-branches, which can in turn be split again, and so on. At the lowest level of the tree are branches that have no more splits. Such branches are known as *terminal branches* (or *leaves*).

Tree rule details

The rule browser shows the input values that define each partition or branch and a summary of output field values for the records in that split. For general information on using the model browser, see [Browsing model nuggets](#).

For splits based on numeric fields, the branch is shown by a line of the form:

```
fieldname relation value [summary]
```

where *relation* is a numeric relation. For example, a branch defined by values greater than 100 for the *revenue* field would be shown as:

```
revenue > 100 [summary]
```

For splits based on symbolic fields, the branch is shown by a line of the form:

```
fieldname = value [summary] or fieldname in [values] [summary]
```

where *values* represents the field values that define the branch. For example, a branch that includes records where the value of *region* can be *North*, *West*, or *South* would be represented as:

```
region in ["North" "West" "South"] [summary]
```

For terminal branches, a prediction is also given, adding an arrow and the predicted value to the end of the rule condition. For example, a leaf defined by *revenue* > 100 that predicts a value of *high* for the output field would be displayed as:

```
revenue > 100 [Mode: high] → high
```

The *summary* for the branch is defined differently for symbolic and numeric output fields. For trees with numeric output fields, the summary is the *average* value for the branch, and the *effect* of the branch is the difference between the average for the branch and the average of its parent branch. For trees with symbolic output fields, the summary is the *mode*, or the most frequent value, for records in the branch.

To fully describe a branch, you need to include the condition that defines the branch, plus the conditions that define the splits further up the tree. For example, in the tree:

```
revenue > 100
region = "North"
region in ["South" "East" "West"]
revenue <= 200
```

the branch represented by the second line is defined by the conditions *revenue* > 100 and *region* = "North".

If you click Show Instances/Confidence on the toolbar, each rule will also show information about the number of records to which the rule applies (*Instances*) and the proportion of those records for which the rule is true (*Confidence*).

Predictor Importance

Optionally, a chart that indicates the relative importance of each predictor in estimating the model may also be displayed on the Model tab. Typically you will want to focus your modeling efforts on the predictors that matter most and consider dropping or ignoring those that matter least.

Note: This chart is only available if Calculate predictor importance is selected on the Analyze tab before generating the model. See the topic [Predictor Importance](#) for more information.

Additional Model Information

If you click Show Additional Information Panel on the toolbar, you will see a panel at the bottom of the window displaying detailed information for the selected rule. The information panel contains three tabs.

History. This tab traces the split conditions from the root node down to the selected node. This provides a list of conditions that determine when a record is assigned to the selected node. Records for which all of the conditions are true will be assigned to this node.

Frequencies. For models with symbolic target fields, this tab shows, for each possible target value, the number of records assigned to this node (in the training data) that have that target value. The frequency figure, expressed as a percentage (shown to a maximum of three decimal places) is also displayed. For models with numeric targets, this tab is empty.

Surrogates. Where applicable, any surrogates for the primary split field are shown for the selected node. Surrogates are alternate fields used if the primary predictor value is missing for a given record. The maximum number of surrogates allowed for a given split is specified in the tree-building node, but the actual number depends on the training data. In general, the more missing data, the more surrogates are likely to be used. For other decision tree models, this tab is empty.

Note: To be included in the model, surrogates must be identified during the training phase. If the training sample has no missing values, then no surrogates will be identified, and any records with missing values encountered during testing or scoring will automatically fall into the child node with the largest number of records. If missing values are expected during testing or scoring, be sure that values are missing from the training sample, as well. Surrogates are not available for CHAID trees.

Effect

The effect of a node is the increase or decrease of the average value (predicted value compared to the parent node). For example, if the average of a node is 0.2 and the average of its parent is 0.6, then the effect for the node is $0.2 - 0.6 = -0.4$. This statistic only applies for a continuous target.

Decision Tree Model Viewer

The Viewer tab for a decision tree model nugget resembles the display in the tree builder. The main difference is that when browsing the model nugget, you can not grow or modify the tree. Other options for viewing and customizing the display are similar between the two components. See the topic [Customizing the Tree View](#) for more information.

Note: The Viewer tab is not displayed for CHAID model nuggets built if you select the Create a model for very large datasets option on the Build Options tab - Objective panel.

When viewing split rules on the Viewer tab, square brackets mean that the adjacent value is included in the range whereas parentheses indicate that the adjacent value is excluded from the range. The expression $(23, 37]$ therefore means from 23 exclusive to 37 inclusive, i.e. from just above 23 to 37. On the Model tab, the same condition would be displayed as:

`Age > 23 and Age <= 37`

Decision Tree/Rule Set model nugget settings

The Settings tab for a decision tree or Rule Set model nugget enables you to specify options for confidences and for SQL generation during model scoring. This tab is available only after the model nugget has been added to a stream.

Calculate confidences Select to include confidences in scoring operations. When scoring models in the database, excluding confidences enables you to generate more efficient SQL. For regression trees, confidences are not assigned.

Note: If you select the Create a model for very large datasets option on the Build Options tab - Method panel for CHAID models, this checkbox is available only in the model nuggets for categorical targets of nominal or flag.

Calculate raw propensity scores For models with a flag target (which return a yes or no prediction), you can request propensity scores that indicate the likelihood of the true outcome specified for the target field. These are in addition to other prediction and confidence values that may be generated during scoring.

Note: If you select the Create a model for very large datasets option on the Build Options tab - Method panel for CHAID models, this checkbox is available only in model nuggets with a categorical target of flag.

Calculate adjusted propensity scores Raw propensity scores are based only on the training data and may be overly optimistic due to the tendency of many models to overfit this data. Adjusted propensities attempt to compensate by evaluating model performance against a test or validation partition. This option requires that a partition field be defined in the stream and adjusted propensity scores be enabled in the modeling node before generating the model.

Note: Adjusted propensity scores are not available for boosted tree and rule set models. See the topic [Boosted C5.0 Models](#) for more information.

Rule identifier For CHAID, QUEST, and C&R Tree models, this option adds a field in the scoring output that indicates the ID for the terminal node to which each record is assigned.

Note: When this option is selected, SQL generation is not available.

Generate SQL for this model When using data from a database, SQL code can be pushed back to the database for execution, providing superior performance for many operations.

Select one of the following options to specify how SQL generation is performed.

- **Default:** Score using Server Scoring Adapter (if installed) otherwise in process If connected to a database with a scoring adapter installed, generates SQL using the scoring adapter and associated user defined functions (UDF) and scores your model within the database. When no scoring adapter is available, this option fetches your data back from the database and scores it in SPSS® Modeler.
- **Score by converting to native SQL without missing value support** If selected, generates native SQL to score the model within the database, without the overhead of handling missing values. This option simply sets the prediction to null (`$null$`) when a missing value is encountered while scoring a case.

Note: This option is not available for CHAID models. For other model types, it is only available for decision trees (not rule sets).

- **Score by converting to native SQL with missing value support** For CHAID, QUEST, and C&R Tree models, you can generate native SQL to score the model within the database with full missing value support. This means that SQL is generated so that missing values are handled as specified in the model. For example, C&R Trees use surrogate rules and biggest child fallback.

Note: For C5.0 models, this option is only available for rule sets (not decision trees).

- **Score outside of the Database** If selected, this option fetches your data back from the database and scores it in SPSS Modeler.

Boosted C5.0 Models

This feature is available in SPSS® Modeler Professional and SPSS Modeler Premium.

When you create a boosted C5.0 model (either a rule set or a decision tree), you actually create a set of related models. The model rule browser for a boosted C5.0 model shows the list of models at the top level of the hierarchy, along with the estimated accuracy of each model and the overall accuracy of the ensemble of boosted models. To examine the rules or splits for a particular model, select that model and expand it as you would a rule or branch in a single model.

You can also extract a particular model from the set of boosted models and create a new Rule Set model nugget containing just that model. To create a new rule set from a boosted C5.0 model, select the rule set or tree of interest and choose either Single Decision Tree (GM Palette) or Single Decision Tree (Canvas) from the Generate menu.

Generating Graphs

The Tree nodes provide a lot of information; however, it may not always be in an easily accessible format for business users. To provide the data in a way that can be easily incorporated into business reports, presentations, and so on, you can produce graphs of selected data. For example, from either the Model or the Viewer tabs of a model nugget, or from the Viewer tab of an interactive tree, you can generate a graph for a selected part of the tree, thereby only creating a graph for the cases in the selected tree or branch node.

Note: You can only generate a graph from a nugget when it is attached to other nodes in a stream.

Generate a graph

The first step is to select the information to be shown on the graph:

- On the Model tab of a nugget, expand the list of conditions and rules in the left pane and select the one in which you are interested.
- On the Viewer tab of a nugget, expand the list of branches and select the node in which you are interested.
- On the Viewer tab of an interactive tree, expand the list of branches and select the node in which you are interested.

Note: You cannot select the top node on either Viewer tab.

The way in which you create a graph is the same, regardless of how you select the data to be shown:

1. From the Generate menu, select Graph (from selection); alternatively, on the Viewer tab, click the Graph (from selection) button in the bottom left corner. The Graphboard Basic tab is displayed.
Note: Only the Basic and Detailed tabs are available when you display the Graphboard in this way.
2. Using either the Basic or Detailed tab settings, specify the details to be displayed on the graph.
3. Click OK to generate the graph.

The graph heading identifies the nodes or rules that were chosen for inclusion.

Model nuggets for boosting, bagging, and very large datasets

If you select Enhance model accuracy (boosting), Enhance model stability (bagging), or Create a model for very large datasets as the main objective on the modeling node, IBM® SPSS® Modeler builds an ensemble of multiple models. See the topic [Models for ensembles](#) for more information.

The resulting model nugget contains the following tabs. The Model tab provides a number of different views of the model.

Table 1. Tabs available in model nugget

Tab	View	Description	Further Information
Model	Model Summary	Displays a summary of the ensemble quality and (except for boosted models and continuous targets) diversity, a measure of how much the predictions vary across the different models.	See the topic Model Summary (ensemble viewer) for more information.
	Predictor Importance	Displays a chart indicating the relative importance of each predictor (input field) in estimating the model.	See the topic Predictor Importance (ensemble viewer) for more information.
	Predictor Frequency	Displays a chart showing the relative frequency with which each predictor is used in the set of models.	See the topic Predictor Frequency (ensemble viewer) for more information.
	Component Model Accuracy	Plots a chart of the predictive accuracy of each of the different models in the ensemble.	
	Component Model Details	Displays information on each of the different models in the ensemble.	See the topic Component Model Details (ensemble viewer) for more information.
	Information	Displays information about the fields, build settings, and model estimation process.	See the topic Model Nugget Summary / Information for more information.
Settings		Enables you to include confidences in scoring operations.	See the topic Decision Tree/Rule Set model nugget settings for more information.
Annotation		Enables you to add descriptive annotations, specify a custom name, add tooltip text and specify search keywords for the model.	

C&R Tree, CHAID, QUEST, C5.0, and Apriori rule set model nuggets

A Rule Set model nugget represents the rules for predicting a particular output field discovered by the association rule modeling node (Apriori) or by one of the tree-building nodes (C&R Tree, CHAID, QUEST, or C5.0). For association rules, the rule set must be generated from an unrefined Rule nugget. For trees, a rule set can be generated from the interactive tree builder, from a C5.0 model-building node, or from any tree model nugget. Unlike unrefined Rule nuggets, Rule Set nuggets can be placed in streams to generate predictions.

When you run a stream containing a Rule Set nugget, two new fields are added to the stream containing the predicted value and the confidence for each record to the data. The new field names are derived from the model name by adding prefixes. For association rule sets, the prefixes are \$A- for the prediction field and \$AC- for the confidence field. For C5.0 rule sets, the prefixes are \$C- for the prediction field and \$CC- for the confidence field. For C&R Tree rule sets, the prefixes are \$R- for the prediction field and \$RC- for the confidence field. In a stream with multiple Rule Set nuggets in a series predicting the same output field(s), the new field names will include numbers in the prefix to distinguish them from each other. The first association Rule Set nugget in the stream will use the usual names, the second node will use names starting with \$A1- and \$AC1-, the third node will use names starting with \$A2- and \$AC2-, and so on.

How rules are applied. Rule Sets generated from association rules are unlike other model nuggets because for any particular record, more than one prediction can be generated, and those predictions may not all agree. There are two methods for generating predictions from rule sets.

Note: Rule Sets that are generated from decision trees return the same results regardless of which method is used, since the rules derived from a decision tree are mutually exclusive.

- **Voting.** This method attempts to combine the predictions of all of the rules that apply to the record. For each record, all rules are examined and each rule that applies to the record is used to generate a prediction and an associated confidence. The sum of confidence

figures for each output value is computed, and the value with the greatest confidence sum is chosen as the final prediction. The confidence for the final prediction is the confidence sum for that value divided by the number of rules that fired for that record.

- **First hit.** This method simply tests the rules in order, and the first rule that applies to the record is the one used to generate the prediction.

The method used can be controlled in the stream options.

Generating nodes. The Generate menu enables you to create new nodes based on the rule set.

- Filter Node Creates a new Filter node to filter fields that are not used by rules in the rule set.
- Select Node Creates a new Select node to select records to which the selected rule applies. The generated node will select records for which all antecedents of the rule are true. This option requires a rule to be selected.
- Rule Trace Node Creates a new SuperNode that will compute a field indicating which rule was used to make the prediction for each record. When a rule set is evaluated using the first hit method, this is simply a symbol indicating the first rule that would fire. When the rule set is evaluated using the voting method, this is a more complex string showing the input to the voting mechanism.
- Single Decision Tree (Canvas) / Single Decision Tree (GM Palette). Creates a new single Rule Set nugget derived from the currently selected rule. Available only for **boosted** C5.0 models. See the topic [Boosted C5.0 Models](#) for more information.
- Model to Palette Returns the model to the models palette. This is useful in situations where a colleague may have sent you a stream containing the model and not the model itself.

Note: The Settings and Summary tabs in the Rule Set nugget are identical to those for decision tree models.

Rule Set Model Tab

The Model tab for a Rule Set nugget displays a list of rules extracted from the data by the algorithm.

Rules are broken down by consequent (predicted category) and are presented in the following format:

```
if antecedent_1  
and antecedent_2  
...  
and antecedent_n  
then predicted value
```

where **consequent** and **antecedent_1** through **antecedent_n** are all conditions. The rule is interpreted as "for records where **antecedent_1** through **antecedent_n** are all true, **consequent** is also likely to be true." If you click the Show Instances/Confidence button on the toolbar, each rule will also show information on the number of records to which the rule applies--that is, for which the antecedents are true (**Instances**) and the proportion of those records for which the entire rule is true (**Confidence**).

Note that confidence is calculated somewhat differently for C5.0 rule sets. C5.0 uses the following formula for calculating the confidence of a rule:

```
(1 + number of records where rule is correct)  
/  
(2 + number of records for which the rule's antecedents are true)
```

This calculation of the confidence estimate adjusts for the process of generalizing rules from a decision tree (which is what C5.0 does when it creates a rule set).

Bayesian Network Models

- [Bayesian Network Node](#)
- [Bayesian Network Model Nuggets](#)

Bayesian Network Node

The **Bayesian Network** node enables you to build a probability model by combining observed and recorded evidence with "common-sense" real-world knowledge to establish the likelihood of occurrences by using seemingly unlinked attributes. The node focuses on Tree Augmented Naïve Bayes (TAN) and Markov Blanket networks that are primarily used for classification.

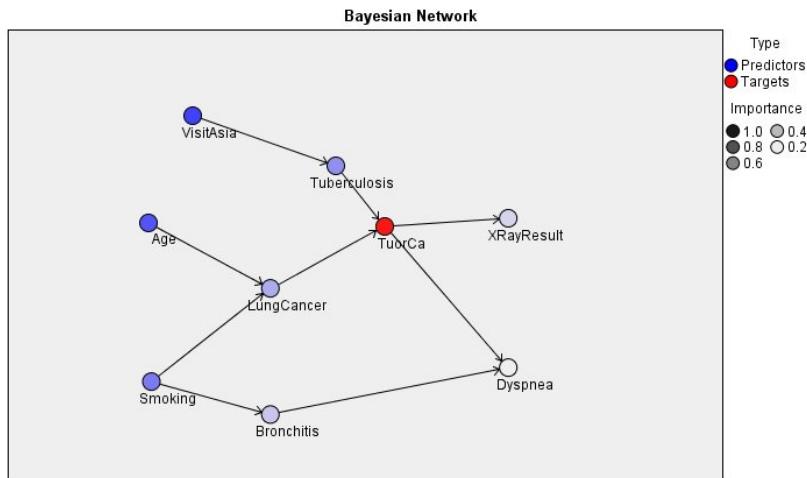

Bayesian networks are used for making predictions in many varied situations; some examples are:

- Selecting loan opportunities with low default risk.
- Estimating when equipment will need service, parts, or replacement, based on sensor input and existing records.
- Resolving customer problems via online troubleshooting tools.
- Diagnosing and troubleshooting cellular telephone networks in real-time.
- Assessing the potential risks and rewards of research-and-development projects in order to focus resources on the best opportunities.

A Bayesian network is a graphical model that displays variables (often referred to as **nodes**) in a dataset and the probabilistic, or conditional, independencies between them. Causal relationships between nodes may be represented by a Bayesian network; however, the links in the network (also known as **arcs**) do not necessarily represent direct cause and effect. For example, a Bayesian network can be used to calculate the probability of a patient having a specific disease, given the presence or absence of certain symptoms and other relevant data, if the probabilistic independencies between symptoms and disease as displayed on the graph hold true. Networks are very robust where information is missing and make the best possible prediction using whatever information is present.

A common, basic, example of a Bayesian network was created by Lauritzen and Spiegelhalter (1988). It is often referred to as the "Asia" model and is a simplified version of a network that may be used to diagnose a doctor's new patients; the direction of the links roughly corresponding to causality. Each node represents a facet that may relate to the patient's condition; for example, "Smoking" indicates that they are a confirmed smoker, and "VisitAsia" shows if they recently visited Asia. Probability relationships are shown by the links between any nodes; for example, smoking increases the chances of the patient developing both bronchitis and lung cancer, whereas age only seems to be associated with the possibility of developing lung cancer. In the same way, abnormalities on an x-ray of the lungs may be caused by either tuberculosis or lung cancer, while the chances of a patient suffering from shortness of breath (dyspnea) are increased if they also suffer from either bronchitis or lung cancer.

Figure 1. Lauritzen and Spiegelhalter's Asia network example

There are several reasons why you might decide to use a Bayesian network:

- It helps you learn about causal relationships. From this, it enables you to understand a problem area and to predict the consequences of any intervention.
- The network provides an efficient approach for avoiding the overfitting of data.
- A clear visualization of the relationships involved is easily observed.

Requirements. Target fields must be categorical and can have a measurement level of *Nominal*, *Ordinal*, or *Flag*. Inputs can be fields of any type. Continuous (numeric range) input fields will be automatically binned; however, if the distribution is skewed, you may obtain better results by manually binning the fields using a Binning node before the Bayesian Network node. For example, use Optimal Binning where the Supervisor field is the same as the Bayesian Network node Target field.

Example. An analyst for a bank wants to be able to predict customers, or potential customers, who are likely to default on their loan repayments. You can use a Bayesian network model to identify the characteristics of customers most likely to default, and build several different types of model to establish which is the best at predicting potential defaulters.

Example. A telecommunications operator wants to reduce the number of customers who leave the business (known as "churn"), and update the model on a monthly basis using each preceding month's data. You can use a Bayesian network model to identify the characteristics of customers most likely to churn, and continue training the model each month with the new data.

Bayesian Network Node Model Options

Model name. You can generate the model name automatically based on the target or ID field (or model type in cases where no such field is specified) or specify a custom name.

Use partitioned data. If a partition field is defined, this option ensures that data from only the training partition is used to build the model.

Build model for each split. Builds a separate model for each possible value of input fields that are specified as split fields. See the topic [Building Split Models](#) for more information.

Partition. This field enables you to specify a field used to partition the data into separate samples for the training, testing, and validation stages of model building. By using one sample to generate the model and a different sample to test it, you can get a good indication of how well the model will generalize to larger datasets that are similar to the current data. If multiple partition fields have been defined by using Type or Partition nodes, a single partition field must be selected on the Fields tab in each modeling node that uses partitioning. (If only one partition is present, it is automatically used whenever partitioning is enabled.) Also note that to apply the selected partition in your analysis, partitioning must also be enabled in the Model Options tab for the node. (Deselecting this option makes it possible to disable partitioning without changing field settings.)

Splits. For split models, select the split field or fields. This is similar to setting the field role to *Split* in a Type node. You can designate only fields with a measurement level of Flag, Nominal, Ordinal or Continuous as split fields. Fields chosen as split fields cannot be used as target, input, partition, frequency or weight fields. See the topic [Building Split Models](#) for more information.

Continue training existing model. If you select this option, the results shown on the model nugget Model tab are regenerated and updated each time the model is run. For example, you would do this when you have added a new or updated data source to an existing model.

Note: This can only update the existing network; it cannot add or remove nodes or connections. Each time you retrain the model the network will be the same shape, only the conditional probabilities and predictor importance will change. If your new data are broadly similar to your old data then this does not matter since you expect the same things to be significant; however, if you want to check or update *what* is significant (as opposed to how significant it is), you will need to build a new model, that is, build a new network

Structure type. Select the structure to be used when building the Bayesian network:

- **TAN.** The Tree Augmented Naïve Bayes model (TAN) creates a simple Bayesian network model that is an improvement over the standard Naïve Bayes model. This is because it allows each predictor to depend on another predictor in addition to the target variable, thereby increasing the classification accuracy.
- **Markov Blanket.** This selects the set of nodes in the dataset that contain the target variable's parents, its children, and its children's parents. Essentially, a Markov blanket identifies all the variables in the network that are needed to predict the target variable. This method of building a network is considered to be more accurate; however, with large datasets there maybe a processing time-penalty due to the high number of variables involved. To reduce the amount of processing, you can use the Feature Selection options on the Expert tab to select the variables that are significantly related to the target variable.

Include feature selection preprocessing step. Selecting this box enables you to use the Feature Selection options on the Expert tab.

Parameter learning method. Bayesian network parameters refer to the conditional probabilities for each node given the values of its parents. There are two possible selections that you can use to control the task of estimating the conditional probability tables between nodes where the values of the parents are known:

- **Maximum likelihood.** Select this box when using a large dataset. This is the default selection.
- **Bayes adjustment for small cell counts.** For smaller datasets there is a danger of overfitting the model, as well as the possibility of a high number of zero-counts. Select this option to alleviate these problems by applying smoothing to reduce the effect of any zero-counts and any unreliable estimate effects.

Bayesian Network Node Expert Options

The node expert options enable you to fine-tune the model-building process. To access the expert options, set Mode to Expert on the Expert tab.

Missing values. By default, IBM® SPSS® Modeler only uses records that have valid values for all fields used in the model. (This is sometimes called **listwise deletion** of missing values.) If you have a lot of missing data, you may find that this approach eliminates too many records, leaving you without enough data to generate a good model. In such cases, you can deselect the Use only complete records option. IBM SPSS Modeler then attempts to use as much information as possible to estimate the model, including records where some of the fields have missing values. (This is sometimes called **pairwise deletion** of missing values.) However, in some situations, using incomplete records in this manner can lead to computational problems in estimating the model.

Append all probabilities. Specifies whether probabilities for each category of the output field are added to each record processed by the node. If this option is not selected, the probability of only the predicted category is added.

Independence test. A test of independence assesses whether paired observations on two variables are independent of each other. Select the type of test to be used, available options are:

- Likelihood ratio. Tests for target-predictor independence by calculating a ratio between the maximum probability of a result under two different hypotheses.
- Pearson chi-square. Tests for target-predictor independence by using a null hypothesis that the relative frequencies of occurrence of observed events follow a specified frequency distribution.

Bayesian network models conduct conditional tests of independence where additional variables are used beyond the tested pairs. In addition, the models explore not only the relations between the target and predictors, but also the relations among the predictors themselves.

Note: The Independence test options are only available if you select either Include feature selection preprocessing step or a Structure type of Markov Blanket on the Model tab.

Significance level. Used in conjunction with the Independence test settings, this enables you to set a cut-off value to be used when conducting the tests. The lower the value, the fewer links remain in the network; the default level is 0.01.

Note: This option is only available if you select either Include feature selection preprocessing step or a Structure type of Markov Blanket on the Model tab.

Maximal conditioning set size. The algorithm for creating a Markov Blanket structure uses conditioning sets of increasing size to carry out independence testing and remove unnecessary links from the network. Because tests involving a high number of conditioning variables require more time and memory for processing you can limit the number of variables to be included. This can be especially useful when processing data with strong dependencies among many variables. Note however that the resulting network may contain some superfluous links.

Specify the maximal number of conditioning variables to be used for independence testing. The default setting is 5.

Note: This option is only available if you select either Include feature selection preprocessing step or a Structure type of Markov Blanket on the Model tab.

Feature selection. These options enable you to restrict the number of inputs used when processing the model in order to speed up the model building process. This is especially useful when creating a Markov Blanket structure due to the possible large number of potential inputs; it enables you to select the inputs that are significantly related to the target variable.

Note: The feature selection options are only available if you select Include feature selection preprocessing step on the Model tab.

- **Inputs always selected.** Using the Field Chooser (button to the right of the text field), select the fields from the dataset that are always to be used when building the Bayesian network model. The target field is always selected. Note that the Bayesian network may still drop the items from this list during the model building process if other tests do not consider it significant. So this option simply ensures that the items in the list are used in the model building process itself, not that they will absolutely appear in the resulting Bayesian model.

- Maximum number of inputs. Specify the total number of inputs from the dataset to be used when building the Bayesian network model. The highest number you can enter is the total number of inputs in the dataset.
Note: If the number of fields selected in Inputs always selected exceeds the value of Maximum number of inputs, an error message is displayed.

Bayesian Network Model Nuggets

Note: If you select Continue training existing parameters on the modeling node Model tab, the information that is shown on the model nugget Model tab is updated each time that you regenerate the model.

The model nugget Model tab is split into two panes.

Left Pane

This view contains a network graph of nodes that displays the relationship between the target and its most important predictors, and the relationship between the predictors. The importance of each predictor is shown by the density of its color; a strong color shows an important predictor, and vice versa.

The bin values for nodes that represent a range are displayed in a tooltip when you hover the mouse pointer over the node.

You can use the graph tools in IBM® SPSS® Modeler to interact, edit, and save the graph. For example, for use in other applications such as MS Word.

Tip: If the network contains many nodes, you can click to select a node and drag it to make the graph more legible.

Distribution This view displays the conditional probabilities for each node in the network as a mini graph. Hover the mouse pointer over a graph to display its values in a tooltip.

Right Pane

Predictor Importance This displays a chart that indicates the relative importance of each predictor in estimating the model. For more information, see [Predictor Importance](#).

Conditional Probabilities When you select a node or mini distribution graph in the left pane the associated conditional probabilities table is displayed in the right pane. This table contains the conditional probability value for each node value and each combination of values in its parent nodes. In addition, it includes the number of records that are observed for each record value and each combination of values in the parent nodes.

Bayesian Network Model Settings

The Settings tab for a Bayesian Network model nugget specifies options for modifying the built model. For example, you may use the Bayesian Network node to build several different models using the same data and settings, then use this tab in each model to slightly modify the settings to see how that affects the results.

Note: This tab is only available after the model nugget has been added to a stream.

Calculate raw propensity scores. For models with a flag target (which return a yes or no prediction), you can request propensity scores that indicate the likelihood of the true outcome specified for the target field. These are in addition to other prediction and confidence values that may be generated during scoring.

Calculate adjusted propensity scores. Raw propensity scores are based only on the training data and may be overly optimistic due to the tendency of many models to overfit this data. Adjusted propensities attempt to compensate by evaluating model performance against a test or validation partition. This option requires that a partition field be defined in the stream and adjusted propensity scores be enabled in the modeling node before generating the model.

Append all probabilities Specifies whether probabilities for each category of the output field are added to each record processed by the node. If this option is not selected, the probability of only the predicted category is added.

The default setting of this check box is determined by the corresponding check box on the Expert tab of the modeling node. See the topic [Bayesian Network Node Expert Options](#) for more information.

Generate SQL for this model When using data from a database, SQL code can be pushed back to the database for execution, providing superior performance for many operations.

Select one of the following options to specify how SQL generation is performed.

- Default: Score using Server Scoring Adapter (if installed) otherwise in process If connected to a database with a scoring adapter installed, generates SQL using the scoring adapter and associated user defined functions (UDF) and scores your model within the database. When no scoring adapter is available, this option fetches your data back from the database and scores it in SPSS® Modeler.
- Score outside of the Database If selected, this option fetches your data back from the database and scores it in SPSS Modeler.

Bayesian Network Model Summary

The Summary tab of a model nugget displays information about the model itself (*Analysis*), fields used in the model (*Fields*), settings used when building the model (*Build Settings*), and model training (*Training Summary*).

When you first browse the node, the Summary tab results are collapsed. To see the results of interest, use the expander control to the left of an item to unfold it or click the Expand All button to show all results. To hide the results when you have finished viewing them, use the expander control to collapse the specific results that you want to hide or click the Collapse All button to collapse all results.

Analysis. Displays information about the specific model.

Fields. Lists the fields used as the target and the inputs in building the model.

Build Settings. Contains information about the settings used in building the model.

Training Summary. Shows the type of model, the stream used to create it, the user who created it, when it was built, and the elapsed time for building the model.

Neural networks

A **neural network** can approximate a wide range of predictive models with minimal demands on model structure and assumption. The form of the relationships is determined during the learning process. If a linear relationship between the target and predictors is appropriate, the results

of the neural network should closely approximate those of a traditional linear model. If a nonlinear relationship is more appropriate, the neural network will automatically approximate the "correct" model structure.

The trade-off for this flexibility is that the neural network is not easily interpretable. If you are trying to explain an underlying process that produces the relationships between the target and predictors, it would be better to use a more traditional statistical model. However, if model interpretability is not important, you can obtain good predictions using a neural network.

Figure 1. Fields tab

Field requirements. There must be at least one Target and one Input. Fields set to Both or None are ignored. There are no measurement level restrictions on targets or predictors (inputs). See [Modeling Node Fields Options](#) for more information.

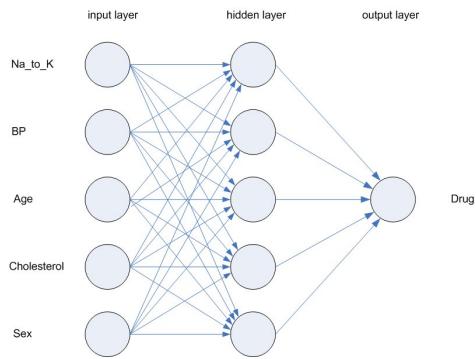

The initial weights assigned to neural networks during model building, and therefore the final models produced, depend on the order of the fields in the data. SPSS® Modeler automatically sorts data by field name before presenting it to the neural network for training. This means that explicitly changing the order of the fields in the data upstream will not affect the generated neural net models when a random seed is set in the model builder. However, changing the input field names in a way that changes their sort order will produce different neural network models, even with a random seed set in the model builder. The model quality will not be affected significantly given different sort order of field names.

The neural networks model

Neural networks are simple models of the way the nervous system operates. The basic units are **neurons**, which are typically organized into **layers**, as shown in the following figure.

Figure 1. Structure of a neural network

A **neural network** is a simplified model of the way the human brain processes information. It works by simulating a large number of interconnected processing units that resemble abstract versions of neurons.

The processing units are arranged in layers. There are typically three parts in a neural network: an **input layer**, with units representing the input fields; one or more **hidden layers**; and an **output layer**, with a unit or units representing the target field(s). The units are connected with varying connection strengths (or **weights**). Input data are presented to the first layer, and values are propagated from each neuron to every neuron in the next layer. Eventually, a result is delivered from the output layer.

The network learns by examining individual records, generating a prediction for each record, and making adjustments to the weights whenever it makes an incorrect prediction. This process is repeated many times, and the network continues to improve its predictions until one or more of the stopping criteria have been met.

Initially, all weights are random, and the answers that come out of the net are probably nonsensical. The network learns through **training**. Examples for which the output is known are repeatedly presented to the network, and the answers it gives are compared to the known outcomes. Information from this comparison is passed back through the network, gradually changing the weights. As training progresses, the network becomes increasingly accurate in replicating the known outcomes. Once trained, the network can be applied to future cases where the outcome is unknown.

Using neural networks with legacy streams

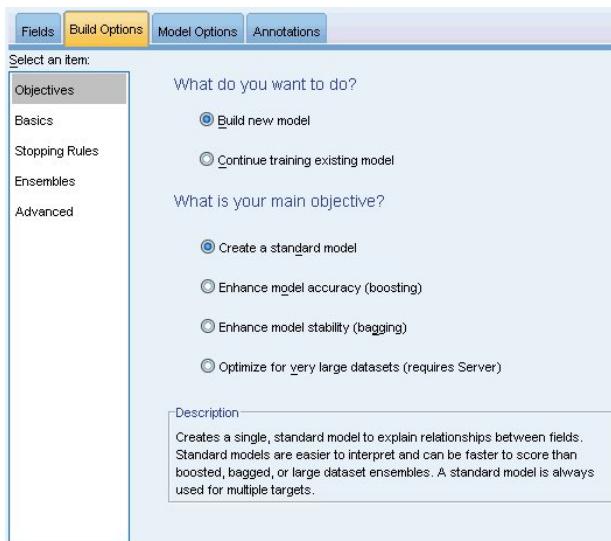

Version 14 of IBM® SPSS® Modeler introduced a new Neural Net node, supporting boosting and bagging techniques and optimization for very large datasets. Existing streams containing the old node may still build and score models in later releases. However, this support will be removed in a future release, so we recommend using the new version.

From version 13 onwards, fields with unknown values (that is, values not present in the training data) are no longer automatically treated as missing values, and are scored with the value `$null$`. Thus if you want to score fields with unknown values as non-null using an older (pre-13) Neural Net model in version 13 or later, you should mark unknown values as missing values (for example, by means of the Type node).

Note that, for compatibility, any legacy streams that still contain the old node may still be using the *Limit set size* option from Tools > Stream Properties > Options; this option only applies to Kohonen nets and K-Means nodes from version 14 onwards.

Objectives (neural networks)

Figure 1. Objectives settings

What do you want to do?

- Build a new model. Build a completely new model. This is the usual operation of the node.
 - Continue training an existing model. Training continues with the last model successfully produced by the node. This makes it possible to update or refresh an existing model without having to access the original data and may result in significantly faster performance since only the new or updated records are fed into the stream. Details on the previous model are stored with the modeling node, making it possible to use this option even if the previous model nugget is no longer available in the stream or Models palette.
- Note: When this option is enabled, all other controls on the Fields and Build Options tabs are disabled.

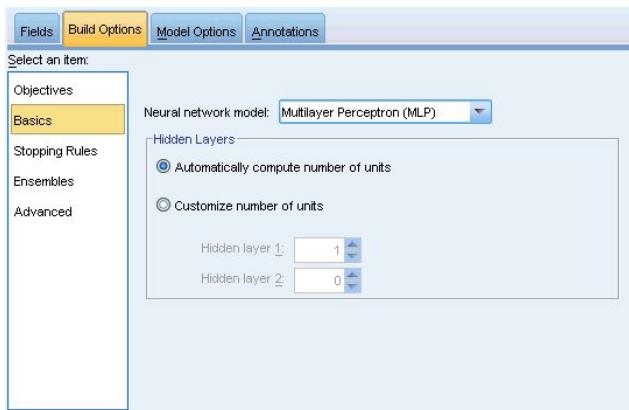

What is your main objective? Select the appropriate objective.

- Create a standard model. The method builds a single model to predict the target using the predictors. Generally speaking, standard models are easier to interpret and can be faster to score than boosted, bagged, or large dataset ensembles.
Note: Continue training existing model is only supported with Build a single tree split models, and you must be connected to Analytic Server.
- Enhance model accuracy (boosting). The method builds an ensemble model using boosting, which generates a sequence of models to obtain more accurate predictions. Ensembles can take longer to build and to score than a standard model.
Boosting produces a succession of "component models", each of which is built on the entire dataset. Prior to building each successive component model, the records are weighted based on the previous component model's residuals. Cases with large residuals are given relatively higher analysis weights so that the next component model will focus on predicting these records well. Together these component models form an ensemble model. The ensemble model scores new records using a combining rule; the available rules depend upon the measurement level of the target.
- Enhance model stability (bagging). The method builds an ensemble model using bagging (bootstrap aggregating), which generates multiple models to obtain more reliable predictions. Ensembles can take longer to build and to score than a standard model.
Bootstrap aggregation (bagging) produces replicates of the training dataset by sampling with replacement from the original dataset. This creates bootstrap samples of equal size to the original dataset. Then a "component model" is built on each replicate. Together these component models form an ensemble model. The ensemble model scores new records using a combining rule; the available rules depend upon the measurement level of the target.
- Create a model for very large datasets. The method builds an ensemble model by splitting the dataset into separate data blocks. Choose this option if your dataset is too large to build any of the models above, or for incremental model building. This option can take less time to build, but can take longer to score than a standard model.

When there are multiple targets, this method will only create a standard model, regardless of the selected objective.

Basics (neural networks)

Figure 1. Basics settings

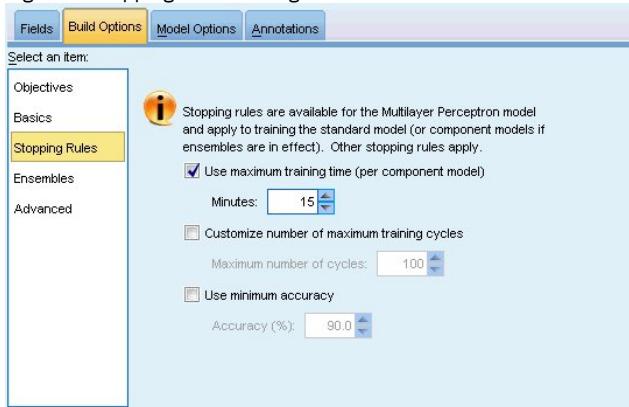

Neural network model. The type of model determines how the network connects the predictors to the targets through the hidden layer(s). The **multilayer perceptron (MLP)** allows for more complex relationships at the possible cost of increasing the training and scoring time. The **radial basis function (RBF)** may have lower training and scoring times, at the possible cost of reduced predictive power compared to the MLP.

Hidden Layers. The hidden layer(s) of a neural network contains unobservable units. The value of each hidden unit is some function of the predictors; the exact form of the function depends in part upon the network type. A multilayer perceptron can have one or two hidden layers; a radial basis function network can have one hidden layer.

- Automatically compute number of units. This option builds a network with one hidden layer and computes the "best" number of units in the hidden layer.
 - Customize number of units. This option allows you to specify the number of units in each hidden layer. The first hidden layer must have at least one unit. Specifying 0 units for the second hidden layer builds a multilayer perceptron with a single hidden layer.
- Note: You should choose values so that the number of nodes does not exceed the number of continuous predictors plus the total number of categories across all categorical (flag, nominal, and ordinal) predictors.

Stopping rules (neural networks)

Figure 1. Stopping Rules settings

These are the rules that determine when to stop training multilayer perceptron networks; these settings are ignored when the radial basis function algorithm is used. Training proceeds through at least one cycle (data pass), and can then be stopped according to the following criteria.

Use maximum training time (per component model). Choose whether to specify a maximum number of minutes for the algorithm to run. Specify a number greater than 0. When an ensemble model is built, this is the training time allowed for each component model of the ensemble. Note that training may go a bit beyond the specified time limit in order to complete the current cycle.

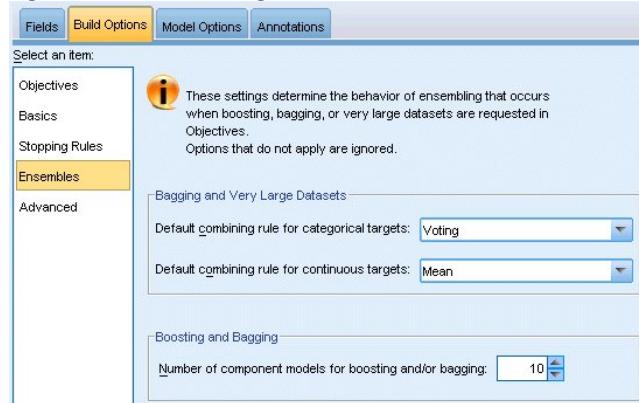

Customize number of maximum training cycles. The maximum number of training cycles allowed. If the maximum number of cycles is exceeded, then training stops. Specify an integer greater than 0.

Use minimum accuracy. With this option, training will continue until the specified accuracy is attained. This may never happen, but you can interrupt training at any point and save the net with the best accuracy achieved so far.

The training algorithm will also stop if the error in the overfit prevention set does not decrease after each cycle, if the relative change in the training error is small, or if the ratio of the current training error is small compared to the initial error.

Ensembles (neural networks)

Figure 1. Ensembles settings

These settings determine the behavior of ensembling that occurs when boosting, bagging, or very large datasets are requested in Objectives. Options that do not apply to the selected objective are ignored.

Bagging and Very Large Datasets. When scoring an ensemble, this is the rule used to combine the predicted values from the base models to compute the ensemble score value.

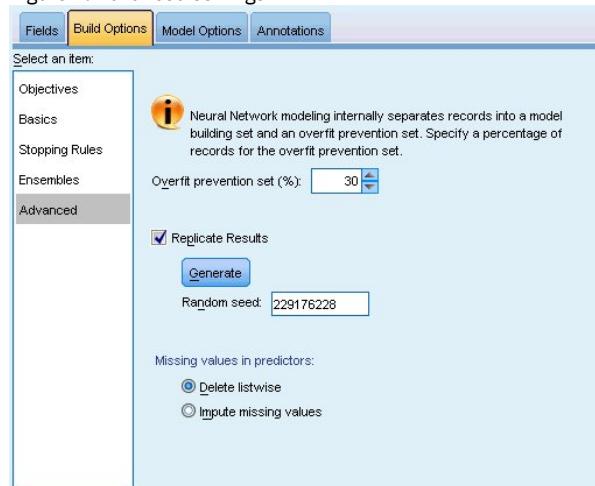

- Default combining rule for categorical targets. Ensemble predicted values for categorical targets can be combined using voting, highest probability, or highest mean probability. **Voting** selects the category that has the highest probability most often across the base models. **Highest probability** selects the category that achieves the single highest probability across all base models. **Highest mean probability** selects the category with the highest value when the category probabilities are averaged across base models.
- Default combining rule for continuous targets. Ensemble predicted values for continuous targets can be combined using the mean or median of the predicted values from the base models.

Note that when the objective is to enhance model accuracy, the combining rule selections are ignored. Boosting always uses a weighted majority vote to score categorical targets and a weighted median to score continuous targets.

Boosting and Bagging. Specify the number of base models to build when the objective is to enhance model accuracy or stability; for bagging, this is the number of bootstrap samples. It should be a positive integer.

Advanced (neural networks)

Figure 1. Advanced settings

Advanced settings provide control over options that do not fit neatly into other groups of settings.

Overfit prevention set. The neural network method internally separates records into a model building set and an overfit prevention set, which is an independent set of data records used to track errors during training in order to prevent the method from modeling chance variation in the data. Specify a percentage of records. The default is 30.

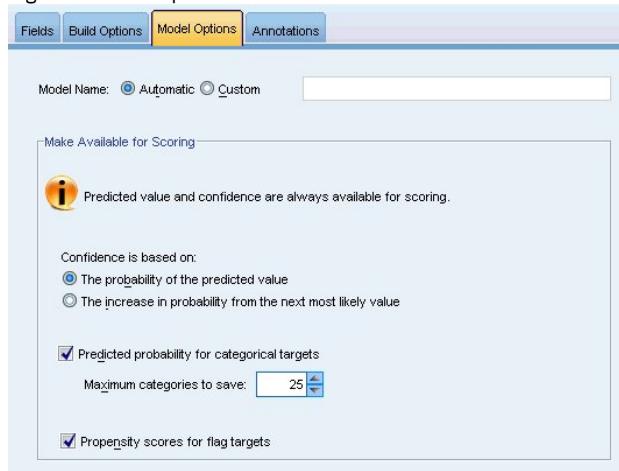

Replicate results. Setting a random seed allows you to replicate analyses. Specify an integer or click Generate, which will create a pseudo-random integer between 1 and 2147483647, inclusive. By default, analyses are replicated with seed 229176228.

Missing values in predictors. This specifies how to treat missing values. **Delete listwise** removes records with missing values on predictors from model building. **Impute missing values** will replace missing values in predictors and use those records in the analysis. Continuous fields impute

the average of the minimum and maximum observed values; categorical fields impute the most frequently occurring category. Note that records with missing values on any other field specified on the Fields tab are always removed from model building.

Model Options (neural networks)

Figure 1. Model Options tab

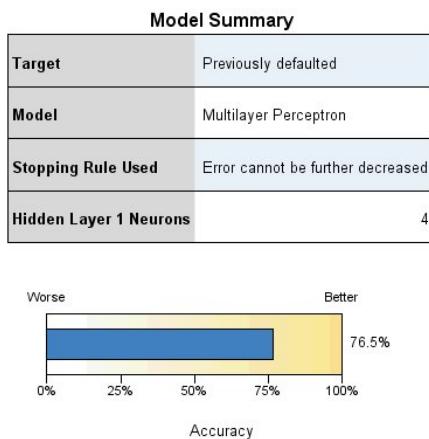

Model Name. You can generate the model name automatically based on the target fields or specify a custom name. The automatically generated name is the target field name. If there are multiple targets, then the model name is the field names in order, connected by ampersands. For example, if *field1* *field2* *field3* are targets, then the model name is: *field1 & field2 & field3*.

Make Available for Scoring. When the model is scored, the selected items in this group should be produced. The predicted value (for all targets) and confidence (for categorical targets) are always computed when the model is scored. The computed confidence can be based on the probability of the predicted value (the highest predicted probability) or the difference between the highest predicted probability and the second highest predicted probability.

- Predicted probability for categorical targets. This produces the predicted probabilities for categorical targets. A field is created for each category.
- Propensity scores for flag targets. For models with a flag target (which return a yes or no prediction), you can request propensity scores that indicate the likelihood of the true outcome specified for the target field. The model produces raw propensity scores; if partitions are in effect, the model also produces adjusted propensity scores based on the testing partition.

Model Summary (neural networks)

Figure 1. Neural Networks Model Summary view

The Model Summary view is a snapshot, at-a-glance summary of the neural network predictive or classification accuracy.

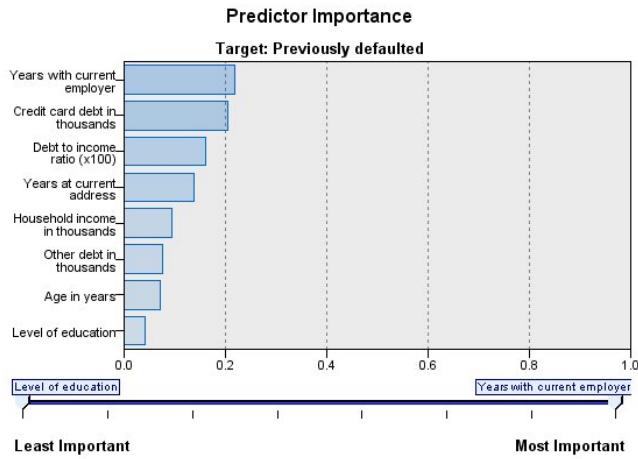

Model summary. The table identifies the target, the type of neural network trained, the stopping rule that stopped training (shown if a multilayer perceptron network was trained), and the number of neurons in each hidden layer of the network.

Neural Network Quality. The chart displays the accuracy of the final model, which is presented in larger is better format. For a categorical target, this is simply the percentage of records for which the predicted value matches the observed value. For a continuous target, the accuracy is given as the R² value.

Multiple targets. If there are multiple targets, then each target is displayed in the Target row of the table. The accuracy displayed in the chart is the average of the individual target accuracies.

Predictor Importance (neural networks)

Figure 1. Predictor Importance view

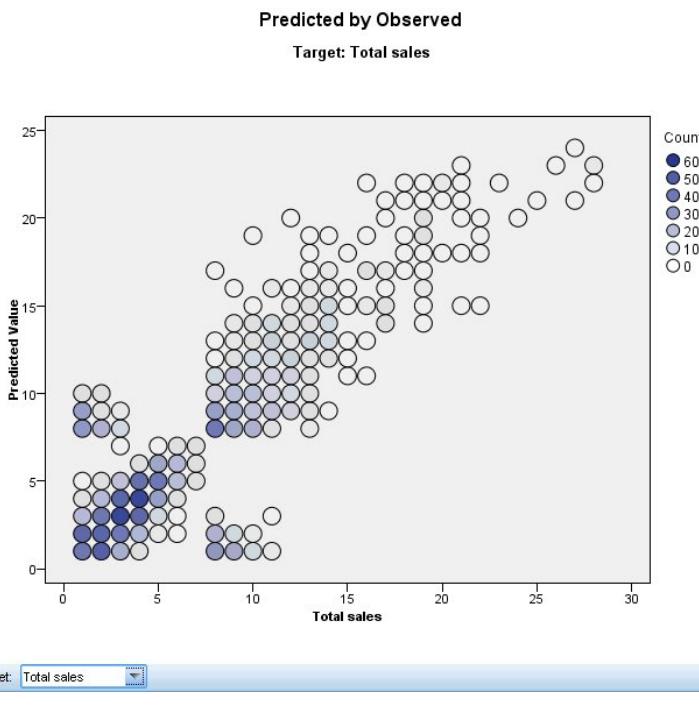

Typically, you will want to focus your modeling efforts on the predictor fields that matter most and consider dropping or ignoring those that matter least. The predictor importance chart helps you do this by indicating the relative importance of each predictor in estimating the model. Since the values are relative, the sum of the values for all predictors on the display is 1.0. Predictor importance does not relate to model accuracy. It just relates to the importance of each predictor in making a prediction, not whether or not the prediction is accurate.

Multiple targets. If there are multiple targets, then each target is displayed in a separate chart and there is a Target drop-down that controls which target to display.

Predicted By Observed (neural networks)

Figure 1. Predicted By Observed view

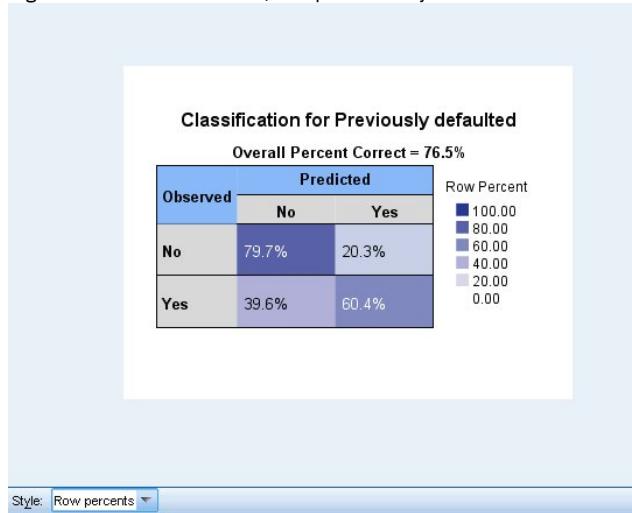

For continuous targets, this displays a binned scatterplot of the predicted values on the vertical axis by the observed values on the horizontal axis.

Multiple targets. If there are multiple continuous targets, then each target is displayed in a separate chart and there is a Target drop-down that controls which target to display.

Classification (neural networks)

Figure 1. Classification view, row percents style

For categorical targets, this displays the cross-classification of observed versus predicted values in a heat map, plus the overall percent correct.

Table styles. There are several different display styles, which are accessible from the Style dropdown list.

- Row percents. This displays the row percentages (the cell counts expressed as a percent of the row totals) in the cells. This is the default.
- Cell counts. This displays the cell counts in the cells. The shading for the heat map is still based on the row percentages.
- Heat map. This displays no values in the cells, just the shading.
- Compressed. This displays no row or column headings, or values in the cells. It can be useful when the target has a lot of categories.

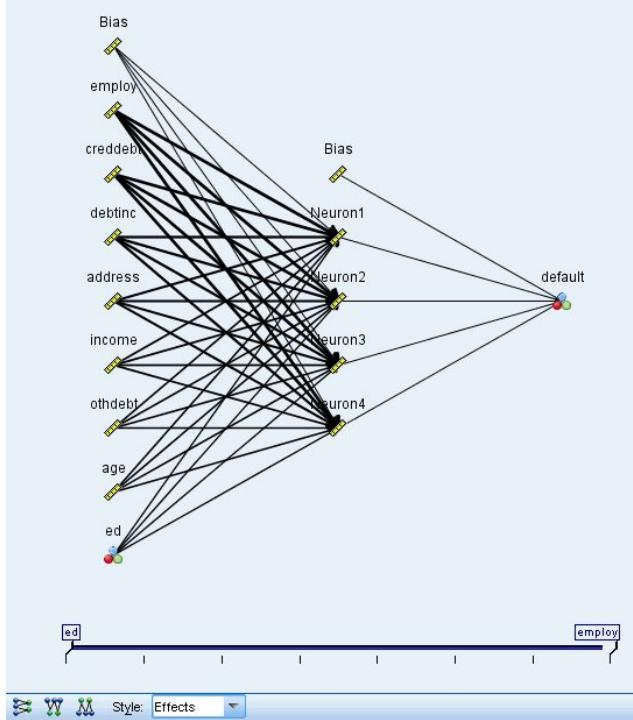

Missing. If any records have missing values on the target, they are displayed in a (Missing) row under all valid rows. Records with missing values do not contribute to the overall percent correct.

Multiple targets. If there are multiple categorical targets, then each target is displayed in a separate table and there is a Target dropdown list that controls which target to display.

Large tables. If the displayed target has more than 100 categories, no table is displayed.

Network (neural networks)

Figure 1. Network view, inputs on the left, effects style

This displays a graphical representation of the neural network.

Chart styles. There are two different display styles, which are accessible from the Style drop-down.

- Effects. This displays each predictor and target as one node in the diagram irrespective of whether the measurement scale is continuous or categorical. This is the default.
- Coefficients. This displays multiple indicator nodes for categorical predictors and targets. The connecting lines in the coefficients-style diagram are colored based on the estimated value of the synaptic weight.

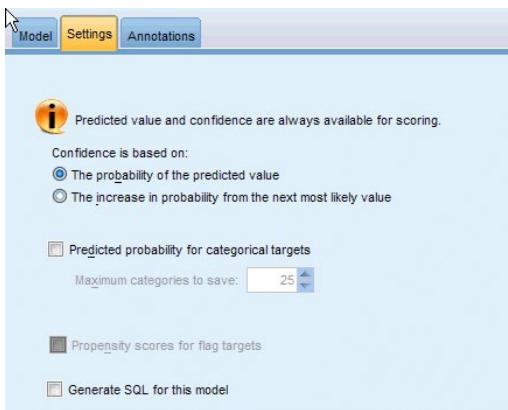

Diagram orientation. By default, the network diagram is arranged with the inputs on the left and the targets on the right. Using toolbar controls, you can change the orientation so that inputs are on top and targets on the bottom, or inputs on the bottom and targets on top.

Predictor importance. Connecting lines in the diagram are weighted based on predictor importance, with greater line width corresponding to greater importance. There is a Predictor Importance slider in the toolbar that controls which predictors are shown in the network diagram. This does not change the model, but simply allows you to focus on the most important predictors.

Multiple targets. If there are multiple targets, all targets are displayed in the chart.

Settings (neural networks)

Figure 1. Settings tab

When the model is scored, the selected items in this tab should be produced. The predicted value (for all targets) and confidence (for categorical targets) are always computed when the model is scored. The computed confidence can be based on the probability of the predicted value (the highest predicted probability) or the difference between the highest predicted probability and the second highest predicted probability.

- Predicted probability for categorical targets. This produces the predicted probabilities for categorical targets. A field is created for each category.
- Propensity scores for flag targets. For models with a flag target (which return a yes or no prediction), you can request propensity scores that indicate the likelihood of the true outcome specified for the target field. The model produces raw propensity scores; if partitions are in effect, the model also produces adjusted propensity scores based on the testing partition.

Generate SQL for this model When using data from a database, SQL code can be pushed back to the database for execution, providing superior performance for many operations.

Default: Score using Server Scoring Adapter (if installed) otherwise in process If connected to a database with a scoring adapter installed, generates SQL using the scoring adapter and associated user defined functions (UDF) and scores your model within the database. When no scoring adapter is available, this option fetches your data back from the database and scores it in SPSS® Modeler.

Score by converting to native SQL If selected, generates native SQL to score the model within the database.

Note: Although this option can provide quicker results, the size and complexity of the native SQL increases as the complexity of the model increases.

Score outside of the Database If selected, this option fetches your data back from the database and scores it in SPSS Modeler.

Decision List

Decision List models identify subgroups or **segments** that show a higher or lower likelihood of a binary (yes or no) outcome relative to the overall sample. For example, you might look for customers who are least likely to churn or most likely to say yes to a particular offer or campaign. The Decision List Viewer gives you complete control over the model, enabling you to edit segments, add your own business rules, specify how each segment is scored, and customize the model in a number of other ways to optimize the proportion of hits across all segments. As such, it is particularly well-suited for generating mailing lists or otherwise identifying which records to target for a particular campaign. You can also use multiple **mining tasks** to combine modeling approaches—for example, by identifying high- and low-performing segments within the same model and including or excluding each in the scoring stage as appropriate.

Segments, Rules, and Conditions

A model consists of a list of segments, each of which is defined by a rule that selects matching records. A given rule may have multiple conditions; for example:

```
RFM_SCORE > 10 and
MONTHS_CURRENT <= 9
```

Rules are applied in the order listed, with the first matching rule determining the outcome for a given record. Taken independently, rules or conditions may overlap, but the order of rules resolves ambiguity. If no rule matches, the record is assigned to the remainder rule.

Complete Control over Scoring

The Decision List Viewer enables you to view, modify, and reorganize segments and to choose which to include or exclude for purposes of scoring. For example, you can choose to exclude one group of customers from future offers and include others and immediately see how this affects your overall hit rate. Decision List models return a score of Yes for included segments and \$null\$ for everything else, including the remainder. This direct control over scoring makes Decision List models ideal for generating mailing lists, and they are widely used in customer relationship management, including call center or marketing applications.

Mining Tasks, Measures, and Selections

The modeling process is driven by **mining tasks**. Each mining task effectively initiates a new modeling run and returns a new set of alternative models to choose from. The default task is based on your initial specifications in the Decision List node, but you can define any number of custom tasks. You can also apply tasks iteratively—for example, you can run a high probability search on the entire training set and then run a low probability search on the remainder to weed out low-performing segments.

Data Selections

You can define data selections and custom model measures for model building and evaluation. For example, you can specify a data selection in a mining task to tailor the model to a specific region and create a custom measure to evaluate how well that model performs on the whole country. Unlike mining tasks, measures don't change the underlying model but provide another lens to assess how well it performs.

Adding Your Business Knowledge

By fine-tuning or extending the segments identified by the algorithm, the Decision List Viewer enables you to incorporate your business knowledge right into the model. You can edit the segments generated by the model or add additional segments based on rules that you specify. You can then apply the changes and preview the results.

For further insight, a dynamic link with Excel enables you to export your data to Excel, where it can be used to create presentation charts and to calculate custom measures, such as complex profit and ROI, which can be viewed in the Decision List Viewer while you are building the model.

Example. The marketing department of a financial institution wants to achieve more profitable results in future campaigns by matching the right offer to each customer. You can use a Decision List model to identify the characteristics of customers most likely to respond favorably based on previous promotions and to generate a mailing list based on the results.

Requirements. A single categorical target field with a measurement level of type *Flag* or *Nominal* that indicates the binary outcome you want to predict (yes/no), and at least one input field. When the target field type is *Nominal*, you must manually choose a single value to be treated as a **hit**, or **response**; all the other values are lumped together as **not hit**. An optional frequency field may also be specified. Continuous date/time fields are ignored. Continuous numeric range inputs are automatically binned by the algorithm as specified on the Expert tab in the modeling node. For finer control over binning, add an upstream binning node and use the binned field as input with a measurement level of *Ordinal*.

Decision List Model Options

Model name. You can generate the model name automatically based on the target or ID field (or model type in cases where no such field is specified) or specify a custom name.

Use partitioned data. If a partition field is defined, this option ensures that data from only the training partition is used to build the model.

Create split models. Builds a separate model for each possible value of input fields that are specified as split fields. See [Building Split Models](#) for more information.

Mode. Specifies the method used to build the model.

- **Generate model.** Automatically generates a model on the models palette when the node is executed. The resulting model can be added to streams for purposes of scoring but cannot be further edited.
- **Launch interactive session.** Opens the interactive Decision List Viewer modeling (output) window, enabling you to pick from multiple alternatives and repeatedly apply the algorithm with different settings to progressively grow or modify the model. See the topic [Decision List Viewer](#) for more information.
- **Use saved interactive session information.** Launches an interactive session using previously saved settings. Interactive settings can be saved from the Decision List Viewer using the Generate menu (to create a model or modeling node) or the File menu (to update the node from which the session was launched).

Target value. Specifies the value of the target field that indicates the outcome you want to model. For example, if the target field churn is coded 0 = **no** and 1 = **yes**, specify 1 to identify rules that indicate which records are likely to churn.

Find segments with. Indicates whether the search for the target variable should look for a High probability or Low probability of occurrence. Finding and excluding them can be a useful way to improve your model and can be particularly useful when the remainder has a low probability.

Maximum number of segments. Specifies the maximum number of segments to return. The top N segments are created, where the best segment is the one with the highest probability or, if more than one model has the same probability, the highest coverage. The minimum allowed setting is 1; there is no maximum setting.

Minimum segment size. The two settings below dictate the minimum segment size. The larger of the two values takes precedence. For example, if the percentage value equates to a number higher than the absolute value, the percentage setting takes precedence.

- **As percentage of previous segment (%)**. Specifies the minimum group size as a percentage of records. The minimum allowed setting is 0; the maximum allowed setting is 99.9.
- **As absolute value (N)**. Specifies the minimum group size as an absolute number of records. The minimum allowed setting is 1; there is no maximum setting.

Segment rules.

Maximum number of attributes. Specifies the maximum number of conditions per segment rule. The minimum allowed setting is 1; there is no maximum setting.

- **Allow attribute re-use.** When enabled, each cycle can consider all attributes, even those that have been used in previous cycles. The conditions for a segment are built up in cycles, where each cycle adds a new condition. The number of cycles is defined using the Maximum number of attributes setting.

Confidence interval for new conditions (%). Specifies the confidence level for testing segment significance. This setting plays a significant role in the number of segments (if any) that are returned as well as the number-of-conditions-per-segment rule. The higher the value, the smaller the returned result set. The minimum allowed setting is 50; the maximum allowed setting is 99.9.

-

Decision List Node Expert Options

Expert options enable you to fine-tune the model-building process.

Binning method. The method used for binning continuous fields (equal count or equal width).

Number of bins. The number of bins to create for continuous fields. The minimum allowed setting is 2; there is no maximum setting.

Model search width. The maximum number of model results per cycle that can be used for the next cycle. The minimum allowed setting is 1; there is no maximum setting.

Rule search width. The maximum number of rule results per cycle that can be used for the next cycle. The minimum allowed setting is 1; there is no maximum setting.

Bin merging factor. The minimum amount by which a segment must grow when merged with its neighbor. The minimum allowed setting is 1.01; there is no maximum setting.

- **Allow missing values in conditions.** `True` to allow the `IS MISSING` test in rules.
 - **Discard intermediate results.** When `True`, only the final results of the search process are returned. A final result is a result that is not refined any further in the search process. When `False`, intermediate results are also returned.
- Maximum number of alternatives.** Specifies the maximum number of alternatives that can be returned upon running the mining task. The minimum allowed setting is 1; there is no maximum setting.

Note that the mining task will only return the actual number of alternatives, up to the maximum specified. For example, if the maximum is set to 100 and only 3 alternatives are found, only those 3 are shown.

Decision List Model Nugget

A model consists of a list of **segments**, each of which is defined by a **rule** that selects matching records. You can easily view or modify the segments before generating the model and choose which ones to include or exclude. When used in scoring, Decision List models return Yes for included segments and \$null\$ for everything else, including the remainder. This direct control over scoring makes Decision List models ideal for generating mailing lists, and they are widely used in customer relationship management, including call center or marketing applications.

When you run a stream containing a Decision List model, the node adds three new fields containing the score, either 1 (meaning Yes) for included fields or \$null\$ for excluded fields, the probability (hit rate) for the segment within which the record falls, and the ID number for the segment. The names of the new fields are derived from the name of the output field being predicted, prefixed with \$D- for the score, \$DP- for the probability, and \$DI- for the segment ID.

The model is scored based on the target value specified when the model was built. You can manually exclude segments so that they score as \$null\$. For example, if you run a low probability search to find segments with lower than average hit rates, these “low” segments will be scored as Yes unless you manually exclude them. If necessary, nulls can be recoded as No using a Derive or Filler node.

PMMI

A Decision List model can be stored as a PMML RuleSetModel with a “first hit” selection criterion. However, all of the rules are expected to have the same score. To allow for changes to the target field or the target value, multiple rule set models can be stored in one file to be applied in order, cases not matched by the first model being passed to the second, and so on. The algorithm name *DecisionList* is used to indicate this non-standard behavior, and only rule set models with this name are recognized as Decision List models and scored as such.

Decision List Model Nugget Settings

The Settings tab for a Decision List model nugget enables you to obtain propensity scores and to enable or disable SQL optimization. This tab is available only after adding the model nugget to a stream.

Calculate raw propensity scores. For models with a flag target (which return a yes or no prediction), you can request propensity scores that indicate the likelihood of the true outcome specified for the target field. These are in addition to other prediction and confidence values that may be generated during scoring.

Calculate adjusted propensity scores. Raw propensity scores are based only on the training data and may be overly optimistic due to the tendency of many models to overfit this data. Adjusted propensities attempt to compensate by evaluating model performance against a test or validation partition. This option requires that a partition field be defined in the stream and adjusted propensity scores be enabled in the modeling node before generating the model.

Generate SQL for this model When using data from a database, SQL code can be pushed back to the database for execution, providing superior performance for many operations.

Select one of the following options to specify how SQL generation is performed.

- Default: Score using Server Scoring Adapter (if installed) otherwise in process If connected to a database with a scoring adapter installed, generates SQL using the scoring adapter and associated user defined functions (UDF) and scores your model within the database. When no scoring adapter is available, this option fetches your data back from the database and scores it in SPSS® Modeler.
- Score by converting to native SQL If selected, generates native SQL to score the model within the database.
Note: Although this option can provide quicker results, the size and complexity of the native SQL increases as the complexity of the model increases.
- Score outside of the Database If selected, this option fetches your data back from the database and scores it in SPSS Modeler.

Working Model Pane

The working model pane displays the current model, including mining tasks and other actions that apply to the working model.

ID. Identifies the sequential segment order. Model segments are calculated, in sequence, according to their ID number.

Segment Rules. Provides the segment name and defined segment conditions. By default, the segment name is the field name or concatenated field names used in the conditions, with a comma as a separator.

Score. Represents the field that you want to predict, whose value is assumed to be related to the values of other fields (the predictors).

Note: The following options can be toggled to display via the [Organizing Model Measures](#) dialog.

Cover. The pie chart visually identifies the coverage each segment has in relation to the entire cover.

Cover (n). Lists the coverage for each segment in relation to the entire cover.

Frequency. Lists the number of hits received in relation to the cover. For example, when the cover is 79 and the frequency is 50, that means that 50 out of 79 responded for the selected segment.

Probability. Indicates the segment probability. For example, when the cover is 79 and the frequency is 50, that means that the probability for the segment is 63.29% (50 divided by 79).

Error. Indicates the segment error.

The information at the bottom of the pane indicates the cover, frequency, and probability for the entire model.

Working Model Toolbar

The working model pane provides the following functions via a toolbar.

Note: Some functions are also available by right-clicking a model segment.

Table 1. Working model toolbar buttons

Toolbar Button	Description
	Launches the Generate New Model dialog, which provides options for creating a new model nugget.
	Saves the current state of the interactive session. The Decision List modeling node is updated with the current settings, including mining tasks, model snapshots, data selections, and custom measures. To restore a session to this state, check the Use saved session information box on the Model tab of the modeling node and click Run.
	Displays the Organize Model Measures dialog. See the topic Organizing Model Measures for more information.
	Displays the Organize Data Selections dialog. See the topic Organizing Data Selections for more information.
	Displays the Snapshots tab. See the topic Snapshots Tab for more information.
	Displays the Alternatives tab. See the topic Alternatives Tab for more information.
	Takes a snapshot of the current model structure. Snapshots display on the Snapshots tab and are commonly used for model comparison purposes.
	Launches the Inserting Segments dialog, which provides options for creating new model segments.
	Launches the Editing Segment Rules dialog, which provides options for adding conditions to model segments or changing previously defined model segment conditions.

	Moves the selected segment up in the model hierarchy.
	Moves the selected segment down in the model hierarchy.
	Deletes the selected segment.
	Toggles whether the selected segment is included in the model. When excluded, the segment results are added to the remainder. This differs from deleting a segment in that you have the option of reactivating the segment.

Related information

- [Decision List Viewer](#)
 - [Alternatives Tab](#)
 - [Snapshots Tab](#)
-

Alternatives Tab

Generated when you click Find Segments, the Alternatives tab lists all alternative mining results for the selected model or segment on the working model pane.

To promote an alternative to be the working model, highlight the required alternative and click Load; the alternative model is displayed in the working model pane.

Note: The Alternatives tab is only displayed if you have set Maximum number of alternatives on the Decision List modeling node Expert tab to create more than one alternative.

Each generated model alternative displays specific model information:

Name. Each alternative is sequentially numbered. The first alternative usually contains the best results.

Target. Indicates the target value. For example: 1, which equals "true".

No. of Segments. The number of segment rules used in the alternative model.

Cover. The coverage of the alternative model.

Freq. The number of hits in relation to the cover.

Prob. Indicates the probability percentage of the alternative model.

Note: Alternative results are not saved with the model; results are valid only during the active session.

Related information

- [Decision List Viewer](#)
 - [Working Model Pane](#)
 - [Snapshots Tab](#)
-

Snapshots Tab

A snapshot is a view of a model at a specific point in time. For example, you could take a model snapshot when you want to load a different alternative model into the working model pane but do not want to lose the work on the current model. The Snapshots tab lists all model snapshots manually taken for any number of working model states.

Note: Snapshots are saved with the model. We recommend that you take a snapshot when you load the first model. This snapshot will then preserve the original model structure, ensuring that you can always return to the original model state. The generated snapshot name displays as a timestamp, indicating when it was generated.

Create a Model Snapshot

1. Select an appropriate model/alternative to display in the working model pane.
2. Make any necessary changes to the working model.
3. Click Take Snapshot. A new snapshot is displayed on the Snapshots tab.

Name. The snapshot name. You can change a snapshot name by double-clicking the snapshot name.

Target. Indicates the target value. For example: 1, which equals "true".

No. of Segments. The number of segment rules used in the model.

Cover. The coverage of the model.

Freq. The number of hits in relation to the cover.

Prob. Indicates the probability percentage of the model.

4. To promote a snapshot to be the working model, highlight the required snapshot and click Load; the snapshot model is displayed in the working model pane.
5. You can delete a snapshot by clicking Delete or by right-clicking the snapshot and choosing Delete from the menu.

Working with Decision List Viewer

A model that will best predict customer response and behavior is built in various stages. When Decision List Viewer launches, the working model is populated with the defined model segments and measures, ready for you start a mining task, modify the segments/measures as required, and generate a new model or modeling node.

You can add one or more segment rules until you have developed a satisfactory model. You can add segment rules to the model by running mining tasks or by using the Edit Segment Rule function.

In the model building process, you can assess the performance of the model by validating the model against measure data, by visualizing the model in a chart, or by generating custom Excel measures.

When you feel certain about the model's quality, you can generate a new model and place it on the IBM® SPSS® Modeler canvas or Model palette.

Mining Tasks

A **mining task** is a collection of parameters that determines the way new rules are generated. Some of these parameters are selectable to provide you with the flexibility to adapt models to new situations. A task consists of a task template (type), a target, and a build selection (mining dataset).

The following sections detail the various mining task operations:

- [Running Mining Tasks](#)
- [Creating and Editing a Mining Task](#)
- [Organizing Data Selections](#)
- [Running Mining Tasks](#)

Running Mining Tasks

Decision List Viewer enables you to manually add segment rules to a model by running mining tasks or by copying and pasting segment rules between models. A mining task holds information on how to generate new segment rules (the data mining parameter settings, such as the search strategy, source attributes, search width, confidence level, and so on), the customer behavior to predict, and the data to investigate. The goal of a mining task is to search for the best possible segment rules.

To generate a model segment rule by running a mining task:

1. Click the Remainder row. If there are already segments displayed on the working model pane, you can also select one of the segments to find additional rules based on the selected segment. After selecting the remainder or segment, use one of the following methods to generate the model, or alternative models:
 - From the Tools menu, choose Find Segments.
 - Right-click the Remainder row/segment and choose Find Segments.
 - Click the Find Segments button on the working model pane.

While the task is processing, the progress is displayed at the bottom of the workspace and informs you when the task has completed. Precisely how long a task takes to complete depends on the complexity of the mining task and the size of the dataset. If there is only a single model in the results it is displayed on the working model pane as soon as the task completes; however, where the results contain more than one model they are displayed on the Alternatives tab.

Note: A task result will either complete with models, complete with no models, or fail.

The process of finding new segment rules can be repeated until no new rules are added to the model. This means that all significant groups of customers have been found.

It is possible to run a mining task on any existing model segment. If the result of a task is not what you are looking for, you can choose to start another mining task on the same segment. This will provide additional found rules based on the selected segment. Segments that are "below" the selected segment (that is, added to the model later than the selected segment) are replaced by the new segments because each segment depends on its predecessors.

Creating and Editing a Mining Task

A mining task is the mechanism that searches for the collection of rules that make up a data model. Alongside the search criteria defined in the selected template, a task also defines the target (the actual question that motivated the analysis, such as how many customers are likely to respond to a mailing), and it identifies the datasets to be used. The goal of a mining task is to search for the best possible models.

Create a mining task

To create a mining task:

1. Select the segment from which you want to mine additional segment conditions.
2. Click Settings. The Create/Edit Mining Task dialog opens. This dialog provides options for defining the mining task.
3. Make any necessary changes and click OK to return to the working model pane. Decision List Viewer uses the settings as the defaults to run for each task until an alternative task or settings is selected.
4. Click Find Segments to start the mining task on the selected segment.

Edit a mining task

The Create/Edit Mining Task dialog provides options for defining a new mining task or editing an existing one.

Most parameters available for mining tasks are similar to those offered in the Decision List node. The exceptions are shown below. See the topic [Decision List Model Options](#) for more information.

Load Settings: When you have created more than one mining task, select the required task.

New... Click to create a new mining task based on the settings of the task currently displayed.

See the topic [New Settings](#) for more information.

Target

Target Field: Represents the field that you want to predict, whose value is assumed to be related to the values of other fields (the predictors).

Target value. Specifies the value of the target field that indicates the outcome you want to model. For example, if the target field churn is coded **0 = no** and **1 = yes**, specify **1** to identify rules that indicate which records are likely to churn.

Simple Settings

Maximum number of alternatives. Specifies the number of alternatives that will be displayed upon running the mining task. The minimum allowed setting is **1**; there is no maximum setting.

Expert Settings

Edit... Opens the Edit Advanced Parameters dialog that enables you to define the advanced settings. See the topic [Edit Advanced Parameters](#) for more information.

Data

Build selection. Provides options for specifying the evaluation measure that Decision List Viewer should analyze to find new rules. The listed evaluation measures are created/edited in the Organize Data Selections dialog.

Available fields. Provides options for displaying all fields or manually selecting which fields to display.

Edit... If the Custom option is selected, this opens the Customize Available Fields dialog that enables you to select which fields are available as segment attributes found by the mining task. See the topic [Customize Available Fields](#) for more information.

Edit Advanced Parameters

The Edit Advanced Parameters dialog provides the following configuration options.

Binning method. The method used for binning continuous fields (equal count or equal width).

Number of bins. The number of bins to create for continuous fields. The minimum allowed setting is 2; there is no maximum setting.

Model search width. The maximum number of model results per cycle that can be used for the next cycle. The minimum allowed setting is 1; there is no maximum setting.

Rule search width. The maximum number of rule results per cycle that can be used for the next cycle. The minimum allowed setting is 1; there is no maximum setting.

Bin merging factor. The minimum amount by which a segment must grow when merged with its neighbor. The minimum allowed setting is 1.01; there is no maximum setting.

- **Allow missing values in conditions.** **True** to allow the `IS MISSING` test in rules.
 - **Discard intermediate results.** When **True**, only the final results of the search process are returned. A final result is a result that is not refined any further in the search process. When **False**, intermediate results are also returned.
-

Customize Available Fields

The Customize Available Fields dialog enables you to select which fields are available as segment attributes found by the mining task.

Available. Lists the fields that are currently available as segment attributes. To remove fields from the list, select the appropriate fields and click Remove >>. The selected fields move from the Available list to the Not Available list.

Not Available. Lists the fields that are not available as segment attributes. To include the fields in the available list, select the appropriate fields and click << Add. The selected fields move from the Not Available list to the Available list.

Organizing Data Selections

By organizing data selections (a mining dataset), you can specify which evaluation measures Decision List Viewer should analyze to find new rules and select which data selections are used as the basis for measures.

To organize data selections:

1. From the Tools menu, choose Organize Data Selections, or right-click a segment and choose the option. The Organize Data Selections dialog opens.
Note: The Organize Data Selections dialog also enables you to edit or delete existing data selections.
2. Click the Add new data selection button. A new data selection entry is added to the existing table.
3. Click Name and enter an appropriate selection name.
4. Click Partition and select an appropriate partition type.
5. Click Condition and select an appropriate condition option. When Specify is selected, the Specify Selection Condition dialog opens, providing options for defining specific field conditions.
6. Define the appropriate condition and click OK.

The data selections are available from the Build Selection drop-down list in the Create/Edit Mining Task dialog. The list enables you to select which evaluation measure is used for a particular mining task.

- [Specify Selection Condition](#)

Related information

 - [Creating and Editing a Mining Task](#)
 - [New Settings](#)
 - [Specify Selection Condition](#)
 - [Insert Value](#)
-

Specify Selection Condition

The Specify Selection Condition dialog provides options for defining selection conditions for data selection partitions. The conditions are used to select records from the defined partition. For example, the default condition for the **Training** partition is **All Records**. By specifying a selection condition for a new or existing data selection, you could filter **All Records** down into more concise results such as `married=yes`. When the data selection is used in a mining task, the result set will only return hits for individuals who are married.

Attribute – lists the available input fields.

Operator – the drop-down list provides all valid operators for the selected input field.

Values – queries values for the selected input field. For example the input field `married` would provide the options YES and NO.

Undo and Redo Actions

Decision List Viewer enables you to undo and redo the last 10 actions that you have performed. For example you can:

- Undo new model rules
- Undo changes you have made to a model
- Undelete elements of a model segment
- Redo selecting alternative models.

To undo or redo an action, from the Edit menu, choose either Undo or Redo.

Segment Rules

You find model segment rules by running a mining task based on a task template. You can manually add segment rules to a model using the Insert Segment or Edit Segment Rule functions.

If you choose to mine for new segment rules, the results, if any, are displayed on the Viewer tab of the Interactive List dialog. You can quickly refine your model by selecting one of the alternative results from the Model Albums dialog and clicking Load. In this way, you can experiment with differing results until you are ready to build a model that accurately describes your optimum target group.

Inserting Segments

You can manually add segment rules to a model using the Insert Segment function.

To add a segment rule condition to a model:

1. In the Interactive List dialog, select a location where you want to add a new segment. The new segment will be inserted directly above the selected segment.
2. From the Edit menu, choose Insert Segment, or access this selection by right-clicking a segment.
The Insert Segment dialog opens, enabling you to insert new segment rule conditions.
3. Click Insert. The Insert Condition dialog opens, enabling you to define the attributes for the new rule condition.
4. Select a field and an operator from the drop-down lists.
Note: If you select the Not in operator, the selected condition will function as an exclusion condition and displays in red in the Insert Rule dialog. For example, when the condition `region = 'TOWN'` displays in red, it means that `TOWN` is excluded from the result set.
5. Enter one or more values or click the Insert Value icon to display the Insert Value dialog. The dialog enables you to choose a value defined for the selected field. For example, the field married will provide the values yes and no.
6. Click OK to return to the Insert Segment dialog. Click OK a second time to add the created segment to the model.

The new segment will display in the specified model location.

Editing Segment Rules

The Edit Segment Rule functionality enables you to add, change, or delete segment rule conditions.

To change a segment rule condition:

1. Select the model segment that you want to edit.
2. From the Edit menu, choose Edit Segment Rule, or right-click on the rule to access this selection.
The Edit Segment Rule dialog opens.
3. Select the appropriate condition and click Edit.
The Edit Condition dialog opens, enabling you to define the attributes for the selected rule condition.
4. Select a field and an operator from the drop-down lists.
Note: If you select the Not in operator, the selected condition will function as an exclusion condition and displays in red in the Edit Segment Rule dialog. For example, when the condition `region = 'TOWN'` displays in red, it means that `TOWN` is excluded from the result set.
5. Enter one or more values or click the Insert Value button to display the Insert Value dialog. The dialog enables you to choose a value defined for the selected field. For example, the field married will provide the values yes and no.
6. Click OK to return to the Edit Segment Rule dialog. Click OK a second time to return to the working model.

The selected segment will display with the updated rule conditions.

Insert/Edit Condition

The Insert/Edit Condition dialog provides options for defining segment rule conditions.

Attribute – lists the available input fields.

Operator – the drop-down provides all valid operators for the selected input field.

Values – queries values for the selected input field. For example the input field married would provide the value options YES and NO.

Note: If you select the **Not in** operator, the selected condition will function as an exclusion condition and displays in red in the **Insert/Edit Segment** dialog. For example when the condition `region = 'TOWN'` displays is red it means that `TOWN` is excluded from the result set.

Related information

- [Editing Segment Rules](#)
 - [Deleting Segment Rule Conditions](#)
-

Deleting Segment Rule Conditions

To delete a segment rule condition:

1. Select the model segment containing the rule conditions that you want to delete.
2. From the Edit menu, choose Edit Segment Rule, or right-click on the segment to access this selection. The Edit Segment Rule dialog opens, enabling you to delete one or more segment rule conditions.
3. Select the appropriate rule condition and click Delete.
4. Click OK.

Deleting one or more segment rule conditions causes the working model pane to refresh its measure metrics.

Related information

- [Editing Segment Rules](#)
 - [Insert/Edit Condition](#)
-

Copying Segments

Decision List Viewer provides you with a convenient way to copy model segments. When you want to apply a segment from one model to another model, simply copy (or cut) the segment from one model and paste it into another model. You can also copy a segment from a model displayed in the Alternative Preview panel and paste it into the model displayed in the working model pane. These cut, copy, and paste functions use a system clipboard to store or retrieve temporary data. This means that in the clipboard the conditions and target are copied. The clipboard contents are not solely reserved to be used in Decision List Viewer but can also be pasted in other applications. For example, when the clipboard contents are pasted in a text editor, the conditions and target are pasted in XML-format.

To copy or cut model segments:

1. Select the model segment that you want to use in another model.
2. From the Edit menu, choose **Copy** (or **Cut**), or right-click on the model segment and select **Copy** or **Cut**.
3. Open the appropriate model (where the model segment will be pasted).
4. Select one of the model segments, and click **Paste**.

Note: Instead of the **Cut**, **Copy**, and **Paste** commands you can also use the key combinations: **Ctrl+X**, **Ctrl+C**, and **Ctrl+V**.

The copied (or cut) segment is inserted above the previously selected model segment. The measures of the pasted segment and segments below are recalculated.

Note: Both models in this procedure must be based on the same underlying model template and contain the same target, otherwise an error message is displayed.

-

Alternative Models

Where there is more than one result, the Alternatives tab displays the results of each mining task. Each result consists of the conditions in the selected data that most closely match the target, as well as any "good enough" alternatives. The total number of alternatives shown depends on the search criteria used in the analysis process.

To view alternative models:

1. Click on an alternative model on the Alternatives tab. The alternative model segments display, or replace the current model segments, in the Alternative Preview panel.
2. To work with an alternative model in the working model pane, select the model and click Load in the Alternative Preview panel or right-click an alternative name on the Alternatives tab and choose Load.

Note: Alternative models are not saved when you generate a new model.

Customizing a Model

Data are not static. Customers move, get married, and change jobs. Products lose market focus and become obsolete.

Decision List Viewer offers business users the flexibility to adapt models to new situations easily and quickly. You can change a model by editing, prioritizing, deleting, or inactivating specific model segments.

- [Prioritizing Segments](#)
- [Deleting Segments](#)
- [Excluding Segments](#)
- [Change Target Value](#)

Related information

- [Prioritizing Segments](#)

 - [Undo and Redo Actions](#)
 - [Segment Rules](#)
 - [Generate New Model](#)
 - [Model Assessment](#)
 - [Assessment in Excel](#)
 - [Visualizing Models](#)
-

Prioritizing Segments

You can rank model rules in any order you choose. By default, model segments are displayed in order of priority, the first segment having the highest priority. When you assign a different priority to one or more of the segments, the model is changed accordingly. You may alter the model as required by moving segments to a higher or lower priority position.

To prioritize model segments:

1. Select the model segment to which you want to assign a different priority.
2. Click one of the two arrow buttons on the working model pane toolbar to move the selected model segment up or down the list.

After prioritization, all previous assessment results are recalculated and the new values are displayed.

Related information

- [Customizing a Model](#)
 - [Deleting Segments](#)
 - [Excluding Segments](#)
-

Deleting Segments

To delete one or more segments:

1. Select a model segment.
2. From the Edit menu, choose Delete Segment, or click the delete button on the toolbar of the working model pane.

The measures are recalculated for the modified model, and the model is changed accordingly.

Related information

- [Customizing a Model](#)
 - [Prioritizing Segments](#)
 - [Excluding Segments](#)
-

Excluding Segments

As you are searching for particular groups, you will probably base business actions on a selection of the model segments. When deploying a model, you may choose to exclude segments within a model. Excluded segments are scored as null values. Excluding a segment does not mean the segment is not used; it means that all records matching this rule are excluded from the mailing list. The rule is still applied but differently.

To exclude specific model segments:

1. Select a segment from the working model pane.
2. Click the Toggle Segment Exclusion button on the toolbar of the working model pane. Excluded is now displayed in the selected Target column of the selected segment.

Note: Unlike deleted segments, excluded segments remain available for reuse in the final model. Excluded segments affect chart results.

Related information

- [Customizing a Model](#)
 - [Prioritizing Segments](#)
 - [Deleting Segments](#)
-

Change Target Value

The Change Target Value dialog enables you to change the target value for the current target field.

Snapshots and session results with a different target value than the Working Model are identified by changing the table background for that row to yellow. This indicates that snapshot/session result is outdated.

The **Create/Edit Mining Task** dialog displays the target value for the current working model. The target value is not saved with the mining task. It is instead taken from the Working Model value.

When you promote a saved model to the Working Model that has a different target value from the current working model (for example, by editing an alternative result or editing a copy of a snapshot), the target value of the saved model is changed to be the same as the working model (the target value shown in the Working Model pane is not changed). The model metrics are reevaluated with the new target.

Generate New Model

The Generate New Model dialog provides options for naming the model and selecting where the new node is created.

Model name. Select Custom to adjust the auto-generated name or to create a unique name for the node as displayed on the stream canvas.

Create node on. Selecting Canvas places the new model on the working canvas; selecting GM Palette places the new model on the Models palette; selecting Both places the new model on both the working canvas and the Models palette.

Include interactive session state. When enabled, the interactive session state is preserved in the generated model. When you later generate a modeling node from the model, the state is carried over and used to initialize the interactive session. Regardless of whether the option is selected, the model itself scores new data identically. When the option is not selected, the model is still able to create a build node, but it will be a more generic build node that starts a new interactive session rather than pick up where the old session left off. If you change the node settings but execute with a saved state, the settings you have changed are ignored in favor of the settings from the saved state.

Note: The standard metrics are the only metrics that remain with the model. Additional metrics are preserved with the interactive state. The generated model does not represent the saved interactive mining task state. Once you launch the Decision List Viewer, it displays the settings originally made through the Viewer.

See the topic [Regenerating a modeling node](#) for more information.

Model Assessment

Successful modeling requires the careful assessment of the model before implementation in the production environment takes place. Decision List Viewer provides a number of statistical and business measures that can be used to assess the impact of a model in the real world. These include gains charts and full interoperability with Excel, thus enabling cost/benefit scenarios to be simulated for assessing the impact of deployment.

You can assess your model in the following ways:

- Using the predefined statistical and business model measures available in Decision List Viewer (probability, frequency).
 - Evaluating measures imported from Microsoft Excel.
 - Visualizing the model using a gains chart.
- [Organizing Model Measures](#)
 - [Assessment in Excel](#)

Organizing Model Measures

Decision List Viewer provides options for defining the measures that are calculated and displayed as columns. Each segment can include the default cover, frequency, probability, and error measures represented as columns. You can also create new measures that will be displayed as columns.

Defining Model Measures

To add a measure to your model or to define an existing measure:

1. From the Tools menu, choose Organize Model Measures, or right-click the model to make this selection. The Organize Model Measures dialog opens.
2. Click the Add new model measure button (to the right of the Show column). A new measure is displayed in the table.
3. Provide a measure name and select an appropriate type, display option, and selection. The Show column indicates whether the measure will display for the working model. When defining an existing measure, select an appropriate metric and selection and indicate if the measure will display for the working model.
4. Click OK to return to the Decision List Viewer workspace. If the Show column for the new measure was checked, the new measure will display for the working model.

Custom Metrics in Excel

See the topic [Assessment in Excel](#) for more information.

- [Refreshing Measures](#)

Related information

- [Model Assessment](#)

-

Refreshing Measures

In certain cases, it may be necessary to recalculate the model measures, such as when you apply an existing model to a new set of customers.

To recalculate (refresh) the model measures:

From the Edit menu, choose Refresh All Measures.

or

Press F5.

All measures are recalculated, and the new values are shown for the working model.

Related information

- [Model Assessment](#)
 - [Organizing Model Measures](#)
-

Assessment in Excel

Decision List Viewer can be integrated with Microsoft Excel, enabling you to use your own value calculations and profit formulas directly within the model building process to simulate cost/benefit scenarios. The link with Excel enables you to export data to Excel, where it can be used to create presentation charts, calculate custom measures, such as complex profit and ROI measures, and view them in Decision List Viewer while building the model.

Note: In order for you to work with an Excel spreadsheet, the analytical CRM expert has to define configuration information for the synchronization of Decision List Viewer with Microsoft Excel. The configuration is contained in an Excel spreadsheet file and indicates which information is transferred from Decision List Viewer to Excel, and vice versa.

The following steps are valid only when MS Excel is installed. If Excel is not installed, the options for synchronizing models with Excel are not displayed.

To synchronize models with MS Excel:

1. Open the model, run an interactive session, and choose Organize Model Measures from the Tools menu.
2. Select Yes for the Calculate custom measures in Excel option. The Workbook field activates, enabling you to select a preconfigured Excel workbook template.
3. Click the Connect to Excel button. The Open dialog opens, enabling you to navigate to the preconfigured template location on your local or network file system.
4. Select the appropriate Excel template and click Open. The selected Excel template launches; use the Windows taskbar (or press Alt-Tab) to navigate back to the Choose Inputs for Custom Measures dialog.
5. Select the appropriate mappings between the metric names defined in the Excel template and the model metric names and click OK.

Once the link is established, Excel starts with the preconfigured Excel template that displays the model rules in the spreadsheet. The results calculated in Excel are displayed as new columns in Decision List Viewer.

Note: Excel metrics do not remain when the model is saved; the metrics are valid only during the active session. However, you can create snapshots that include Excel metrics. The Excel metrics saved in the snapshot views are valid only for historical comparison purposes and do not refresh when reopened. See the topic [Snapshots Tab](#) for more information. The Excel metrics will not display in the snapshots until you reestablish a connection to the Excel template.

Choose Inputs for Custom Measures

The Choose Inputs for Custom Measures dialog provides options for mapping custom Excel input metrics to existing model measures.

Input – lists the custom Excel input metrics from the Excel template.

Model Measure – lists the available model measures. Select an appropriate measure to map to each custom Excel input metric.

Related information

- [Assessment in Excel](#)
 - [MS Excel Integration Setup](#)
-

MS Excel Integration Setup

The integration between Decision List Viewer and Microsoft Excel is accomplished through the use of a preconfigured Excel spreadsheet template. The template consists of three worksheets:

Model Measures. Displays the imported Decision List Viewer measures, the custom Excel measures, and the calculation totals (defined on the Settings worksheet).

Settings. Provides the variables to generate calculations based on the imported Decision List Viewer measures and the custom Excel measures.

Configuration. Provides options for specifying which measures are imported from Decision List Viewer and for defining the custom Excel measures.

WARNING: The structure of the Configuration worksheet is rigidly defined. Do **NOT** edit any cells in the green shaded area.

- **Metrics From Model.** Indicates which Decision List Viewer metrics are used in the calculations.
- **Metrics To Model.** Indicates which Excel-generated metric(s) will be returned to Decision List Viewer. The Excel-generated metrics display as new measure columns in Decision List Viewer.

Note: Excel metrics do not remain with the model when you generate a new model; the metrics are valid only during the active session.

Related information

- [Assessment in Excel](#)
 - [Choose Inputs for Custom Measures](#)
-

Changing the Model Measures

The following examples explain how to change Model Measures in several ways:

- Change an existing measure.
- Import an additional standard measure from the model.
- Export an additional custom measure to the model.

Change an existing measure

1. Open the template and select the Configuration worksheet.
2. Edit any Name or Description by highlighting and typing over them.

Note that if you want to change a measure--for example, to prompt the user for Probability instead of Frequency--you only need to change the name and description in Metrics From Model – this is then displayed in the model and the user can choose the appropriate measure to

map.

Import an additional standard measure from the model

1. Open the template and select the Configuration worksheet.
2. From the menus choose:
Tools > Protection > Unprotect Sheet
3. Select cell A5, which is shaded yellow and contains the word End.
4. From the menus choose:
Insert > Rows
5. Type in the Name and Description of the new measure. For example, Error and Error associated with segment.
6. In cell C5, enter the formula =COLUMN('Model Measures'!N3).
7. In cell D5, enter the formula =ROW('Model Measures'!N3)+1.
These formulae will cause the new measure to be displayed in column N of the Model Measures worksheet, which is currently empty.
8. From the menus choose:
Tools > Protection > Protect Sheet
9. Click OK.
10. On the Model Measures worksheet, ensure that cell N3 has Error as a title for the new column.
11. Select all of column N.
12. From the menus choose:
Format > Cells
13. By default, all of the cells have a General number category. Click Percentage to change how the figures are displayed. This helps you check your figures in Excel; in addition, it enables you to utilize the data in other ways, for example, as an output to a graph.
14. Click OK.
15. Save the spreadsheet as an Excel 2003 template, with a unique name and the file extension .xlt. For ease of locating the new template, we recommend you save it in the preconfigured template location on your local or network file system.

Export an additional custom measure to the model

1. Open the template to which you added the Error column in the previous example; select the Configuration worksheet.
2. From the menus choose:
Tools > Protection > Unprotect Sheet
3. Select cell A14, which is shaded yellow and contains the word End.
4. From the menus choose:
Insert > Rows
5. Type in the Name and Description of the new measure. For example, Scaled Error and Scaling applied to error from Excel.
6. In cell C14, enter the formula =COLUMN('Model Measures'!O3).
7. In cell D14, enter the formula =ROW('Model Measures'!O3)+1.
These formulae specify that the column O will supply the new measure to the model.
8. Select the Settings worksheet.
9. In cell A17, enter the description '- Scaled Error.
10. In cell B17, enter the scaling factor of 10.
11. On the Model Measures worksheet, enter the description Scaled Error in cell O3 as a title for the new column.
12. In cell O4, enter the formula =N4*Settings!\$B\$17.
13. Select the corner of cell O4 and drag it down to cell O22 to copy the formula into each cell.
14. From the menus choose:
Tools > Protection > Protect Sheet
15. Click OK.
16. Save the spreadsheet as an Excel 2003 template, with a unique name and the file extension .xlt. For ease of locating the new template, we recommend you save it in the preconfigured template location on your local or network file system.

When you connect to Excel using this template, the Error value is available as a new custom measure.

Visualizing Models

The best way to understand the impact of a model is to visualize it. Using a gains chart, you can obtain valuable day-to-day insight into the business and technical benefit of your model by studying the effect of multiple alternatives in real time. The [Gains Chart](#) section shows the benefit of a model over randomized decision-making and enables the direct comparison of multiple charts when there are alternative models.

- [Gains Chart](#)

Related information

- [Gains Chart](#)

 - [Generate New Model](#)
 - [Model Assessment](#)
 - [Assessment in Excel](#)
-

Gains Chart

The gains chart plots the values in the *Gains %* column from the table. Gains are defined as the proportion of hits in each increment relative to the total number of hits in the tree, using the equation:

$$(\text{hits in increment} / \text{total number of hits}) \times 100\%$$

Gains charts effectively illustrate how widely you need to cast the net to capture a given percentage of all of the hits in the tree. The diagonal line plots the expected response for the entire sample if the model is not used. In this case, the response rate would be constant, since one person is just as likely to respond as another. To double your yield, you would need to ask twice as many people. The curved line indicates how much you can improve your response by including only those who rank in the higher percentiles based on gain. For example, including the top 50% might net you more than 70% of the positive responses. The steeper the curve, the higher the gain.

To view a gains chart:

1. Open a stream that contains a Decision List node and launch an interactive session from the node.
2. Click the Gains tab. Depending on which partitions are specified, you may see one or two charts (two charts would display, for example, when both the training and testing partitions are defined for the model measures).

By default, the charts display as segments. You can switch the charts to display as quantiles by selecting Quantiles and then selecting the appropriate quantile method from the drop-down menu.

- [Chart Options](#)

Related information

- [Visualizing Models](#)
-

Chart Options

The Chart Options feature provides options for selecting which models and snapshots are charted, which partitions are plotted, and whether or not segment labels display.

Models to Plot

Current Models. Enables you to select which models to chart. You can select the working model or any created snapshot models.

Partitions to Plot

Partitions for left-hand chart. The drop-down list provides options for displaying all defined partitions or all data.

Partitions for right-hand chart. The drop-down list provides options for displaying all defined partitions, all data, or only the left-hand chart. When Graph only left is selected, only the left chart is displayed.

Display Segment Labels. When enabled, each segment label is displayed on the charts.

Statistical Models

Statistical models use mathematical equations to encode information extracted from the data. In some cases, statistical modeling techniques can provide adequate models very quickly. Even for problems in which more flexible machine-learning techniques (such as neural networks) can

ultimately give better results, you can use some statistical models as baseline predictive models to judge the performance of more advanced techniques.

The following statistical modeling nodes are available.

	Linear regression models predict a continuous target based on linear relationships between the target and one or more predictors.
	Logistic regression is a statistical technique for classifying records based on values of input fields. It is analogous to linear regression but takes a categorical target field instead of a numeric range.
	The PCA/Factor node provides powerful data-reduction techniques to reduce the complexity of your data. Principal components analysis (PCA) finds linear combinations of the input fields that do the best job of capturing the variance in the entire set of fields, where the components are orthogonal (perpendicular) to each other. Factor analysis attempts to identify underlying factors that explain the pattern of correlations within a set of observed fields. For both approaches, the goal is to find a small number of derived fields that effectively summarizes the information in the original set of fields.
	Discriminant analysis makes more stringent assumptions than logistic regression but can be a valuable alternative or supplement to a logistic regression analysis when those assumptions are met.
	The Generalized Linear model expands the general linear model so that the dependent variable is linearly related to the factors and covariates through a specified link function. Moreover, the model allows for the dependent variable to have a non-normal distribution. It covers the functionality of a wide number of statistical models, including linear regression, logistic regression, loglinear models for count data, and interval-censored survival models.
	A generalized linear mixed model (GLMM) extends the linear model so that the target can have a non-normal distribution, is linearly related to the factors and covariates via a specified link function, and so that the observations can be correlated. Generalized linear mixed models cover a wide variety of models, from simple linear regression to complex multilevel models for non-normal longitudinal data.
	The Cox regression node enables you to build a survival model for time-to-event data in the presence of censored records. The model produces a survival function that predicts the probability that the event of interest has occurred at a given time (t) for given values of the input variables.

Linear Node

Linear regression is a common statistical technique for classifying records based on the values of numeric input fields. Linear regression fits a straight line or surface that minimizes the discrepancies between predicted and actual output values.

Requirements. Only numeric fields can be used in a linear regression model. You must have exactly one target field (with the role set to Target) and one or more predictors (with the role set to Input). Fields with a role of Both or None are ignored, as are non-numeric fields. (If necessary, non-numeric fields can be recoded using a Derive node.)

Strengths. Linear regression models are relatively simple and give an easily interpreted mathematical formula for generating predictions. Because linear regression is a long-established statistical procedure, the properties of these models are well understood. Linear models are also

typically very fast to train. The Linear node provides methods for automatic field selection in order to eliminate nonsignificant input fields from the equation.

Note: In cases where the target field is categorical rather than a continuous range, such as yes/no or churn/don't churn, logistic regression can be used as an alternative. Logistic regression also provides support for non-numeric inputs, removing the need to recode these fields. See the topic [Logistic Node](#) for more information.

- [Linear models](#)
-

Linear models

Linear models predict a continuous target based on linear relationships between the target and one or more predictors.

Linear models are relatively simple and give an easily interpreted mathematical formula for scoring. The properties of these models are well understood and can typically be built very quickly compared to other model types (such as neural networks or decision trees) on the same dataset.

Example. An insurance company with limited resources to investigate homeowners' insurance claims wants to build a model for estimating claims costs. By deploying this model to service centers, representatives can enter claim information while on the phone with a customer and immediately obtain the "expected" cost of the claim based on past data.

Field requirements. There must be a Target and at least one Input. By default, fields with predefined roles of Both or None are not used. The target must be continuous (scale). There are no measurement level restrictions on predictors (inputs); categorical (flag, nominal, and ordinal) fields are used as factors in the model and continuous fields are used as covariates.

Objectives (linear models)

What do you want to do?

- Build a new model. Build a completely new model. This is the usual operation of the node.
- Continue training an existing model. Training continues with the last model successfully produced by the node. This makes it possible to update or refresh an existing model without having to access the original data and may result in significantly faster performance since only the new or updated records are fed into the stream. Details on the previous model are stored with the modeling node, making it possible to use this option even if the previous model nugget is no longer available in the stream or Models palette.

Note: When this option is enabled, all other controls on the Fields and Build Options tabs are disabled.

What is your main objective? Select the appropriate objective.

- Create a standard model. The method builds a single model to predict the target using the predictors. Generally speaking, standard models are easier to interpret and can be faster to score than boosted, bagged, or large dataset ensembles.
Note: Continue training existing model is only supported with Build a single tree split models, and you must be connected to Analytic Server.
- Enhance model accuracy (boosting). The method builds an ensemble model using boosting, which generates a sequence of models to obtain more accurate predictions. Ensembles can take longer to build and to score than a standard model.
Boosting produces a succession of "component models", each of which is built on the entire dataset. Prior to building each successive component model, the records are weighted based on the previous component model's residuals. Cases with large residuals are given

relatively higher analysis weights so that the next component model will focus on predicting these records well. Together these component models form an ensemble model. The ensemble model scores new records using a combining rule; the available rules depend upon the measurement level of the target.

- Enhance model stability (bagging). The method builds an ensemble model using bagging (bootstrap aggregating), which generates multiple models to obtain more reliable predictions. Ensembles can take longer to build and to score than a standard model. Bootstrap aggregation (bagging) produces replicates of the training dataset by sampling with replacement from the original dataset. This creates bootstrap samples of equal size to the original dataset. Then a "component model" is built on each replicate. Together these component models form an ensemble model. The ensemble model scores new records using a combining rule; the available rules depend upon the measurement level of the target.
- Create a model for very large datasets. The method builds an ensemble model by splitting the dataset into separate data blocks. Choose this option if your dataset is too large to build any of the models above, or for incremental model building. This option can take less time to build, but can take longer to score than a standard model.

See [Ensembles \(linear models\)](#) for settings related to boosting, bagging, and very large datasets.

Basics (linear models)

Automatically prepare data. This option allows the procedure to internally transform the target and predictors in order to maximize the predictive power of the model; any transformations are saved with the model and applied to new data for scoring. The original versions of transformed fields are excluded from the model. By default, the following automatic data preparation are performed.

- Date and Time handling. Each date predictor is transformed into new a continuous predictor containing the elapsed time since a reference date (1970-01-01). Each time predictor is transformed into a new continuous predictor containing the time elapsed since a reference time (00:00:00).
- Adjust measurement level. Continuous predictors with less than 5 distinct values are recast as ordinal predictors. Ordinal predictors with greater than 10 distinct values are recast as continuous predictors.
- Outlier handling. Values of continuous predictors that lie beyond a cutoff value (3 standard deviations from the mean) are set to the cutoff value.
- Missing value handling. Missing values of nominal predictors are replaced with the mode of the training partition. Missing values of ordinal predictors are replaced with the median of the training partition. Missing values of continuous predictors are replaced with the mean of the training partition.
- Supervised merging. This makes a more parsimonious model by reducing the number of fields to be processed in association with the target. Similar categories are identified based upon the relationship between the input and the target. Categories that are not significantly different (that is, having a p-value greater than 0.1) are merged. If all categories are merged into one, the original and derived versions of the field are excluded from the model because they have no value as a predictor.

Confidence level. This is the level of confidence used to compute interval estimates of the model coefficients in the [Coefficients](#) view. Specify a value greater than 0 and less than 100. The default is 95.

Model selection (linear models)

Model selection method. Choose one of the model selection methods (details below) or Include all predictors, which simply enters all available predictors as main effects model terms. By default, Forward stepwise is used.

Forward Stepwise Selection. This starts with no effects in the model and adds and removes effects one step at a time until no more can be added or removed according to the stepwise criteria.

- Criteria for entry/removal. This is the statistic used to determine whether an effect should be added to or removed from the model. Information Criterion (AICC) is based on the likelihood of the training set given the model, and is adjusted to penalize overly complex models. F Statistics is based on a statistical test of the improvement in model error. Adjusted R-squared is based on the fit of the training set, and is adjusted to penalize overly complex models. Overfit Prevention Criterion (ASE) is based on the fit (average squared error, or ASE) of the overfit prevention set. The overfit prevention set is a random subsample of approximately 30% of the original dataset that is not used to train the model.

If any criterion other than F Statistics is chosen, then at each step the effect that corresponds to the greatest positive increase in the criterion is added to the model. Any effects in the model that correspond to a decrease in the criterion are removed.

If F Statistics is chosen as the criterion, then at each step the effect that has the smallest p-value less than the specified threshold, Include effects with p-values less than, is added to the model. The default is 0.05. Any effects in the model with a p-value greater than the specified threshold, Remove effects with p-values greater than, are removed. The default is 0.10.

- Customize maximum number of effects in the final model. By default, all available effects can be entered into the model. Alternatively, if the stepwise algorithm ends a step with the specified maximum number of effects, the algorithm stops with the current set of effects.

- Customize maximum number of steps. The stepwise algorithm stops after a certain number of steps. By default, this is 3 times the number of available effects. Alternatively, specify a positive integer maximum number of steps.

Best Subsets Selection. This checks "all possible" models, or at least a larger subset of the possible models than forward stepwise, to choose the best according to the best subsets criterion. Information Criterion (AICC) is based on the likelihood of the training set given the model, and is adjusted to penalize overly complex models. Adjusted R-squared is based on the fit of the training set, and is adjusted to penalize overly complex models. Overfit Prevention Criterion (ASE) is based on the fit (average squared error, or ASE) of the overfit prevention set. The overfit prevention set is a random subsample of approximately 30% of the original dataset that is not used to train the model.

The model with the greatest value of the criterion is chosen as the best model.

Note: Best subsets selection is more computationally intensive than forward stepwise selection. When best subsets is performed in conjunction with boosting, bagging, or very large datasets, it can take considerably longer to build than a standard model built using forward stepwise selection.

Ensembles (linear models)

These settings determine the behavior of ensembling that occurs when boosting, bagging, or very large datasets are requested in Objectives. Options that do not apply to the selected objective are ignored.

Bagging and Very Large Datasets. When scoring an ensemble, this is the rule used to combine the predicted values from the base models to compute the ensemble score value.

- Default combining rule for continuous targets. Ensemble predicted values for continuous targets can be combined using the mean or median of the predicted values from the base models.

Note that when the objective is to enhance model accuracy, the combining rule selections are ignored. Boosting always uses a weighted majority vote to score categorical targets and a weighted median to score continuous targets.

Boosting and Bagging. Specify the number of base models to build when the objective is to enhance model accuracy or stability; for bagging, this is the number of bootstrap samples. It should be a positive integer.

Advanced (linear models)

Replicate results. Setting a random seed allows you to replicate analyses. The random number generator is used to choose which records are in the overfit prevention set. Specify an integer or click Generate, which will create a pseudo-random integer between 1 and 2147483647, inclusive. The default is 54752075.

Model Options (linear models)

Model Name. You can generate the model name automatically based on the target fields or specify a custom name. The automatically generated name is the target field name.

Note that the predicted value is always computed when the model is scored. The name of the new field is the name of the target field, prefixed with \$L-. For example, for a target field named *sales*, the new field would be named *\$L-sales*.

Model Summary (linear models)

The Model Summary view is a snapshot, at-a-glance summary of the model and its fit.

Table

The table identifies some high-level model settings, including:

- The name of the target specified on the [Fields](#) tab,
- Whether automatic data preparation was performed as specified on the [Basics](#) settings,
- The model selection method and selection criterion specified on the [Model Selection](#) settings. The value of the selection criterion for the final model is also displayed, and is presented in smaller is better format.

Chart

The chart displays the accuracy of the final model, which is presented in larger is better format. The value is $100 \times$ the adjusted R^2 for the final model.

Automatic Data Preparation (linear models)

This view shows information about which fields were excluded and how transformed fields were derived in the automatic data preparation (ADP) step. For each field that was transformed or excluded, the table lists the field name, its role in the analysis, and the action taken by the ADP step. Fields are sorted by ascending alphabetical order of field names. The possible actions taken for each field include:

- Derive duration: months computes the elapsed time in months from the values in a field containing dates to the current system date.
 - Derive duration: hours computes the elapsed time in hours from the values in a field containing times to the current system time.
 - Change measurement level from continuous to ordinal recasts continuous fields with less than 5 unique values as ordinal fields.
 - Change measurement level from ordinal to continuous recasts ordinal fields with more than 10 unique values as continuous fields.
 - Trim outliers sets values of continuous predictors that lie beyond a cutoff value (3 standard deviations from the mean) to the cutoff value.
 - Replace missing values replaces missing values of nominal fields with the mode, ordinal fields with the median, and continuous fields with the mean.
 - Merge categories to maximize association with target identifies "similar" predictor categories based upon the relationship between the input and the target. Categories that are not significantly different (that is, having a p -value greater than 0.05) are merged.
 - Exclude constant predictor / after outlier handling / after merging of categories removes predictors that have a single value, possibly after other ADP actions have been taken.
-

Predictor Importance (linear models)

Typically, you will want to focus your modeling efforts on the predictor fields that matter most and consider dropping or ignoring those that matter least. The predictor importance chart helps you do this by indicating the relative importance of each predictor in estimating the model. Since the values are relative, the sum of the values for all predictors on the display is 1.0. Predictor importance does not relate to model accuracy. It just relates to the importance of each predictor in making a prediction, not whether or not the prediction is accurate.

Predicted By Observed (linear models)

This displays a binned scatterplot of the predicted values on the vertical axis by the observed values on the horizontal axis. Ideally, the points should lie on a 45-degree line; this view can tell you whether any records are predicted particularly badly by the model.

Residuals (linear models)

This displays a diagnostic chart of model residuals.

Chart styles. There are different display styles, which are accessible from the Style drop-down.

- Histogram. This is a binned histogram of the studentized residuals with an overlay of the normal distribution. Linear models assume that the residuals have a normal distribution, so the histogram should ideally closely approximate the smooth line.
 - P-P Plot. This is a binned probability-probability plot comparing the studentized residuals to a normal distribution. If the slope of the plotted points is less steep than the normal line, the residuals show greater variability than a normal distribution; if the slope is steeper, the residuals show less variability than a normal distribution. If the plotted points have an S-shaped curve, then the distribution of residuals is skewed.
-

Outliers (linear models)

This table lists records that exert undue influence upon the model, and displays the record ID (if specified on the Fields tab), target value, and Cook's distance. Cook's distance is a measure of how much the residuals of all records would change if a particular record were excluded from the calculation of the model coefficients. A large Cook's distance indicates that excluding a record from changes the coefficients substantially, and should therefore be considered influential.

Influential records should be examined carefully to determine whether you can give them less weight in estimating the model, or truncate the outlying values to some acceptable threshold, or remove the influential records completely.

Effects (linear models)

This view displays the size of each effect in the model.

Styles. There are different display styles, which are accessible from the Style dropdown list.

- Diagram. This is a chart in which effects are sorted from top to bottom by decreasing predictor importance. Connecting lines in the diagram are weighted based on effect significance, with greater line width corresponding to more significant effects (smaller p -values). Hovering over a connecting line reveals a tooltip that shows the p -value and importance of the effect. This is the default.
- Table. This is an ANOVA table for the overall model and the individual model effects. The individual effects are sorted from top to bottom by decreasing predictor importance. Note that by default, the table is collapsed to only show the results for the overall model. To see the results for the individual model effects, click the Corrected Model cell in the table.

Predictor importance. There is a Predictor Importance slider that controls which predictors are shown in the view. This does not change the model, but simply allows you to focus on the most important predictors. By default, the top 10 effects are displayed.

Significance. There is a Significance slider that further controls which effects are shown in the view, beyond those shown based on predictor importance. Effects with significance values greater than the slider value are hidden. This does not change the model, but simply allows you to focus on the most important effects. By default the value is 1.00, so that no effects are filtered based on significance.

Coefficients (linear models)

This view displays the value of each coefficient in the model. Note that factors (categorical predictors) are indicator-coded within the model, so that **effects** containing factors will generally have multiple associated **coefficients**; one for each category except the category corresponding to the redundant (reference) parameter.

Styles. There are different display styles, which are accessible from the Style dropdown list.

- Diagram. This is a chart which displays the intercept first, and then sorts effects from top to bottom by decreasing predictor importance. Within effects containing factors, coefficients are sorted by ascending order of data values. Connecting lines in the diagram are colored based on the sign of the coefficient (see the diagram key) and weighted based on coefficient significance, with greater line width corresponding to more significant coefficients (smaller p -values). Hovering over a connecting line reveals a tooltip that shows the value of the coefficient, its p -value, and the importance of the effect the parameter is associated with. This is the default style.
- Table. This shows the values, significance tests, and confidence intervals for the individual model coefficients. After the intercept, the effects are sorted from top to bottom by decreasing predictor importance. Within effects containing factors, coefficients are sorted by ascending order of data values. Note that by default the table is collapsed to only show the coefficient, significance, and importance of each model parameter. To see the standard error, t statistic, and confidence interval, click the Coefficient cell in the table. Hovering over the name of a model parameter in the table reveals a tooltip that shows the name of the parameter, the effect the parameter is associated with, and (for categorical predictors), the value labels associated with the model parameter. This can be particularly useful to see the new categories created when automatic data preparation merges similar categories of a categorical predictor.

Predictor importance. There is a Predictor Importance slider that controls which predictors are shown in the view. This does not change the model, but simply allows you to focus on the most important predictors. By default, the top 10 effects are displayed.

Significance. There is a Significance slider that further controls which coefficients are shown in the view, beyond those shown based on predictor importance. Coefficients with significance values greater than the slider value are hidden. This does not change the model, but simply allows you to focus on the most important coefficients. By default the value is 1.00, so that no coefficients are filtered based on significance.

Estimated means (linear models)

These are charts displayed for significant predictors. The chart displays the model-estimated value of the target on the vertical axis for each value of the predictor on the horizontal axis, holding all other predictors constant. It provides a useful visualization of the effects of each predictor's coefficients on the target.

Note: If no predictors are significant, no estimated means are produced.

Model Building Summary (linear models)

When a model selection algorithm other than None is chosen on the Model Selection settings, this provides some details of the model building process.

Forward stepwise. When forward stepwise is the selection algorithm, the table displays the last 10 steps in the stepwise algorithm. For each step, the value of the selection criterion and the effects in the model at that step are shown. This gives you a sense of how much each step contributes to the model. Each column allows you to sort the rows so that you can more easily see which effects are in the model at a given step.

Best subsets. When best subsets is the selection algorithm, the table displays the top 10 models. For each model, the value of the selection criterion and the effects in the model are shown. This gives you a sense of the stability of the top models; if they tend to have many similar effects with a few differences, then you can be fairly confident in the "top" model; if they tend to have very different effects, then some of the effects may be too similar and should be combined (or one removed). Each column allows you to sort the rows so that you can more easily see which effects are in the model at a given step.

Settings (linear models)

Note that the predicted value is always computed when the model is scored. The name of the new field is the name of the target field, prefixed with `$L-`. For example, for a target field named `sales`, the new field would be named `$L-sales`.

Generate SQL for this model When using data from a database, SQL code can be pushed back to the database for execution, providing superior performance for many operations.

Select one of the following options to specify how SQL generation is performed.

- Default: Score using Server Scoring Adapter (if installed) otherwise in process If connected to a database with a scoring adapter installed, generates SQL using the scoring adapter and associated user defined functions (UDF) and scores your model within the database. When no scoring adapter is available, this option fetches your data back from the database and scores it in SPSS® Modeler.
- Score by converting to native SQL If selected, generates native SQL to score the model within the database.
Note: Although this option can provide quicker results, the size and complexity of the native SQL increases as the complexity of the model increases.
- Score outside of the Database If selected, this option fetches your data back from the database and scores it in SPSS Modeler.

Linear-AS Node

IBM® SPSS® Modeler has two different versions of the Linear node:

- Linear is the traditional node that runs on the IBM SPSS Modeler Server.
- Linear-AS can run when connected to IBM SPSS Analytic Server.

Linear regression is a common statistical technique for classifying records based on the values of numeric input fields. Linear regression fits a straight line or surface that minimizes the discrepancies between predicted and actual output values.

Requirements. Only numeric fields and categorical predictors can be used in a linear regression model. You must have exactly one target field (with the role set to Target) and one or more predictors (with the role set to Input). Fields with a role of Both or None are ignored, as are non-numeric fields. (If necessary, non-numeric fields can be recoded using a Derive node.)

Strengths. Linear regression models are relatively simple and give an easily interpreted mathematical formula for generating predictions. Because linear regression is a long-established statistical procedure, the properties of these models are well understood. Linear models are also typically very fast to train. The Linear node provides methods for automatic field selection in order to eliminate nonsignificant input fields from the equation.

Note: In cases where the target field is categorical rather than a continuous range, such as yes/no or churn/don't churn, logistic regression can be used as an alternative. Logistic regression also provides support for non-numeric inputs, removing the need to recode these fields. See the topic [Logistic Node](#) for more information.

Linear-AS models

Linear models predict a continuous target based on linear relationships between the target and one or more predictors.

Linear models are relatively simple and give an easily interpreted mathematical formula for scoring. The properties of these models are well understood and can typically be built very quickly compared to other model types (such as neural networks or decision trees) on the same dataset.

Example. An insurance company with limited resources to investigate homeowners' insurance claims wants to build a model for estimating claims costs. By deploying this model to service centers, representatives can enter claim information while on the phone with a customer and immediately obtain the "expected" cost of the claim based on past data.

Field requirements. There must be a Target and at least one Input. By default, fields with predefined roles of Both or None are not used. The target must be continuous (scale). There are no measurement level restrictions on predictors (inputs); categorical (flag, nominal, and ordinal) fields are used as factors in the model and continuous fields are used as covariates.

 - [Model Selection \(linear-AS models\)](#)
 - [Model Options \(linear-AS models\)](#)
 - [Interactive Output \(linear-AS models\)](#)
 - [Settings \(linear-AS models\)](#)
-

Basics (linear-AS models)

Include intercept. This option includes an offset on the y axis when the x axis is 0. The intercept is usually included in the model. If you can assume the data pass through the origin, you can exclude the intercept.

Consider two way interaction. This option tells the model to compare each possible pair of inputs to see if the trend of one affects the other. If it does, then those inputs are more likely to be included in the design matrix.

Confidence interval for coefficient estimates (%). This is the interval of confidence used to compute estimates of the model coefficients in the [Coefficients](#) view. Specify a value greater than 0 and less than 100. The default is 95.

Sorting order for categorical predictors. These controls determine the order of the categories for the factors (categorical inputs) for purposes of determining the "last" category. The sort order setting is ignored if the input is not categorical or if a custom reference category is specified.

Model Selection (linear-AS models)

Model selection method. Choose one of the model selection methods (details below) or Include all predictors, which simply enters all available predictors as main effects model terms. By default, Forward stepwise is used.

Forward Stepwise Selection. This starts with no effects in the model and adds and removes effects one step at a time until no more can be added or removed according to the stepwise criteria.

- Criteria for entry/removal. This is the statistic used to determine whether an effect should be added to or removed from the model. Information Criterion (AICC) is based on the likelihood of the training set given the model, and is adjusted to penalize overly complex models. F Statistics is based on a statistical test of the improvement in model error. Adjusted R-squared is based on the fit of the training set, and is adjusted to penalize overly complex models. Overfit Prevention Criterion (ASE) is based on the fit (average squared error, or ASE) of the overfit prevention set. The overfit prevention set is a random subsample of approximately 30% of the original dataset that is not used to train the model.

If any criterion other than F Statistics is chosen, then at each step the effect that corresponds to the greatest positive increase in the criterion is added to the model. Any effects in the model that correspond to a decrease in the criterion are removed.

If F Statistics is chosen as the criterion, then at each step the effect that has the smallest *p*-value less than the specified threshold, Include effects with *p*-values less than, is added to the model. The default is 0.05. Any effects in the model with a *p*-value greater than the specified threshold, Remove effects with *p*-values greater than, are removed. The default is 0.10.

- Customize maximum number of effects in the final model. By default, all available effects can be entered into the model. Alternatively, if the stepwise algorithm ends a step with the specified maximum number of effects, the algorithm stops with the current set of effects.
- Customize maximum number of steps. The stepwise algorithm stops after a certain number of steps. By default, this is 3 times the number of available effects. Alternatively, specify a positive integer maximum number of steps.

Best Subsets Selection. This checks "all possible" models, or at least a larger subset of the possible models than forward stepwise, to choose the best according to the best subsets criterion. Information Criterion (AICC) is based on the likelihood of the training set given the model, and is adjusted to penalize overly complex models. Adjusted R-squared is based on the fit of the training set, and is adjusted to penalize overly complex models. Overfit Prevention Criterion (ASE) is based on the fit (average squared error, or ASE) of the overfit prevention set. The overfit prevention set is a random subsample of approximately 30% of the original dataset that is not used to train the model.

The model with the greatest value of the criterion is chosen as the best model.

Note: Best subsets selection is more computationally intensive than forward stepwise selection. When best subsets is performed in conjunction with boosting, bagging, or very large datasets, it can take considerably longer to build than a standard model built using forward stepwise selection.

Model Options (linear-AS models)

Model Name. You can generate the model name automatically based on the target fields or specify a custom name. The automatically generated name is the target field name.

Note that the predicted value is always computed when the model is scored. The name of the new field is the name of the target field, prefixed with $\$L$ - . For example, for a target field named *sales*, the new field would be named $\$L\text{-}sales$.

Interactive Output (linear-AS models)

After running a Linear-AS model, the following output is available.

Model Information

The Model Information view provides key information about the model. The table identifies some high-level model settings, such as:

- The name of the target specified on the [Fields](#) tab
- The regression weight field
- The model building method specified on the [Model Selection](#) settings
- The number of predictors input
- The number of predictors in the final model
- Akaike Information Criterion Corrected (AICC). AICC is a measure for selecting and comparing mixed models based on the -2 (Restricted) log likelihood. Smaller values indicate better models. The AICC "corrects" the AIC for small sample sizes. As the sample size increases, the AICC converges to the AIC.
- R Square. This is the goodness-of-fit measure of a linear model, sometimes called the coefficient of determination. It is the proportion of variation in the dependent variable explained by the regression model. It ranges in value from 0 to 1. Small values indicate that the model does not fit the data well.
- Adjusted R Square

Records Summary

The Records Summary view provides information about the number and percentage of records (cases) included and excluded from the model.

Predictor Importance

Typically, you will want to focus your modeling efforts on the predictor fields that matter most and consider dropping or ignoring those that matter least. The predictor importance chart helps you do this by indicating the relative importance of each predictor in estimating the model. Since the values are relative, the sum of the values for all predictors on the display is 1.0. Predictor importance does not relate to model accuracy. It just relates to the importance of each predictor in making a prediction, not whether or not the prediction is accurate.

Predicted by Observed

This displays a binned scatterplot of the predicted values on the vertical axis by the observed values on the horizontal axis. Ideally, the points should lie on a 45-degree line; this view can tell you whether any records are predicted particularly badly by the model.

Settings (linear-AS models)

Note that the predicted value is always computed when the model is scored. The name of the new field is the name of the target field, prefixed with $\$L$ - . For example, for a target field named *sales*, the new field would be named $\$L\text{-}sales$.

Generate SQL for this model When using data from a database, SQL code can be pushed back to the database for execution, providing superior performance for many operations.

Select one of the following options to specify how SQL generation is performed.

- Default: Score using Server Scoring Adapter (if installed) otherwise in process. If connected to a database with a scoring adapter installed, generates SQL using the scoring adapter and associated user defined functions (UDF) and scores your model within the database. When no scoring adapter is available, this option fetches your data back from the database and scores it in SPSS® Modeler.
 - Score outside of the Database. If selected, this option fetches your data back from the database and scores it in SPSS Modeler.
-

Logistic Node

Logistic regression, also known as **nominal regression**, is a statistical technique for classifying records based on values of input fields. It is analogous to linear regression but takes a categorical target field instead of a numeric one. Both binomial models (for targets with two discrete categories) and multinomial models (for targets with more than two categories) are supported.

Logistic regression works by building a set of equations that relate the input field values to the probabilities associated with each of the output field categories. Once the model is generated, it can be used to estimate probabilities for new data. For each record, a probability of membership is computed for each possible output category. The target category with the highest probability is assigned as the predicted output value for that record.

Binomial example. A telecommunications provider is concerned about the number of customers it is losing to competitors. Using service usage data, you can create a binomial model to predict which customers are liable to transfer to another provider and customize offers so as to retain as many customers as possible. A binomial model is used because the target has two distinct categories (likely to transfer or not).

Note: For binomial models only, string fields are limited to eight characters. If necessary, longer strings can be recoded using a Reclassify node or by using the Anonymize node.

Multinomial example. A telecommunications provider has segmented its customer base by service usage patterns, categorizing the customers into four groups. Using demographic data to predict group membership, you can create a multinomial model to classify prospective customers into groups and then customize offers for individual customers.

Requirements. One or more input fields and exactly one categorical target field with two or more categories. For a binomial model the target must have a measurement level of *Flag*. For a multinomial model the target can have a measurement level of *Flag*, or of *Nominal* with two or more categories. Fields set to *Both* or *None* are ignored. Fields used in the model must have their types fully instantiated.

Strengths. Logistic regression models are often quite accurate. They can handle symbolic and numeric input fields. They can give predicted probabilities for all target categories so that a second-best guess can easily be identified. Logistic models are most effective when group membership is a truly categorical field; if group membership is based on values of a continuous range field (for example, high IQ versus low IQ), you should consider using linear regression to take advantage of the richer information offered by the full range of values. Logistic models can also perform automatic field selection, although other approaches such as tree models or Feature Selection might do this more quickly on large datasets. Finally, since logistic models are well understood by many analysts and data miners, they may be used by some as a baseline against which other modeling techniques can be compared.

When processing large datasets, you can improve performance noticeably by disabling the likelihood-ratio test, an advanced output option. See the topic [Logistic Regression Advanced Output](#) for more information.

Important: If temporary disk space is low, Binomial Logistic Regression can fail to build, and will display an error. When building from a large data set (10GB or more), the same amount of free disk space is needed. You can use the environment variable SPSSTMPDIR to set the location of the temporary directory.

Logistic Node Model Options

Model name. You can generate the model name automatically based on the target or ID field (or model type in cases where no such field is specified) or specify a custom name.

Use partitioned data. If a partition field is defined, this option ensures that data from only the training partition is used to build the model.

Create split models. Builds a separate model for each possible value of input fields that are specified as split fields. See [Building Split Models](#) for more information.

Procedure. Specifies whether a binomial or multinomial model is created. The options available in the dialog box vary depending on which type of modeling procedure is selected.

- **Binomial.** Used when the target field is a flag or nominal field with two discrete values (dichotomous), such as yes/no, on/off, male/female.
- **Multinomial.** Used when the target field is a nominal field with more than two values. You can specify Main effects, Full factorial, or Custom.

Include constant in equation. This option determines whether the resulting equations will include a constant term. In most situations, you should leave this option selected.

Binomial Models

For binomial models, the following methods and options are available:

Method. Specify the method to be used in building the logistic regression model.

- **Enter.** This is the default method, which enters all of the terms into the equation directly. No field selection is performed in building the model.
- **Forwards Stepwise.** The Forwards Stepwise method of field selection builds the equation in steps, as the name implies. The initial model is the simplest model possible, with no model terms (except the constant) in the equation. At each step, terms that have not yet been added to the model are evaluated, and if the best of those terms adds significantly to the predictive power of the model, it is added. In addition, terms that are currently in the model are reevaluated to determine if any of them can be removed without significantly detracting from the model. If so, they are removed. The process repeats, and other terms are added and/or removed. When no more terms can be added to improve the model, and no more terms can be removed without detracting from the model, the final model is generated.
- **Backwards Stepwise.** The Backwards Stepwise method is essentially the opposite of the Forwards Stepwise method. With this method, the initial model contains all of the terms as predictors. At each step, terms in the model are evaluated, and any terms that can be removed without significantly detracting from the model are removed. In addition, previously removed terms are reevaluated to determine if the best of those terms adds significantly to the predictive power of the model. If so, it is added back into the model. When no more terms can be removed without significantly detracting from the model, and no more terms can be added to improve the model, the final model is generated.

Categorical inputs. Lists the fields that are identified as categorical, that is, those with a measurement level of flag, nominal, or ordinal. You can specify the contrast and base category for each categorical field.

- **Field Name.** This column contains the field names of the categorical inputs. To add continuous or numerical inputs into this column, click the Add Fields icon to the right of the list and select the required inputs.
- **Contrast.** The interpretation of the regression coefficients for a categorical field depends on the contrasts that are used. The contrast determines how hypothesis tests are set up to compare the estimated means. For example, if you know that a categorical field has implicit order, such as a pattern or grouping, you can use the contrast to model that order. The available contrasts are:
Indicator. Contrasts indicate the presence or absence of category membership. This is the default method.

Simple. Each category of the predictor field, except the reference category, is compared to the reference category.

Difference. Each category of the predictor field, except the first category, is compared to the average effect of previous categories. Also known as reverse Helmert contrasts.

Helmert. Each category of the predictor field, except the last category, is compared to the average effect of subsequent categories.

Repeated. Each category of the predictor field, except the first category, is compared to the category that precedes it.

Polynomial. Orthogonal polynomial contrasts. Categories are assumed to be equally spaced. Polynomial contrasts are available for numeric fields only.

Deviation. Each category of the predictor field, except the reference category, is compared to the overall effect.

- **Base Category.** Specifies how the reference category is determined for the selected contrast type. Select First to use the first category for the input field—sorted alphabetically—or select Last to use the last category. The default base category applies to variables that are listed in the Categorical inputs area.

Note: This field is unavailable if the contrast setting is Difference, Helmert, Repeated, or Polynomial.

The estimate of each field's effect on the overall response is computed as an increase or decrease in the likelihood of each of the other categories relative to the reference category. This can help you identify the fields and values that are more likely to give a specific response.

The base category is shown in the output as 0.0. This is because comparing it to itself produces an empty result. All other categories are shown as equations relevant to the base category. See the topic [Logistic Nugget Model Details](#) for more information.

Multinomial Models

For multinomial models the following methods and options are available:

Method. Specify the method to be used in building the logistic regression model.

- **Enter.** This is the default method, which enters all of the terms into the equation directly. No field selection is performed in building the model.
- **Stepwise.** The Stepwise method of field selection builds the equation in steps, as the name implies. The initial model is the simplest model possible, with no model terms (except the constant) in the equation. At each step, terms that have not yet been added to the model are evaluated, and if the best of those terms adds significantly to the predictive power of the model, it is added. In addition, terms that are currently in the model are reevaluated to determine if any of them can be removed without significantly detracting from the model. If so, they are removed. The process repeats, and other terms are added and/or removed. When no more terms can be added to improve the model, and no more terms can be removed without detracting from the model, the final model is generated.
- **Forwards.** The Forwards method of field selection is similar to the Stepwise method in that the model is built in steps. However, with this method, the initial model is the simplest model, and only the constant and terms can be added to the model. At each step, terms not yet in the model are tested based on how much they would improve the model, and the best of those terms is added to the model. When no more terms can be added, or the best candidate term does not produce a large-enough improvement in the model, the final model is generated.
- **Backwards.** The Backwards method is essentially the opposite of the Forwards method. With this method, the initial model contains all of the terms as predictors, and terms can only be removed from the model. Model terms that contribute little to the model are removed one by one until no more terms can be removed without significantly worsening the model, yielding the final model.
- **Backwards Stepwise.** The Backwards Stepwise method is essentially the opposite of the Stepwise method. With this method, the initial model contains all of the terms as predictors. At each step, terms in the model are evaluated, and any terms that can be removed without significantly detracting from the model are removed. In addition, previously removed terms are reevaluated to determine if the best of those terms adds significantly to the predictive power of the model. If so, it is added back into the model. When no more terms can be removed without significantly detracting from the model, and no more terms can be added to improve the model, the final model is generated.

Note: The automatic methods, including Stepwise, Forwards, and Backwards, are highly adaptable learning methods and have a strong tendency to overfit the training data. When using these methods, it is especially important to verify the validity of the resulting model either with new data or a hold-out test sample created using the Partition node.

Base category for target. Specifies how the reference category is determined. This is used as the baseline against which the regression equations for all other categories in the target are estimated. Select First to use the first category for the current target field—sorted alphabetically—or select Last to use the last category. Alternatively, you can select Specify to choose a specific category and select the desired value from the list. Available values can be defined for each field in a Type node.

Often you would specify the category in which you are least interested to be the base category, for example, a loss-leader product. The other categories are then related to this base category in a relative fashion to identify what makes them more likely to be in their own category. This can help you identify the fields and values that are more likely to give a specific response.

The base category is shown in the output as 0.0. This is because comparing it to itself produces an empty result. All other categories are shown as equations relevant to the base category. See the topic [Logistic Nugget Model Details](#) for more information.

Model type. There are three options for defining the terms in the model. **Main Effects** models include only the input fields individually and do not test interactions (multiplicative effects) between input fields. **Full Factorial** models include all interactions as well as the input field main effects. Full factorial models are better able to capture complex relationships but are also much more difficult to interpret and are more likely to suffer from overfitting. Because of the potentially large number of possible combinations, automatic field selection methods (methods other than Enter) are disabled for full factorial models. **Custom** models include only the terms (main effects and interactions) that you specify. When selecting this option, use the Model Terms list to add or remove terms in the model.

Model Terms. When building a Custom model, you will need to explicitly specify the terms in the model. The list shows the current set of terms for the model. The buttons on the right side of the Model Terms list enable you to add and remove model terms.

- To add terms to the model, click the *Add new model terms* button. See the topic [Adding Terms to a Logistic Regression Model](#) for more information.
- To delete terms, select the desired terms and click the *Delete selected model terms* button.

Adding Terms to a Logistic Regression Model

When requesting a custom logistic regression model, you can add terms to the model by clicking the *Add new model terms* button on the Logistic Regression Model tab. The New Terms dialog box opens in which you can specify terms.

Type of term to add. There are several ways to add terms to the model, based on the selection of input fields in the Available fields list.

- **Single interaction.** Inserts the term representing the interaction of all selected fields.
- **Main effects.** Inserts one main effect term (the field itself) for each selected input field.
- **All 2-way interactions.** Inserts a 2-way interaction term (the product of the input fields) for each possible pair of selected input fields. For example, if you have selected input fields A, B, and C in the Available fields list, this method will insert the terms $A * B$, $A * C$, and $B * C$.
- **All 3-way interactions.** Inserts a 3-way interaction term (the product of the input fields) for each possible combination of selected input fields, taken three at a time. For example, if you have selected input fields A, B, C, and D in the Available fields list, this method will insert the terms $A * B * C$, $A * B * D$, $A * C * D$, and $B * C * D$.
- **All 4-way interactions.** Inserts a 4-way interaction term (the product of the input fields) for each possible combination of selected input fields, taken four at a time. For example, if you have selected input fields A, B, C, D, and E in the Available fields list, this method will insert the terms $A * B * C * D$, $A * B * C * E$, $A * B * D * E$, $A * C * D * E$, and $B * C * D * E$.

Available fields. Lists the available input fields to be used in constructing model terms.

Preview. Shows the terms that will be added to the model if you click Insert, based on the selected fields and term type.

Insert. Inserts terms in the model (based on the current selection of fields and term type) and closes the dialog box.

Logistic Node Expert Options

If you have detailed knowledge of logistic regression, expert options enable you to fine-tune the training process. To access expert options, set Mode to Expert on the Expert tab.

Scale (Multinomial models only). You can specify a dispersion scaling value that will be used to correct the estimate of the parameter covariance matrix. Pearson estimates the scaling value by using the Pearson chi-square statistic. Deviance estimates the scaling value by using the deviance function (likelihood-ratio chi-square) statistic. You can also specify your own user-defined scaling value. It must be a positive numeric value.

Append all probabilities. If this option is selected, probabilities for each category of the output field will be added to each record processed by the node. If this option is not selected, the probability of only the predicted category is added.

For example, a table containing the results of a multinomial model with three categories will include five new columns. One column will list the probability of the outcome being correctly predicted, the next column will show the probability that this prediction is a hit or miss, and a further three columns will show the probability that each category's prediction is a miss or hit. See the topic [Logistic Model Nugget](#) for more information.

Note: This option is always selected for binomial models.

Singularity tolerance. Specify the tolerance used in checking for singularities.

Convergence. These options enable you to control the parameters for model convergence. When you execute the model, the convergence settings control how many times the different parameters are repeatedly run through to see how well they fit. The more often the parameters are tried, the closer the results will be (that is, the results will converge). See the topic [Logistic Regression Convergence Options](#) for more information.

Output. These options enable you to request additional statistics that will be displayed in the advanced output of the model nugget built by the node. See the topic [Logistic Regression Advanced Output](#) for more information.

Stepping. These options enable you to control the criteria for adding and removing fields with the Stepwise, Forwards, Backwards, or Backwards Stepwise estimation methods. (The button is disabled if the Enter method is selected.) See the topic [Logistic Regression Stepping Options](#) for more information.

Logistic Regression Convergence Options

You can set the convergence parameters for logistic regression model estimation.

Maximum iterations. Specify the maximum number of iterations for estimating the model.

Maximum step-halving. Step-halving is a technique used by logistic regression to deal with complexities in the estimation process. Under normal circumstances, you should use the default setting.

Log-likelihood convergence. Iterations stop if the relative change in the log-likelihood is less than this value. The criterion is not used if the value is 0.

Parameter convergence. Iterations stop if the absolute change or relative change in the parameter estimates is less than this value. The criterion is not used if the value is 0.

Delta (Multinomial models only). You can specify a value between 0 and 1 to be added to each empty cell (combination of input field and output field values). This can help the estimation algorithm deal with data where there are many possible combinations of field values relative to the number of records in the data. The default is 0.

Logistic Regression Advanced Output

Select the optional output you want to display in the advanced output of the Regression model nugget. To view the advanced output, browse the model nugget and click the Advanced tab. See the topic [Logistic Model Nugget Advanced Output](#) for more information.

Binomial Options

Select the types of output to be generated for the model. See the topic [Logistic Model Nugget Advanced Output](#) for more information.

Display. Select whether to display the results at each step, or to wait until all steps have been worked through.

CI for exp(B). Select the confidence intervals for each coefficient (shown as Beta) in the expression. Specify the level of the confidence interval (the default is 95%).

Residual Diagnosis. Requests a Casewise Diagnostics table of residuals.

- **Outliers outside (std. dev.).** List only residual cases for which the absolute standardized value of the listed variable is at least as large as the value you specify. The default value is 2.
- **All cases.** Include all cases in the Casewise Diagnostic table of residuals.
Note: Because this option lists each of the input records, it may result in an exceptionally large table in the report, with one line for every record.

Classification cutoff. This enables you to determine the cutpoint for classifying cases. Cases with predicted values that exceed the classification cutoff are classified as positive, while those with predicted values smaller than the cutoff are classified as negative. To change the default, enter a value between 0.01 and 0.99.

Multinomial Options

Select the types of output to be generated for the model. See the topic [Logistic Model Nugget Advanced Output](#) for more information.

Note: Selecting the Likelihood ratio tests option greatly increases the processing time required to build a logistic regression model. If your model is taking too long to build, consider disabling this option or utilize the Wald and Score statistics instead. See the topic [Logistic Regression Stepping Options](#) for more information.

Iteration history for every. Select the step interval for printing iteration status in the advanced output.

Confidence Interval. The confidence intervals for coefficients in the equations. Specify the level of the confidence interval (the default is 95%).

 - [Logistic Regression Stepping Options](#)
-

Logistic Regression Stepping Options

These options enable you to control the criteria for adding and removing fields with the Stepwise, Forwards, Backwards, or Backwards Stepwise estimation methods.

Number of terms in model (Multinomial models only). You can specify the minimum number of terms in the model for Backwards and Backwards Stepwise models and the maximum number of terms for Forwards and Stepwise models. If you specify a minimum value greater than 0, the model will include that many terms, even if some of the terms would have been removed based on statistical criteria. The minimum setting is ignored for Forwards, Stepwise, and Enter models. If you specify a maximum, some terms may be omitted from the model, even though they would have been selected based on statistical criteria. The Specify Maximum setting is ignored for Backwards, Backwards Stepwise, and Enter models.

Entry criterion (Multinomial models only). Select Score to maximize speed of processing. The Likelihood Ratio option may provide somewhat more robust estimates but take longer to compute. The default setting is to use the Score statistic.

Removal criterion. Select Likelihood Ratio for a more robust model. To shorten the time required to build the model, you can try selecting Wald. However, if you have complete or quasi-complete separation in the data (which you can determine by using the Advanced tab on the model nugget), the Wald statistic becomes particularly unreliable and should not be used. The default setting is to use the likelihood-ratio statistic. For binomial models, there is the additional option Conditional. This provides removal testing based on the probability of the likelihood-ratio statistic based on conditional parameter estimates.

Significance thresholds for criteria. This option enables you to specify selection criteria based on the statistical probability (the *p* value) associated with each field. Fields will be added to the model only if the associated *p* value is smaller than the Entry value and will be removed only if the *p* value is larger than the Removal value. The Entry value must be smaller than the Removal value.

Requirements for entry or removal (Multinomial models only). For some applications, it doesn't make mathematical sense to add interaction terms to the model unless the model also contains the lower-order terms for the fields involved in the interaction term. For example, it may not make sense to include $A * B$ in the model unless A and B are also included in the model. These options let you determine how such dependencies are handled during stepwise term selection.

- **Hierarchy for discrete effects.** Higher-order effects (interactions involving more fields) will enter the model only if all lower-order effects (main effects or interactions involving fewer fields) for the relevant fields are already in the model, and lower-order effects will not be removed if higher-order effects involving the same fields are in the model. This option applies only to categorical fields.
- **Hierarchy for all effects.** This option works in the same way as the previous option, except that it applies to all input fields.
- **Containment for all effects.** Effects can be included in the model only if all of the effects contained in the effect are also included in the model. This option is similar to the Hierarchy for all effects option except that continuous fields are treated somewhat differently. For an effect to contain another effect, the contained (lower-order) effect must include *all* of the continuous fields involved in the containing (higher-order) effect, and the contained effect's categorical fields must be a subset of those in the containing effect. For example, if A and B are categorical fields and X is a continuous field, the term $A * B * X$ contains the terms $A * X$ and $B * X$.
- **None.** No relationships are enforced; terms are added to and removed from the model independently.

Logistic Model Nugget

A Logistic model nugget represents the equation estimated by a Logistic node. It contains all of the information captured by the logistic regression model, as well as information about the model structure and performance. This type of equation may also be generated by other models such as Oracle SVM.

When you run a stream containing a Logistic model nugget, the node adds two new fields containing the model's prediction and the associated probability. The names of the new fields are derived from the name of the output field being predicted, prefixed with $\$L-$ for the predicted category and $\$LP-$ for the associated probability. For example, for an output field named *colorpref*, the new fields would be named $\$L-colorpref$ and $\$LP-colorpref$. In addition, if you have selected the Append all probabilities option in the Logistic node, an additional field will be added for each category of the output field, containing the probability belonging to the corresponding category for each record. These additional fields are named based on the values of the output field, prefixed by $\$LP-$. For example, if the legal values of *colorpref* are *Red*, *Green*, and *Blue*, three new fields will be added: $\$LP-Red$, $\$LP-Green$, and $\$LP-Blue$.

Generating a Filter node. The Generate menu enables you to create a new Filter node to pass input fields based on the results of the model. Fields that are dropped from the model due to multicollinearity will be filtered by the generated node, as well as fields not used in the model.

Logistic Nugget Model Details

For multinomial models, the Model tab in a Logistic model nugget has a split display with model equations in the left pane, and predictor importance on the right. For binomial models, the tab displays predictor importance only. See the topic [Predictor Importance](#) for more information.

Model Equations

For multinomial models, the left pane displays the actual equations estimated for the logistic regression model. There is one equation for each category in the target field, except the baseline category. The equations are displayed in a tree format. This type of equation may also be generated by certain other models such as Oracle SVM.

Equation For. Shows the regression equations used to derive the target category probabilities, given a set of predictor values. The last category of the target field is considered the **baseline category**; the equations shown give the log-odds for the other target categories relative to the baseline category for a particular set of predictor values. The predicted probability for each category of the given predictor pattern is derived from these log-odds values.

How Probabilities Are Calculated

Each equation calculates the log-odds for a particular target category, relative to the baseline category. The **log-odds**, also called the **logit**, is the ratio of the probability for the specified target category to that of the baseline category, with the natural logarithm function applied to the result. For the baseline category, the odds of the category relative to itself is 1.0, and thus the log-odds is 0. You can think of this as an implicit equation for the baseline category where all coefficients are 0.

To derive the probability from the log-odds for a particular target category, you take the logit value calculated by the equation for that category and apply the following formula:

$$P(\text{group}_i) = \exp(g_i) / \sum_k \exp(g_k)$$

where g is the calculated log-odds, i is the category index, and k goes from 1 to the number of target categories.

Predictor Importance

Optionally, a chart that indicates the relative importance of each predictor in estimating the model may also be displayed on the Model tab. Typically you will want to focus your modeling efforts on the predictors that matter most and consider dropping or ignoring those that matter least. Note this chart is only available if Calculate predictor importance is selected on the Analyze tab before generating the model. See the topic [Predictor Importance](#) for more information.

Note: Predictor importance may take longer to calculate for logistic regression than for other types of models, and is not selected on the Analyze tab by default. Selecting this option may slow performance, particularly with large datasets.

Logistic Model Nugget Summary

The summary for a logistic regression model displays the fields and settings used to generate the model. In addition, if you have executed an Analysis node attached to this modeling node, information from that analysis will also be displayed in this section. For general information on using the model browser, see [Browsing model nuggets](#).

Logistic Model Nugget Settings

The Settings tab in a Logistic model nugget specifies options for confidences, probabilities, propensity scores, and SQL generation during model scoring. This tab is only available after the model nugget has been added to a stream and displays different options depending on the type of model and target.

Multinomial Models

For multinomial models, the following options are available.

Calculate confidences Specifies whether confidences are calculated during scoring.

Calculate raw propensity scores (flag targets only) For models with flag targets only, you can request raw propensity scores that indicate the likelihood of the true outcome specified for the target field. These are in addition to standard prediction and confidence values. Adjusted propensity scores are not available. See the topic [Modeling Node Analyze Options](#) for more information.

Append all probabilities Specifies whether probabilities for each category of the output field are added to each record processed by the node. If this option is not selected, the probability of only the predicted category is added. For a nominal target with three categories, for example, the scoring output will include a column for each of the three categories, plus a fourth column indicating the probability for whichever category is predicted. For example if the probabilities for categories *Red*, *Green*, and *Blue* are 0.6, 0.3, and 0.1 respectively, the predicted category would be *Red*, with a probability of 0.6.

Generate SQL for this model When using data from a database, SQL code can be pushed back to the database for execution, providing superior performance for many operations.

Select one of the following options to specify how SQL generation is performed.

- Default: Score using Server Scoring Adapter (if installed) otherwise in process If connected to a database with a scoring adapter installed, generates SQL using the scoring adapter and associated user defined functions (UDF) and scores your model within the database. When no scoring adapter is available, this option fetches your data back from the database and scores it in SPSS® Modeler.
- Score by converting to native SQL If selected, generates native SQL to score the model within the database.
Note: Although this option can provide quicker results, the size and complexity of the native SQL increases as the complexity of the model increases.
- Score outside of the Database If selected, this option fetches your data back from the database and scores it in SPSS Modeler.

Note: For multinomial models, SQL generation is unavailable if Append all probabilities has been selected, or—for models with nominal targets—if Calculate confidences has been selected. SQL generation with confidence calculations is supported for multinomial models with flag targets only. SQL generation is not available for binomial models.

Binomial Models

For binomial models, confidences and probabilities are always enabled, and the settings that would enable you to disable these options are not available. SQL generation is not available for binomial models. The only setting that can be changed for binomial models is the ability to calculate raw propensity scores. As noted earlier for multinomial models, this applies to models with flag targets only. See the topic [Modeling Node Analyze Options](#) for more information.

Logistic Model Nugget Advanced Output

The advanced output for logistic regression (also known as **nominal regression**) gives detailed information about the estimated model and its performance. Most of the information contained in the advanced output is quite technical, and extensive knowledge of logistic regression analysis is required to properly interpret this output.

Warnings. Indicates any warnings or potential problems with the results.

Case processing summary. Lists the number of records processed, broken down by each symbolic field in the model.

Step summary (optional). Lists the effects added or removed at each step of model creation, when using automatic field selection.

Note: Only shown for the Stepwise, Forwards, Backwards, or Backwards Stepwise methods.

Iteration history (optional). Shows the iteration history of parameter estimates for every n iterations beginning with the initial estimates, where n is the value of the print interval. The default is to print every iteration ($n=1$).

Model fitting information (Multinomial models). Shows the likelihood-ratio test of your model (Final) against one in which all of the parameter coefficients are 0 (Intercept Only).

Classification (optional). Shows the matrix of predicted and actual output field values with percentages.

Goodness-of-fit chi-square statistics (optional). Shows Pearson's and likelihood-ratio chi-square statistics. These statistics test the overall fit of the model to the training data.

Hosmer and Lemeshow goodness-of-fit (optional). Shows the results of grouping cases into deciles of risk and comparing the observed probability with the expected probability within each decile. This goodness-of-fit statistic is more robust than the traditional goodness-of-fit statistic used in multinomial models, particularly for models with continuous covariates and studies with small sample sizes.

Pseudo R-square (optional). Shows the Cox and Snell, Nagelkerke, and McFadden R -square measures of model fit. These statistics are in some ways analogous to the R -square statistic in linear regression.

Monotonicity measures (optional). Shows the number of concordant pairs, discordant pairs, and tied pairs in the data, as well as the percentage of the total number of pairs that each represents. The Somers' D, Goodman and Kruskal's Gamma, Kendall's tau-a, and Concordance Index C are also displayed in this table.

Information criteria (optional). Shows Akaike's information criterion (AIC) and Schwarz's Bayesian information criterion (BIC).

Likelihood ratio tests (optional). Shows statistics testing of whether the coefficients of the model effects are statistically different from 0. Significant input fields are those with very small significance levels in the output (labeled *Sig.*).

Parameter estimates (optional). Shows estimates of the equation coefficients, tests of those coefficients, odds ratios derived from the coefficients labeled *Exp(B)*, and confidence intervals for the odds ratios.

Asymptotic covariance/correlation matrix (optional). Shows the asymptotic covariances and/or correlations of the coefficient estimates.

Observed and predicted frequencies (optional). For each covariate pattern, shows the observed and predicted frequencies for each output field value. This table can be quite large, especially for models with numeric input fields. If the resulting table would be too large to be practical, it is omitted, and a warning is displayed.

PCA/Factor Node

The PCA/Factor node provides powerful data-reduction techniques to reduce the complexity of your data. Two similar but distinct approaches are provided.

- **Principal components analysis (PCA)** finds linear combinations of the input fields that do the best job of capturing the variance in the entire set of fields, where the components are orthogonal (perpendicular) to each other. PCA focuses on all variance, including both shared and unique variance.
- **Factor analysis** attempts to identify underlying concepts, or **factors**, that explain the pattern of correlations within a set of observed fields. Factor analysis focuses on shared variance only. Variance that is unique to specific fields is not considered in estimating the model. Several methods of factor analysis are provided by the Factor/PCA node.

For both approaches, the goal is to find a small number of derived fields that effectively summarize the information in the original set of fields.

Requirements. Only numeric fields can be used in a PCA-Factor model. To estimate a factor analysis or PCA, you need one or more fields with the role set to *Input* fields. Fields with the role set to *Target*, *Both*, or *None* are ignored, as are non-numeric fields.

Strengths. Factor analysis and PCA can effectively reduce the complexity of your data without sacrificing much of the information content. These techniques can help you build more robust models that execute more quickly than would be possible with the raw input fields.

-

PCA/Factor Node Model Options

Model name. You can generate the model name automatically based on the target or ID field (or model type in cases where no such field is specified) or specify a custom name.

Use partitioned data. If a partition field is defined, this option ensures that data from only the training partition is used to build the model.

Extraction Method. Specify the method to be used for data reduction.

- **Principal Components.** This is the default method, which uses PCA to find components that summarize the input fields.
- **Unweighted Least Squares.** This factor analysis method works by finding the set of factors that is best able to reproduce the pattern of relationships (correlations) among the input fields.
- **Generalized Least Squares.** This factor analysis method is similar to unweighted least squares, except that it uses weighting to de-emphasize fields with a lot of unique (unshared) variance.
- **Maximum Likelihood.** This factor analysis method produces factor equations that are most likely to have produced the observed pattern of relationships (correlations) in the input fields, based on assumptions about the form of those relationships.
- **Principal Axis Factoring.** This factor analysis method is very similar to the principal components method, except that it focuses on shared variance only.
- **Alpha Factoring.** This factor analysis method considers the fields in the analysis to be a sample from the universe of potential input fields. It maximizes the statistical reliability of the factors.
- **Image Factoring.** This factor analysis method uses data estimation to isolate the common variance and find factors that describe it.

 - [PCA/Factor Node Expert Options](#)
 - [PCA/Factor Node Rotation Options](#)
-

PCA/Factor Node Expert Options

If you have detailed knowledge of factor analysis and PCA, expert options enable you to fine-tune the training process. To access expert options, set Mode to Expert on the Expert tab.

Missing values. By default, IBM® SPSS® Modeler only uses records that have valid values for all fields used in the model. (This is sometimes called **listwise deletion** of missing values.) If you have a lot of missing data, you may find that this approach eliminates too many records, leaving you without enough data to generate a good model. In such cases, you can deselect the Only use complete records option. IBM SPSS Modeler then attempts to use as much information as possible to estimate the model, including records where some of the fields have missing values. (This is sometimes called **pairwise deletion** of missing values.) However, in some situations, using incomplete records in this manner can lead to computational problems in estimating the model.

Fields. Specify whether to use the correlation matrix (the default) or the covariance matrix of the input fields in estimating the model.

Maximum iterations for convergence. Specify the maximum number of iterations for estimating the model.

Extract factors. There are two ways to select the number of factors to extract from the input fields.

- **Eigenvalues over.** This option will retain all factors or components with eigenvalues larger than the specified criterion. **Eigenvalues** measure the ability of each factor or component to summarize variance in the set of input fields. The model will retain all factors or components with eigenvalues greater than the specified value when using the correlation matrix. When using the covariance matrix, the criterion is the specified value times the mean eigenvalue. That scaling gives this option a similar meaning for both types of matrix.
- **Maximum number.** This option will retain the specified number of factors or components in descending order of eigenvalues. In other words, the factors or components corresponding to the n highest eigenvalues are retained, where n is the specified criterion. The default extraction criterion is five factors/components.

Component/factor matrix format. These options control the format of the factor matrix (or component matrix for PCA models).

- **Sort values.** If this option is selected, factor loadings in the model output will be sorted numerically.
- **Hide values below.** If this option is selected, scores below the specified threshold will be hidden in the matrix to make it easier to see the pattern in the matrix.

Rotation. These options enable you to control the rotation method for the model. See the topic [PCA/Factor Node Rotation Options](#) for more information.

Related information

- [PCA/Factor Node](#)
 - [PCA/Factor Node Model Options](#)
 - [PCA/Factor Node Rotation Options](#)
-

PCA/Factor Node Rotation Options

In many cases, mathematically rotating the set of retained factors can increase their usefulness and especially their interpretability. Select a rotation method:

- **No rotation.** The default option. No rotation is used.
- **Varimax.** An orthogonal rotation method that minimizes the number of fields with high loadings on each factor. It simplifies the interpretation of the factors.
- **Direct oblimin.** A method for oblique (non-orthogonal) rotation. When Delta equals 0 (the default), solutions are oblique. As delta becomes more negative, the factors become less oblique. To override the default delta of 0, enter a number less than or equal to 0.8.
- **Quartimax.** An orthogonal method that minimizes the number of factors needed to explain each field. It simplifies the interpretation of the observed fields.
- **Equamax.** A rotation method that is a combination of the Varimax method, which simplifies the factors, and the Quartimax method, which simplifies the fields. The number of fields that load highly on a factor and the number of factors needed to explain a field are minimized.
- **Promax.** An oblique rotation, which enables factors to be correlated. It can be calculated more quickly than a direct oblimin rotation, so it can be useful for large datasets. Kappa controls the obliqueness of the solution (the extent to which factors can be correlated).

PCA/Factor Model Nugget

A PCA/Factor model nugget represents the factor analysis and principal component analysis (PCA) model created by a PCA/Factor node. They contain all of the information captured by the trained model, as well as information about the model's performance and characteristics.

When you run a stream containing a factor equation model, the node adds a new field for each factor or component in the model. The new field names are derived from the model name, prefixed by $\$F\text{-}$ and suffixed by $-n$, where n is the number of the factor or component. For example, if your model is named *Factor* and contains three factors, the new fields would be named $\$F\text{-Factor-1}$, $\$F\text{-Factor-2}$, and $\$F\text{-Factor-3}$.

To get a better sense of what the factor model has encoded, you can do some more downstream analysis. A useful way to view the result of the factor model is to view the correlations between factors and input fields using a Statistics node. This shows you which input fields load heavily on which factors and can help you discover if your factors have any underlying meaning or interpretation.

You can also assess the factor model by using the information available in the advanced output. To view the advanced output, click the Advanced tab of the model nugget browser. The advanced output contains a lot of detailed information and is meant for users with extensive knowledge of factor analysis or PCA. See the topic [PCA/Factor Model Nugget Advanced Output](#) for more information.

PCA/Factor Model Nugget Advanced Output

The advanced output for factor analysis gives detailed information on the estimated model and its performance. Most of the information contained in the advanced output is quite technical, and extensive knowledge of factor analysis is required to properly interpret this output.

Warnings. Indicates any warnings or potential problems with the results.

Communalities. Shows the proportion of each field's variance that is accounted for by the factors or components. *Initial* gives the initial communalities with the full set of factors (the model starts with as many factors as input fields), and *Extraction* gives the communalities based on the retained set of factors.

Total variance explained. Shows the total variance explained by the factors in the model. *Initial Eigenvalues* shows the variance explained by the full set of initial factors. *Extraction Sums of Squared Loadings* shows the variance explained by factors retained in the model. *Rotation Sums of Squared Loadings* shows the variance explained by the rotated factors. Note that for oblique rotations, *Rotation Sums of Squared Loadings* shows only the sums of squared loadings and does not show variance percentages.

Factor (or component) matrix. Shows correlations between input fields and unrotated factors.

Rotated factor (or component) matrix. Shows correlations between input fields and rotated factors for orthogonal rotations.

Pattern matrix. Shows the partial correlations between input fields and rotated factors for oblique rotations.

Structure matrix. Shows the simple correlations between input fields and rotated factors for oblique rotations.

Factor correlation matrix. Shows correlations among factors for oblique rotations.

Discriminant node

Discriminant analysis builds a predictive model for group membership. The model is composed of a discriminant function (or, for more than two groups, a set of discriminant functions) based on linear combinations of the predictor variables that provide the best discrimination between the groups. The functions are generated from a sample of cases for which group membership is known; the functions can then be applied to new cases that have measurements for the predictor variables but have unknown group membership.

Example. A telecommunications company can use discriminant analysis to classify customers into groups based on usage data. This allows them to score potential customers and target those who are most likely to be in the most valuable groups.

Requirements. You need one or more input fields and exactly one target field. The target must be a categorical field (with a measurement level of *Flag* or *Nominal*) with string or integer storage. (Storage can be converted using a Filler or Derive node if necessary.) Fields set to *Both* or *None* are ignored. Fields used in the model must have their types fully instantiated.

Strengths. Discriminant analysis and Logistic Regression are both suitable classification models. However, Discriminant analysis makes more assumptions about the input fields—for example, they are normally distributed and should be continuous, and they give better results if those requirements are met, especially if the sample size is small.

- [Discriminant Node Expert Options](#)
- [Discriminant Node Output Options](#)
- [Discriminant Node Stepping Options](#)

- [Discriminant Model Nugget](#)
-

Discriminant Node Model Options

Model name. You can generate the model name automatically based on the target or ID field (or model type in cases where no such field is specified) or specify a custom name.

Use partitioned data. If a partition field is defined, this option ensures that data from only the training partition is used to build the model.

Create split models. Builds a separate model for each possible value of input fields that are specified as split fields. See [Building Split Models](#) for more information.

Method. The following options are available for entering predictors into the model:

- **Enter.** This is the default method, which enters all of the terms into the equation directly. Terms that do not add significantly to the predictive power of the model are not added.
- **Stepwise.** The initial model is the simplest model possible, with no model terms (except the constant) in the equation. At each step, terms that have not yet been added to the model are evaluated, and if the best of those terms adds significantly to the predictive power of the model, it is added.

Note: The Stepwise method has a strong tendency to overfit the training data. When using these methods, it is especially important to verify the validity of the resulting model with a hold-out test sample or new data.

Discriminant Node Expert Options

If you have detailed knowledge of discriminant analysis, expert options allow you to fine-tune the training process. To access expert options, set Mode to Expert on the Expert tab.

Prior Probabilities. This option determines whether the classification coefficients are adjusted for a priori knowledge of group membership.

- **All groups equal.** Equal prior probabilities are assumed for all groups; this has no effect on the coefficients.
- **Compute from group sizes.** The observed group sizes in your sample determine the prior probabilities of group membership. For example, if 50% of the observations included in the analysis fall into the first group, 25% in the second, and 25% in the third, the classification coefficients are adjusted to increase the likelihood of membership in the first group relative to the other two.

Use Covariance Matrix. You can choose to classify cases using a within-groups covariance matrix or a separate-groups covariance matrix.

- *Within-groups.* The pooled within-groups covariance matrix is used to classify cases.
- *Separate-groups.* Separate-groups covariance matrices are used for classification. Because classification is based on the discriminant functions (not based on the original variables), this option is not always equivalent to quadratic discrimination.

Output. These options allow you to request additional statistics that will be displayed in the advanced output of the model nugget built by the node. See the topic [Discriminant Node Output Options](#) for more information.

Stepping. These options allow you to control the criteria for adding and removing fields with the Stepwise estimation method. (The button is disabled if the Enter method is selected.) See the topic [Discriminant Node Stepping Options](#) for more information.

Discriminant Node Output Options

Select the optional output you want to display in the advanced output of the logistic regression model nugget. To view the advanced output, browse the model nugget and click the Advanced tab. See the topic [Discriminant Model Nugget Advanced Output](#) for more information.

Descriptives. Available options are means (including standard deviations), univariate ANOVAs, and Box's M test.

- *Means.* Displays total and group means, as well as standard deviations for the independent variables.
- *Univariate ANOVAs.* Performs a one-way analysis-of-variance test for equality of group means for each independent variable.
- *Box's M .* A test for the equality of the group covariance matrices. For sufficiently large samples, a nonsignificant p value means there is insufficient evidence that the matrices differ. The test is sensitive to departures from multivariate normality.

Function Coefficients. Available options are Fisher's classification coefficients and unstandardized coefficients.

- *Fisher's.* Displays Fisher's classification function coefficients that can be used directly for classification. A separate set of classification function coefficients is obtained for each group, and a case is assigned to the group for which it has the largest discriminant score (classification function value).
- *Unstandardized.* Displays the unstandardized discriminant function coefficients.

Matrices. Available matrices of coefficients for independent variables are within-groups correlation matrix, within-groups covariance matrix, separate-groups covariance matrix, and total covariance matrix.

- *Within-groups correlation.* Displays a pooled within-groups correlation matrix that is obtained by averaging the separate covariance matrices for all groups before computing the correlations.
- *Within-groups covariance.* Displays a pooled within-groups covariance matrix, which may differ from the total covariance matrix. The matrix is obtained by averaging the separate covariance matrices for all groups.
- *Separate-groups covariance.* Displays separate covariance matrices for each group.
- *Total covariance.* Displays a covariance matrix from all cases as if they were from a single sample.

Classification. The following output pertains to the classification results.

- *Casewise results.* Codes for actual group, predicted group, posterior probabilities, and discriminant scores are displayed for each case.
- *Summary table.* The number of cases correctly and incorrectly assigned to each of the groups based on the discriminant analysis. Sometimes called the "Confusion Matrix."
- *Leave-one-out classification.* Each case in the analysis is classified by the functions derived from all cases other than that case. It is also known as the "U-method."
- *Territorial map.* A plot of the boundaries used to classify cases into groups based on function values. The numbers correspond to groups into which cases are classified. The mean for each group is indicated by an asterisk within its boundaries. The map is not displayed if there is only one discriminant function.
- *Combined-groups.* Creates an all-groups scatterplot of the first two discriminant function values. If there is only one function, a histogram is displayed instead.
- *Separate-groups.* Creates separate-group scatterplots of the first two discriminant function values. If there is only one function, histograms are displayed instead.

Stepwise. Summary of Steps displays statistics for all variables after each step; F for pairwise distances displays a matrix of pairwise F ratios for each pair of groups. The F ratios can be used for significance tests of the Mahalanobis distances between groups.

Related information

-

Discriminant Node Stepping Options

These options allow you to control the method and criteria for adding fields with the Stepwise estimation method.

Method. Select the statistic to be used for entering or removing new variables. Available alternatives are Wilks' lambda, unexplained variance, Mahalanobis distance, smallest F ratio, and Rao's V . With Rao's V , you can specify the minimum increase in V for a variable to enter.

- *Wilks' lambda.* A variable selection method for stepwise discriminant analysis that chooses variables for entry into the equation on the basis of how much they lower Wilks' lambda. At each step, the variable that minimizes the overall Wilks' lambda is entered.
- *Unexplained variance.* At each step, the variable that minimizes the sum of the unexplained variation between groups is entered.
- *Mahalanobis distance.* A measure of how much a case's values on the independent variables differ from the average of all cases. A large Mahalanobis distance identifies a case as having extreme values on one or more of the independent variables.
- *Smallest F ratio.* A method of variable selection in stepwise analysis based on maximizing an F ratio computed from the Mahalanobis distance between groups.
- *Rao's V .* A measure of the differences between group means. Also called the Lawley-Hotelling trace. At each step, the variable that maximizes the increase in Rao's V is entered. After selecting this option, enter the minimum value a variable must have to enter the

analysis.

Criteria. Available alternatives are Use F value and Use probability of F. Enter values for entering and removing variables.

- **Use F value.** A variable is entered into the model if its F value is greater than the Entry value and is removed if the F value is less than the Removal value. Entry must be greater than Removal, and both values must be positive. To enter more variables into the model, lower the Entry value. To remove more variables from the model, increase the Removal value.
- **Use probability of F.** A variable is entered into the model if the significance level of its F value is less than the Entry value and is removed if the significance level is greater than the Removal value. Entry must be less than Removal, and both values must be positive. To enter more variables into the model, increase the Entry value. To remove more variables from the model, lower the Removal value.

Discriminant Model Nugget

Discriminant model nuggets represent the equations estimated by Discriminant nodes. They contain all of the information captured by the discriminant model, as well as information about the model structure and performance.

When you run a stream containing a Discriminant model nugget, the node adds two new fields containing the model's prediction and the associated probability. The names of the new fields are derived from the name of the output field being predicted, prefixed with \$D- for the predicted category and \$DP- for the associated probability. For example, for an output field named *colorpref*, the new fields would be named \$D-colorpref and \$DP-colorpref.

Generating a Filter node. The Generate menu allows you to create a new Filter node to pass input fields based on the results of the model.

Predictor Importance

Optionally, a chart that indicates the relative importance of each predictor in estimating the model may also be displayed on the Model tab. Typically you will want to focus your modeling efforts on the predictors that matter most and consider dropping or ignoring those that matter least. Note this chart is only available if Calculate predictor importance is selected on the Analyze tab before generating the model. See the topic [Predictor Importance](#) for more information.

Discriminant Model Nugget Settings

The Settings tab in a Discriminant model nugget allows you to obtain propensity scores when scoring the model. This tab is available for models with flag targets only, and only after the model nugget has been added to a stream.

Calculate raw propensity scores. For models with a flag target (which return a yes or no prediction), you can request propensity scores that indicate the likelihood of the true outcome specified for the target field. These are in addition to other prediction and confidence values that may be generated during scoring.

Calculate adjusted propensity scores. Raw propensity scores are based only on the training data and may be overly optimistic due to the tendency of many models to overfit this data. Adjusted propensities attempt to compensate by evaluating model performance against a test or validation partition. This option requires that a partition field be defined in the stream and adjusted propensity scores be enabled in the modeling node before generating the model.

Generate SQL for this model When using data from a database, SQL code can be pushed back to the database for execution, providing superior performance for many operations.

Select one of the following options to specify how SQL generation is performed.

- Default: Score using Server Scoring Adapter (if installed) otherwise in process If connected to a database with a scoring adapter installed, generates SQL using the scoring adapter and associated user defined functions (UDF) and scores your model within the database. When no scoring adapter is available, this option fetches your data back from the database and scores it in SPSS® Modeler.
- Score outside of the Database If selected, this option fetches your data back from the database and scores it in SPSS Modeler.

Discriminant Model Nugget Summary

The Summary tab for a Discriminant model nugget displays the fields and settings used to generate the model. In addition, if you have executed an Analysis node attached to this modeling node, information from that analysis will also be displayed in this section. For general information on using the model browser, see [Browsing model nuggets](#).

GenLin Node

The generalized linear model expands the general linear model so that the dependent variable is linearly related to the factors and covariates via a specified link function. Moreover, the model allows for the dependent variable to have a non-normal distribution. It covers widely used statistical models, such as linear regression for normally distributed responses, logistic models for binary data, loglinear models for count data,

complementary log-log models for interval-censored survival data, plus many other statistical models through its very general model formulation.

Examples. A shipping company can use generalized linear models to fit a Poisson regression to damage counts for several types of ships constructed in different time periods, and the resulting model can help determine which ship types are most prone to damage.

A car insurance company can use generalized linear models to fit a gamma regression to damage claims for cars, and the resulting model can help determine the factors that contribute the most to claim size.

Medical researchers can use generalized linear models to fit a complementary log-log regression to interval-censored survival data to predict the time to recurrence for a medical condition.

Generalized linear models work by building an equation that relates the input field values to the output field values. Once the model is generated, it can be used to estimate values for new data. For each record, a probability of membership is computed for each possible output category. The target category with the highest probability is assigned as the predicted output value for that record.

Requirements. You need one or more input fields and exactly one target field (which can have a measurement level of *Continuous* or *Flag*) with two or more categories. Fields used in the model must have their types fully instantiated.

Strengths. The generalized linear model is extremely flexible, but the process of choosing the model structure is not automated and thus demands a level of familiarity with your data that is not required by "black box" algorithms.

GenLin Node Field Options

In addition to the target, input, and partition custom options typically offered on modeling node Fields tabs (see [Modeling Node Fields Options](#)), the GenLin node offers the following extra functionality.

Use weight field. The scale parameter is an estimated model parameter related to the variance of the response. The scale weights are "known" values that can vary from observation to observation. If the scale weight variable is specified, the scale parameter, which is related to the variance of the response, is divided by it for each observation. Records with scale weight values that are less than or equal to 0 or are missing are not used in the analysis.

Target field represents number of events occurring in a set of trials. When the response is a number of events occurring in a set of trials, the target field contains the number of events and you can select an additional variable containing the number of trials. Alternatively, if the number of trials is the same across all subjects, then trials may be specified using a fixed value. The number of trials should be greater than or equal to the number of events for each record. Events should be non-negative integers, and trials should be positive integers.

- [GenLin Node Model Options](#)
- [GenLin Node Expert Options](#)
- [Generalized Linear Models Iterations](#)
- [Generalized Linear Models Advanced Output](#)

GenLin Node Model Options

Model name. You can generate the model name automatically based on the target or ID field (or model type in cases where no such field is specified) or specify a custom name.

Use partitioned data. If a partition field is defined, this option ensures that data from only the training partition is used to build the model.

Create split models. Builds a separate model for each possible value of input fields that are specified as split fields. See [Building Split Models](#) for more information.

Model type. There are two options for the type of model to build. Main effects only causes the model to include only the input fields individually, and not to test interactions (multiplicative effects) between input fields. Main effects and all two-way interactions includes all two-way interactions as well as the input field main effects.

Offset. The offset term is a "structural" predictor. Its coefficient is not estimated by the model but is assumed to have the value 1; thus, the values of the offset are simply added to the linear predictor of the target. This is especially useful in Poisson regression models, where each case may have different levels of exposure to the event of interest.

For example, when modeling accident rates for individual drivers, there is an important difference between a driver who has been at fault in one accident in three years of experience and a driver who has been at fault in one accident in 25 years! The number of accidents can be modeled as a Poisson or negative binomial response with a log link if the natural log of the experience of the driver is included as an offset term.

Other combinations of distribution and link types would require other transformations of the offset variable.

Note: If a variable offset field is used, the specified field should not also be used as an input. Set the role for the offset field to None in an upstream source or Type node if necessary.

Base category for flag target.

For binary response, you can choose the reference category for the dependent variable. This can affect certain output, such as parameter estimates and saved values, but it should not change the model fit. For example, if your binary response takes values 0 and 1:

- By default, the procedure makes the last (highest-valued) category, or 1, the reference category. In this situation, model-saved probabilities estimate the chance that a given case takes the value 0, and parameter estimates should be interpreted as relating to the likelihood of category 0.
- If you specify the first (lowest-valued) category, or 0, as the reference category, then model-saved probabilities estimate the chance that a given case takes the value 1.
- If you specify the custom category and your variable has defined labels, you can set the reference category by choosing a value from the list. This can be convenient when, in the middle of specifying a model, you don't remember exactly how a particular variable was coded.

Include intercept in model. The intercept is usually included in the model. If you can assume the data pass through the origin, you can exclude the intercept.

GenLin Node Expert Options

If you have detailed knowledge of generalized linear models, expert options allow you to fine-tune the training process. To access expert options, set Mode to Expert on the Expert tab.

Target Field Distribution and Link Function

Distribution.

This selection specifies the distribution of the dependent variable. The ability to specify a non-normal distribution and non-identity link function is the essential improvement of the generalized linear model over the general linear model. There are many possible distribution-link function combinations, and several may be appropriate for any given dataset, so your choice can be guided by a priori theoretical considerations or which combination seems to fit best.

- **Binomial.** This distribution is appropriate only for variables that represent a binary response or number of events.
- **Gamma.** This distribution is appropriate for variables with positive scale values that are skewed toward larger positive values. If a data value is less than or equal to 0 or is missing, then the corresponding case is not used in the analysis.
- **Inverse Gaussian.** This distribution is appropriate for variables with positive scale values that are skewed toward larger positive values. If a data value is less than or equal to 0 or is missing, then the corresponding case is not used in the analysis.

- **Negative binomial.** This distribution can be thought of as the number of trials required to observe k successes and is appropriate for variables with non-negative integer values. If a data value is non-integer, less than 0, or missing, then the corresponding case is not used in the analysis. The fixed value of the negative binomial distribution's ancillary parameter can be any number greater than or equal to 0. When the ancillary parameter is set to 0, using this distribution is equivalent to using the Poisson distribution.
- **Normal.** This is appropriate for scale variables whose values take a symmetric, bell-shaped distribution about a central (mean) value. The dependent variable must be numeric.
- **Poisson.** This distribution can be thought of as the number of occurrences of an event of interest in a fixed period of time and is appropriate for variables with non-negative integer values. If a data value is non-integer, less than 0, or missing, then the corresponding case is not used in the analysis.
- **Tweedie.** This distribution is appropriate for variables that can be represented by Poisson mixtures of gamma distributions; the distribution is "mixed" in the sense that it combines properties of continuous (takes non-negative real values) and discrete distributions (positive probability mass at a single value, 0). The dependent variable must be numeric, with data values greater than or equal to zero. If a data value is less than zero or missing, then the corresponding case is not used in the analysis. The fixed value of the Tweedie distribution's parameter can be any number greater than one and less than two.
- **Multinomial.** This distribution is appropriate for variables that represent an ordinal response. The dependent variable can be numeric or string, and it must have at least two distinct valid data values.

Link Functions.

The link function is a transformation of the dependent variable that allows estimation of the model. The following functions are available:

- **Identity.** $f(x)=x$. The dependent variable is not transformed. This link can be used with any distribution.
- **Complementary log-log.** $f(x)=\log(-\log(1-x))$. This is appropriate only with the binomial distribution.
- **Cumulative Cauchit.** $f(x)=\tan(\pi(x-0.5))$, applied to the cumulative probability of each category of the response. This is appropriate only with the multinomial distribution.
- **Cumulative complementary log-log.** $f(x)=\ln(-\ln(1-x))$, applied to the cumulative probability of each category of the response. This is appropriate only with the multinomial distribution.
- **Cumulative logit.** $f(x)=\ln(x/(1-x))$, applied to the cumulative probability of each category of the response. This is appropriate only with the multinomial distribution.
- **Cumulative negative log-log.** $f(x)=-\ln(-\ln(x))$, applied to the cumulative probability of each category of the response. This is appropriate only with the multinomial distribution.
- **Cumulative probit.** $f(x)=\Phi^{-1}(x)$, applied to the cumulative probability of each category of the response, where Φ^{-1} is the inverse standard normal cumulative distribution function. This is appropriate only with the multinomial distribution.
- **Log.** $f(x)=\log(x)$. This link can be used with any distribution.
- **Log complement.** $f(x)=\log(1-x)$. This is appropriate only with the binomial distribution.
- **Logit.** $f(x)=\log(x/(1-x))$. This is appropriate only with the binomial distribution.
- **Negative binomial.** $f(x)=\log(x/(x+k^{-1}))$, where k is the ancillary parameter of the negative binomial distribution. This is appropriate only with the negative binomial distribution.
- **Negative log-log.** $f(x)=-\log(-\log(x))$. This is appropriate only with the binomial distribution.
- **Odds power.** $f(x)=[(x/(1-x))^{\alpha}-1]/\alpha$, if $\alpha \neq 0$. $f(x)=\log(x)$, if $\alpha=0$. α is the required number specification and must be a real number. This is appropriate only with the binomial distribution.
- **Probit.** $f(x)=\Phi^{-1}(x)$, where Φ^{-1} is the inverse standard normal cumulative distribution function. This is appropriate only with the binomial distribution.
- **Power.** $f(x)=x^{\alpha}$, if $\alpha \neq 0$. $f(x)=\log(x)$, if $\alpha=0$. α is the required number specification and must be a real number. This link can be used with any distribution.

Parameters. The controls in this group allow you to specify parameter values when certain distribution options are chosen.

- **Parameter for negative binomial.** For negative binomial distribution, choose either to specify a value or to allow the system to provide an estimated value.
- **Parameter for Tweedie.** For Tweedie distribution, specify a number between 1.0 and 2.0 for the fixed value.
- **Parameter Estimation.** The controls in this group allow you to specify estimation methods and to provide initial values for the parameter estimates.
 - **Method.** You can select a parameter estimation method. Choose between Newton-Raphson, Fisher scoring, or a hybrid method in which Fisher scoring iterations are performed before switching to the Newton-Raphson method. If convergence is achieved during the Fisher scoring phase of the hybrid method before the maximum number of Fisher iterations is reached, the algorithm continues with the Newton-Raphson method.
 - **Scale Parameter Method.** You can select the scale parameter estimation method. Maximum-likelihood jointly estimates the scale parameter with the model effects; note that this option is not valid if the response has a negative binomial, Poisson, or binomial distribution. The deviance and Pearson chi-square options estimate the scale parameter from the value of those statistics. Alternatively, you can specify a fixed value for the scale parameter.
- **Covariance matrix.** The model-based estimator is the negative of the generalized inverse of the Hessian matrix. The robust (also called the Huber/White/sandwich) estimator is a "corrected" model-based estimator that provides a consistent estimate of the covariance, even when the specification of the variance and link functions is incorrect.

Iterations. These options allow you to control the parameters for model convergence. See the topic [Generalized Linear Models Iterations](#) for more information.

Output. These options allow you to request additional statistics that will be displayed in the advanced output of the model nugget built by the node. See the topic [Generalized Linear Models Advanced Output](#) for more information.

Singularity Tolerance. Singular (or non-invertible) matrices have linearly dependent columns, which can cause serious problems for the estimation algorithm. Even near-singular matrices can lead to poor results, so the procedure will treat a matrix whose determinant is less than the tolerance as singular. Specify a positive value.

-

Generalized Linear Models Iterations

You can set the convergence parameters for estimating the generalized linear model.

Iterations. The following options are available:

- **Maximum iterations.** The maximum number of iterations the algorithm will execute. Specify a non-negative integer.
- **Maximum step-halving.** At each iteration, the step size is reduced by a factor of 0.5 until the log-likelihood increases or maximum step-halving is reached. Specify a positive integer.
- **Check for separation of data points.** When selected, the algorithm performs tests to ensure that the parameter estimates have unique values. Separation occurs when the procedure can produce a model that correctly classifies every case. This option is available for binomial responses with binary format .

Convergence Criteria. The following options are available

- **Change in parameter estimates.** When selected, the algorithm stops after an iteration in which the absolute or relative change in the parameter estimates is less than the value specified, which must be positive.
- **Change in log-likelihood.** When selected, the algorithm stops after an iteration in which the absolute or relative change in the log-likelihood function is less than the value specified, which must be positive.
- **Hessian convergence.** For the Absolute specification, convergence is assumed if a statistic based on the Hessian convergence is less than the positive value specified. For the Relative specification, convergence is assumed if the statistic is less than the product of the positive value specified and the absolute value of the log-likelihood.

Generalized Linear Models Advanced Output

Select the optional output you want to display in the advanced output of the generalized linear model nugget. To view the advanced output, browse the model nugget and click the Advanced tab. See the topic [GenLin Model Nugget Advanced Output](#) for more information.

The following output is available:

- **Case processing summary.** Displays the number and percentage of cases included and excluded from the analysis and the Correlated Data Summary table.
- **Descriptive statistics.** Displays descriptive statistics and summary information about the dependent variable, covariates, and factors.
- **Model information.** Displays the dataset name, dependent variable or events and trials variables, offset variable, scale weight variable, probability distribution, and link function.
- **Goodness of fit statistics.** Displays deviance and scaled deviance, Pearson chi-square and scaled Pearson chi-square, log-likelihood, Akaike's information criterion (AIC), finite sample corrected AIC (AICC), Bayesian information criterion (BIC), and consistent AIC (CAIC).
- **Model summary statistics.** Displays model fit tests, including likelihood-ratio statistics for the model fit omnibus test and statistics for the Type I or III contrasts for each effect.

- **Parameter estimates.** Displays parameter estimates and corresponding test statistics and confidence intervals. You can optionally display exponentiated parameter estimates in addition to the raw parameter estimates.
- **Covariance matrix for parameter estimates.** Displays the estimated parameter covariance matrix.
- **Correlation matrix for parameter estimates.** Displays the estimated parameter correlation matrix.
- **Contrast coefficient (L) matrices.** Displays contrast coefficients for the default effects and for the estimated marginal means, if requested on the EM Means tab.
- **General estimable functions.** Displays the matrices for generating the contrast coefficient (L) matrices.
- **Iteration history.** Displays the iteration history for the parameter estimates and log-likelihood and prints the last evaluation of the gradient vector and the Hessian matrix. The iteration history table displays parameter estimates for every n^{th} iterations beginning with the 0th iteration (the initial estimates), where n is the value of the print interval. If the iteration history is requested, then the last iteration is always displayed regardless of n .
- **Lagrange multiplier test.** Displays Lagrange multiplier test statistics for assessing the validity of a scale parameter that is computed using the deviance or Pearson chi-square, or set at a fixed number, for the normal, gamma, and inverse Gaussian distributions. For the negative binomial distribution, this tests the fixed ancillary parameter.

Model Effects. The following options are available:

- **Analysis Type.** Specify the type of analysis to produce. Type I analysis is generally appropriate when you have a priori reasons for ordering predictors in the model, while Type III is more generally applicable. Wald or likelihood-ratio statistics are computed based upon the selection in the Chi-Square Statistics group.
- **Confidence Interval Level (%).** Specify a confidence level greater than 50 and less than 100. Wald intervals are based on the assumption that parameters have an asymptotic normal distribution; profile likelihood intervals are more accurate but can be computationally expensive. The tolerance level for profile likelihood intervals is the criteria used to stop the iterative algorithm used to compute the intervals.
- **Log-Likelihood Function.** This controls the display format of the log-likelihood function. The full function includes an additional term that is constant with respect to the parameter estimates; it has no effect on parameter estimation and is left out of the display in some software products.

GenLin Model Nugget

A GenLin model nugget represents the equations estimated by a GenLin node. They contain all of the information captured by the model, as well as information about the model structure and performance.

When you run a stream containing a GenLin model nugget, the node adds new fields whose contents depend on the nature of the target field:

- **Flag target.** Adds fields containing the predicted category and associated probability and the probabilities for each category. The names of the first two new fields are derived from the name of the output field being predicted, prefixed with $\$G-$ for the predicted category and $\$GP-$ for the associated probability. For example, for an output field named *default*, the new fields would be named $\$G-default$ and $\$GP-default$. The latter two additional fields are named based on the values of the output field, prefixed by $\$GP-$. For example, if the legal values of *default* are Yes and No, the new fields would be named $\$GP-Yes$ and $\$GP-No$.
- **Continuous target.** Adds fields containing the predicted mean and standard error.
- **Continuous target, representing number of events in a series of trials.** Adds fields containing the predicted mean and standard error.
- **Ordinal target.** Adds fields containing the predicted category and associated probability for each value of the ordered set. The names of the fields are derived from the value of the ordered set being predicted, prefixed with $\$G-$ for the predicted category and $\$GP-$ for the associated probability.

Generating a Filter node. The Generate menu allows you to create a new Filter node to pass input fields based on the results of the model.

Predictor Importance

Optionally, a chart that indicates the relative importance of each predictor in estimating the model may also be displayed on the Model tab. Typically you will want to focus your modeling efforts on the predictors that matter most and consider dropping or ignoring those that matter least. Note this chart is only available if Calculate predictor importance is selected on the Analyze tab before generating the model. See the topic [Predictor Importance](#) for more information.

GenLin Model Nugget Settings

The Settings tab for a GenLin model nugget allows you to obtain propensity scores when scoring the model, and also for SQL generation during model scoring. This tab is available for models with flag targets only, and only after the model nugget has been added to a stream.

Calculate raw propensity scores. For models with a flag target (which return a yes or no prediction), you can request propensity scores that indicate the likelihood of the true outcome specified for the target field. These are in addition to other prediction and confidence values that may be generated during scoring.

Calculate adjusted propensity scores. Raw propensity scores are based only on the training data and may be overly optimistic due to the tendency of many models to overfit this data. Adjusted propensities attempt to compensate by evaluating model performance against a test or validation partition. This option requires that a partition field be defined in the stream and adjusted propensity scores be enabled in the modeling node before generating the model.

Generate SQL for this model When using data from a database, SQL code can be pushed back to the database for execution, providing superior performance for many operations.

Select one of the following options to specify how SQL generation is performed.

- Default: Score using Server Scoring Adapter (if installed) otherwise in process If connected to a database with a scoring adapter installed, generates SQL using the scoring adapter and associated user defined functions (UDF) and scores your model within the database. When no scoring adapter is available, this option fetches your data back from the database and scores it in SPSS® Modeler.
- Score outside of the Database If selected, this option fetches your data back from the database and scores it in SPSS Modeler.

Generalized Linear Mixed Models

- [GLMM Node](#)

GLMM Node

Use this node to create a generalized linear mixed model (GLMM).

- [Generalized linear mixed models](#)

Generalized linear mixed models

Generalized linear mixed models extend the linear model so that:

- The target is linearly related to the factors and covariates via a specified link function.
- The target can have a non-normal distribution.
- The observations can be correlated.

Generalized linear mixed models cover a wide variety of models, from simple linear regression to complex multilevel models for non-normal longitudinal data.

Examples. The district school board can use a generalized linear mixed model to determine whether an experimental teaching method is effective at improving math scores. Students from the same classroom should be correlated since they are taught by the same teacher, and classrooms within the same school may also be correlated, so we can include random effects at school and class levels to account for different sources of variability.

Medical researchers can use a generalized linear mixed model to determine whether a new anticonvulsant drug can reduce a patient's rate of epileptic seizures. Repeated measurements from the same patient are typically positively correlated so a mixed model with some random effects should be appropriate. The target field, the number of seizures, takes positive integer values, so a generalized linear mixed model with a Poisson distribution and log link may be appropriate.

Executives at a cable provider of television, phone, and internet services can use a generalized linear mixed model to know more about potential customers. Since possible answers have nominal measurement levels, the company analyst uses a generalized logit mixed model with a random intercept to capture correlation between answers to the service usage questions across service types (tv, phone, internet) within a given survey responder's answers.

The Data Structure tab allows you to specify the structural relationships between records in your dataset when observations are correlated. If the records in the dataset represent independent observations, you do not need to specify anything on this tab.

Subjects. The combination of values of the specified categorical fields should uniquely define subjects within the dataset. For example, a single *Patient ID* field should be sufficient to define subjects in a single hospital, but the combination of *Hospital ID* and *Patient ID* may be necessary if patient identification numbers are not unique across hospitals. In a repeated measures setting, multiple observations are recorded for each subject, so each subject may occupy multiple records in the dataset.

A **subject** is an observational unit that can be considered independent of other subjects. For example, the blood pressure readings from a patient in a medical study can be considered independent of the readings from other patients. Defining subjects becomes particularly important when there are repeated measurements per subject and you want to model the correlation between these observations. For example, you might expect that blood pressure readings from a single patient during consecutive visits to the doctor are correlated.

All of the fields specified as Subjects on the Data Structure tab are used to define subjects for the residual covariance structure, and provide the list of possible fields for defining subjects for random-effects covariance structures on the [Random Effect Block](#).

Repeated measures. The fields specified here are used to identify repeated observations. For example, a single variable *Week* might identify the 10 weeks of observations in a medical study, or *Month* and *Day* might be used together to identify daily observations over the course of a year.

Define covariance groups by. The categorical fields specified here define independent sets of repeated effects covariance parameters; one for each category defined by the cross-classification of the grouping fields. All subjects have the same covariance type; subjects within the same covariance grouping will have the same values for the parameters.

Spatial covariance coordinates. The variables in this list specify the coordinates of the repeated observations when one of the spatial covariance types is selected for the repeated covariance type.

Repeated covariance type. This specifies the covariance structure for the residuals. The available structures are:

- First-order autoregressive (AR1)
 - Autoregressive moving average (1,1) (ARMA11)
 - Compound symmetry
 - Diagonal
 - Scaled identity
 - Spatial: Power
 - Spatial: Exponential
 - Spatial: Gaussian
 - Spatial: Linear
 - Spatial: Linear-log
 - Spatial: Spherical
 - Toeplitz
 - Unstructured
 - Variance components

Target (generalized linear mixed models)

These settings define the target, its distribution, and its relationship to the predictors through the link function.

Target. The target is required. It can have any measurement level, and the measurement level of the target restricts which distributions and link functions are appropriate.

- **Use number of trials as denominator.** When the target response is a number of events occurring in a set of trials, the target field contains the number of events and you can select an additional field containing the number of trials. For example, when testing a new pesticide you might expose samples of ants to different concentrations of the pesticide and then record the number of ants killed and the number of ants in each sample. In this case, the field recording the number of ants killed should be specified as the target (events) field, and the field recording the number of ants in each sample should be specified as the trials field. If the number of ants is the same for each sample, then the number of trials may be specified using a fixed value.
The number of trials should be greater than or equal to the number of events for each record. Events should be non-negative integers, and trials should be positive integers.
- **Customize reference category.** For a categorical target, you can choose the reference category. This can affect certain output, such as parameter estimates, but it should not change the model fit. For example, if your target takes values 0, 1, and 2, by default, the procedure makes the last (highest-valued) category, or 2, the reference category. In this situation, parameter estimates should be interpreted as relating to the likelihood of category 0 or 1 relative to the likelihood of category 2. If you specify a custom category and your target has defined labels, you can set the reference category by choosing a value from the list. This can be convenient when, in the middle of specifying a model, you don't remember exactly how a particular field was coded.

Target Distribution and Relationship (Link) with the Linear Model. Given the values of the predictors, the model expects the distribution of values of the target to follow the specified shape, and for the target values to be linearly related to the predictors through the specified link function. Short cuts for several common models are provided, or choose a Custom setting if there is a particular distribution and link function combination you want to fit that is not on the short list.

- **Linear model.** Specifies a normal distribution with an identity link, which is useful when the target can be predicted using a linear regression or ANOVA model.
- **Gamma regression.** Specifies a Gamma distribution with a log link, which should be used when the target contains all positive values and is skewed towards larger values.
- **Loglinear.** Specifies a Poisson distribution with a log link, which should be used when the target represents a count of occurrences in a fixed period of time.
- **Negative binomial regression.** Specifies a negative binomial distribution with a log link, which should be used when the target and denominator represent the number of trials required to observe k successes.
- **Multinomial logistic regression.** Specifies a multinomial distribution, which should be used when the target is a multi-category response. It uses either a cumulative logit link (ordinal outcomes) or a generalized logit link (multi-category nominal responses).
- **Binary logistic regression.** Specifies a binomial distribution with a logit link, which should be used when the target is a binary response predicted by a logistic regression model.
- **Binary probit.** Specifies a binomial distribution with a probit link, which should be used when the target is a binary response with an underlying normal distribution.
- **Interval censored survival.** Specifies a binomial distribution with a complementary log-log link, which is useful in survival analysis when some observations have no termination event.

Distribution

This selection specifies the distribution of the target. The ability to specify a non-normal distribution and non-identity link function is the essential improvement of the generalized linear mixed model over the linear mixed model. There are many possible distribution-link function combinations, and several may be appropriate for any given dataset, so your choice can be guided by a priori theoretical considerations or which combination seems to fit best.

Binomial

This distribution is appropriate only for a target that represents a binary response or number of events.

Gamma

This distribution is appropriate for a target with positive scale values that are skewed toward larger positive values. If a data value is less than or equal to 0 or is missing, then the corresponding case is not used in the analysis.

Inverse Gaussian

This distribution is appropriate for a target with positive scale values that are skewed toward larger positive values. If a data value is less than or equal to 0 or is missing, then the corresponding case is not used in the analysis.

Multinomial

This distribution is appropriate for a target that represents a multi-category response. The form of the model will depend on the measurement level of the target.

A **nominal** target will result in a nominal multinomial model in which a separate set of model parameters are estimated for each category of the target (except the reference category). The parameter estimates for a given predictor show the relationship between that predictor and the likelihood of each category of the target, relative to the reference category.

An **ordinal** target will result in an ordinal multinomial model in which the traditional intercept term is replaced with a set of **threshold** parameters that relate to the cumulative probability of the target categories.

Negative binomial

Negative binomial regression uses a negative binomial distribution with a log link, which should be used when the target represents a count of occurrences with high variance.

Normal

This is appropriate for a continuous target whose values take a symmetric, bell-shaped distribution about a central (mean) value.

Poisson

This distribution can be thought of as the number of occurrences of an event of interest in a fixed period of time and is appropriate for variables with non-negative integer values. If a data value is non-integer, less than 0, or missing, then the corresponding case is not used in the analysis.

Link function

The link function is a transformation of the target that allows estimation of the model. The following functions are available:

Identity

$f(x)=x$. The target is not transformed. This link can be used with any distribution, except the multinomial.

Complementary log-log

$f(x)=\log(-\log(1-x))$. This is appropriate only with the binomial or multinomial distribution.

Cauchit

$f(x) = \tan(\pi(x - 0.5))$. This is appropriate only with the binomial or multinomial distribution.

Log

$f(x)=\log(x)$. This link can be used with any distribution, except the multinomial.

Log complement

$f(x)=\log(1-x)$. This is appropriate only with the binomial distribution.

Logit

$f(x)=\log(x / (1-x))$. This is appropriate only with the binomial or multinomial distribution.

Negative log-log

$f(x)=-\log(-\log(x))$. This is appropriate only with the binomial or multinomial distribution.

Probit

$f(x)=\Phi^{-1}(x)$, where Φ^{-1} is the inverse standard normal cumulative distribution function. This is appropriate only with the binomial or multinomial distribution.

Power

$f(x)=x^\alpha$, if $\alpha \neq 0$. $f(x)=\log(x)$, if $\alpha=0$. α is the required number specification and must be a real number. This link can be used with any distribution, except the multinomial.

Fixed Effects (generalized linear mixed models)

Fixed effects factors are generally thought of as fields whose values of interest are all represented in the dataset, and can be used for scoring. By default, fields with the predefined input role that are not specified elsewhere in the dialog are entered in the fixed effects portion of the model. Categorical (flag, nominal, and ordinal) fields are used as factors in the model and continuous fields are used as covariates.

Enter effects into the model by selecting one or more fields in the source list and dragging to the effects list. The type of effect created depends upon which hotspot you drop the selection.

- **Main.** Dropped fields appear as separate main effects at the bottom of the effects list.
- **2-way.** All possible pairs of the dropped fields appear as 2-way interactions at the bottom of the effects list.
- **3-way.** All possible triplets of the dropped fields appear as 3-way interactions at the bottom of the effects list.
- *****. The combination of all dropped fields appear as a single interaction at the bottom of the effects list.

Buttons to the right of the Effect Builder allow you to perform various actions.

Table 1. Effect builder button descriptions

Icon	Description
	Delete terms from the fixed effects model by selecting the terms you want to delete and clicking the delete button.
	Reorder the terms within the fixed effects model by selecting the terms you want to reorder and clicking the up or down arrow.
	Add nested terms to the model using the Add a Custom Term (generalized linear mixed models) dialog, by clicking on the Add a Custom Term button.

Include Intercept. The intercept is usually included in the model. If you can assume the data pass through the origin, you can exclude the intercept.

-

Add a Custom Term (generalized linear mixed models)

You can build nested terms for your model in this procedure. Nested terms are useful for modeling the effect of a factor or covariate whose values do not interact with the levels of another factor. For example, a grocery store chain may follow the spending habits of its customers at several store locations. Since each customer frequents only one of these locations, the *Customer* effect can be said to be **nested within** the *Store location* effect.

Additionally, you can include interaction effects, such as polynomial terms involving the same covariate, or add multiple levels of nesting to the nested term.

Limitations: Nested terms have the following restrictions:

- All factors within an interaction must be unique. Thus, if A is a factor, then specifying A*A is invalid.
- All factors within a nested effect must be unique. Thus, if A is a factor, then specifying A(A) is invalid.
- No effect can be nested within a covariate. Thus, if A is a factor and X is a covariate, then specifying A(X) is invalid.

Constructing a nested term

1. Select a factor or covariate that is nested within another factor, and then click the arrow button.
2. Click (Within).
3. Select the factor within which the previous factor or covariate is nested, and then click the arrow button.
4. Click Add Term.

Optionally, you can include interaction effects or add multiple levels of nesting to the nested term.

Random Effects (generalized linear mixed models)

Random effects factors are fields whose values in the data file can be considered a random sample from a larger population of values. They are useful for explaining excess variability in the target. By default, if you have selected more than one subject in the Data Structure tab, a Random Effect block will be created for each subject beyond the innermost subject. For example, if you selected School, Class, and Student as subjects on the Data Structure tab, the following random effect blocks are automatically created:

- Random Effect 1: subject is school (with no effects, intercept only)
- Random Effect 2: subject is school * class (no effects, intercept only)

You can work with random effects blocks in the following ways:

1. To add a new block, click Add Block... This opens the [Random Effect Block \(generalized linear mixed models\)](#) dialog.
 2. To edit an existing block, select the block you want to edit and click Edit Block... This opens the [Random Effect Block \(generalized linear mixed models\)](#) dialog.
 3. To delete one or more blocks, select the blocks you want to delete and click the delete button.
- [Random Effect Block \(generalized linear mixed models\)](#)

Table 1. Effect builder button descriptions

Icon	Description
	Delete terms from the model by selecting the terms you want to delete and clicking the delete button.
	Reorder the terms within the model by selecting the terms you want to reorder and clicking the up or down arrow.
	Add nested terms to the model using the Add a Custom Term (generalized linear mixed models) dialog, by clicking on the Add a Custom Term button.

Include Intercept. The intercept is not included in the random effects model by default. If you can assume the data pass through the origin, you can exclude the intercept.

Display parameter predictions for this block. Specifies to display the random-effects parameter estimates.

Define covariance groups by. The categorical fields specified here define independent sets of random effects covariance parameters; one for each category defined by the cross-classification of the grouping fields. A different set of grouping fields can be specified for each random effect block. All subjects have the same covariance type; subjects within the same covariance grouping will have the same values for the parameters.

Subject combination. This allows you to specify random effect subjects from preset combinations of subjects from the Data Structure tab. For example, if *School*, *Class*, and *Student* are defined as subjects on the Data Structure tab, and in that order, then the Subject combination dropdown list will have None, *School*, *School * Class*, and *School * Class * Student* as options.

Random effect covariance type. This specifies the covariance structure for the residuals. The available structures are:

- First-order autoregressive (AR1)
- Heterogeneous autoregressive (ARH1)
- Autoregressive moving average (1,1) (ARMA11)
- Compound symmetry
- Heterogeneous compound symmetry (CSH)
- Diagonal
- Scaled identity
- Toeplitz
- Unstructured
- Variance components

Weight and Offset (generalized linear mixed models)

Analysis weight. The scale parameter is an estimated model parameter related to the variance of the response. The analysis weights are "known" values that can vary from observation to observation. If the analysis weight field is specified, the scale parameter, which is related to the variance of the response, is divided by the analysis weight values for each observation. Records with analysis weight values that are less than or equal to 0 or are missing are not used in the analysis.

Offset. The offset term is a "structural" predictor. Its coefficient is not estimated by the model but is assumed to have the value 1; thus, the values of the offset are simply added to the linear predictor of the target. This is especially useful in Poisson regression models, where each case may have different levels of exposure to the event of interest.

For example, when modeling accident rates for individual drivers, there is an important difference between a driver who has been at fault in one accident in three years of experience and a driver who has been at fault in one accident in 25 years! The number of accidents can be modeled as a Poisson or negative binomial response with a log link if the natural log of the experience of the driver is included as an offset term.

Other combinations of distribution and link types would require other transformations of the offset variable.

General Build Options (generalized linear mixed models)

These selections specify some more advanced criteria used to build the model.

Sorting Order

These controls determine the order of the categories for the target and factors (categorical inputs) for purposes of determining the "last" category. The target sort order setting is ignored if the target is not categorical or if a custom reference category is specified on the [Target \(generalized linear mixed models\)](#) settings.

Stopping Rules

You can specify the maximum number of iterations the algorithm will execute. The algorithm uses a doubly iterative process that consists of an inner loop and an outer loop. The value that is specified for the maximum number of iterations applies to both loops. Specify a non-negative integer. The default is 100.

Post-Estimation Settings

These settings determine how some of the model output is computed for viewing.

Confidence level (%)

This is the level of confidence used to compute interval estimates of the model coefficients. Specify a value greater than 0 and less than 100. The default is 95.

Degrees of freedom

This specifies how degrees of freedom are computed for significance tests. Choose Residual method if your sample size is sufficiently large, or the data are balanced, or the model uses a simpler covariance type (for example, scaled identity or diagonal). This is the default setting. Choose Satterthwaite approximation if your sample size is small, or the data are unbalanced, or the model uses a complicated covariance type (for example, unstructured). Choose Kenward-Roger approximation if your sample size is small and you have a Restricted Maximum Likelihood (REML) model.

Tests of fixed effects and coefficients

This is the method for computing the parameter estimates covariance matrix. Choose the robust estimate if you are concerned that the model assumptions are violated.

 - [Estimation \(generalized linear mixed models\)](#)
-

Estimation (generalized linear mixed models)

The model building algorithm uses a doubly iterative process that consists of an inner loop and an outer loop. The following settings apply to the inner loop.

Sorting Order

These controls determine the order of the categories for the target and factors (categorical inputs) for purposes of determining the "last" category. The target sort order setting is ignored if the target is not categorical or if a custom reference category is specified on the [Target \(generalized linear mixed models\)](#) settings.

Parameter Convergence.

Convergence is assumed if the maximum absolute change or maximum relative change in the parameter estimates is less than the value specified, which must be non-negative. The criterion is not used if the value specified equals 0.

Log-likelihood Convergence.

Convergence is assumed if the absolute change or relative change in the log-likelihood function is less than the value specified, which must be non-negative. The criterion is not used if the value specified equals 0.

Hessian Convergence.

For the Absolute specification, convergence is assumed if a statistic based on the Hessian is less than the value specified. For the Relative specification, convergence is assumed if the statistic is less than the product of the value specified and the absolute value of the log-likelihood. The criterion is not used if the value specified equals 0.

Maximum Fisher scoring steps.

Specify a non-negative integer. A value of 0 specifies the Newton-Raphson method. Values greater than 0 specify to use the Fisher scoring algorithm up to iteration number n , where n is the specified integer, and Newton-Raphson thereafter.

Singularity tolerance.

This value is used as the tolerance in checking singularity. Specify a positive value.

Stopping Rules

You can specify the maximum number of iterations the algorithm will execute. The algorithm uses a doubly iterative process that consists of an inner loop and an outer loop. The value that is specified for the maximum number of iterations applies to both loops. Specify a non-negative integer. The default is 100.

Post-Estimation Settings

These settings determine how some of the model output is computed for viewing.

Confidence level (%)

This is the level of confidence used to compute interval estimates of the model coefficients. Specify a value greater than 0 and less than 100. The default is 95.

Degrees of freedom

This specifies how degrees of freedom are computed for significance tests. Choose Residual method if your sample size is sufficiently large, or the data are balanced, or the model uses a simpler covariance type (for example, scaled identity or diagonal). This is the default setting. Choose Satterthwaite approximation if your sample size is small, or the data are unbalanced, or the model uses a complicated covariance type (for example, unstructured). Choose Kenward-Roger approximation if your sample size is small and you have a Restricted Maximum Likelihood (REML) model.

Tests of fixed effects and coefficients

This is the method for computing the parameter estimates covariance matrix. Choose the robust estimate if you are concerned that the model assumptions are violated.

Note: By default, Parameter Convergence is used, where the maximum Absolute change at a tolerance of 1E-6 is checked. This setting might produce results that differ from the results that are obtained in versions before version 22. To reproduce results from pre-22 versions, use Relative for the Parameter Convergence criterion and keep the default tolerance value of 1E-6.

General (generalized linear mixed models)

Model Name. You can generate the model name automatically based on the target fields or specify a custom name. The automatically generated name is the target field name. If there are multiple targets, then the model name is the field names in order, connected by ampersands. For example, if *field1* *field2* *field3* are targets, then the model name is: *field1 & field2 & field3*.

Make Available for Scoring. When the model is scored, the selected items in this group should be produced. The predicted value (for all targets) and confidence (for categorical targets) are always computed when the model is scored. The computed confidence can be based on the probability of the predicted value (the highest predicted probability) or the difference between the highest predicted probability and the second highest predicted probability.

- Predicted probability for categorical targets. This produces the predicted probabilities for categorical targets. A field is created for each category.
- Propensity scores for flag targets. For models with a flag target (which return a yes or no prediction), you can request propensity scores that indicate the likelihood of the true outcome specified for the target field. The model produces raw propensity scores; if partitions are in effect, the model also produces adjusted propensity scores based on the testing partition.

Estimated Means (generalized linear mixed models)

This tab allows you to display the estimated marginal means for levels of factors and factor interactions. Estimated marginal means are not available for multinomial models.

Terms

The model terms in the Fixed Effects that are entirely comprised of categorical fields are listed here. Check each term for which you want the model to produce estimated marginal means.

Contrast Type

This specifies the type of contrast to use for the levels of the contrast field.

None

No contrasts are produced.

Pairwise

Produces pairwise comparisons for all level combinations of the specified factors. This is the only available contrast for factor interactions.

Deviation

Contrasts compare each level of the factor to the grand mean.

Simple

Contrasts compare each level of the factor, except the last, to the last level. The "last" level is determined by the sort order for factors specified on the Build Options. Note that all of these contrast types are not orthogonal.

Contrast Field

This specifies a factor, the levels of which are compared using the selected contrast type. If None is selected as the contrast type, no contrast field can (or need) be selected.

Continuous Fields

The listed continuous fields are extracted from the terms in the Fixed Effects that use continuous fields. When computing estimated marginal means, covariates are fixed at the specified values. Select the mean or specify a custom value.

Adjust for multiple comparisons using

When performing hypothesis tests with multiple contrasts, the overall significance level can be adjusted from the significance levels for the included contrasts. This allows you to choose the adjustment method.

Least significant difference

This method does not control the overall probability of rejecting the hypotheses that some linear contrasts are different from the null hypothesis values.

Sequential Bonferroni

This is a sequentially step-down rejective Bonferroni procedure that is much less conservative in terms of rejecting individual hypotheses but maintains the same overall significance level.

Sequential Sidak

This is a sequentially step-down rejective Sidak procedure that is much less conservative in terms of rejecting individual hypotheses but maintains the same overall significance level.

The least significant difference method is less conservative than the sequential Sidak method, which in turn is less conservative than the sequential Bonferroni; that is, least significant difference will reject at least as many individual hypotheses as sequential Sidak, which in turn will reject at least as many individual hypotheses as sequential Bonferroni.

Display estimated means in terms of

This specifies whether to compute estimated marginal means based on the original scale of the target or based on the link function transformation.

Original target scale

Computes estimated marginal means for the target. Note that when the target is specified using the events/trials option, this gives the estimated marginal means for the events/trials proportion rather than for the number of events.

Link function transformation

Computes estimated marginal means for the linear predictor.

Model Summary (generalized linear mixed models)

This view is a snapshot, at-a-glance summary of the model and its fit.

Table. The table identifies the target, probability distribution, and link function specified on the [Target settings](#). If the target is defined by events and trials, the cell is split to show the events field and the trials field or fixed number of trials. Additionally the finite sample corrected Akaike information criterion (AICC) and Bayesian information criterion (BIC) are displayed.

- *Akaike Corrected*. A measure for selecting and comparing mixed models based on the -2 (Restricted) log likelihood. Smaller values indicate better models. The AICC "corrects" the AIC for small sample sizes. As the sample size increases, the AICC converges to the AIC.
- *Bayesian*. A measure for selecting and comparing models based on the -2 log likelihood. Smaller values indicate better models. The BIC also "penalizes" overparameterized models (complex models with a large number of inputs, for example), but more strictly than the AIC.

Chart. If the target is categorical, a chart displays the accuracy of the final model, which is the percentage of correct classifications.

Data Structure (generalized linear mixed models)

This view provides a summary of the data structure you specified, and helps you to check that the subjects and repeated measures have been specified correctly. The observed information for the first subject is displayed for each subject field and repeated measures field, and the target. Additionally, the number of levels for each subject field and repeated measures field is displayed.

Predicted by Observed (generalized linear mixed models)

For continuous targets, including targets specified as events/trials, this displays a binned scatterplot of the predicted values on the vertical axis by the observed values on the horizontal axis. Ideally, the points should lie on a 45-degree line; this view can tell you whether any records are predicted particularly badly by the model.

Classification (generalized linear mixed models)

For categorical targets, this displays the cross-classification of observed versus predicted values in a heat map, plus the overall percent correct.

Table styles. There are several different display styles, which are accessible from the Style dropdown list.

- **Row percents.** This displays the row percentages (the cell counts expressed as a percent of the row totals) in the cells. This is the default.
- **Cell counts.** This displays the cell counts in the cells. The shading for the heat map is still based on the row percentages.
- **Heat map.** This displays no values in the cells, just the shading.
- **Compressed.** This displays no row or column headings, or values in the cells. It can be useful when the target has a lot of categories.

Missing. If any records have missing values on the target, they are displayed in a (Missing) row under all valid rows. Records with missing values do not contribute to the overall percent correct.

Multiple targets. If there are multiple categorical targets, then each target is displayed in a separate table and there is a Target dropdown list that controls which target to display.

Large tables. If the displayed target has more than 100 categories, no table is displayed.

Fixed Effects (generalized linear mixed models)

This view displays the size of each fixed effect in the model.

Styles. There are different display styles, which are accessible from the Style dropdown list.

- **Diagram.** This is a chart in which effects are sorted from top to bottom in the order in which they were specified on the Fixed Effects settings. Connecting lines in the diagram are weighted based on effect significance, with greater line width corresponding to more significant effects (smaller p -values). This is the default.
- **Table.** This is an ANOVA table for the overall model and the individual model effects. The individual effects are sorted from top to bottom in the order in which they were specified on the Fixed Effects settings.

Significance. There is a Significance slider that controls which effects are shown in the view. Effects with significance values greater than the slider value are hidden. This does not change the model, but simply allows you to focus on the most important effects. By default the value is 1.00, so that no effects are filtered based on significance.

Fixed Coefficients (generalized linear mixed models)

This view displays the value of each fixed coefficient in the model. Note that factors (categorical predictors) are indicator-coded within the model, so that **effects** containing factors will generally have multiple associated **coefficients**; one for each category except the category corresponding to the redundant coefficient.

Styles. There are different display styles, which are accessible from the Style dropdown list.

- **Diagram.** This is a chart which displays the intercept first, and then sorts effects from top to bottom in the order in which they were specified on the Fixed Effects settings. Within effects containing factors, coefficients are sorted by ascending order of data values. Connecting lines in the diagram are colored and weighted based on coefficient significance, with greater line width corresponding to more significant coefficients (smaller p -values). This is the default style.
- **Table.** This shows the values, significance tests, and confidence intervals for the individual model coefficients. After the intercept, the effects are sorted from top to bottom in the order in which they were specified on the Fixed Effects settings. Within effects containing factors, coefficients are sorted by ascending order of data values.

Multinomial. If the multinomial distribution is in effect, then the Multinomial drop-down list controls which target category to display. The sort order of the values in the list is determined by the specification on the Build Options settings.

Exponential. This displays exponential coefficient estimates and confidence intervals for certain model types, including Binary logistic regression (binomial distribution and logit link), Nominal logistic regression (multinomial distribution and logit link), Negative binomial regression (negative binomial distribution and log link), and Log-linear model (Poisson distribution and log link).

Significance. There is a Significance slider that controls which coefficients are shown in the view. Coefficients with significance values greater than the slider value are hidden. This does not change the model, but simply allows you to focus on the most important coefficients. By default the value is 1.00, so that no coefficients are filtered based on significance.

Random Effect Covariances (generalized linear mixed models)

This view displays the random effects covariance matrix (\mathbf{G}).

Styles. There are different display styles, which are accessible from the Style dropdown list.

- **Covariance values.** This is a heat map of the covariance matrix in which effects are sorted from top to bottom in the order in which they were specified on the Fixed Effects settings. Colors in the corrgram correspond to the cell values as shown in the key. This is the default.
- **Corrgram.** This is a heat map of the covariance matrix.
- **Compressed.** This is a heat map of the covariance matrix without the row and column headings.

Blocks. If there are multiple random effect blocks, then there is a Block dropdown list for selecting the block to display.

Groups. If a random effect block has a group specification, then there is a Group dropdown list for selecting the group level to display.

Multinomial. If the multinomial distribution is in effect, then the Multinomial drop-down list controls which target category to display. The sort order of the values in the list is determined by the specification on the Build Options settings.

Covariance Parameters (generalized linear mixed models)

This view displays the covariance parameter estimates and related statistics for residual and random effects. These are advanced, but fundamental, results that provide information on whether the covariance structure is suitable.

Summary table. This is a quick reference for the number of parameters in the residual (**R**) and random effect (**G**) covariance matrices, the rank (number of columns) in the fixed effect (**X**) and random effect (**Z**) design matrices, and the number of subjects defined by the subject fields that define the data structure.

Covariance parameter table. For the selected effect, the estimate, standard error, and confidence interval are displayed for each covariance parameter. The number of parameters shown depends upon the covariance structure for the effect and, for random effect blocks, the number of effects in the block. If you see that the off-diagonal parameters are not significant, you may be able to use a simpler covariance structure.

Effects. If there are random effect blocks, then there is an Effect dropdown list for selecting the residual or random effect block to display. The residual effect is always available.

Groups. If a residual or random effect block has a group specification, then there is a Group dropdown list for selecting the group level to display.

Multinomial. If the multinomial distribution is in effect, then the Multinomial drop-down list controls which target category to display. The sort order of the values in the list is determined by the specification on the Build Options settings.

Estimated Means: Significant Effects (generalized linear mixed models)

These are charts displayed for the 10 "most significant" fixed all-factor effects, starting with the three-way interactions, then the two-way interactions, and finally main effects. The chart displays the model-estimated value of the target on the vertical axis for each value of the main effect (or first listed effect in an interaction) on the horizontal axis; a separate line is produced for each value of the second listed effect in an interaction; a separate chart is produced for each value of the third listed effect in a three-way interaction; all other predictors are held constant. It provides a useful visualization of the effects of each predictor's coefficients on the target. Note that if no predictors are significant, no estimated means are produced.

Confidence. This displays upper and lower confidence limits for the marginal means, using the confidence level specified as part of the Build Options.

- [Covariance Parameters \(generalized linear mixed models\)](#)
- [Estimated Means: Custom Effects \(generalized linear mixed models\)](#)

Estimated Means: Custom Effects (generalized linear mixed models)

These are tables and charts for user-requested fixed all-factor effects.

Styles. There are different display styles, which are accessible from the Style dropdown list.

- **Diagram.** This style displays a line chart of the model-estimated value of the target on the vertical axis for each value of the main effect (or first listed effect in an interaction) on the horizontal axis; a separate line is produced for each value of the second listed effect in an interaction; a separate chart is produced for each value of the third listed effect in a three-way interaction; all other predictors are held constant.

If contrasts were requested, another chart is displayed to compare levels of the contrast field; for interactions, a chart is displayed for each level combination of the effects other than the contrast field. For **pairwise** contrasts, it is a distance network chart; that is, a graphical representation of the comparisons table in which the distances between nodes in the network correspond to differences between samples. Yellow lines correspond to statistically significant differences; black lines correspond to non-significant differences. Hovering over a line in the network displays a tooltip with the adjusted significance of the difference between the nodes connected by the line.

For **deviation** contrasts, a bar chart is displayed with the model-estimated value of the target on the vertical axis and the values of the contrast field on the horizontal axis; for interactions, a chart is displayed for each level combination of the effects other than the contrast field. The bars show the difference between each level of the contrast field and the overall mean, which is represented by a black horizontal line.

For **simple** contrasts, a bar chart is displayed with the model-estimated value of the target on the vertical axis and the values of the contrast field on the horizontal axis; for interactions, a chart is displayed for each level combination of the effects other than the contrast field. The bars show the difference between each level of the contrast field (except the last) and the last level, which is represented by a black horizontal line.

- **Table.** This style displays a table of the model-estimated value of the target, its standard error, and confidence interval for each level combination of the fields in the effect; all other predictors are held constant. If contrasts were requested, another table is displayed with the estimate, standard error, significance test, and confidence interval for each contrast; for interactions, there a separate set of rows for each level combination of the effects other than the contrast field. Additionally, a table with the overall test results is displayed; for interactions, there is a separate overall test for each level combination of the effects other than the contrast field.

Confidence. This toggles the display of upper and lower confidence limits for the marginal means, using the confidence level specified as part of the Build Options.

Layout. This toggles the layout of the pairwise contrasts diagram. The circle layout is less revealing of contrasts than the network layout but avoids overlapping lines.

Settings (generalized linear mixed models)

When the model is scored, the selected items in this tab should be produced. The predicted value (for all targets) and confidence (for categorical targets) are always computed when the model is scored. The computed confidence can be based on the probability of the predicted value (the highest predicted probability) or the difference between the highest predicted probability and the second highest predicted probability.

- Predicted probability for categorical targets. This produces the predicted probabilities for categorical targets. A field is created for each category.
- Propensity scores for flag targets. For models with a flag target (which return a yes or no prediction), you can request propensity scores that indicate the likelihood of the true outcome specified for the target field. The model produces raw propensity scores; if partitions are in effect, the model also produces adjusted propensity scores based on the testing partition.

Generate SQL for this model When using data from a database, SQL code can be pushed back to the database for execution, providing superior performance for many operations.

Select one of the following options to specify how SQL generation is performed.

- Default: Score using Server Scoring Adapter (if installed) otherwise in process If connected to a database with a scoring adapter installed, generates SQL using the scoring adapter and associated user defined functions (UDF) and scores your model within the database. When no scoring adapter is available, this option fetches your data back from the database and scores it in SPSS® Modeler.
- Score outside of the Database If selected, this option fetches your data back from the database and scores it in SPSS Modeler.

GLE Node

The GLE model identifies the dependent variable that is linearly related to the factors and covariates via a specified link function. Moreover, the model allows for the dependent variable to have a non-normal distribution. It covers widely used statistical models, such as linear regression for normally distributed responses, logistic models for binary data, loglinear models for count data, complementary log-log models for interval-censored survival data, plus many other statistical models through its very general model formulation.

Examples. A shipping company can use generalized linear models to fit a Poisson regression to damage counts for several types of ships constructed in different time periods, and the resulting model can help determine which ship types are most prone to damage.

A car insurance company can use generalized linear models to fit a gamma regression to damage claims for cars, and the resulting model can help determine the factors that contribute the most to claim size.

Medical researchers can use generalized linear models to fit a complementary log-log regression to interval-censored survival data to predict the time to recurrence for a medical condition.

GLE models work by building an equation that relates the input field values to the output field values. Once the model is generated, it can be used to estimate values for new data.

For a categorical target, for each record, a probability of membership is computed for each possible output category. The target category with the highest probability is assigned as the predicted output value for that record.

Requirements. You need one or more input fields and exactly one target field (which can have a measurement level of *Continuous*, *Categorical*, or *Flag*) with two or more categories. Fields used in the model must have their types fully instantiated.

 - [Model selection \(GLE models\)](#)
 - [Model options \(GLE models\)](#)
 - [GLE model nugget](#)
-

Target (GLE models)

These settings define the target, its distribution, and its relationship to the predictors through the link function.

Target The target is required. It can have any measurement level, and the measurement level of the target affects which distributions and link functions are appropriate.

- Use predefined target To use the target settings from an upstream Type node (or the Types tab of an upstream source node), select this option.
- Use custom target To manually assign a target, select this option.
- Use number of trials as denominator When the target response is a number of events occurring in a set of trials, the target field contains the number of events and you can select an additional field containing the number of trials. For example, when testing a new pesticide you might expose samples of ants to different concentrations of the pesticide and then record the number of ants killed and the number of ants in each sample. In this case, the field recording the number of ants killed should be specified as the target (events) field, and the field recording the number of ants in each sample should be specified as the trials field. If the number of ants is the same for each sample, then the number of trials may be specified using a fixed value.

The number of trials should be greater than or equal to the number of events for each record. Events should be non-negative integers, and trials should be positive integers.

- Customize reference category. For a categorical target, you can choose the reference category. This can affect certain output, such as parameter estimates, but it should not change the model fit. For example, if your target takes values 0, 1, and 2, by default, the procedure makes the last (highest-valued) category, or 2, the reference category. In this situation, parameter estimates should be interpreted as relating to the likelihood of category 0 or 1 *relative* to the likelihood of category 2. If you specify a custom category and your target has defined labels, you can set the reference category by choosing a value from the list. This can be convenient when, in the middle of specifying a model, you don't remember exactly how a particular field was coded.

Target Distribution and Relationship (Link) with the Linear Model Given the values of the predictors, the model expects the distribution of values of the target to follow the specified shape, and for the target values to be linearly related to the predictors through the specified link function. Short cuts for several common models are provided, or choose a Custom setting if there is a particular distribution and link function combination you want to fit that is not on the short list.

- Linear model Specifies a normal distribution with an identity link, which is useful when the target can be predicted using a linear regression or ANOVA model.
- Gamma regression Specifies a Gamma distribution with a log link, which should be used when the target contains all positive values and is skewed towards larger values.
- Loglinear Specifies a Poisson distribution with a log link, which should be used when the target represents a count of occurrences in a fixed period of time.
- Negative binomial regression Specifies a negative binomial distribution with a log link, which should be used when the target and denominator represent the number of trials required to observe k successes.
- Tweedie regression Specifies a Tweedie distribution with identity, log, or power link functions and are useful for modeling responses that are a mixture of zeros and positive real values. These distributions are also called *compound Poisson*, *compound gamma*, and *Poisson-gamma* distributions.
- Multinomial logistic regression Specifies a multinomial distribution, which should be used when the target is a multi-category response. It uses either a cumulative logit link (ordinal outcomes) or a generalized logit link (multi-category nominal responses).
- Binary logistic regression Specifies a binomial distribution with a logit link, which should be used when the target is a binary response predicted by a logistic regression model.
- Binary probit Specifies a binomial distribution with a probit link, which should be used when the target is a binary response with an underlying normal distribution.
- Interval censored survival Specifies a binomial distribution with a complementary log-log link, which is useful in survival analysis when some observations have no termination event.
- Custom Specify your own combination of distribution and link function.

Distribution

This selection specifies the Distribution of the target. The ability to specify a non-normal distribution and non-identity link function is the essential improvement of the generalized linear model over the linear model. There are many possible distribution-link function combinations, and several may be appropriate for any given dataset, so your choice can be guided by a priori theoretical considerations or which combination seems to fit best.

- Automatic If you are unsure which distribution to use, select this option; the node analyzes your data to estimate and apply the best distribution method.
- Binomial This distribution is appropriate only for a target that represents a binary response or number of events.
- Gamma This distribution is appropriate for a target with positive scale values that are skewed toward larger positive values. If a data value is less than or equal to 0 or is missing, then the corresponding case is not used in the analysis.
- Inverse Gaussian This distribution is appropriate for a target with positive scale values that are skewed toward larger positive values. If a data value is less than or equal to 0 or is missing, then the corresponding case is not used in the analysis.
- Multinomial This distribution is appropriate for a target that represents a multi-category response. The form of the model will depend on the measurement level of the target.

A **nominal** target will result in a nominal multinomial model in which a separate set of model parameters are estimated for each category of the target (except the reference category). The parameter estimates for a given predictor show the relationship between that predictor and the likelihood of each category of the target, relative to the reference category.

An **ordinal** target will result in an ordinal multinomial model in which the traditional intercept term is replaced with a set of **threshold** parameters that relate to the cumulative probability of the target categories.

- Negative binomial Negative binomial regression uses a negative binomial distribution with a log link, which should be used when the target represents a count of occurrences with high variance.
- Normal This is appropriate for a continuous target whose values take a symmetric, bell-shaped distribution about a central (mean) value.
- Poisson This distribution can be thought of as the number of occurrences of an event of interest in a fixed period of time and is appropriate for variables with non-negative integer values. If a data value is non-integer, less than 0, or missing, then the corresponding case is not used in the analysis.
- Tweedie This distribution is appropriate for variables that can be represented by Poisson mixtures of gamma distributions; the distribution is "mixed" in the sense that it combines properties of continuous (takes non-negative real values) and discrete distributions (positive probability mass at a single value, 0). The dependent variable must be numeric, with data values greater than or equal to zero. If a data

value is less than zero or missing, then the corresponding case is not used in the analysis. The fixed value of the Tweedie distribution's parameter can be any number greater than one and less than two.

Link functions

The Link function is a transformation of the target that allows estimation of the model. The following functions are available:

- Automatic If you are unsure which link to use, select this option; the node analyzes your data to estimate and apply the best link function.
- Identity $f(x)=x$. The target is not transformed. This link can be used with any distribution, except the multinomial.
- Complementary log-log $f(x)=\log(-\log(1-x))$. This is appropriate only with the binomial or multinomial distribution.
- Cauchit $f(x) = \tan(\pi(x - 0.5))$. This is appropriate only with the binomial or multinomial distribution.
- Log $f(x)=\log(x)$. This link can be used with any distribution, except the multinomial.
- Log complement $f(x)=\log(1-x)$. This is appropriate only with the binomial distribution.
- Logit $f(x)=\log(x / (1-x))$. This is appropriate only with the binomial or multinomial distribution.
- Negative log-log $f(x)=-\log(-\log(x))$. This is appropriate only with the binomial or multinomial distribution.
- Probit $f(x)=\Phi^{-1}(x)$, where Φ^{-1} is the inverse standard normal cumulative distribution function. This is appropriate only with the binomial or multinomial distribution.
- Power $f(x)=x^\alpha$, if $\alpha \neq 0$. $f(x)=\log(x)$, if $\alpha=0$. α is the required number specification and must be a real number. This link can be used with any distribution, except the multinomial.

Parameter for Tweedie Only available if you have selected either the Tweedie regression radio button or Tweedie as the Distribution method. Select a value between 1 and 2.

Model effects (GLE models)

Fixed effects factors are generally thought of as fields whose values of interest are all represented in the dataset, and can be used for scoring. By default, fields with the predefined input role that are not specified elsewhere in the dialog are entered in the fixed effects portion of the model. Categorical (flag, nominal, and ordinal) fields are used as factors in the model and continuous fields are used as covariates.

Enter effects into the model by selecting one or more fields in the source list and dragging to the effects list. The type of effect created depends upon which hotspot you drop the selection.

- Main Dropped fields appear as separate main effects at the bottom of the effects list.
- 2-way All possible pairs of the dropped fields appear as 2-way interactions at the bottom of the effects list.
- 3-way All possible triplets of the dropped fields appear as 3-way interactions at the bottom of the effects list.
- * The combination of all dropped fields appear as a single interaction at the bottom of the effects list.

Buttons to the right of the Effect Builder allow you to perform various actions.

Table 1. Effect builder button descriptions

Icon	Description
	Delete terms from the fixed effects model by selecting the terms you want to delete and clicking the delete button.
	Reorder the terms within the fixed effects model by selecting the terms you want to reorder and clicking the up or down arrow.
	Add nested terms to the model using the Add a Custom Term dialog, by clicking on the Add a Custom Term button.

Include Intercept The intercept is usually included in the model. If you can assume the data pass through the origin, you can exclude the intercept.

- [Add a custom term \(GLE models\)](#)

Add a custom term (GLE models)

You can build nested terms for your model in this procedure. Nested terms are useful for modeling the effect of a factor or covariate whose values do not interact with the levels of another factor. For example, a grocery store chain may follow the spending habits of its customers at several store locations. Since each customer frequents only one of these locations, the Customer effect can be said to be *nested within* the Store location effect.

Additionally, you can include interaction effects, such as polynomial terms involving the same covariate, or add multiple levels of nesting to the nested term.

Limitations. Nested terms have the following restrictions:

- All factors within an interaction must be unique. Thus, if A is a factor, then specifying A*A is invalid.
- All factors within a nested effect must be unique. Thus, if A is a factor, then specifying A(A) is invalid.
- No effect can be nested within a covariate. Thus, if A is a factor and X is a covariate, then specifying A(X) is invalid.

Constructing a nested term

1. Select a factor or covariate that is nested within another factor, and then click the arrow button.
2. Click (Within).
3. Select the factor within which the previous factor or covariate is nested, and then click the arrow button.
4. Click Add Term.

Optionally, you can include interaction effects or add multiple levels of nesting to the nested term.

Weight and Offset (GLE models)

Analysis weight The scale parameter is an estimated model parameter related to the variance of the response. The analysis weights are "known" values that can vary from observation to observation. If the Analysis weight field is specified, the scale parameter, which is related to the variance of the response, is divided by the analysis weight values for each observation. Records with analysis weight values that are less than or equal to 0, or are missing, are not used in the analysis.

Offset The offset term is a *structural* predictor. Its coefficient is not estimated by the model but is assumed to have the value 1; thus, the values of the offset are simply added to the linear predictor of the target. This is especially useful in Poisson regression models, where each case may have different levels of exposure to the event of interest.

For example, when modeling accident rates for individual drivers, there is an important difference between a driver who has been at fault in one accident in three years of experience and a driver who has been at fault in one accident in 25 years. The number of accidents can be modeled as a Poisson or negative binomial response with a log link if the natural log of the experience of the driver is included as an offset term.

Other combinations of distribution and link types would require other transformations of the offset variable.

Build options (GLE models)

These selections specify some more advanced criteria used to build the model.

Sorting Order These controls determine the order of the categories for the target and factors (categorical inputs) for purposes of determining the "last" category. The target sort order setting is ignored if the target is not categorical or if a custom reference category is specified on the [Target \(GLE models\)](#) settings.

Post-Estimation Settings These settings determine how some of the model output is computed for viewing.

- **Confidence level %** This is the level of confidence used to compute interval estimates of the model coefficients. Specify a value greater than 0 and less than 100. The default is 95.
- **Degrees of freedom** This specifies how degrees of freedom are computed for significance tests. Choose Fixed for all tests (Residual method) if your sample size is sufficiently large, or the data are balanced, or the model uses a simpler covariance type; for example, scaled identity or diagonal. This is the default. Choose Varied across tests (Satterthwaite approximation) if your sample size is small, or the data are unbalanced, or the model uses a complicated covariance type; for example, unstructured.
- **Tests of fixed effects and coefficients.** This is the method for computing the parameter estimates covariance matrix. Choose the robust estimate if you are concerned that the model assumptions are violated.

Detect influential outliers For all distributions except multinomial distribution, select this option to identify influential outliers.

Conduct trend analysis For a scatter plot, select this option to conduct trend analysis.

Estimation (GLE models)

Method Select the maximum likelihood estimation method to be used; the available options are:

- Fisher scoring
- Newton-Raphson
- Hybrid

Maximum Fisher iterations Specify a non-negative integer. A value of 0 specifies the Newton-Raphson method. Values greater than 0 specify to use the Fisher scoring algorithm up to iteration number n , where n is the specified integer, and Newton-Raphson thereafter.

Scale parameter method Select the method for the estimation of the scale parameter; the available options are:

- Maximum likelihood estimate
- Fixed value. You also set the Value to be used.
- Deviance
- Pearson Chi-square

Negative Binomial method Select the method for the estimation of the negative binomial ancillary parameter; the available options are:

- Maximum likelihood estimate
- Fixed value. You also set the Value to be used.

Perform non negative least squares. Select this option to perform non-negative least squares (NNLS) estimation. NNLS is a type of constrained least squares problem where the coefficients are not allowed to become negative. Not all data sets are suitable for NNLS, which requires a positive or no correlation between predictors and target.

Parameter Convergence Convergence is assumed if the maximum absolute change or maximum relative change in the parameter estimates is less than the value specified, which must be non-negative. The criterion is not used if the value specified equals 0.

Log-Likelihood Convergence Convergence is assumed if the absolute change or relative change in the log-likelihood function is less than the value specified, which must be non-negative. The criterion is not used if the value specified equals 0.

Hessian Convergence For the Absolute specification, convergence is assumed if a statistic based on the Hessian is less than the value specified. For the Relative specification, convergence is assumed if the statistic is less than the product of the value specified and the absolute value of the log-likelihood. The criterion is not used if the value specified equals 0.

Maximum iterations You can specify the maximum number of iterations the algorithm will execute. The algorithm uses a doubly iterative process that consists of an inner loop and an outer loop. The value that is specified for the maximum number of iterations applies to both loops. Specify a non-negative integer. The default is 100.

Singularity tolerance This value is used as the tolerance in checking singularity. Specify a positive value.

Note: By default, Parameter Convergence is used, where the maximum Absolute change at a tolerance of 1E-6 is checked. This setting might produce results that differ from the results that are obtained in versions before version 17. To reproduce results from pre-17 versions, use Relative for the Parameter Convergence criterion and keep the default tolerance value of 1E-6.

Model selection (GLE models)

Use model selection or regularization. To activate the controls on this pane, select this check box.

Method. Select the method of model selection or (if using Ridge) the regularization to be used. You can choose from the following options:

- Lasso. Also known as L1 Regularization, this method is faster than Forward Stepwise if there are a large number of predictors. This method prevents overfitting by shrinking (that is, by imposing a penalty) on the parameters. It can shrink some parameters to zero, performing a variable selection lasso.
- Ridge. Also known as L2 Regularization, this method prevents overfitting by shrinking (that is, by imposing a penalty) on the parameters. It shrinks all the parameters by the same proportions but eliminates none and is not a variable selection method.
- Elastic Net. Also known as L1 + L2 Regularization, this method prevents overfitting by shrinking (that is, by imposing a penalty) on the parameters. It can shrink some parameters to zero, performing variable selection.
- Forward Stepwise. This method starts with no effects in the model and adds or removes effects one step at a time until no more can be added or removed, according to the stepwise criteria.

Automatically detect two-way interactions. To automatically detect two-way interactions, select this option.

Penalty Parameters

These options are only available if you select either the Lasso or Elastic Net Method.

Automatically select penalty parameters. If you are unsure what parameter penalties to set, select this check box and the node identifies and applies the penalties.

Lasso penalty parameter. Enter the penalty parameter to be used by the Lasso model selection Method.

Elastic net penalty parameter 1. Enter the L1 penalty parameter to be used by the Elastic Net model selection Method.

Elastic net penalty parameter 2. Enter the L2 penalty parameter to be used by the Elastic Net model selection Method.

Forward Stepwise

These options are only available if you select the Forward Stepwise Method.

Include effects with p-value no less than. Specify the minimum probability value that effects can have to be included in the calculation.

Remove effects with p-value greater than. Specify the maximum probability value that effects can have to be included in the calculation.

Customize maximum number of effects in the final model. To activate the Maximum number of effects option, select this check box.

Maximum number of effects. Specify the maximum number of effects when using the forward stepwise building method. To optimize performance, 10 is the highest supported number.

Customize maximum number of steps. To activate the Maximum number of steps option, select this check box.

Maximum number of steps. Specify the maximum number of steps when using the forward stepwise building method.

Model options (GLE models)

Model name You can generate the model name automatically based on the target field, or specify a Custom name. The automatically generated name is the target field name. If there are multiple targets, then the model name is the field names in order, connected by ampersands. For example, if field1, field2, and field3 are targets, then the model name is: *field1 & field2 & field3*.

Calculate predictor importance For models that produce an appropriate measure of importance, you can display a chart that indicates the relative importance of each predictor in estimating the model. Typically you will want to focus your modeling efforts on the predictors that matter most, and consider dropping or ignoring those that matter least. Note that predictor importance may take longer to calculate for some models, particularly when working with large datasets, and is off by default for some models as a result.

For more information, see [Predictor Importance](#).

GLE model nugget

- [GLE model nugget output](#)
- [GLE model nugget settings](#)

GLE model nugget output

After you create a GLE model, the following information is available in the output.

Model Information table

The Model Information table provides key information about the model. The table identifies some high-level model settings, such as:

- The name of the target field selected in either the Type node or the GLE node Fields tab.
- The modeled and reference target category percentages.
- The probability distribution and associated link function.
- The model building method used.
- The number of predictors input and the number in the final model.
- The classification accuracy percentage.
- The model type.
- The percentage accuracy of the model, if the target is continuous.

Records Summary

The summary table shows how many records were used to fit the model, and how many were excluded. The details shown include the number and percentage of the records included and excluded, as well as the unweighted number if you used frequency weighting.

Predictor Importance

The Predictor Importance graph shows the importance of the top 10 inputs (predictors) in the model as a bar chart.

If there are more than 10 fields in the chart, you can change the selection of predictors that are included in the chart by using the slider beneath the chart. The indicator marks on the slider are a fixed width, and each mark on the slider represents 10 fields. You can move the indicator marks along the slider to display the next or previous 10 fields, ordered by predictor importance.

You can double-click the chart to open a separate dialog box in which you can edit the graph settings. For example, you can amend items such as the size of the graph, and the size and color of the fonts used. When you close this separate editing dialog box, the changes are applied to the chart that is displayed in the Output tab.

Residual by Predicted plot

You can use this plot either to identify outliers, or to diagnose non-linearity or non constant error variance. An ideal plot will show the points randomly scattered about the zero line.

The expected pattern is that the distribution of standardized deviance residuals across predicted values of the linear predictor has a mean value of zero and a constant range. The expected pattern is a horizontal line through zero.

GLE model nugget settings

On the Settings tab for a GLE model nugget, you specify options for raw propensity and for SQL generation during model scoring. This tab is available only after the model nugget is added to a stream.

Calculate raw propensity scores For models with flag targets only, you can request raw propensity scores that indicate the likelihood of the true outcome specified for the target field. These are in addition to standard prediction and confidence values. Adjusted propensity scores are not available.

Generate SQL for this model When using data from a database, SQL code can be pushed back to the database for execution, providing superior performance for many operations.

Select one of the following options to specify how SQL is generated:

- **Default:** Score using Server Scoring Adapter (if installed) otherwise in process If connected to a database with a scoring adapter installed, generates SQL by using the scoring adapter and associated user-defined functions (UDF) and scores your model within the database. When no scoring adapter is available, this option fetches your data back from the database and scores it in SPSS® Modeler.
- **Score outside of the Database** If selected, this option fetches your data back from the database and scores it in SPSS Modeler.

Cox Node

Cox regression builds a predictive model for time-to-event data. The model produces a survival function that predicts the probability that the event of interest has occurred at a given time t for given values of the predictor variables. The shape of the survival function and the regression coefficients for the predictors are estimated from observed subjects; the model can then be applied to new cases that have measurements for the predictor variables. Note that information from censored subjects, that is, those that do not experience the event of interest during the time of observation, contributes usefully to the estimation of the model.

Example. As part of its efforts to reduce customer churn, a telecommunications company is interested in modeling the "time to churn" in order to determine the factors that are associated with customers who are quick to switch to another service. To this end, a random sample of customers is selected, and their time spent as customers (whether or not they are still active customers) and various demographic fields are pulled from the database.

Requirements. You need one or more input fields, exactly one target field, and you must specify a survival time field within the Cox node. The target field should be coded so that the "false" value indicates survival and the "true" value indicates that the event of interest has occurred; it must have a measurement level of *Flag*, with string or integer storage. (Storage can be converted using a Filler or Derive node if necessary.) Fields set to *Both* or *None* are ignored. Fields used in the model must have their types fully instantiated. The survival time can be any numeric field.

Note: On scoring a Cox Regression model, an error is reported if empty strings in categorical variables are used as input to model building. Avoid using empty strings as input.

Dates & Times. Date & Time fields cannot be used to directly define the survival time; if you have Date & Time fields, you should use them to create a field containing survival times, based upon the difference between the date of entry into the study and the observation date.

Kaplan-Meier Analysis. Cox regression can be performed with no input fields. This is equivalent to a Kaplan-Meier analysis.

Cox Node Fields Options

Survival time. Choose a numeric field (one with a measurement level of *Continuous*) in order to make the node executable. Survival time indicates the lifespan of the record being predicted. For example, when modeling customer time to churn, this would be the field that records how long the customer has been with the organization. The date on which the customer joined or churned would not affect the model; only the duration of the customer's tenure would be relevant.

Survival time is taken to be a duration with no units. You must make sure that the input fields match the survival time. For example, in a study to measure churn by months, you would use sales per month as an input instead of sales per year. If your data has start and end dates instead of a duration, you must recode those dates to a duration upstream from the Cox node.

The remaining fields in this dialog box are the standard ones used throughout IBM® SPSS® Modeler. See the topic [Modeling Node Fields Options](#) for more information.

Cox Node Model Options

Model name. You can generate the model name automatically based on the target or ID field (or model type in cases where no such field is specified) or specify a custom name.

Use partitioned data. If a partition field is defined, this option ensures that data from only the training partition is used to build the model.

Create split models. Builds a separate model for each possible value of input fields that are specified as split fields. See [Building Split Models](#) for more information.

Method. The following options are available for entering predictors into the model:

- **Enter.** This is the default method, which enters all of the terms into the model directly. No field selection is performed in building the model.
- **Stepwise.** The Stepwise method of field selection builds the model in steps, as the name implies. The initial model is the simplest model possible, with no model terms (except the constant) in the model. At each step, terms that have not yet been added to the model are evaluated, and if the best of those terms adds significantly to the predictive power of the model, it is added. In addition, terms that are currently in the model are reevaluated to determine if any of them can be removed without significantly detracting from the model. If so, they are removed. The process repeats, and other terms are added and/or removed. When no more terms can be added to improve the model, and no more terms can be removed without detracting from the model, the final model is generated.
- **Backwards Stepwise.** The Backwards Stepwise method is essentially the opposite of the Stepwise method. With this method, the initial model contains all of the terms as predictors. At each step, terms in the model are evaluated, and any terms that can be removed without significantly detracting from the model are removed. In addition, previously removed terms are reevaluated to determine if the best of those terms adds significantly to the predictive power of the model. If so, it is added back into the model. When no more terms can be removed without significantly detracting from the model, and no more terms can be added to improve the model, the final model is generated.

Note: The automatic methods, including Stepwise and Backwards Stepwise, are highly adaptable learning methods and have a strong tendency to overfit the training data. When using these methods, it is especially important to verify the validity of the resulting model either with new data or a hold-out test sample created using the Partition node.

Groups. Specifying a groups field causes the node to compute separate models for each category of the field. It can be any categorical field (Flag or Nominal) with string or integer storage.

Model type. There are two options for defining the terms in the model. **Main effects** models include only the input fields individually and do not test interactions (multiplicative effects) between input fields. **Custom** models include only the terms (main effects and interactions) that you specify. When selecting this option, use the Model Terms list to add or remove terms in the model.

Model Terms. When building a Custom model, you will need to explicitly specify the terms in the model. The list shows the current set of terms for the model. The buttons on the right side of the Model Terms list allow you to add and remove model terms.

- To add terms to the model, click the *Add new model terms* button. See the topic [Adding Terms to a Cox Regression Model](#) for more information.
- To delete terms, select the desired terms and click the *Delete selected model terms* button.
- [Adding Terms to a Cox Regression Model](#)

Adding Terms to a Cox Regression Model

When requesting a custom model, you can add terms to the model by clicking the *Add new model terms* button on the Model tab. A new dialog box opens in which you can specify terms.

Type of term to add. There are several ways to add terms to the model, based on the selection of input fields in the Available fields list.

- **Single interaction.** Inserts the term representing the interaction of all selected fields.
- **Main effects.** Inserts one main effect term (the field itself) for each selected input field.
- **All 2-way interactions.** Inserts a 2-way interaction term (the product of the input fields) for each possible pair of selected input fields. For example, if you have selected input fields *A*, *B*, and *C* in the Available fields list, this method will insert the terms *A * B*, *A * C*, and *B * C*.
- **All 3-way interactions.** Inserts a 3-way interaction term (the product of the input fields) for each possible combination of selected input fields, taken three at a time. For example, if you have selected input fields *A*, *B*, *C*, and *D* in the Available fields list, this method will insert the terms *A * B * C*, *A * B * D*, *A * C * D*, and *B * C * D*.
- **All 4-way interactions.** Inserts a 4-way interaction term (the product of the input fields) for each possible combination of selected input fields, taken four at a time. For example, if you have selected input fields *A*, *B*, *C*, *D*, and *E* in the Available fields list, this method will insert the terms *A * B * C * D*, *A * B * C * E*, *A * B * D * E*, *A * C * D * E*, and *B * C * D * E*.

Available fields. Lists the available input fields to be used in constructing model terms. Note that the list may include fields that are not legal input fields, so take care to ensure that all model terms include only input fields.

Preview. Shows the terms that will be added to the model if you click Insert, based on the selected fields and the term type selected above.

Insert. Inserts terms in the model (based on the current selection of fields and term type) and closes the dialog box.

Cox Node Expert Options

Convergence. These options allow you to control the parameters for model convergence. When you execute the model, the convergence settings control how many times the different parameters are repeatedly run through to see how well they fit. The more often the parameters are tried, the closer the results will be (that is, the results will converge). See the topic [Cox Node Convergence Criteria](#) for more information.

Output. These options allow you to request additional statistics and plots, including the survival curve, that will be displayed in the advanced output of the generated model built by the node. See the topic [Cox Node Advanced Output Options](#) for more information.

Stepping. These options allow you to control the criteria for adding and removing fields with the Stepwise estimation method. (The button is disabled if the Enter method is selected.) See the topic [Cox Node Stepping Criteria](#) for more information.

Cox Node Convergence Criteria

Maximum iterations. Allows you to specify the maximum iterations for the model, which controls how long the procedure will search for a solution.

Log-likelihood convergence. Iterations stop if the relative change in the log-likelihood is less than this value. The criterion is not used if the value is 0.

Parameter convergence. Iterations stop if the absolute change or relative change in the parameter estimates is less than this value. The criterion is not used if the value is 0.

Cox Node Advanced Output Options

Statistics. You can obtain statistics for your model parameters, including confidence intervals for $\exp(B)$ and correlation of estimates. You can request these statistics either at each step or at the last step only.

Display baseline function. Allows you to display the baseline hazard function and cumulative survival at the mean of the covariates.

Plots

Plots can help you to evaluate your estimated model and interpret the results. You can plot the survival, hazard, log-minus-log, and one-minus-survival functions.

- **Survival.** Displays the cumulative survival function on a linear scale.
- **Hazard.** Displays the cumulative hazard function on a linear scale.
- **Log minus log.** Displays the cumulative survival estimate after the $\ln(-\ln)$ transformation is applied to the estimate.
- **One minus survival.** Plots one-minus the survival function on a linear scale.

Plot a separate line for each value. This option is available only for categorical fields.

Value to use for plots. Because these functions depend on values of the predictors, you must use constant values for the predictors to plot the functions versus time. The default is to use the mean of each predictor as a constant value, but you can enter your own values for the plot using the grid. For categorical inputs, indicator coding is used, so there is a regression coefficient for each category (except the last). Thus, a categorical input has a mean value for each indicator contrast, equal to the proportion of cases in the category corresponding to the indicator contrast.

Cox Node Stepping Criteria

Removal criterion. Select Likelihood Ratio for a more robust model. To shorten the time required to build the model, you can try selecting Wald. There is the additional option Conditional, which provides removal testing based on the probability of the likelihood-ratio statistic based on conditional parameter estimates.

Significance thresholds for criteria. This option allows you to specify selection criteria based on the statistical probability (the p value) associated with each field. Fields will be added to the model only if the associated p value is smaller than the Entry value and will be removed only if the p value is larger than the Removal value. The Entry value must be smaller than the Removal value.

Cox Node Settings Options

Predict survival at future times. Specify one or more future times. Survival, that is, whether each case is likely to survive for at least that length of time (from now) without the terminal event occurring, is predicted for each record at each time value, one prediction per time value. Note that survival is the "false" value of the target field.

- **Regular intervals.** Survival time values are generated from the specified Time interval and Number of time periods to score. For example, if 3 time periods are requested with an interval of 2 between each time, survival will be predicted for future times 2, 4, 6. Every record is evaluated at the same time values.
- **Time fields.** Survival times are provided for each record in the time field chosen (one prediction field is generated), thus each record can be evaluated at different times.

Past survival time. Specify the survival time of the record so far—for example, the tenure of an existing customer as a field. Scoring the likelihood of survival at a future time will be conditional on past survival time.

Note: The values of future and past survival times must be within range of survival times in the data used to train the model. Records whose times fall outside this range are scored as null.

Append all probabilities. Specifies whether probabilities for each category of the output field are added to each record processed by the node. If this option is not selected, the probability of only the predicted category is added. Probabilities are computed for each future time.

Calculate cumulative hazard function. Specifies whether the value of the cumulative hazard is added to each record. The cumulative hazard is computed for each future time.

Cox Model Nugget

Cox regression models represent the equations estimated by Cox nodes. They contain all of the information captured by the model, as well as information about the model structure and performance.

When you run a stream containing a generated Cox regression model, the node adds two new fields containing the model's prediction and the associated probability. The names of the new fields are derived from the name of the output field being predicted, prefixed with \$C- for the predicted category and \$CP- for the associated probability, suffixed with the number of the future time interval or the name of the time field that defines the time interval. For example, for an output field named *churn* and two future time intervals defined at regular intervals, the new fields would be named \$C-churn-1, \$CP-churn-1, \$C-churn-2, and \$CP-churn-2. If future times are defined with a time field *tenure*, the new fields would be \$C-churn_tenure and \$CP-churn_tenure.

If you have selected the Append all probabilities settings option in the Cox node, two additional fields will be added for each future time, containing the probabilities of survival and failure for each record. These additional fields are named based on the name of the output field, prefixed by \$CP-<false value>- for the probability of survival and \$CP-<true value>- for the probability the event has occurred, suffixed with the number of the future time interval. For example, for an output field where the "false" value is 0 and the "true" value is 1, and two future time intervals defined at regular intervals, the new fields would be named \$CP-0-1, \$CP-1-1, \$CP-0-2, and \$CP-1-2. If future times are defined with a single time field *tenure*, the new fields would be \$CP-0-1 and \$CP-1-1, since there is a single future interval

If you have selected the Calculate cumulative hazard function settings option in the Cox Node, an additional field will be added for each future time, containing the cumulative hazard function for each record. These additional fields are named based on the name of the output field, prefixed by \$CH-, suffixed with the number of the future time interval or the name of the time field that defines the time interval. For example, for an output field named *churn* and two future time intervals defined at regular intervals, the new fields would be named \$CH-churn-1 and \$CH-churn-2. If future times are defined with a time field *tenure*, the new field would be \$CH-churn-1.

Cox Regression Output Settings

Except for SQL generation, the Settings tab of the nugget contains the same controls as the Settings tab of the model node. The default values of the nugget controls are determined by the values set in the model node. See the topic [Cox Node Settings Options](#) for more information.

Generate SQL for this model When using data from a database, SQL code can be pushed back to the database for execution, providing superior performance for many operations.

Select one of the following options to specify how SQL generation is performed.

- Default: Score using Server Scoring Adapter (if installed) otherwise in process If connected to a database with a scoring adapter installed, generates SQL using the scoring adapter and associated user defined functions (UDF) and scores your model within the database. When no scoring adapter is available, this option fetches your data back from the database and scores it in SPSS® Modeler.
- Score outside of the Database If selected, this option fetches your data back from the database and scores it in SPSS Modeler.

Cox Regression Advanced Output

The advanced output for Cox regression gives detailed information about the estimated model and its performance, including the survival curve. Most of the information contained in the advanced output is quite technical, and extensive knowledge of Cox regression is required to properly interpret this output.

Clustering models

Clustering models focus on identifying groups of similar records and labeling the records according to the group to which they belong. This is done without the benefit of prior knowledge about the groups and their characteristics. In fact, you may not even know exactly how many groups to look for. This is what distinguishes clustering models from the other machine-learning techniques—there is no predefined output or target field for the model to predict. These models are often referred to as **unsupervised learning** models, since there is no external standard by which to judge the model's classification performance. There are no *right* or *wrong* answers for these models. Their value is determined by their ability to capture interesting groupings in the data and provide useful descriptions of those groupings.

Clustering methods are based on measuring distances between records and between clusters. Records are assigned to clusters in a way that tends to minimize the distance between records belonging to the same cluster.

The following clustering methods are provided:

	The K-Means node clusters the data set into distinct groups (or clusters). The method defines a fixed number of clusters, iteratively assigns records to clusters, and adjusts the cluster centers until further refinement can no longer improve the model. Instead of trying to predict an outcome, <i>k</i> -means uses a process known as unsupervised learning to uncover patterns in the set of input fields.
	The TwoStep node uses a two-step clustering method. The first step makes a single pass through the data to compress the raw input data into a manageable set of subclusters. The second step uses a hierarchical clustering method to progressively merge the subclusters into larger and larger clusters. TwoStep has the advantage of automatically estimating the optimal number of clusters for the training data. It can handle mixed field types and large data sets efficiently.
	The Kohonen node generates a type of neural network that can be used to cluster the data set into distinct groups. When the network is fully trained, records that are similar should be close together on the output map, while records that are different will be far apart. You can look at the number of observations captured by each unit in the model nugget to identify the strong units. This may give you a sense of the appropriate number of clusters.
	Hierarchical Density-Based Spatial Clustering (HDBSCAN)® uses unsupervised learning to find clusters, or dense regions, of a data set. The HDBSCAN node in SPSS® Modeler exposes the core features and commonly used parameters of the HDBSCAN library. The node is implemented in Python, and you can use it to cluster your dataset into distinct groups when you don't know what those groups are at first.

Clustering models are often used to create clusters or segments that are then used as inputs in subsequent analyses. A common example of this is the market segments used by marketers to partition their overall market into homogeneous subgroups. Each segment has special characteristics that affect the success of marketing efforts targeted toward it. If you are using data mining to optimize your marketing strategy, you can usually improve your model significantly by identifying the appropriate segments and using that segment information in your predictive models.

Kohonen node

Kohonen networks are a type of neural network that perform clustering, also known as a **knet** or a **self-organizing map**. This type of network can be used to cluster the dataset into distinct groups when you don't know what those groups are at the beginning. Records are grouped so that records within a group or cluster tend to be similar to each other, and records in different groups are dissimilar.

The basic units are **neurons**, and they are organized into two layers: the **input layer** and the **output layer** (also called the **output map**). All of the input neurons are connected to all of the output neurons, and these connections have **strengths**, or **weights**, associated with them. During training, each unit competes with all of the others to "win" each record.

The output map is a two-dimensional grid of neurons, with no connections between the units.

Input data is presented to the input layer, and the values are propagated to the output layer. The output neuron with the strongest response is said to be the **winner** and is the answer for that input.

Initially, all weights are random. When a unit wins a record, its weights (along with those of other nearby units, collectively referred to as a **neighborhood**) are adjusted to better match the pattern of predictor values for that record. All of the input records are shown, and weights are updated accordingly. This process is repeated many times until the changes become very small. As training proceeds, the weights on the grid units are adjusted so that they form a two-dimensional "map" of the clusters (hence the term **self-organizing map**).

When the network is fully trained, records that are similar should be close together on the output map, whereas records that are vastly different will be far apart.

Unlike most learning methods in IBM® SPSS® Modeler, Kohonen networks do *not* use a target field. This type of learning, with no target field, is called **unsupervised learning**. Instead of trying to predict an outcome, Kohonen nets try to uncover patterns in the set of input fields. Usually, a Kohonen net will end up with a few units that summarize many observations (**strong** units), and several units that don't really correspond to any of the observations (**weak** units). The strong units (and sometimes other units adjacent to them in the grid) represent probable cluster centers.

Another use of Kohonen networks is in **dimension reduction**. The spatial characteristic of the two-dimensional grid provides a mapping from the k original predictors to two derived features that preserve the similarity relationships in the original predictors. In some cases, this can give you the same kind of benefit as factor analysis or PCA.

Requirements. To train a Kohonen net, you need one or more fields with the role set to *Input*. Fields with the role set to *Target*, *Both*, or *None* are ignored.

Strengths. You do not need to have data on group membership to build a Kohonen network model. You don't even need to know the number of groups to look for. Kohonen networks start with a large number of units, and as training progresses, the units gravitate toward the natural clusters in the data. You can look at the number of observations captured by each unit in the model nugget to identify the strong units, which can give you a sense of the appropriate number of clusters.

Kohonen Node Model Options

Model name. You can generate the model name automatically based on the target or ID field (or model type in cases where no such field is specified) or specify a custom name.

Use partitioned data. If a partition field is defined, this option ensures that data from only the training partition is used to build the model.

Continue training existing model. By default, each time you execute a Kohonen node, a completely new network is created. If you select this option, training continues with the last net successfully produced by the node.

Show feedback graph. If this option is selected, a visual representation of the two-dimensional array is displayed during training. The strength of each node is represented by color. Red denotes a unit that is winning many records (a **strong** unit), and white denotes a unit that is winning few or no records (a **weak** unit). Feedback may not display if the time taken to build the model is relatively short. Note that this feature can slow training time. To speed up training time, deselect this option.

Stop on. The default stopping criterion stops training, based on internal parameters. You can also specify time as the stopping criterion. Enter the time (in minutes) for the network to train.

Set random seed. If no random seed is set, the sequence of random values used to initialize the network weights will be different every time the node is executed. This can cause the node to create different models on different runs, even if the node settings and data values are exactly the same. By selecting this option, you can set the random seed to a specific value so the resulting model is exactly reproducible. A specific random seed always generates the same sequence of random values, in which case executing the node always yields the same generated model.

Note: When using the Set random seed option with records read from a database, a Sort node may be required prior to sampling in order to ensure the same result each time the node is executed. This is because the random seed depends on the order of records, which is not guaranteed to stay the same in a relational database.

Note: If you want to include nominal (set) fields in your model but are having memory problems in building the model, or the model is taking too long to build, consider recoding large set fields to reduce the number of values, or consider using a different field with fewer values as a proxy for the large set. For example, if you are having a problem with a *product_id* field containing values for individual products, you might consider removing it from the model and adding a less detailed *product_category* field instead.

Optimize. Select options designed to increase performance during model building based on your specific needs.

- Select Speed to instruct the algorithm to never use disk spilling in order to improve performance.
- Select Memory to instruct the algorithm to use disk spilling when appropriate at some sacrifice to speed. This option is selected by default.
Note: When running in distributed mode, this setting can be overridden by administrator options specified in options.cfg.

Append cluster label. Selected by default for new models, but deselected for models loaded from earlier versions of IBM® SPSS® Modeler, this creates a single categorical score field of the same type that is created by both the K-Means and TwoStep nodes. This string field is used in the Auto Cluster node when calculating ranking measures for the different model types. See the topic [Auto Cluster node](#) for more information.

Kohonen Node Expert Options

For those with detailed knowledge of Kohonen networks, expert options allow you to fine-tune the training process. To access expert options, set the Mode to Expert on the Expert tab.

Width and Length. Specify the size (width and length) of the two-dimensional output map as number of output units along each dimension.

Learning rate decay. Select either linear or exponential learning rate decay. The **learning rate** is a weighting factor that decreases over time, such that the network starts off encoding large-scale features of the data and gradually focuses on more fine-level detail.

Phase 1 and Phase 2. Kohonen net training is split into two phases. Phase 1 is a rough estimation phase, used to capture the gross patterns in the data. Phase 2 is a tuning phase, used to adjust the map to model the finer features of the data. For each phase, there are three parameters:

- **Neighborhood.** Sets the starting size (radius) of the neighborhood. This determines the number of "nearby" units that get updated along with the winning unit during training. During phase 1, the neighborhood size starts at *Phase 1 Neighborhood* and decreases to (*Phase 2 Neighborhood* + 1). During phase 2, neighborhood size starts at *Phase 2 Neighborhood* and decreases to 1.0. *Phase 1 Neighborhood* should be larger than *Phase 2 Neighborhood*.
- **Initial Eta.** Sets the starting value for learning rate **eta**. During phase 1, eta starts at *Phase 1 Initial Eta* and decreases to *Phase 2 Initial Eta*. During phase 2, eta starts at *Phase 2 Initial Eta* and decreases to 0. *Phase 1 Initial Eta* should be larger than *Phase 2 Initial Eta*.
- **Cycles.** Sets the number of cycles for each phase of training. Each phase continues for the specified number of passes through the data.

Kohonen Model Nuggets

Kohonen model nuggets contain all of the information captured by the trained Kohonen network, as well as information about the network's architecture.

When you run a stream containing a Kohonen model nugget, the node adds two new fields containing the X and Y coordinates of the unit in the Kohonen output grid that responded most strongly to that record. The new field names are derived from the model name, prefixed by \$KX- and \$KY-. For example, if your model is named *Kohonen*, the new fields would be named \$KX-*Kohonen* and \$KY-*Kohonen*.

To get a better sense of what the Kohonen net has encoded, click the Model tab on the model nugget browser. This displays the Cluster Viewer, providing a graphical representation of clusters, fields, and importance levels. See the topic [Cluster Viewer - Model Tab](#) for more information.

If you prefer to visualize the clusters as a grid, you can view the result of the Kohonen net by plotting the \$KX- and \$KY- fields using a Plot node. (You should select X-Agitation and Y-Agitation in the Plot node to prevent each unit's records from all being plotted on top of each other.) In the plot, you can also overlay a symbolic field to investigate how the Kohonen net has clustered the data.

Another powerful technique for gaining insight into the Kohonen network is to use rule induction to discover the characteristics that distinguish the clusters found by the network.

K-Means Node

The K-Means node provides a method of **cluster analysis**. It can be used to cluster the dataset into distinct groups when you don't know what those groups are at the beginning. Unlike most learning methods in IBM® SPSS® Modeler, K-Means models do *not* use a target field. This type of learning, with no target field, is called **unsupervised learning**. Instead of trying to predict an outcome, K-Means tries to uncover patterns in the set of input fields. Records are grouped so that records within a group or cluster tend to be similar to each other, but records in different groups are dissimilar.

K-Means works by defining a set of starting cluster centers derived from data. It then assigns each record to the cluster to which it is most similar, based on the record's input field values. After all cases have been assigned, the cluster centers are updated to reflect the new set of records assigned to each cluster. The records are then checked again to see whether they should be reassigned to a different cluster, and the record assignment/cluster iteration process continues until either the maximum number of iterations is reached, or the change between one iteration and the next fails to exceed a specified threshold.

Note: The resulting model depends to a certain extent on the order of the training data. Reordering the data and rebuilding the model may lead to a different final cluster model.

Requirements. To train a K-Means model, you need one or more fields with the role set to *Input*. Fields with the role set to *Output*, *Both*, or *None* are ignored.

Strengths. You do not need to have data on group membership to build a K-Means model. The K-Means model is often the fastest method of clustering for large datasets.

K-Means Node Model Options

Model name. You can generate the model name automatically based on the target or ID field (or model type in cases where no such field is specified) or specify a custom name.

Use partitioned data. If a partition field is defined, this option ensures that data from only the training partition is used to build the model.

Specified number of clusters. Specify the number of clusters to generate. The default is 5.

Generate distance field. If this option is selected, the model nugget will include a field containing the distance of each record from the center of its assigned cluster.

Cluster label. Specify the format for the values in the generated cluster membership field. Cluster membership can be indicated as a String with the specified Label prefix (for example "Cluster 1", "Cluster 2", and so on), or as a Number.

Note: If you want to include nominal (set) fields in your model but are having memory problems in building the model or the model is taking too long to build, consider recoding large set fields to reduce the number of values, or consider using a different field with fewer values as a proxy for the large set. For example, if you are having a problem with a *product_id* field containing values for individual products, you might consider removing it from the model and adding a less detailed *product_category* field instead.

Optimize. Select options designed to increase performance during model building based on your specific needs.

- Select Speed to instruct the algorithm to never use disk spilling in order to improve performance.
- Select Memory to instruct the algorithm to use disk spilling when appropriate at some sacrifice to speed. This option is selected by default.
Note: When running in distributed mode, this setting can be overridden by administrator options specified in options.cfg.

K-Means Node Expert Options

For those with detailed knowledge of *k*-means clustering, expert options allow you to fine-tune the training process. To access expert options, set the Mode to Expert on the Expert tab.

Stop on. Specify the stopping criterion to be used in training the model. The Default stopping criterion is 20 iterations or change < 0.000001, whichever occurs first. Select Custom to specify your own stopping criteria.

- **Maximum Iterations.** This option allows you to stop model training after the number of iterations specified.
- **Change tolerance.** This option allows you to stop model training when the largest change in cluster centers for an iteration is less than the level specified.

Encoding value for sets. Specify a value between 0 and 1.0 to use for recoding set fields as groups of numeric fields. The default value is the square root of 0.5 (approximately 0.707107), which provides the proper weighting for recoded flag fields. Values closer to 1.0 will weight set fields more heavily than numeric fields.

TwoStep Cluster node

The TwoStep Cluster node provides a form of **cluster analysis**. It can be used to cluster the dataset into distinct groups when you don't know what those groups are at the beginning. As with Kohonen nodes and K-Means nodes, TwoStep Cluster models do *not* use a target field. Instead of trying to predict an outcome, TwoStep Cluster tries to uncover patterns in the set of input fields. Records are grouped so that records within a group or cluster tend to be similar to each other, but records in different groups are dissimilar.

TwoStep Cluster is a two-step clustering method. The first step makes a single pass through the data, during which it compresses the raw input data into a manageable set of subclusters. The second step uses a hierarchical clustering method to progressively merge the subclusters into larger and larger clusters, without requiring another pass through the data. Hierarchical clustering has the advantage of not requiring the number of clusters to be selected ahead of time. Many hierarchical clustering methods start with individual records as starting clusters and merge them recursively to produce ever larger clusters. Though such approaches often break down with large amounts of data, TwoStep's initial preclustering makes hierarchical clustering fast even for large datasets.

Note: The resulting model depends to a certain extent on the order of the training data. Reordering the data and rebuilding the model may lead to a different final cluster model.

Requirements. To train a TwoStep Cluster model, you need one or more fields with the role set to *Input*. Fields with the role set to *Target*, *Both*, or *None* are ignored. The TwoStep Cluster algorithm does not handle missing values. Records with blanks for any of the input fields will be ignored when building the model.

Strengths. TwoStep Cluster can handle mixed field types and is able to handle large datasets efficiently. It also has the ability to test several cluster solutions and choose the best, so you don't need to know how many clusters to ask for at the outset. TwoStep Cluster can be set to automatically exclude **outliers**, or extremely unusual cases that can contaminate your results.

IBM® SPSS® Modeler has two different versions of the TwoStep Cluster node:

- TwoStep Cluster is the traditional node that runs on the IBM SPSS Modeler Server.
- TwoStep-AS Cluster can run when connected to IBM SPSS Analytic Server.
- [TwoStep Cluster Node Model Options](#)

TwoStep Cluster Node Model Options

Model name. You can generate the model name automatically based on the target or ID field (or model type in cases where no such field is specified) or specify a custom name.

Use partitioned data. If a partition field is defined, this option ensures that data from only the training partition is used to build the model.

Standardize numeric fields. By default, TwoStep will standardize all numeric input fields to the same scale, with a mean of 0 and a variance of 1. To retain the original scaling for numeric fields, deselect this option. Symbolic fields are not affected.

Exclude outliers. If you select this option, records that don't seem to fit into a substantive cluster will be automatically excluded from the analysis. This prevents such cases from distorting the results.

Outlier detection occurs during the preclustering step. When this option is selected, subclusters with few records relative to other subclusters are considered potential outliers, and the tree of subclusters is rebuilt excluding those records. The size below which subclusters are considered to contain potential outliers is controlled by the Percentage option. Some of those potential outlier records can be added to the rebuilt

subclusters if they are similar enough to any of the new subcluster profiles. The rest of the potential outliers that cannot be merged are considered outliers and are added to a "noise" cluster and excluded from the hierarchical clustering step.

When scoring data with a TwoStep model that uses outlier handling, new cases that are more than a certain threshold distance (based on the log-likelihood) from the nearest substantive cluster are considered outliers and are assigned to the "noise" cluster with the name -1.

Cluster label. Specify the format for the generated cluster membership field. Cluster membership can be indicated as a String with the specified Label prefix (for example, "Cluster 1", "Cluster 2", and so on) or as a Number.

Automatically calculate number of clusters. TwoStep cluster can very rapidly analyze a large number of cluster solutions to choose the optimal number of clusters for the training data. Specify a range of solutions to try by setting the Maximum and the Minimum number of clusters.

Specify number of clusters. If you know how many clusters to include in your model, select this option and enter the number of clusters.

Distance measure. This selection determines how the similarity between two clusters is computed.

- **Log-likelihood.** The likelihood measure places a probability distribution on the variables. Continuous variables are assumed to be normally distributed, while categorical variables are assumed to be multinomial. All variables are assumed to be independent.
- **Euclidean.** The Euclidean measure is the "straight line" distance between two clusters. It can be used only when all of the variables are continuous.

Clustering Criterion. This selection determines how the automatic clustering algorithm determines the number of clusters. Either the Bayesian Information Criterion (BIC) or the Akaike Information Criterion (AIC) can be specified.

Twostep-AS cluster analysis

TwoStep Cluster is an exploratory tool that is designed to reveal natural groupings (or clusters) within a data set that would otherwise not be apparent. The algorithm that is employed by this procedure has several desirable features that differentiate it from traditional clustering techniques:

- Handling of categorical and continuous variables. By assuming variables to be independent, a joint multinomial-normal distribution can be placed on categorical and continuous variables.
- Automatic selection of number of clusters. By comparing the values of a model-choice criterion across different clustering solutions, the procedure can automatically determine the optimal number of clusters.
- Scalability. By constructing a cluster feature (CF) tree that summarizes the records, the TwoStep algorithm can analyze large data files.

For example, retail and consumer product companies regularly apply clustering techniques to information that describes their customers' buying habits, gender, age, income level, and other attributes. These companies tailor their marketing and product development strategies to each consumer group to increase sales and build brand loyalty.

Fields tab (Twostep-AS Cluster)

The Fields tab specifies which fields are used in the analysis.

Use predefined roles. All fields with a defined role of Input are selected.

Use custom field assignments. Add and remove fields regardless of their defined role assignments. You can select fields with any role and move them in or out of the Predictors (Inputs) list.

Basics (Twostep-AS Cluster)

Number of Clusters

Determine automatically

The procedure determines the best number of clusters, within the specified range. The Minimum must be greater than 1. This is the default option.

Specify fixed

The procedure generates the specified number of clusters. The Number must be greater than 1.

Clustering Criterion

This selection controls how the automatic clustering algorithm determines the number of clusters.

Bayesian Information Criterion (BIC)

A measure for selecting and comparing models based on the -2 log likelihood. Smaller values indicate better models. The BIC also "penalizes" overparameterized models (complex models with a large number of inputs, for example), but more strictly than the AIC.

Akaike Information Criterion (AIC)

A measure for selecting and comparing models based on the -2 log likelihood. Smaller values indicate better models. The AIC "penalizes" overparameterized models (complex models with a large number of inputs, for example).

Automatic Clustering Method

If you select Determine automatically, choose from the following clustering methods used to automatically determine the number of clusters:

Use Clustering Criterion setting

Information criteria convergence is the ratio of information criteria corresponding to two current cluster solutions and the first cluster solution. The criterion used is the one selected in the Clustering Criterion group.

Distance jump

Distance jump is the ratio of distances corresponding to two consecutive cluster solutions.

Maximum

Combine results from the information criteria convergence method and the distance jump method to produce the number of clusters corresponding to the second jump.

Minimum

Combine results from the information criteria convergence method and the distance jump method to produce the number of clusters corresponding to the first jump.

Feature Importance Method

Feature Importance Method determines how important the features (fields) are in the cluster solution. The output includes information about overall feature importance and the importance of each feature field in each cluster. Features that do not meet a minimum threshold are excluded.

Use Clustering Criterion setting

This is the default method, based on the criterion that is selected in the Clustering Criterion group.

Effect size

Feature importance is based on effect size instead of significance values.

Feature Tree Criteria (Twostep-AS Cluster)

These settings determine how the cluster feature tree is built. By building a cluster feature tree and summarizing the records, the TwoStep algorithm can analyze large data files. In other words, TwoStep Cluster uses a cluster feature tree to build clusters, enabling it to process many cases.

Distance Measure

This selection determines how the similarity between two clusters is computed.

Log-likelihood

The likelihood measure places a probability distribution on the fields. Continuous fields are assumed to be normally distributed, while categorical fields are assumed to be multinomial. All fields are assumed to be independent.

Euclidean

The Euclidean measure is the "straight line" distance between two clusters. Squared Euclidean measure and the Ward method are used to compute similarity between clusters. It can be used only when all of the fields are continuous.

Outlier Clusters

Include outlier clusters

Include clusters for cases that are outliers from the regular clusters. If this option is not selected, all cases are included in regular clusters.

Number of cases in feature tree leaf is less than.

If the number of cases in the feature tree leaf is less than the specified value, the leaf is considered an outlier. The value must be an integer greater than 1. If you change this value, higher values are likely to result in more outlier clusters.

Top percentage of outliers.

When the cluster model is built, outliers are ranked by outlier strength. The outlier strength that is required to be in the top percentage of outliers is used as the threshold for determining whether a case is classified as an outlier. Higher values mean that more cases are classified as outliers. The value must be between 1 - 100.

Additional settings

Initial distance change threshold

The initial threshold that is used to grow the cluster feature tree. If insertion of a leaf into a leaf of the tree yields tightness less than this threshold, the leaf is not split. If the tightness exceeds this threshold, the leaf is split.

Leaf node maximum branches

The maximum number of child nodes that a leaf node can have.

Non-leaf node maximum branches

The maximum number of child nodes that a non-leaf node can have.

Maximum tree depth

The maximum number of levels that the cluster tree can have.

Adjustment weight on measurement level

Reduces the influence of categorical fields by increasing the weight for continuous fields. This value represents a denominator for reducing the weight for categorical fields. So a default of 6, for example, gives categorical fields a weight of 1/6.

Memory allocation

The maximum amount of memory in megabytes (MB) that the cluster algorithm uses. If the procedure exceeds this maximum, it uses the disk to store information that does not fit in memory.

Delayed split

Delay rebuilding of the cluster feature tree. The clustering algorithm rebuilds the cluster feature tree multiple times as it evaluates new cases. This option can improve performance by delaying that operation and reducing the number of times the tree is rebuilt.

Standardize

The clustering algorithm works with standardized continuous fields. By default, all continuous fields are standardized. To save some time and computational effort, you can move continuous fields that are already standardized to the Do not standardize list.

Feature Selection

On the Feature Selection screen, you can set rules that determine when fields are excluded. For example, you can exclude fields that have numerous missing values.

Rules for Excluding Fields

Percentage of missing values is greater than.

Fields with a percentage of missing values greater than the specified value are excluded from the analysis. The value must be a positive number greater than zero and less than 100.

Number of categories for categorical fields is greater than.

Categorical fields with more than the specified number of categories are excluded from the analysis. The value must be a positive integer greater than 1.

Fields with a Tendency Toward a Single Value

Coefficient of variation for continuous fields is less than.

Continuous fields with a coefficient of variation less than the specified value are excluded from the analysis. The coefficient of variation is the ratio of the standard deviation to the mean. Lower values tend to indicate less variation in values. The value must be between 0 and 1.

Percentage of cases in a single category for categorical fields is greater than.

Categorical fields with a percentage of cases in a single category greater than the specified value are excluded from the analysis. The value must be greater than 0 and less than 100.

Adaptive feature selection

This option runs an extra data pass to find and remove the least important fields.

Model Output

Model Building Summary

Model specifications

Summary of model specifications, number of clusters in the final model, and inputs (fields) included in the final model.

Record summary

Number and percentage of records (cases) included and excluded from the model.

Excluded inputs

For any fields not included in the final model, the reason the field was excluded.

Evaluation

Model quality

Table of goodness and importance for each cluster and overall model goodness of fit.

Feature importance bar chart

Bar chart of feature (field) importance across all clusters. Features (fields) with longer bars in the chart are more important than fields with shorter bars. They are also sorted in descending order of importance (the bar at the top is the most important).

Feature importance word cloud

Word cloud of feature (field) importance across all clusters. Features (fields) with larger text are more important than those with smaller text.

Outlier clusters

These options are disabled if you chose not to include outliers.

Interactive table and chart

Table and chart of outlier strength and the relative similarity of outlier clusters to regular clusters. Selecting different rows in the table displays information for different outlier clusters in the chart.

Pivot table

Table of outlier strength and the relative similarity of outlier clusters to regular clusters. This table contains the same information as the interactive display. This table supports all standard features for pivoting and editing tables.

Maximum number

The maximum number of outliers to display in the output. If there are more than twenty outlier clusters, a pivot table will be displayed instead.

Interpretation

Across cluster feature importance profiles

Interactive table and chart.

Table and charts of feature importance and cluster centers for each input (field) used in the cluster solution. Selecting different rows in the table displays a different chart. For categorical fields, a bar chart is displayed. For continuous fields, a chart of means and standard deviations is displayed.

Pivot table.

Table of feature importance and cluster centers for each input (field). This table contains the same information as the interactive display. This table supports all standard features for pivoting and editing tables.

Within cluster feature importance

For each cluster, the cluster center and feature importance for each input (field). There is a separate table for each cluster.

Cluster distances

A panel chart that displays the distances between clusters. There is a separate panel for each cluster.

Cluster label

Text

The label for each cluster is the value that is specified for Prefix, followed by a sequential number.

Number

The label for each cluster is a sequential number.

Model Options

Model name. You can generate the model name automatically based on the target or ID field (or model type in cases where no such field is specified) or specify a custom name.

TwoStep-AS Cluster Model Nuggets

The TwoStep-AS model nugget displays details of the model in the Model tab of the Output Viewer. For more information on using the viewer, see [Working with output](#).

The TwoStep-AS cluster model nuggets contain all of the information captured by the clustering model, as well as information about the training data and the estimation process.

When you run a stream containing a TwoStep-AS cluster model nugget, the node adds a new field containing the cluster membership for that record. The new field name is derived from the model name, prefixed by **\$AS-**. For example, if your model is named TwoStep, the new field will be named **\$AS-TwoStep**.

A powerful technique for gaining insight into the TwoStep-AS model is to use rule induction to discover the characteristics that distinguish the clusters found by the model.

For general information on using the model browser, see [Browsing model nuggets](#).

Note: In the TwoStep-AS model viewer, under the Evaluation > Model Quality section, the number of records is displayed for each cluster. If you connect a Distribution node to calculate the score result, you may find that the number of records in each cluster is different from what you see under Model Quality section. This functions as it should. From the algorithm perspective, the evaluation result comes from a hierarchical clustering process, while the scoring table comes from directly comparing the data case with the distribution of the final clusters. These two different scoring processes may result in different results if the clustering model is not perfect. But in most cases, the difference is quite small.

- [TwoStep-AS Cluster Model Nugget Settings](#)

TwoStep-AS Cluster Model Nugget Settings

Generate SQL for this model When using data from a database, SQL code can be pushed back to the database for execution, providing superior performance for many operations.

Select one of the following options to specify how SQL generation is performed.

- Default: Score using Server Scoring Adapter (if installed) otherwise in process If connected to a database with a scoring adapter installed, generates SQL using the scoring adapter and associated user defined functions (UDF) and scores your model within the database. When no scoring adapter is available, this option fetches your data back from the database and scores it in SPSS® Modeler.
- Score by converting to native SQL If selected, generates native SQL to score the model within the database.
Note: Although this option can provide quicker results, the size and complexity of the native SQL increases as the complexity of the model increases.
- Score outside of the database If selected, this option fetches your data back from the database and scores it in SPSS Modeler.

K-Means-AS node

K-Means is one of the most commonly used clustering algorithms. It clusters data points into a predefined number of clusters.¹ The K-Means-AS node in SPSS® Modeler is implemented in Spark.

For details about K-Means algorithms, see <https://spark.apache.org/docs/2.2.0/ml-clustering.html>.

Note that the K-Means-AS node performs one-hot encoding automatically for categorical variables.

¹ "Clustering." Apache Spark. MLlib: Main Guide. Web. 3 Oct 2017.

- [K-Means-AS node Fields](#)
- [K-Means-AS node Build Options](#)
- [K-Means-AS node Fields](#)
- [K-Means-AS node Build Options](#)

K-Means-AS node Fields

The Fields tab specifies which fields are used in the analysis.

Use predefined roles. This option tells the node to use field information from an upstream Type node. It's selected by default.

Use custom field assignments. If you want to manually assign input fields, select this option and then select the input field or fields. Using this option is similar to setting the field role in Input in a Type node.

K-Means-AS node Build Options

Use the Build Options tab to specify build options for the K-Means-AS node, including regular options for model building, initialization options for initializing cluster centers, and advanced options for the computing iteration and random seed. For more information, see the [JavaDoc for K-Means on SparkML](#).¹

Regular

Model Name. The name of the field generated after scoring to a specific cluster. Select Auto (default) or select Custom and type a name.

Number of Clusters. Specify the number of clusters to generate. The default is 5 and the minimum is 2.

Initialization

Initialization Mode. Specify the method for initializing the cluster centers. K-Means|| is the default. For details about these two methods, see [Scalable K-Means++](#).²

Initialization Steps. If the K-Means|| initialization mode is selected, specify the number of initialization steps. 2 is the default.

Advanced

Advanced Settings. Select this option if you want to set advanced options as follows.

Max Iteration. Specify the maximum number of iterations to perform when searching cluster centers. 20 is the default.

Tolerance. Specify the convergence tolerance for iterative algorithms. 1.0E-4 is the default.

Set Random Seed. Select this option and click Generate to generate the seed used by the random number generator.

Display

Display Graph. Select this option if you want a graph to be included in the output.

The following table shows the relationship between the settings in the SPSS® Modeler K-Means-AS node and the K-Means Spark parameters.

Table 1. Node properties mapped to Spark parameters

SPSS Modeler setting	Script name (property name)	K-Means SparkML parameter
Input Fields	<code>features</code>	
Number of Clusters	<code>clustersNum</code>	<code>k</code>
Initialization Mode	<code>initMode</code>	<code>initMode</code>
Initialization Steps	<code>initSteps</code>	<code>initSteps</code>
Max Iteration	<code>maxIter</code>	<code>maxIter</code>
Tolerance	<code>toleration</code>	<code>tol</code>
Random Seed	<code>randomSeed</code>	<code>seed</code>

The Cluster Viewer

Cluster models are typically used to find groups (or clusters) of similar records based on the variables examined, where the similarity between members of the same group is high and the similarity between members of different groups is low. The results can be used to identify associations that would otherwise not be apparent. For example, through cluster analysis of customer preferences, income level, and buying habits, it may be possible to identify the types of customers who are more likely to respond to a particular marketing campaign.

There are two approaches to interpreting the results in a cluster display:

- Examine clusters to determine characteristics unique to that cluster. *Does one cluster contain all the high-income borrowers? Does this cluster contain more records than the others?*
- Examine fields across clusters to determine how values are distributed among clusters. *Does one's level of education determine membership in a cluster? Does a high credit score distinguish between membership in one cluster or another?*

Using the main views and the various linked views in the Cluster Viewer, you can gain insight to help you answer these questions.

Who uses clustering?

Clustering techniques are useful in a wide variety of situations, including:

- **Market Segmentation.** Identify distinct groups among a customer base, allowing precise targeting of sales efforts.
- **Product Bundling.** Identify groups of products that tend to appeal to specific customer types.
- **Formal Classification.** Classify groups, such as plants or animals into formal taxonomies.
- **Medical Diagnosis.** Use biological patterns to uncover rules for identifying or diagnosing medical disorders.

The following cluster model nuggets can be generated in IBM® SPSS® Modeler:

- Kohonen net model nugget
- K-Means model nugget
- TwoStep cluster model nugget

To see information about the cluster model nuggets, right-click the model node and choose Browse from the context menu (or Edit for nodes in a stream). Alternatively, if you are using the Auto Cluster modeling node, double-click on the required cluster nugget within the Auto Cluster model nugget. See the topic [Auto Cluster node](#) for more information.

Cluster Viewer - Model Tab

The Model tab for cluster models shows a graphical display of summary statistics and distributions for fields between clusters; this is known as the **Cluster Viewer**.

Note: The Model tab is not available for models built in versions of IBM® SPSS® Modeler prior to 13.

The Cluster Viewer is made up of two panels, the main view on the left and the linked, or auxiliary, view on the right. There are two main views:

- Model Summary (the default). See the topic [Model Summary View](#) for more information.
- Clusters. See the topic [Clusters View](#) for more information.

There are four linked/auxiliary views:

- Predictor Importance. See the topic [Cluster Predictor Importance View](#) for more information.
 - Cluster Sizes (the default). See the topic [Cluster Sizes View](#) for more information.
 - Cell Distribution. See the topic [Cell Distribution View](#) for more information.
 - Cluster Comparison. See the topic [Cluster Comparison View](#) for more information.

Model Summary View

The Model Summary view shows a snapshot, or summary, of the cluster model, including a Silhouette measure of cluster cohesion and separation that is shaded to indicate poor, fair, or good results. This snapshot enables you to quickly check if the quality is poor, in which case you may decide to return to the modeling node to amend the cluster model settings to produce a better result.

The results of poor, fair, and good are based on the work of Kaufman and Rousseeuw (1990) regarding interpretation of cluster structures. In the Model Summary view, a good result equates to data that reflects Kaufman and Rousseeuw's rating as either reasonable or strong evidence of cluster structure, fair reflects their rating of weak evidence, and poor reflects their rating of no significant evidence.

The silhouette measure averages, over all records, $(B-A) / \max(A,B)$, where A is the record's distance to its cluster center and B is the record's distance to the nearest cluster center that it doesn't belong to. A silhouette coefficient of 1 would mean that all cases are located directly on their cluster centers. A value of -1 would mean all cases are located on the cluster centers of some other cluster. A value of 0 means, on average, cases are equidistant between their own cluster center and the nearest other cluster.

The summary includes a table that contains the following information:

- **Algorithm.** The clustering algorithm used, for example, "TwoStep".
- **Input Features.** The number of fields, also known as **inputs** or **predictors**.
- **Clusters.** The number of clusters in the solution.

-

Clusters View

The Clusters view contains a cluster-by-features grid that includes cluster names, sizes, and profiles for each cluster.

The columns in the grid contain the following information:

- **Cluster.** The cluster numbers created by the algorithm.
- **Label.** Any labels applied to each cluster (this is blank by default). Double-click in the cell to enter a label that describes the cluster contents; for example, "Luxury car buyers".
- **Description.** Any description of the cluster contents (this is blank by default). Double-click in the cell to enter a description of the cluster; for example, "55+ years of age, professionals, earning over \$100,000".
- **Size.** The size of each cluster as a percentage of the overall cluster sample. Each size cell within the grid displays a vertical bar that shows the size percentage within the cluster, a size percentage in numeric format, and the cluster case counts.

- **Features.** The individual inputs or predictors, sorted by overall importance by default. If any columns have equal sizes they are shown in ascending sort order of the cluster numbers.

Overall feature importance is indicated by the color of the cell background shading; the most important feature is darkest; the least important feature is unshaded. A guide above the table indicates the importance attached to each feature cell color.

When you hover your mouse over a cell, the full name/label of the feature and the importance value for the cell is displayed. Further information may be displayed, depending on the view and feature type. In the Cluster Centers view, this includes the cell statistic and the cell value; for example: "Mean: 4.32". For categorical features the cell shows the name of the most frequent (modal) category and its percentage.

Within the Clusters view, you can select various ways to display the cluster information:

- Transpose clusters and features. See the topic [Transpose Clusters and Features](#) for more information.
- Sort features. See the topic [Sort Features](#) for more information.
- Sort clusters. See the topic [Sort Clusters](#) for more information.
- Select cell contents. See the topic [Cell Contents](#) for more information.

- [Navigating the Cluster Viewer](#)

Transpose Clusters and Features

By default, clusters are displayed as columns and features are displayed as rows. To reverse this display, click the Transpose Clusters and Features button to the left of the Sort Features By buttons. For example you may want to do this when you have many clusters displayed, to reduce the amount of horizontal scrolling required to see the data.

Related information

- [Cell Distribution View](#)
- [Cluster Comparison View](#)
- [Navigating the Cluster Viewer](#)

Sort Features

The Sort Features By buttons enable you to select how feature cells are displayed:

- **Overall Importance.** This is the default sort order. Features are sorted in descending order of overall importance, and sort order is the same across clusters. If any features have tied importance values, the tied features are listed in ascending sort order of the feature names.
- **Within-Cluster Importance.** Features are sorted with respect to their importance for each cluster. If any features have tied importance values, the tied features are listed in ascending sort order of the feature names. When this option is chosen the sort order usually varies

across clusters.

- **Name.** Features are sorted by name in alphabetical order.
- **Data order.** Features are sorted by their order in the dataset.

-

Sort Clusters

By default clusters are sorted in descending order of size. The Sort Clusters By buttons enable you to sort them by name in alphabetical order, or, if you have created unique labels, in alphanumeric label order instead.

Features that have the same label are sorted by cluster name. If clusters are sorted by label and you edit the label of a cluster, the sort order is automatically updated.

 - [Navigating the Cluster Viewer](#)
-

Cell Contents

The Cells buttons enable you to change the display of the cell contents for features and evaluation fields.

- **Cluster Centers.** By default, cells display feature names/labels and the central tendency for each cluster/feature combination. The mean is shown for continuous fields and the mode (most frequently occurring category) with category percentage for categorical fields.
- **Absolute Distributions.** Shows feature names/labels and absolute distributions of the features within each cluster. For categorical features, the display shows bar charts overlaid with categories ordered in ascending order of the data values. For continuous features, the display shows a smooth density plot which use the same endpoints and intervals for each cluster.
The solid red colored display shows the cluster distribution, whilst the paler display represents the overall data.
- **Relative Distributions.** Shows feature names/labels and relative distributions in the cells. In general the displays are similar to those shown for absolute distributions, except that relative distributions are displayed instead.
The solid red colored display shows the cluster distribution, while the paler display represents the overall data.
- **Basic View.** Where there are a lot of clusters, it can be difficult to see all the detail without scrolling. To reduce the amount of scrolling, select this view to change the display to a more compact version of the table.

Cluster Sizes View

The Cluster Sizes view shows a pie chart that contains each cluster. The percentage size of each cluster is shown on each slice; hover the mouse over each slice to display the count in that slice.

Below the chart, a table lists the following size information:

- The size of the smallest cluster (both a count and percentage of the whole).
- The size of the largest cluster (both a count and percentage of the whole).
- The ratio of size of the largest cluster to the smallest cluster.

Cluster Comparison View

The Cluster Comparison view consists of a grid-style layout, with features in the rows and selected clusters in the columns. This view helps you to better understand the factors that make up the clusters; it also enables you to see differences between clusters not only as compared with the overall data, but with each other.

To select clusters for display, click on the top of the cluster column in the Clusters main panel. Use either Ctrl-click or Shift-click to select or deselect more than one cluster for comparison.

Note: You can select up to five clusters for display.

Clusters are shown in the order in which they were selected, while the order of fields is determined by the Sort Features By option. When you select Within-Cluster Importance, fields are always sorted by overall importance .

The background plots show the overall distributions of each features:

- Categorical features are shown as dot plots, where the size of the dot indicates the most frequent/modal category for each cluster (by feature).
- Continuous features are displayed as boxplots, which show overall medians and the interquartile ranges.

Overlaid on these background views are boxplots for selected clusters:

- For continuous features, square point markers and horizontal lines indicate the median and interquartile range for each cluster.
- Each cluster is represented by a different color, shown at the top of the view.

Navigating the Cluster Viewer

The Cluster Viewer is an interactive display. You can:

- Select a field or cluster to view more details.
- Compare clusters to select items of interest.
- Alter the display.
- Transpose axes.
- Generate Derive, Filter, and Select nodes using the Generate menu.

Using the Toolbars

You control the information shown in both the left and right panels by using the toolbar options. You can change the orientation of the display (top-down, left-to-right, or right-to-left) using the toolbar controls. In addition, you can also reset the viewer to the default settings, and open a dialog box to specify the contents of the Clusters view in the main panel.

The Sort Features By, Sort Clusters By, Cells, and Display options are only available when you select the Clusters view in the main panel. See the topic [Clusters View](#) for more information.

Table 1. Toolbar icons

Icon	Topic

Generating Nodes from Cluster Models

The Generate menu enables you to create new nodes based on the cluster model. This option is available from the Model tab of the generated model and enables you to generate nodes based on either the current display or selection (that is, all visible clusters or all selected ones). For example, you can select a single feature and then generate a Filter node to discard all other (nonvisible) features. The generated nodes are placed unconnected on the canvas. In addition, you can generate a copy of the model nugget to the models palette. Remember to connect the nodes and make any desired edits before execution.

- **Generate Modeling Node.** Creates a modeling node on the stream canvas. This would be useful, for example, if you have a stream in which you want to use these model settings but you no longer have the modeling node used to generate them.
- **Model to Palette.** Creates a the nugget on the Models palette. This is useful in situations where a colleague may have sent you a stream containing the model and not the model itself.
- **Filter Node.** Creates a new Filter node to filter fields that are not used by the cluster model, and/or not visible in the current Cluster Viewer display. If there is a Type node upstream from this Cluster node, any fields with the role *Target* are discarded by the generated Filter node.
- **Filter Node (from selection).** Creates a new Filter node to filter fields based on selections in the Cluster Viewer. Select multiple fields using the Ctrl-click method. Fields selected in the Cluster Viewer are discarded downstream, but you can change this behavior by editing the Filter node before execution.
- **Select Node.** Creates a new Select node to select records based on their membership in any of the clusters visible in the current Cluster Viewer display. A select condition is automatically generated.
- **Select Node (from selection).** Creates a new Select node to select records based on membership in clusters selected in the Cluster Viewer. Select multiple clusters using the Ctrl-click method.
- **Derive Node.** Creates a new Derive node, which derives a flag field that assigns records a value of *True* or *False* based on membership in all clusters visible in the Cluster Viewer. A derive condition is automatically generated.
- **Derive Node (from selection).** Creates a new Derive node, which derives a flag field based on membership in clusters selected in the Cluster Viewer. Select multiple clusters using the Ctrl-click method.

In addition to generating nodes, you can also create graphs from the Generate menu. See the topic [Generating Graphs from Cluster Models](#) for more information.

Control Cluster View Display

To control what is shown in the Clusters view on the main panel, click the Display button; the Display dialog opens.

Features. Selected by default. To hide all input features, deselect the check box.

Evaluation Fields. Choose the evaluation fields (fields not used to create the cluster model, but sent to the model viewer to evaluate the clusters) to display; none are shown by default. Note The evaluation field must be a string with more than one value. This check box is unavailable if no evaluation fields are available.

Cluster Descriptions. Selected by default. To hide all cluster description cells, deselect the check box.

Cluster Sizes. Selected by default. To hide all cluster size cells, deselect the check box.

Maximum Number of Categories. Specify the maximum number of categories to display in charts of categorical features; the default is 20.

Generating Graphs from Cluster Models

Cluster models provide a lot of information; however, it may not always be in an easily accessible format for business users. To provide the data in a way that can be easily incorporated into business reports, presentations, and so on, you can produce graphs of selected data. For example, from the Cluster Viewer you can generate a graph for a selected cluster, thereby only creating a graph for the cases in that cluster.

Note: You can only generate a graph from the Cluster Viewer when the model nugget is attached to other nodes in a stream.

Generate a graph

1. Open the model nugget containing the Cluster Viewer.
2. On the Model tab select *Clusters* from the View drop-down list.
3. In the main view, select the cluster, or clusters, for which you want to produce a graph.
4. From the Generate menu, select Graph (from selection); the Graphboard Basic tab is displayed.
Note: Only the Basic and Detailed tabs are available when you display the Graphboard in this way.
5. Using either the Basic or Detailed tab settings, specify the details to be displayed on the graph.
6. Click OK to generate the graph.

The graph heading identifies the model type and cluster, or clusters, that were chosen for inclusion.

Association Rules

Association rules associate a particular conclusion (the purchase of a particular product, for example) with a set of conditions (the purchase of several other products, for example). For example, the rule

```
beer <= cannedveg & frozenmeal (173, 17.0%, 0.84)
```

states that *beer* often occurs when *cannedveg* and *frozenmeal* occur together. The rule is 84% reliable and applies to 17% of the data, or 173 records. Association rule algorithms automatically find the associations that you could find manually using visualization techniques, such as the Web node.

Figure 1. Web node showing associations between market basket items

The advantage of association rule algorithms over the more standard decision tree algorithms (C5.0 and C&R Trees) is that associations can exist between *any* of the attributes. A decision tree algorithm will build rules with only a single conclusion, whereas association algorithms attempt to find many rules, each of which may have a different conclusion.

The disadvantage of association algorithms is that they are trying to find patterns within a potentially very large search space and, hence, can require much more time to run than a decision tree algorithm. The algorithms use a **generate and test** method for finding rules--simple rules are generated initially, and these are validated against the dataset. The good rules are stored and all rules, subject to various constraints, are then specialized. **Specialization** is the process of adding conditions to a rule. These new rules are then validated against the data, and the process iteratively stores the best or most interesting rules found. The user usually supplies some limit to the possible number of antecedents to allow in a rule, and various techniques based on information theory or efficient indexing schemes are used to reduce the potentially large search space.

At the end of the processing, a table of the best rules is presented. Unlike a decision tree, this set of association rules cannot be used directly to make predictions in the way that a standard model (such as a decision tree or a neural network) can. This is due to the many different possible conclusions for the rules. Another level of transformation is required to transform the association rules into a classification rule set. Hence, the association rules produced by association algorithms are known as **unrefined models**. Although the user can browse these unrefined models, they cannot be used explicitly as classification models unless the user tells the system to generate a classification model from the unrefined model. This is done from the browser through a Generate menu option.

Two association rule algorithms are supported:

	The Apriori node extracts a set of rules from the data, pulling out the rules with the highest information content. Apriori offers five different methods of selecting rules and uses a sophisticated indexing scheme to process large data sets efficiently. For large problems, Apriori is generally faster to train; it has no arbitrary limit on the number of rules that can be retained, and it can handle rules with up to 32 preconditions. Apriori requires that input and output fields all be categorical but delivers better performance because it is optimized for this type of data.
	The Sequence node discovers association rules in sequential or time-oriented data. A sequence is a list of item sets that tends to occur in a predictable order. For example, a customer who purchases a razor and aftershave lotion may purchase shaving cream the next time he shops. The Sequence node is based on the CARMA association rules algorithm, which uses an efficient two-pass method for finding sequences.

Tabular versus Transactional Data

Data used by association rule models may be in transactional or tabular format, as described below. These are general descriptions; specific requirements may vary as discussed in the documentation for each model type. Note that when scoring models, the data to be scored must mirror the format of the data used to build the model. Models built using tabular data can be used to score only tabular data; models built using transactional data can score only transactional data.

Transactional Format

Transactional data have a separate record for each transaction or item. If a customer makes multiple purchases, for example, each would be a separate record, with associated items linked by a customer ID. This is also sometimes known as **till-roll** format.

Customer	Purchase	
1	jam	
2	milk	
3	jam	
3	bread	
4	jam	
4	bread	
4	milk	

The Apriori, CARMA, and Sequence nodes can all use transactional data.

Tabular Data

Tabular data (also known as **basket** or **truth-table** data) have items represented by separate flags, where each flag field represents the presence or absence of a specific item. Each record represents a complete set of associated items. Flag fields can be categorical or numeric, although certain models may have more specific requirements.

Customer	Jam	Bread	Milk	
1	T	F	F	
2	F	F	T	
3	T	T	F	
4	T	T	T	

The Apriori, CARMA, GSAR, and Sequence nodes can all use tabular data.

Apriori node

The Apriori node discovers association rules in the data. Association rules are statements of the form

```
if antecedent(s) then consequent(s)
```

For example, "if a customer purchases a razor and after shave, then that customer will purchase shaving cream with 80% confidence." Apriori extracts a set of rules from the data, pulling out the rules with the highest information content. Apriori offers five different methods of selecting rules and uses a sophisticated indexing scheme to efficiently process large data sets.

Requirements. To create an Apriori rule set, you need one or more *Input* fields and one or more *Target* fields. Input and output fields (those with the role *Input*, *Target*, or *Both*) must be symbolic. Fields with the role *None* are ignored. Field types must be fully instantiated before executing the node. Data can be in tabular or transactional format. See the topic [Tabular versus Transactional Data](#) for more information.

Strengths. For large problems, Apriori is generally faster to train. It also has no arbitrary limit on the number of rules that can be retained and can handle rules with up to 32 preconditions. Apriori offers five different training methods, allowing more flexibility in matching the data mining method to the problem at hand.

- [Apriori Node Model Options](#)
- [Apriori Node Expert Options](#)

Apriori Node Model Options

Model name. You can generate the model name automatically based on the target or ID field (or model type in cases where no such field is specified) or specify a custom name.

Minimum antecedent support. You can specify a support criterion for keeping rules in the rule set. Support refers to the percentage of records in the training data for which the antecedents (the "if" part of the rule) are true. (Note that this definition of support differs from that used in the CARMA and Sequence nodes. See the topic [Sequence Node Model Options](#) for more information.) If you are getting rules that apply to very small subsets of the data, try increasing this setting.

Note: The definition of support for Apriori is based on the number of records with the antecedents. This is in contrast to the CARMA and Sequence algorithms for which the definition of support is based on the number of records with all the items in a rule (that is, both the antecedents and consequent). The results for association models show both the (antecedent) support and rule support measures.

Minimum rule confidence. You can also specify a confidence criterion. Confidence is based on the records for which the rule's antecedents are true and is the percentage of those records for which the consequent(s) are also true. In other words, it's the percentage of predictions based on the rule that are correct. Rules with lower confidence than the specified criterion are discarded. If you are getting too many rules, try increasing this setting. If you are getting too few rules (or no rules at all), try decreasing this setting.

Note: If necessary, you can highlight the value and type in your own value. Be aware that if you reduce the confidence value below 1.0, in addition to the process requiring a lot of free memory, you might find that the rules take an extremely long time to build.

Maximum number of antecedents. You can specify the maximum number of preconditions for any rule. This is a way to limit the complexity of the rules. If the rules are too complex or too specific, try decreasing this setting. This setting also has a large influence on training time. If your rule set is taking too long to train, try reducing this setting.

Only true values for flags. If this option is selected for data in tabular (truth table) format, then only true values will be included in the resulting rules. This can help make rules easier to understand. The option does not apply to data in transactional format. See the topic [Tabular versus Transactional Data](#) for more information.

Note: The CARMA model building node ignores empty records when building a model if the field type is a flag, whereas the Apriori model building node includes empty records. Empty records are records where all the fields used in the model build have a false value.

Optimize. Select options designed to increase performance during model building based on your specific needs.

- Select Speed to instruct the algorithm to never use disk spilling in order to improve performance.
 - Select Memory to instruct the algorithm to use disk spilling when appropriate at some sacrifice to speed. This option is selected by default.
- Note: When running in distributed mode, this setting can be overridden by administrator options specified in the *options.cfg* file. For more information, see the *IBM® SPSS® Modeler Server Administrator's Guide*.

-

Apriori Node Expert Options

For those with detailed knowledge of Apriori's operation, the following expert options allow you to fine-tune the induction process. To access expert options, set the Mode to Expert on the Expert tab.

Evaluation measure. Apriori supports five methods of evaluating potential rules.

- **Rule Confidence.** The default method uses the confidence (or accuracy) of the rule to evaluate rules. For this measure, the Evaluation measure lower bound is disabled, since it is redundant with the Minimum rule confidence option on the Model tab. See the topic [Apriori Node Model Options](#) for more information.
- **Confidence Difference.** (Also called **absolute confidence difference to prior**.) This evaluation measure is the absolute difference between the rule's confidence and its prior confidence. This option prevents bias where the outcomes are not evenly distributed. This helps prevent "obvious" rules from being kept. Set the evaluation measure lower bound to the minimum difference in confidence for which you want rules to be kept.
- **Confidence Ratio.** (Also called **difference of confidence quotient to 1**.) This evaluation measure is the ratio of rule confidence to prior confidence (or, if the ratio is greater than one, its reciprocal) subtracted from 1. Like Confidence Difference, this method takes uneven distributions into account. It is especially good at finding rules that predict rare events. Set the evaluation measure lower bound to the difference for which you want rules to be kept.
- **Information Difference.** (Also called **information difference to prior**.) This measure is based on the **information gain** measure. If the probability of a particular consequent is considered as a logical value (a **bit**), then the information gain is the proportion of that bit that can be determined, based on the antecedents. The information difference is the difference between the information gain, given the antecedents, and the information gain, given only the prior confidence of the consequent. An important feature of this method is that it takes support into account so that rules that cover more records are preferred for a given level of confidence. Set the evaluation measure lower bound to the information difference for which you want rules to be kept.
- **Normalized Chi-square.** (Also called **normalized chi-squared measure**.) This measure is a statistical index of association between antecedents and consequents. The measure is normalized to take values between 0 and 1. This measure is even more strongly dependent on support than the information difference measure. Set the evaluation measure lower bound to the information difference for which you want rules to be kept.

Allow rules without antecedents. Select to allow rules that include only the consequent (item or item set). This is useful when you are interested in determining common items or item sets. For example, `cannedveg` is a single-item rule without an antecedent that indicates purchasing `cannedveg` is a common occurrence in the data. In some cases, you may want to include such rules if you are simply interested in the most confident predictions. This option is off by default. By convention, antecedent support for rules without antecedents is expressed as 100%, and rule support will be the same as confidence.

Related information

- [Apriori node](#)
 - [Apriori Node Model Options](#)
-

CARMA Node

The CARMA node uses an association rules discovery algorithm to discover association rules in the data. Association rules are statements in the form

```
if antecedent(s) then consequent(s)
```

For example, if a Web customer purchases a wireless card and a high-end wireless router, the customer is also likely to purchase a wireless music server if offered. The CARMA model extracts a set of rules from the data without requiring you to specify input or target fields. This means that the rules generated can be used for a wider variety of applications. For example, you can use rules generated by this node to find a list of products or services (antecedents) whose consequent is the item that you want to promote this holiday season. Using IBM® SPSS® Modeler, you can determine which clients have purchased the antecedent products and construct a marketing campaign designed to promote the consequent product.

Requirements. In contrast to Apriori, the CARMA node does not require *Input* or *Target* fields. This is integral to the way the algorithm works and is equivalent to building an Apriori model with all fields set to *Both*. You can constrain which items are listed only as antecedents or consequents by filtering the model after it is built. For example, you can use the model browser to find a list of products or services (antecedents) whose consequent is the item that you want to promote this holiday season.

To create a CARMA rule set, you need to specify an ID field and one or more content fields. The ID field can have any role or measurement level. Fields with the role *None* are ignored. Field types must be fully instantiated before executing the node. Like Apriori, data may be in tabular or transactional format. See the topic [Tabular versus Transactional Data](#) for more information.

Strengths. The CARMA node is based on the CARMA association rules algorithm. In contrast to Apriori, the CARMA node offers build settings for rule support (support for both antecedent and consequent) rather than antecedent support. CARMA also allows rules with multiple consequents. Like Apriori, models generated by a CARMA node can be inserted into a data stream to create predictions. See the topic [Model Nuggets](#) for more information.

-

CARMA Node Fields Options

Before executing a CARMA node, you must specify input fields on the Fields tab of the CARMA node. While most modeling nodes share identical Fields tab options, the CARMA node contains several unique options. All options are discussed below.

Use Type node settings. This option tells the node to use field information from an upstream type node. This is the default.

Use custom settings. This option tells the node to use field information specified here instead of that given in any upstream Type node(s). After selecting this option, specify fields below according to whether you are reading data in transactional or tabular format.

Use transactional format. This option changes the field controls in the rest of this dialog box depending on whether your data are in transactional or tabular format. If you use multiple fields with transactional data, the items specified in these fields for a particular record are assumed to represent items found in a single transaction with a single timestamp. See the topic [Tabular versus Transactional Data](#) for more information.

Tabular data

If Use transactional format is not selected, the following fields are displayed.

- Inputs. Select the input field or fields. This is similar to setting the field role to *Input* in a Type node.
- Partition. This field allows you to specify a field used to partition the data into separate samples for the training, testing, and validation stages of model building. By using one sample to generate the model and a different sample to test it, you can get a good indication of how well the model will generalize to larger datasets that are similar to the current data. If multiple partition fields have been defined by using Type or Partition nodes, a single partition field must be selected on the Fields tab in each modeling node that uses partitioning. (If only one partition is present, it is automatically used whenever partitioning is enabled.) Also note that to apply the selected partition in your analysis, partitioning must also be enabled in the Model Options tab for the node. (Deselecting this option makes it possible to disable partitioning without changing field settings.)

Transactional data

If you select Use transactional format, the following fields are displayed.

- ID. For transactional data, select an ID field from the list. Numeric or symbolic fields can be used as the ID field. Each unique value of this field should indicate a specific unit of analysis. For example, in a market basket application, each ID might represent a single customer. For a Web log analysis application, each ID might represent a computer (by IP address) or a user (by login data).
- IDs are contiguous. (Apriori and CARMA nodes only) If your data are presorted so that all records with the same ID are grouped together in the data stream, select this option to speed up processing. If your data are not presorted (or you are not sure), leave this option unselected and the node will sort the data automatically.
Note: If your data are not sorted and you select this option, you may get invalid results in your model.
- Content. Specify the content field(s) for the model. These fields contain the items of interest in association modeling. You can specify multiple flag fields (if data are in tabular format) or a single nominal field (if data are in transactional format).

Related information

 - [CARMA Node Model Options](#)
 - [CARMA Node Expert Options](#)
-

CARMA Node Model Options

Model name. You can generate the model name automatically based on the target or ID field (or model type in cases where no such field is specified) or specify a custom name.

Minimum rule support (%). You can specify a support criterion. Rule support refers to the proportion of IDs in the training data that contain the entire rule. (Note that this definition of support differs from antecedent support used in the Apriori nodes.) If you want to focus on more common rules, increase this setting.

Minimum rule confidence (%). You can specify a confidence criterion for keeping rules in the rule set. Confidence refers to the percentage of IDs where a correct prediction is made (out of all IDs for which the rule makes a prediction). It is calculated as the number of IDs for which the entire rule is found divided by the number of IDs for which the antecedents are found, based on the training data. Rules with lower confidence than the specified criterion are discarded. If you are getting uninteresting or too many rules, try increasing this setting. If you are getting too few rules, try decreasing this setting.

Note: If necessary, you can highlight the value and type in your own value. Be aware that if you reduce the confidence value below 1.0, in addition to the process requiring a lot of free memory, you might find that the rules take an extremely long time to build.

Maximum rule size. You can set the maximum number of distinct **item sets** (as opposed to **items**) in a rule. If the rules of interest are relatively short, you can decrease this setting to speed up building the rule set.

Note: The CARMA model building node ignores empty records when building a model if the field type is a flag, whereas the Apriori model building node includes empty records. Empty records are records where all the fields used in the model build have a false value.

Related information

- [CARMA Node](#)
 - [CARMA Node Fields Options](#)
 - [CARMA Node Expert Options](#)
-

CARMA Node Expert Options

For those with detailed knowledge of the CARMA node's operation, the following expert options allow you to fine-tune the model-building process. To access expert options, set the mode to Expert on the Expert tab.

Exclude rules with multiple consequents. Select to exclude "two-headed" consequents—that is, consequents that contain two items. For example, the rule `bread & cheese & fish`

-> `wine&fruit` contains a two-headed consequent, `wine&fruit`. By default, such rules are included.

Set pruning value. To conserve memory, the CARMA algorithm used periodically removes (**prunes**) infrequent item sets from its list of potential item sets during processing. Select this option to adjust the frequency of pruning, and the number you specify determines the frequency of pruning. Enter a smaller value to decrease the memory requirements of the algorithm (but potentially increase the training time required), or enter a larger value to speed up training (but potentially increase memory requirements). The default value is 500.

Vary support. Select to increase efficiency by excluding infrequent item sets that seem to be frequent when they are included unevenly. This is achieved by starting with a higher support level and tapering it down to the level specified on the Model tab. Enter a value for Estimated number of transactions to specify how quickly the support level should be tapered.

Allow rules without antecedents. Select to allow rules that include only the consequent (item or item set). This is useful when you are interested in determining common items or item sets. For example, `cannedveg` is a single-item rule without an antecedent that indicates purchasing `cannedveg` is a common occurrence in the data. In some cases, you may want to include such rules if you are simply interested in the most confident predictions. This option is unselected by default.

Association Rule Model Nuggets

Association rule model nuggets represent the rules discovered by one of the following association rule modeling nodes:

- Apriori
- CARMA

The model nuggets contain information about the rules extracted from the data during model building.

Note: Association rule nugget scoring may be incorrect if you do not sort transactional data by ID.
Viewing Results

You can browse the rules generated by association models (Apriori and CARMA) and Sequence models using the Model tab on the dialog box. Browsing a model nugget shows you the information about the rules and provides options for filtering and sorting results before generating new nodes or scoring the model. See the topic [Association Rule model nugget details](#) for more information.

Scoring the Model

Refined model nuggets (Apriori, CARMA, and Sequence) may be added to a stream and used for scoring. See the topic [Using Model Nuggets in Streams](#) for more information. Model nuggets used for scoring include an extra Settings tab on their respective dialog boxes. See the topic [Association Rule Model Nugget Settings](#) for more information.

An unrefined model nugget cannot be used for scoring in its raw format. Instead, you can generate a rule set and use the rule set for scoring. See the topic [Generating a Rule Set from an Association Model Nugget](#) for more information.

Association Rule model nugget details

On the Model tab of an Association Rule model nugget, you can see a table containing the rules extracted by the algorithm. Each row in the table represents a rule. The first column represents the consequents (the "then" part of the rule), while the next column represents the antecedents (the "if" part of the rule). Subsequent columns contain rule information, such as confidence, support, and lift.

Association rules are often shown in the format in the following table.

Table 1. Example of an association rule	
Consequent	Antecedent
Drug = drugY	Sex = F BP = HIGH

The example rule is interpreted as *if Sex = "F" and BP = "HIGH," then Drug is likely to be drugY*; or to phrase it another way, *for records where Sex = "F" and BP = "HIGH," Drug is likely to be drugY*. Using the dialog box toolbar, you can choose to display additional information, such as confidence, support, and instances.

Sort menu. The Sort menu button on the toolbar controls the sorting of rules. Direction of sorting (ascending or descending) can be changed using the sort direction button (up or down arrow).

You can sort rules by:

- Support
- Confidence
- Rule Support
- Consequent
- Evaluation
- Lift
- Deployability

Show/Hide menu. The Show/Hide menu (criteria toolbar button) controls options for the display of rules.

Figure 1. Show/Hide button

The following display options are available:

- Rule ID displays the rule ID assigned during model building. A rule ID enables you to identify which rules are being applied for a given prediction. Rule IDs also allow you to merge additional rule information, such as deployability, product information, or antecedents, at a later time.
- Instances displays information about the number of unique IDs to which the rule applies—that is, for which the antecedents are true. For example, given the rule `bread -> cheese`, the number of records in the training data that include the antecedent `bread` are referred to as **instances**.
- Support displays antecedent support—that is, the proportion of IDs for which the antecedents are true, based on the training data. For example, if 50% of the training data includes the purchase of bread, then the rule `bread -> cheese` will have an antecedent support of 50%. Note: Support as defined here is the same as the instances but is represented as a percentage.
- Confidence displays the ratio of rule support to antecedent support. This indicates the proportion of IDs with the specified antecedent(s) for which the consequent(s) is/are also true. For example, if 50% of the training data contains bread (indicating antecedent support) but only 20% contains both bread and cheese (indicating rule support), then confidence for the rule `bread -> cheese` would be **Rule Support / Antecedent Support** or, in this case, 40%.
- Rule Support displays the proportion of IDs for which the entire rule, antecedents, and consequent(s), are true. For example, if 20% of the training data contains both bread and cheese, then rule support for the rule `bread -> cheese` is 20%.
- Evaluation is included if you select one of the expert association rule criterion (Confidence Difference, Confidence Ratio, Information Difference, or Normalized Chi-Square). These expert criteria measures are compared to the Evaluation measure lower bound number set by the user (and only applies when an expert criterion rule is selected). The Evaluation statistic has the following meanings for each expert association rule criterion:
 - Confidence Difference: Posterior Confidence - Prior Confidence
 - Confidence Ratio: (Posterior Confidence - Prior Confidence)/Posterior Confidence

- Information Difference: Information Gain Measure
- Normalized Chi-Square: Normalized Chi-Square Statistic

Each of these statistics are compared to the Evaluation measure lower bound number set by the user, and a rule is selected if the statistics exceed this number.

- Lift displays the ratio of confidence for the rule to the prior probability of having the consequent. For example, if 10% of the entire population buys bread, then a rule that predicts whether people will buy bread with 20% confidence will have a lift of $20/10 = 2$. If another rule tells you that people will buy bread with 11% confidence, then the rule has a lift of close to 1, meaning that having the antecedent(s) does not make a lot of difference in the probability of having the consequent. In general, rules with lift different from 1 will be more interesting than rules with lift close to 1.
- Deployability is a measure of what percentage of the training data satisfies the conditions of the antecedent but does not satisfy the consequent. In product purchase terms, it basically means what percentage of the total customer base owns (or has purchased) the antecedent(s) but has not yet purchased the consequent. The deployability statistic is defined as $((\text{Antecedent Support in } \# \text{ of Records} - \text{Rule Support in } \# \text{ of Records}) / \text{Number of Records}) * 100$, where *Antecedent Support* means the number of records for which the antecedents are true and *Rule Support* means the number of records for which both antecedents and the consequent are true.

Filter button. The Filter button (funnel icon) on the menu expands the bottom of the dialog box to show a panel where active rule filters are displayed. Filters are used to narrow the number of rules displayed on the Models tab.

Figure 2. Filter button

To create a filter, click the Filter icon to the right of the expanded panel. This opens a separate dialog box in which you can specify constraints for displaying rules. Note that the Filter button is often used in conjunction with the Generate menu to first filter rules and then generate a model containing that subset of rules. For more information, see [Specifying Filters for Rules](#) below.

Find Rule button. The Find Rule button (binoculars icon) enables you to search the rules shown for a specified rule ID. The adjacent display box indicates the number of rules currently displayed out of the number available. Rule IDs are assigned by the model in the order of discovery at the time and are added to the data during scoring.

Figure 3. Find Rule button

To reorder rule IDs:

1. You can rearrange rule IDs in IBM® SPSS® Modeler by first sorting the rule display table according to the desired measurement, such as confidence or lift.
2. Then using options from the Generate menu, create a filtered model.
3. In the Filtered Model dialog box, select Renumber rules consecutively starting with, and specify a start number.

See [Generating a Filtered Model](#) for more information.

- [Specifying Filters for Rules](#)
- [Generating Graphs for Rules](#)

Specifying Filters for Rules

By default, rule algorithms, such as Apriori, CARMA, and Sequence, may generate a large and cumbersome number of rules. To enhance clarity when browsing or to streamline rule scoring, you should consider filtering rules so that consequents and antecedents of interest are more prominently displayed. Using the filtering options on the Model tab of a rule browser, you can open a dialog box for specifying filter qualifications.

To create a filter, click the Edit Filters button (funnel icon) to the right of the expanded panel. This opens a separate Edit Filters dialog box where you can specify constraints for displaying rules.

Consequents. Select Enable Filter to activate options for filtering rules based on the inclusion or exclusion of specified consequents. Select Includes any of to create a filter where rules contain at least one of the specified consequents. Alternatively, select Excludes to create a filter excluding specified consequents. You can select consequents using the picker icon to the right of the list box. This opens a dialog box listing all consequents present in the generated rules.

Note: Consequents may contain more than one item. Filters will check only that a consequent contains one of the items specified.

Antecedents. Select Enable Filter to activate options for filtering rules based on the inclusion or exclusion of specified antecedents. You can select items using the picker icon to the right of the list box. This opens a dialog box listing all antecedents present in the generated rules.

- Select Includes all of to set the filter as an inclusionary one where all antecedents specified must be included in a rule.
- Select Includes any of to create a filter where rules contain at least one of the specified antecedents.
- Select Excludes to create a filter excluding rules that contain a specified antecedent.

Confidence. Select Enable Filter to activate options for filtering rules based on the level of confidence for a rule. You can use the Min and Max controls to specify a confidence range. When you are browsing generated models, confidence is listed as a percentage. When you are scoring output, confidence is expressed as a number between 0 and 1.

Antecedent Support. Select Enable Filter to activate options for filtering rules based on the level of antecedent support for a rule. Antecedent support indicates the proportion of training data that contains the same antecedents as the current rule, making it analogous to a popularity index. You can use the Min and Max controls to specify a range used to filter rules based on support level.

Lift. Select Enable Filter to activate options for filtering rules based on the lift measurement for a rule. *Note:* Lift filtering is available only for association models built after release 8.5 or for earlier models that contain a lift measurement. Sequence models do not contain this option.

Click OK to apply all filters that have been enabled in this dialog box.

Generating Graphs for Rules

The Association nodes provide a lot of information; however, it may not always be in an easily accessible format for business users. To provide the data in a way that can be easily incorporated into business reports, presentations, and so on, you can produce graphs of selected data. From the Model tab, you can generate a graph for a selected rule, thereby only creating a graph for the cases in that rule.

1. On the Model tab, select the rule in which you are interested.
2. From the Generate menu, select Graph (from selection). The Graphboard Basic tab is displayed.
Note: Only the Basic and Detailed tabs are available when you display the Graphboard in this way.
3. Using either the Basic or Detailed tab settings, specify the details to be displayed on the graph.
4. Click OK to generate the graph.

The graph heading identifies the rule and antecedent details that were chosen for inclusion.

Association Rule Model Nugget Settings

This Settings tab is used to specify scoring options for association models (Apriori and CARMA). This tab is available only after the model nugget has been added to a stream for purposes of scoring.

Note: The dialog box for browsing an unrefined model does not include the Settings tab, since it cannot be scored. To score the "unrefined" model, you must first generate a rule set. See the topic [Generating a Rule Set from an Association Model Nugget](#) for more information.

Maximum number of predictions Specify the maximum number of predictions included for each set of basket items. This option is used in conjunction with Rule Criterion below to produce the "top" predictions, where *top* indicates the highest level of confidence, support, lift, and so on, as specified below.

Rule Criterion Select the measure used to determine the strength of rules. Rules are sorted by the strength of criteria selected here in order to return the top predictions for an item set. Available criteria are shown in the following list.

- Confidence
- Support
- Rule support (Support * Confidence)
- Lift

- Deployability

Allow repeat predictions Select to include multiple rules with the same consequent when scoring. For example, selecting this option allows the following rules to be scored:

```
bread & cheese -> wine
cheese & fruit -> wine
```

Turn off this option to exclude repeat predictions when scoring.

Note: Rules with multiple consequents (**bread & cheese & fruit -> wine & pate**) are considered repeat predictions only if all consequents (**wine & pate**) have been predicted before.

Ignore unmatched basket items Select to ignore the presence of additional items in the item set. For example, when this option is selected for a basket that contains [**tent & sleeping bag & kettle**], the rule **tent & sleeping bag -> gas_stove** will apply despite the extra item (**kettle**) present in the basket.

There may be some circumstances where extra items should be excluded. For example, it is likely that someone who purchases a tent, sleeping bag, and kettle may already have a gas stove, indicated by the presence of the kettle. In other words, a gas stove may not be the best prediction. In such cases, you should deselect Ignore unmatched basket items to ensure that rule antecedents exactly match the contents of a basket. By default, unmatched items are ignored.

Check that predictions are not in basket. Select to ensure that consequents are not also present in the basket. For example, if the purpose of scoring is to make a home furniture product recommendation, then it is unlikely that a basket that already contains a dining room table will be likely to purchase another one. In such a case, you should select this option. On the other hand, if products are perishable or disposable (such as cheese, baby formula, or tissue), then rules where the consequent is already present in the basket may be of value. In the latter case, the most useful option might be Do not check basket for predictions below.

Check that predictions are in basket Select this option to ensure that consequents are also present in the basket. This approach is useful when you are attempting to gain insight into existing customers or transactions. For example, you may want to identify rules with the highest lift and then explore which customers fit these rules.

Do not check basket for predictions Select to include all rules when scoring, regardless of the presence or absence of consequents in the basket.

Generate SQL for this model When using data from a database, SQL code can be pushed back to the database for execution, providing superior performance for many operations.

Select one of the following options to specify how SQL generation is performed.

- Default: Score using Server Scoring Adapter (if installed) otherwise in process If connected to a database with a scoring adapter installed, generates SQL using the scoring adapter and associated user defined functions (UDF) and scores your model within the database. When no scoring adapter is available, this option fetches your data back from the database and scores it in SPSS® Modeler.
- Score outside of the Database If selected, this option fetches your data back from the database and scores it in SPSS Modeler.

Generating a Rule Set from an Association Model Nugget

Association model nuggets, such as Apriori and CARMA, can be used to score data directly, or you can first generate a subset of rules, known as a **rule set**. Rule sets are particularly useful when you are working with an unrefined model, which cannot be used directly for scoring. See the topic [Unrefined Models](#) for more information.

To generate a rule set, choose Rule set from the Generate menu in the model nugget browser. You can specify the following options for translating the rules into a rule set:

Rule set name. Allows you to specify the name of the new generated Rule Set node.

Create node on. Controls the location of the new generated Rule Set node. Select Canvas, GM Palette, or Both.

Target field. Determines which output field will be used for the generated Rule Set node. Select a single output field from the list.

Minimum support. Specify the minimum support for rules to be preserved in the generated rule set. Rules with support less than the specified value will not be included in the new rule set.

Minimum confidence. Specify the minimum confidence for rules to be preserved in the generated rule set. Rules with confidence less than the specified value will not be included in the new rule set.

Default value. Allows you to specify a default value for the target field that is assigned to scored records for which no rule fires.

Generating a Filtered Model

To generate a filtered model from an association model nugget, such as an Apriori, CARMA, or Sequence Rule Set node, choose Filtered Model from the Generate menu in the model nugget browser. This creates a subset model that includes only those rules currently displayed in the browser. *Note:* You cannot generate filtered models for unrefined models.

You can specify the following options for filtering rules:

Name for New Model. Allows you to specify the name of the new Filtered Model node.

Create node on. Controls the location of the new Filtered Model node. Select Canvas, GM Palette, or Both.

Rule numbering. Specify how rule IDs will be numbered in the subset of rules included in the filtered model.

- **Retain original rule ID numbers.** Select to maintain the original numbering of rules. By default, rules are given an ID that corresponds with their order of discovery by the algorithm. That order may vary depending on the algorithm employed.
- **Renumber rules consecutively starting with.** Select to assign new rule IDs for the filtered rules. New IDs are assigned based on the sort order displayed in the rule browser table on the Model tab, beginning with the number you specify here. You can specify the start number for IDs using the arrows to the right.

Scoring Association Rules

Scores produced by running new data through an association rule model nugget are returned in separate fields. Three new fields are added for each prediction, with *P* representing the prediction, *C* representing confidence, and *I* representing the rule ID. The organization of these output fields depends on whether the input data are in transactional or tabular format. See [Tabular versus Transactional Data](#) for an overview of these formats.

For example, suppose you are scoring basket data using a model that generates predictions based on the following three rules:

```
Rule_15 bread&wine -> meat (confidence 54%)
Rule_22 cheese -> fruit (confidence 43%)
Rule_5 bread&cheese -> frozveg (confidence 24%)
```

Tabular data. For tabular data, the three predictions (3 is the default) are returned in a single record.

Table 1. Scores in tabular format

ID	Bread	Wine	Cheese	P1	C1	I1	P2	C2	I2	P3	C3	I3
Fred	1	1	1	meat	0.54	15	fruit	0.43	22	frozveg	.24	5

Transactional data. For transactional data, a separate record is generated for each prediction. Predictions are still added in separate columns, but scores are returned as they are calculated. This results in records with incomplete predictions, as shown in the sample output below. The second and third predictions (P2 and P3) are blank in the first record, along with the associated confidences and rule IDs. As scores are returned, however, the final record contains all three predictions.

Table 2. Scores in transactional format

ID	Item	P1	C1	I1	P2	C2	I2	P3	C3	I3
Fred	bread	meat	0.54	14	\$null\$	\$null\$	\$null\$	\$null\$	\$null\$	\$null\$
Fred	cheese	meat	0.54	14	fruit	0.43	22	\$null\$	\$null\$	\$null\$
Fred	wine	meat	0.54	14	fruit	0.43	22	frozveg	0.24	5

To include only complete predictions for reporting or deployment purposes, use a Select node to select complete records.

Note: The field names used in these examples are abbreviated for clarity. During actual use, results fields for association models are named as shown in the following table.

Table 3. Names of results fields for association models

New field	Example field name
Prediction	\$A-TRANSACTION_NUMBER-1
Confidence (or other criterion)	\$AC-TRANSACTION_NUMBER-1
Rule ID	\$A-Rule_ID-1

Rules with Multiple Consequents

The CARMA algorithm allows rules with multiple consequents—for example:

```
bread -> wine&cheese
```

When you are scoring such “two-headed” rules, predictions are returned in the format displayed in the following table.

Table 4. Scoring results including a prediction with multiple consequents

ID	Bread	Wine	Cheese	P1	C1	I1	P2	C2	I2	P3	C3	I3
Fred	1	1	1	meat&veg	0.54	16	fruit	0.43	22	frozveg	.24	5

In some cases, you may need to split such scores before deployment. To split a prediction with multiple consequents, you will need to parse the field using the CLEM string functions.

Deploying Association Models

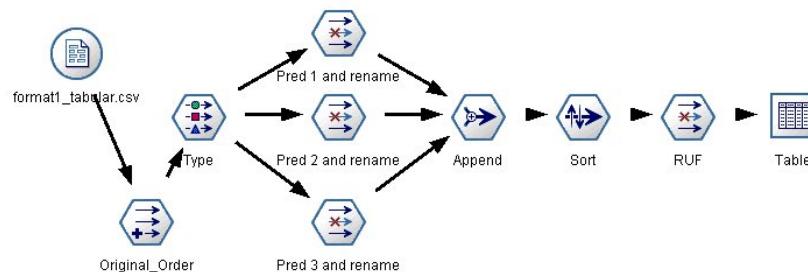

When scoring association models, predictions and confidences are output in separate columns (where P represents the prediction, C represents confidence, and I represents the rule ID). This is the case whether the input data are tabular or transactional. See the topic [Scoring Association Rules](#) for more information.

When preparing scores for deployment, you might find that your application requires you to transpose your output data to a format with predictions in rows rather than columns (one prediction per row, sometimes known as "till-roll" format).

Transposing Tabular Scores

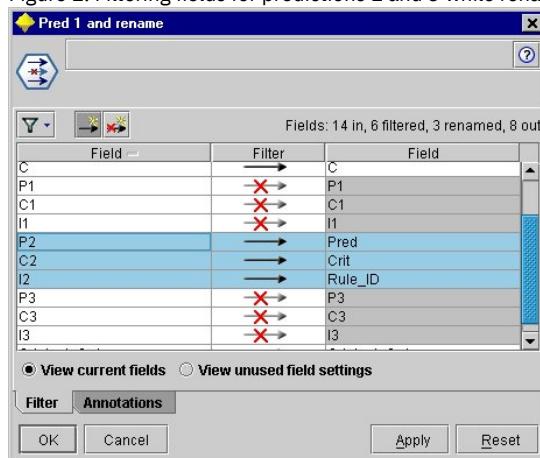

You can transpose tabular scores from columns to rows using a combination of steps in IBM® SPSS® Modeler, as described in the steps that follow.

Figure 1. Example stream used to transpose tabular data into till-roll format

1. Use the `@INDEX` function in a Derive node to ascertain the current order of predictions and save this indicator in a new field, such as `Original_order`.
2. Add a Type node to ensure that all fields are instantiated.
3. Use a Filter node to rename the default prediction, confidence, and ID fields ($P1, C1, I1$) to common fields, such as `Pred`, `Crit`, and `Rule_ID`, which will be used to append records later on. You will need one Filter node for each prediction generated.

Figure 2. Filtering fields for predictions 1 and 3 while renaming fields for prediction 2.

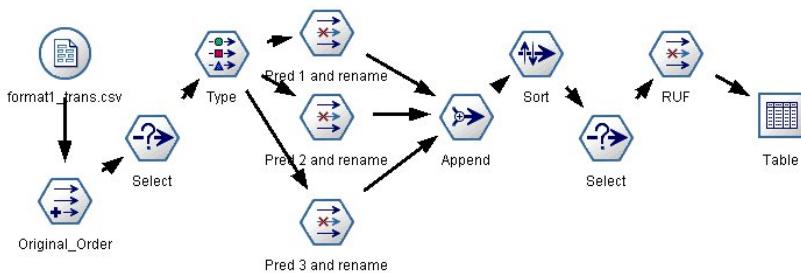

4. Use an Append node to append values for the shared `Pred`, `Crit`, and `Rule_ID`.
5. Attach a Sort node to sort records in ascending order for the field `Original_order` and in descending order for `Crit`, which is the field used to sort predictions by criteria such as confidence, lift, and support.
6. Use another Filter node to filter the field `Original_order` from the output.

At this point, the data are ready for deployment.

Transposing Transactional Scores

The process is similar for transposing transactional scores. For example, the stream shown below transposes scores to a format with a single prediction in each row as needed for deployment.

Figure 3. Example stream used to transpose transactional data into till-roll format

With the addition of two Select nodes, the process is identical to that explained earlier for tabular data.

- The first Select node is used to compare rule IDs across adjacent records and include only unique or undefined records. This Select node uses the CLEM expression to select records: `ID /= @OFFSET(ID,-1) or @OFFSET(ID,-1) = undef`.
- The second Select node is used to discard extraneous rules, or rules where `Rule_ID` has a null value. This Select node uses the following CLEM expression to discard records: `not (@NULL(Rule_ID))`.

For more information on transposing scores for deployment, contact Technical Support.

Sequence node

The Sequence node discovers patterns in sequential or time-oriented data, in the format `bread -> cheese`. The elements of a sequence are **item sets** that constitute a single transaction. For example, if a person goes to the store and purchases bread and milk and then a few days later returns to the store and purchases some cheese, that person's buying activity can be represented as two item sets. The first item set contains bread and milk, and the second one contains cheese. A **sequence** is a list of item sets that tend to occur in a predictable order. The Sequence node detects frequent sequences and creates a generated model node that can be used to make predictions.

Requirements. To create a Sequence rule set, you need to specify an ID field, an optional time field, and one or more content fields. Note that these settings must be made on the Fields tab of the modeling node; they cannot be read from an upstream Type node. The ID field can have any role or measurement level. If you specify a time field, it can have any role but its storage must be numeric, date, time, or timestamp. If you do not specify a time field, the Sequence node will use an implied timestamp, in effect using row numbers as time values. Content fields can have any measurement level and role, but all content fields must be of the same type. If they are numeric, they must be integer ranges (not real ranges).

Strengths. The Sequence node is based on the CARMA association rules algorithm, which uses an efficient two-pass method for finding sequences. In addition, the generated model node created by a Sequence node can be inserted into a data stream to create predictions. The generated model node can also generate SuperNodes for detecting and counting specific sequences and for making predictions based on specific sequences.

- [Sequence Node Fields Options](#)
- [Sequence Node Model Options](#)
- [Sequence Node Expert Options](#)
- [Sequence Model Nuggets](#)

Sequence Node Fields Options

Before executing a Sequence node, you must specify ID and content fields on the Fields tab of the Sequence node. If you want to use a time field, you also need to specify that here.

ID field. Select an ID field from the list. Numeric or symbolic fields can be used as the ID field. Each unique value of this field should indicate a specific unit of analysis. For example, in a market basket application, each ID might represent a single customer. For a Web log analysis application, each ID might represent a computer (by IP address) or a user (by login data).

- IDs are contiguous.** If your data are presorted so that all records with the same ID are grouped together in the data stream, select this option to speed up processing. If your data are not presorted (or you are not sure), leave this option unselected, and the Sequence node will sort the data automatically.

Note: If your data are not sorted and you select this option, you may get invalid results in your Sequence model.

Time field. If you want to use a field in the data to indicate event times, select Use time field and specify the field to be used. The time field must be numeric, date, time, or timestamp. If no time field is specified, records are assumed to arrive from the data source in sequential order, and record numbers are used as time values (the first record occurs at time "1"; the second, at time "2", and so on).

Content fields. Specify the content field(s) for the model. These fields contain the events of interest in sequence modeling.

The Sequence node can handle data in either tabular or transactional format. If you use multiple fields with transactional data, the items specified in these fields for a particular record are assumed to represent items found in a single transaction with a single timestamp. See the topic [Tabular versus Transactional Data](#) for more information.

Partition. This field allows you to specify a field used to partition the data into separate samples for the training, testing, and validation stages of model building. By using one sample to generate the model and a different sample to test it, you can get a good indication of how well the model will generalize to larger datasets that are similar to the current data. If multiple partition fields have been defined by using Type or Partition nodes, a single partition field must be selected on the Fields tab in each modeling node that uses partitioning. (If only one partition is present, it is automatically used whenever partitioning is enabled.) Also note that to apply the selected partition in your analysis, partitioning must also be enabled in the Model Options tab for the node. (Deselecting this option makes it possible to disable partitioning without changing field settings.)

-

Sequence Node Model Options

Model name. You can generate the model name automatically based on the target or ID field (or model type in cases where no such field is specified) or specify a custom name.

Use partitioned data. If a partition field is defined, this option ensures that data from only the training partition is used to build the model.

Minimum rule support (%) You can specify a support criterion. *Rule support* refers to the proportion of IDs in the training data that contain the entire sequence. If you want to focus on more common sequences, increase this setting.

Minimum rule confidence (%) You can specify a confidence criterion for keeping sequences in the sequence set. *Confidence* refers to the percentage of the IDs where a correct prediction is made, out of all the IDs for which the rule makes a prediction. It is calculated as the number of IDs for which the entire sequence is found divided by the number of IDs for which the antecedents are found, based on the training data. Sequences with lower confidence than the specified criterion are discarded. If you are getting too many sequences or uninteresting sequences, try increasing this setting. If you are getting too few sequences, try decreasing this setting.

Note: If necessary, you can highlight the value and type in your own value. Be aware that if you reduce the confidence value below 1.0, in addition to the process requiring a lot of free memory, you might find that the rules take an extremely long time to build.

Maximum sequence size You can set the maximum number of distinct items in a sequence. If the sequences of interest are relatively short, you can decrease this setting to speed up building the sequence set.

Predictions to add to stream Specify the number of predictions to be added to the stream by the resulting generated Model node. For more information, see [Sequence Model Nuggets](#).

Related information

 - [Sequence Node Fields Options](#)
 - [Sequence Node Expert Options](#)
-

Sequence Node Expert Options

For those with detailed knowledge of the Sequence node's operation, the following expert options allow you to fine-tune the model-building process. To access expert options, set the Mode to Expert on the Expert tab.

Set maximum duration. If this option is selected, sequences will be limited to those with a duration (the time between the first and last item set) less than or equal to the value specified. If you haven't specified a time field, the duration is expressed in terms of rows (records) in the raw data. If the time field used is a time, date, or timestamp field, the duration is expressed in seconds. For numeric fields, the duration is expressed in the same units as the field itself.

Set pruning value. The CARMA algorithm used in the Sequence node periodically removes (**prunes**) infrequent item sets from its list of potential item sets during processing to conserve memory. Select this option to adjust the frequency of pruning. The number specified determines the frequency of pruning. Enter a smaller value to decrease the memory requirements of the algorithm (but potentially increase the training time required), or enter a larger value to speed up training (but potentially increase memory requirements).

Set maximum sequences in memory. If this option is selected, the CARMA algorithm will limit its memory store of candidate sequences during model building to the number of sequences specified. Select this option if IBM® SPSS® Modeler is using too much memory during the building of

Sequence models. Note that the maximum sequences value you specify here is the number of candidate sequences tracked internally as the model is built. This number should be much larger than the number of sequences you expect in the final model.

Constrain gaps between item sets. This option allows you to specify constraints on the time gaps that separate item sets. If selected, item sets with time gaps smaller than the Minimum gap or larger than the Maximum gap that you specify will not be considered to form part of a sequence. Use this option to avoid counting sequences that include long time intervals or those that take place in a very short time span.

Note: If the time field used is a time, date, or timestamp field, the time gap is expressed in seconds. For numeric fields, the time gap is expressed in the same units as the time field.

For example, consider the following list of transactions.

Table 1. Example list of transactions

ID	Time	Content
1001	1	apples
1001	2	bread
1001	5	cheese
1001	6	dressing

If you build a model on these data with the minimum gap set to 2, you would get the following sequences:

`apples -> cheese`

`apples -> dressing`

`bread -> cheese`

`bread -> dressing`

You would not see sequences such as `apples -> bread` because the gap between `apples` and `bread` is smaller than the minimum gap. Similarly, consider the following alternative data.

Table 2. Example list of transactions

ID	Time	Content
1001	1	apples
1001	2	bread
1001	5	cheese
1001	20	dressing

If the maximum gap were set to 10, you would not see any sequences with `dressing`, because the gap between `cheese` and `dressing` is too large for them to be considered part of the same sequence.

- [Sequence node](#)
- [Sequence Node Fields Options](#)
- [Sequence Node Model Options](#)

Sequence Model Nuggets

Sequence model nuggets represent the sequences found for a particular output field discovered by the Sequence node and can be added to streams to generate predictions.

When you run a stream containing a Sequence node, the node adds a pair of fields containing predictions and associated confidence values for each prediction from the sequence model to the data. By default, three pairs of fields containing the top three predictions (and their associated confidence values) are added. You can change the number of predictions generated when you build the model by setting the Sequence node model options at build time, as well as on the Settings tab after adding the model nugget to a stream. See the topic [Sequence Model Nugget Settings](#) for more information.

The new field names are derived from the model name. The field names are `$S-sequence-n` for the prediction field (where *n* indicates the *n*th prediction) and `$SC-sequence-n` for the confidence field. In a stream with multiple Sequence Rules nodes in a series, the new field names will include numbers in the prefix to distinguish them from each other. The first Sequence Set node in the stream will use the usual names, the second node will use names starting with `$S1-` and `$SC1-`, the third node will use names starting with `$S2-` and `$SC2-`, and so on. Predictions are displayed in order by confidence, so that `$S-sequence-1` contains the prediction with the highest confidence, `$S-sequence-2` contains the prediction with the next highest confidence, and so on. For records where the number of available predictions is smaller than the number of predictions requested, remaining predictions contain the value `$null$`. For example, if only two predictions can be made for a particular record, the values of `$S-sequence-3` and `$SC-sequence-3` will be `$null$`.

For each record, the rules in the model are compared to the set of transactions processed for the current ID so far, including the current record and any previous records with the same ID and earlier timestamp. The k rules with the highest confidence values that apply to this set of transactions are used to generate the k predictions for the record, where k is the number of predictions specified on the Settings tab after adding the model to the stream. (If multiple rules predict the same outcome for the transaction set, only the rule with the highest confidence is used.) See the topic [Sequence Model Nugget Settings](#) for more information.

As with other types of association rule models, the data format must match the format used in building the sequence model. For example, models built using tabular data can be used to score only tabular data. See the topic [Scoring Association Rules](#) for more information.

Note: When scoring data using a generated Sequence Set node in a stream, any tolerance or gap settings that you selected in building the model are ignored for scoring purposes.

Predictions from Sequence Rules

The node handles the records in a time-dependent manner (or order-dependent, if no timestamp field was used to build the model). Records should be sorted by the ID field and timestamp field (if present). However, predictions are not tied to the timestamp of the record to which they are added. They simply refer to the most likely items to occur *at some point in the future*, given the history of transactions for the current ID up to the current record.

Note that the predictions for each record do not necessarily depend on that record's transactions. If the current record's transactions do not trigger a specific rule, rules will be selected based on the previous transactions for the current ID. In other words, if the current record doesn't add any useful predictive information to the sequence, the prediction from the last useful transaction for this ID is carried forward to the current record.

For example, suppose you have a Sequence model with the single rule

Jam → Bread (0.66)

and you pass it the following records.

Table 1. Example records

ID	Purchase	Prediction
001	jam	bread
001	milk	bread

Notice that the first record generates a prediction of *bread*, as you would expect. The second record also contains a prediction of *bread*, because there's no rule for *jam* followed by *milk*; therefore, the *milk* transaction doesn't add any useful information, and the rule **Jam → Bread** still applies.

Generating New Nodes

The Generate menu allows you to create new SuperNodes based on the sequence model.

- **Rule SuperNode.** Creates a SuperNode that can detect and count occurrences of sequences in scored data. This option is disabled if no rule is selected. See the topic [Generating a Rule SuperNode from a Sequence Model Nugget](#) for more information.
- **Model to Palette.** Returns the model to the Models palette. This is useful in situations where a colleague may have sent you a stream containing the model and not the model itself.

Sequence Model Nugget Details

The Model tab for a Sequence model nugget displays the rules extracted by the algorithm. Each row in the table represents a rule, with the antecedent (the "if" part of the rule) in the first column followed by the consequent (the "then" part of the rule) in the second column.

Each rule is shown in the following format.

Table 1. Rule format

Antecedent	Consequent
beer and cannedveg	beer
fish fish	fish

The first example rule is interpreted as *for IDs that had "beer" and "cannedveg" in the same transaction, there is likely a subsequent occurrence of "beer."* The second example rule can be interpreted as *for IDs that had "fish" in one transaction and then "fish" in another, there is a likely subsequent occurrence of "fish."* Note that in the first rule, *beer* and *cannedveg* are purchased at the same time; in the second rule, *fish* is purchased in two separate transactions.

Sort menu. The Sort menu button on the toolbar controls the sorting of rules. Direction of sorting (ascending or descending) can be changed using the sort direction button (up or down arrow).

You can sort rules by:

- Support %
- Confidence %
- Rule Support %
- Consequent
- First Antecedent
- Last Antecedent
- Number of Items (antecedents)

For example, the following table is sorted in descending order by number of items. Rules with multiple items in the antecedent set precede those with fewer items.

Table 2. Rules sorted by number of items

Antecedent	Consequent
beer and cannedveg and frozenmeal	frozenmeal
beer and cannedveg	beer
fish fish	fish
softdrink	softdrink

Show/hide criteria menu. The Show/hide criteria menu button (grid icon) controls options for the display of rules. The following display options are available:

- **Instances** displays information about the number of unique IDs for which the *full sequence*—both antecedents and consequent—occurs. (Note this differs from Association models, for which the number of instances refers to the number of IDs for which *only* the antecedents apply.) For example, given the rule **bread** → **cheese**, the number of IDs in the training data that include both *bread* and *cheese* are referred to as **instances**.
- **Support** displays the proportion of IDs in the training data for which the antecedents are true. For example, if 50% of the training data includes the antecedent *bread* then the support for the **bread** → **cheese** rule would be 50%. (Unlike Association models, support is not based on the number of instances, as noted earlier.)
- **Confidence** displays the percentage of the IDs where a correct prediction is made, out of all the IDs for which the rule makes a prediction. It is calculated as the number of IDs for which the entire sequence is found divided by the number of IDs for which the antecedents are found, based on the training data. For example, if 50% of the training data contains *cannedveg* (indicating antecedent support) but only 20% contains both *cannedveg* and *frozenmeal*, then confidence for the rule **cannedveg** → **frozenmeal** would be **Rule Support / Antecedent Support** or, in this case, 40%.
- **Rule Support** for Sequence models is based on instances and displays the proportion of training records for which the entire rule, antecedents, and consequent(s), are true. For example, if 20% of the training data contains both *bread* and *cheese*, then rule support for the rule **bread** → **cheese** is 20%.

Note that the proportions are based on valid transactions (transactions with at least one observed item or true value) rather than total transactions. Invalid transactions—those with no items or true values—are discarded for these calculations.

Filter button. The Filter button (funnel icon) on the menu expands the bottom of the dialog box to show a panel where active rule filters are displayed. Filters are used to narrow the number of rules displayed on the Models tab.

Figure 1. Filter button

To create a filter, click the Filter icon to the right of the expanded panel. This opens a separate dialog box in which you can specify constraints for displaying rules. Note that the Filter button is often used in conjunction with the Generate menu to first filter rules and then generate a model containing that subset of rules. For more information, see [Specifying Filters for Rules](#) below.

Generating a Rule SuperNode from a Sequence Model Nugget

To generate a rule SuperNode based on a sequence rule:

1. On the Model tab for the sequence rule model nugget, click on a row in the table to select the desired rule.
2. From the rule browser menus choose:
Generate > Rule SuperNode

Important: To use the generated SuperNode, you must sort the data by ID field (and Time field, if any) before passing them into the SuperNode. The SuperNode will not detect sequences properly in unsorted data.

You can specify the following options for generating a rule SuperNode:

Detect. Specifies how matches are defined for data passed into the SuperNode.

- **Antecedents only.** The SuperNode will identify a match any time it finds the antecedents for the selected rule in the correct order within a set of records having the same ID, regardless of whether the consequent is also found. Note that this does not take into account timestamp tolerance or item gap constraint settings from the original Sequence modeling node. When the last antecedent item set is detected in the stream (and all other antecedents have been found in the proper order), all subsequent records with the current ID will contain the summary selected below.
- **Entire sequence.** The SuperNode will identify a match any time it finds the antecedents and the consequent for the selected rule in the correct order within a set of records having the same ID. This does not take into account timestamp tolerance or item gap constraint settings from the original Sequence modeling node. When the consequent is detected in the stream (and all antecedents have also been found in the correct order), the current record and all subsequent records with the current ID will contain the summary selected below.

Display. Controls how match summaries are added to the data in the Rule SuperNode output.

- **Consequent value for first occurrence.** The value added to the data is the consequent value predicted based on the first occurrence of the match. Values are added as a new field named *rule_n_consequent*, where *n* is the rule number (based on the order of creation of Rule SuperNodes in the stream).
- **True value for first occurrence.** The value added to the data is true if there is at least one match for the ID and false if there is no match. Values are added as a new field named *rule_n_flag*.
- **Count of occurrences.** The value added to the data is the number of matches for the ID. Values are added as a new field named *rule_n_count*.
- **Rule number.** The value added is the rule number for the selected rule. **Rule numbers** are assigned based on the order in which the SuperNode was added to the stream. For example, the first Rule SuperNode is considered *rule 1*, the second Rule SuperNode is considered *rule 2*, etc. This option is most useful when you will be including multiple Rule SuperNodes in your stream. Values are added as a new field named *rule_n_number*.
- **Include confidence figures.** If selected, this option will add the rule confidence to the data stream as well as the selected summary. Values are added as a new field named *rule_n_confidence*.

Association Rules node

Association rules are statements of the following form.

```
if condition(s) then prediction(s)
```

For example, "If a customer purchases a razor and after shave, then that customer will purchase shaving cream with 80% confidence." The Association Rules node extracts a set of rules from the data, pulling out the rules with the highest information content. The Association Rules node is very similar to the Apriori node, however, there are some notable differences:

- The Association Rules node cannot process transactional data.
- The Association Rules node can process data that has the List storage type and the Collection measurement level.
- The Association Rules node can be used with IBM® SPSS® Analytic Server. This provides scalability and means that you can process big data and take advantage of faster parallel processing.
- The Association Rules node provides additional settings, such as the ability to restrict the number of rules that are generated, thereby increasing the processing speed.
- Output from the model nugget is shown in the Output Viewer.

Note: The Association Rules node does not support the Model Evaluation or Champion Challenger steps in IBM SPSS Collaboration and Deployment Services.

Note: The Association Rules node ignores empty records when building a model if the field type is a flag. Empty records are records where all the fields used in the model build have a false value.

A stream that shows a working example of using Association Rules, named geospatial_association.str, and which references the data files InsuranceData.sav, CountyData.sav, and ChicagoAreaCounties.ships available from the Demos directory of your IBM SPSS Modeler installation. You can access the Demos directory from the IBM SPSS Modeler program group on the Windows Start menu. The geospatial_association.str file is in the streams directory.

- [Association Rules - Fields Options](#)
 - [Association Rules - Rule building](#)

 - [Association Rules - Output](#)
 - [Association Rules - Model Options](#)
 - [Association Rules Model Nuggets](#)
-

Association Rules - Fields Options

On the Fields tab, you choose whether you want to use the field role settings that are already defined in upstream nodes, such as a previous Type node, or make the field assignments manually.

Use predefined roles

This option uses the role settings (such as targets, or predictors) from an upstream Type node (or the Types tab of an upstream source node). Fields with an input role are considered to be Conditions, fields with a target role are considered to be Predictions, and those fields that are used as inputs and targets are considered to have both roles.

Use custom field assignments

Choose this option if you want to assign targets, predictors, and other roles manually on this screen.

Fields

If you selected Use custom field assignments, use the arrow buttons to assign items manually from this list to the boxes on the right of the screen. The icons indicate the valid measurement levels for each field.

Both (Condition or Prediction)

Fields added to this list can take either the condition or prediction role in rules that are generated by the model. This is on a rule by rule basis, so a field might be a condition in one rule and a prediction in another.

Prediction only

Fields added to this list can appear only as a prediction (also known as a "consequent") of a rule. The presence of a field in this list does not mean that the field is used in any rules, only that if it is used it can be only a prediction.

Condition only

Fields added to this list can appear only as a condition (also known as an "antecedent") of a rule. The presence of a field in this list does not mean that the field is used in any rules, only that if it is used it can be only a condition.

 - [Association Rules - Model Options](#)
-

Association Rules - Rule building

Items per rule

Use these options to specify how many items, or values, can be used in each rule.

Note: The combined total of these two fields cannot exceed 10.

Maximum conditions

Select the maximum number of conditions that can be included in a single rule.

Maximum predictions

Select the maximum number of predictions that can be included in a single rule.

Rule building

Use these options to specify the number and type of rules to build.

Maximum number of rules

Specify the maximum number of rules that can be considered for use in the building of rules for your model.
Rule criterion for top N

Select the criterion that is used to establish which are the top N rules, where N is the value that is entered in the Maximum number of rules field. You can choose from the following criterion.

- Confidence
- Rule Support
- Condition Support
- Lift
- Deployability

Only true values for flags

When your data is in tabular format, select this option to include only true values for flag fields in the resulting rules. Selecting true values can help make rules easier to understand. The option does not apply to data in transactional format. For more information, see [Tabular versus Transactional Data](#).

Rule criterion

If you select Enable rule criterion, you can use these options to select the minimum strength that rules must meet to be considered for use in your model.

- Confidence Specify the minimum percentage value for the Confidence level for a rule that is produced by the model. If the model produces a rule with a level less than this amount, the rule is discarded.
- Rule Support Specify the minimum percentage value for the Rule Support level for a rule that is produced by the model. If the model produces a rule with a level less than this amount, the rule is discarded.
- Condition Support Specify the minimum percentage value for the Condition Support level for a rule that is produced by the model. If the model produces a rule with a level less than the specified amount, the rule is discarded.
- Lift Specify the minimum Lift value that is allowed for a rule that is produced by the model. If the model produces a rule with a value less than the specified amount, the rule is discarded.

Exclude rules

In some cases, the association between two or more fields is known or is self-evident, in such a case you can exclude rules where the fields predict each other. By excluding rules that contain both values, you reduce irrelevant input and increase the chances of finding useful results.

Fields

Select the associated fields that you do not want to use together in rule building. For example, associated fields might be Car Manufacturer and Car Model, or School Year and Age of Pupil. When the model creates rules, if the rule contains at least one of the fields selected on either side of the rule (condition or prediction), the rule is discarded.

- [Association Rules - Transformations](#)
- [Association Rules - Output](#)
- [Association Rules - Model Options](#)

Association Rules - Transformations

Binning

Use these options to specify how continuous (numeric range) fields are binned.

Number of bins

Any continuous fields set to be automatically binned are divided into the number of equally spaced bins that you specify. You can select any number in the range 2 - 10.

List fields

Maximum list length

To restrict the number of items to be included in the model if the length of a list field is unknown, enter the maximum length of the list. You can select any number in the range 1 - 100. If a list is longer than the number you enter, the model will still use the field but only include values up to this number; any extra values in the field are ignored.

Related information

- [Association Rules - Fields Options](#)
 - [Association Rules - Rule building](#)
 - [Association Rules - Output](#)
 - [Association Rules - Model Options](#)
-

Association Rules - Output

Use the options in this pane to control what output is generated when the model is built.

Rules tables

Use these options to create one or more table types that display the best number of rules (based on a number you specify) for each selected criterion.

Confidence

Confidence is the ratio of rule support to condition support. Of the items with the listed condition values, the percentage that has the predicted consequent values. Creates a table that contains the best N association rules that are based on confidence to be included in the output (where N is the Rules to display value).

Rule Support

The proportion of items for which the entire rule, conditions, and predictions are true. For all items in the dataset, the percentage that is correctly accounted for and predicted by the rule. This measure gives an overall importance of the rule. Creates a table that contains the best N association rules that are based on rule support to be included in the output (where N is the Rules to display value).

Lift

The ratio of rule confidence and the prior probability of having the prediction. The ratio of the Confidence value for a rule versus the percentage the Consequent values occur in the overall population. This ratio gives a measure of how well the rule improves over chance. Creates a table that contains the best N association rules that are based on lift to be included in the output (where N is the Rules to display value).

Condition Support

The proportion of items for which the conditions are true. Creates a table that contains the best N association rules that are based on antecedent support to be included in the output (where N is the Rules to display value).

Deployability

A measure of what percentage of the training data satisfies the condition but not the prediction. This measure shows how often the rule misses. It is effectively the opposite of Confidence. Creates a table that contains the best N association rules that are based on deployability to be included in the output (N is the Rules to display value).

Rules to display

Set the maximum number of rules to display in the tables.

Model information tables

Use one or more of these options to select which model tables to include in the output.

- Field Transformations
- Records Summary
- Rule Statistics
- Most Frequent Values
- Most Frequent Fields

Sortable word cloud of rules.

Use these options to create a word cloud that displays the rules outputs. Words are displayed in increasing text sizes to indicate their importance.

Create a sortable word cloud.

Check this box to create a sortable word cloud in your output.

Default sort

Select the sort type to be used to when initially creating the word cloud. The word cloud is interactive and you can change the criterion in the Model Viewer to see different rules and sorts. You can choose from the following sort options:

- Confidence.
- Rule Support
- Lift
- Condition Support.

- Deployability

Max rules to display

Set the number of rules to be displayed in the word cloud; the maximum you can choose is 20.

Related information

- [Association Rules - Fields Options](#)
 - [Association Rules - Rule building](#)
 - [Association Rules - Transformations](#)
 - [Association Rules - Model Options](#)
-

Association Rules - Model Options

Use the settings on this tab to specify the scoring options for Association Rules models.

Model name You can generate the model name that is automatically based on the target field (or model type in cases where no such field is specified), or specify a custom name.

Maximum number of predictions Specify the maximum number of predictions that are included in the score result. This option is used with the Rule Criterion entries to produce the “top” predictions, where “top” indicates the highest level of confidence, support, lift, and so on.

Rule Criterion Select the measure that is used to determine the strength of the rules. Rules are sorted by the strength of criteria that are selected here in order to return the top predictions for an item set. You can choose from 5 different criteria.

- Confidence Confidence is the ratio of rule support to condition support. Of the items with the listed condition values, the percentage that has the predicted consequent values.
- Condition Support The proportion of items for which the conditions are true.
- Rule Support The proportion of items for which the entire rule, conditions, and predictions are true. Calculated by multiplying the Condition Support value by the Confidence value.
- Lift The ratio of rule confidence and the prior probability of having the prediction.
- Deployability A measure of what percentage of the training data satisfies the condition but not the prediction.

Allow repeat predictions To include multiple rules with the same prediction during scoring, select this check box. For example, selecting this enables the following rules to be scored.

```
bread & cheese -> wine
cheese & fruit -> wine
```

Note: Rules with multiple predictions (`bread & cheese & fruit -> wine & pate`) are considered repeat predictions only if all predictions (`wine & pate`) were predicted before.

Only score rules when predictions are not present in the input To ensure that predictions are not also present in the input, select this option. For example, if the purpose of scoring is to make a home furniture product recommendation, then it is unlikely that input that already contains a dining room table is likely to purchase another. In such a case, select this option. However, if products are perishable or disposable (such as cheese, baby formula, or tissue), then rules where the consequent is already present in the input might be of value. In the latter case, the most useful option might be Score all rules.

Only score rules when predictions are present in the input To ensure that predictions are also present in the input, select this option. This approach is useful when you are attempting to gain insight into existing customers or transactions. For example, you might want to identify rules with the highest lift and then explore which customers fit these rules.

Score all rules To include all rules during scoring, regardless of the presence or absence of predictions, select this option.

Association Rules Model Nugget Details

The Association Rules model nugget displays details of the model in the Model tab of the Output Viewer. For more information on using the viewer, see [Working with output](#).

The GSAR modeling operation creates a number of new fields with the prefix \$A as shown in the following table.

Table 1. New fields created by the Association Rules modeling operation

Field name	Description
\$A-<prediction>#	This field contains the prediction from the model for the scored records. <prediction> is the name of the field included in the Predictions role in the model, and # is a sequence of numbers for the output rules (for example, if the score is set to include 3 rules the sequence of numbers will be from 1 to 3).
\$AC-<prediction>#	This field contains the confidence in the prediction. <prediction> is the name of the field included in the Predictions role in the model, and # is a sequence of numbers for the output rules (for example, if the score is set to include 3 rules the sequence of numbers will be from 1 to 3).
\$A-Rule_ID#	This column contains the ID of the rule predicted for each record in the scored data set. # is a sequence of numbers for the output rules (for example, if the score is set to include 3 rules the sequence of numbers will be from 1 to 3).

Association Rules Model Nugget Settings

The Settings tab for an Association Rules model nugget displays scoring options for the model. This tab is available only after the model is added to the stream canvas for scoring.

Maximum number of predictions Specify the maximum number of predictions that are included for each set of items. The rules with the highest confidence values that apply to this set of transactions are used to generate predictions for the record up to the specified limit. Use this option with the Rule Criterion option to produce the “top” predictions, where *top* indicates the highest level of confidence, support, lift, and so on.

Rule Criterion Select the measure that is used to determine the strength of rules. Rules are sorted by the strength of criteria that are selected here in order to return the top predictions for an item set. You can choose from the following criteria.

- Confidence
- Rule Support
- Lift
- Condition Support
- Deployability

Allow repeat predictions To include multiple rules with the same consequent when scoring, select this check box. For example, selecting this option means that the following rule can be scored:

```
bread & cheese -> wine  
cheese & fruit -> wine
```

To exclude repeat predictions when scoring, clear the check box.

Note: Rules with multiple consequents (`bread & cheese & fruit -> wine & pate`) are considered repeat predictions only if all consequents (`wine & pate`) have been predicted before.

Only score rules when predictions are not present in the input Select to ensure that consequents are not also present in the input. For example, if the purpose of scoring is to make a home furniture product recommendation, then it is unlikely that input that already contains a dining room table is likely to purchase another one. In such a case, select this option. On the other hand, if products are perishable or disposable (such as cheese, baby formula, or tissue), then rules where the consequent is already present in the input might be of value. In the latter case, the most useful option might be Score all rules.

Only score rules when predictions are present in the input Select this option to ensure that consequents are also present in the input. This approach is useful when you are attempting to gain insight into existing customers or transactions. For example, you might want to identify rules with the highest lift and then explore which customers fit these rules.

Score all rules To include all rules when scoring, regardless of the presence or absence of consequents in the input, select this option.

Time Series Models

- [Why forecast?](#)
 - [Time series data](#)
 - [Predictor series](#)
 - [Spatio-Temporal Prediction modeling node](#)
 - [TCM Node](#)
 - [Time Series node](#)
 - [Time Series Node \(deprecated\)](#)
-

Why forecast?

To forecast means to predict the values of one or more series over time. For example, you may want to predict the expected demand for a line of products or services in order to allocate resources for manufacturing or distribution. Because planning decisions take time to implement, forecasts are an essential tool in many planning processes.

Methods of modeling time series assume that history repeats itself—if not exactly, then closely enough that by studying the past, you can make better decisions in the future. To predict sales for next year, for example, you would probably start by looking at this year's sales and work backward to figure out what trends or patterns, if any, have developed in recent years. But patterns can be difficult to gauge. If your sales increase several weeks in a row, for example, is this part of a seasonal cycle or the beginning of a long-term trend?

Using statistical modeling techniques, you can analyze the patterns in your past data and project those patterns to determine a range within which future values of the series are likely to fall. The result is more accurate forecasts on which to base your decisions.

Time series data

A **time series** is an ordered collection of measurements taken at regular intervals—for example, daily stock prices or weekly sales data. The measurements may be of anything that interests you, and each series can generally be classified as one of the following:

- Dependent. A series that you want to forecast.
- Predictor. A series that may help to explain the target—for example, using an advertising budget to predict sales. Predictors can only be used with ARIMA models.
- Event. A special predictor series used to account for predictable recurring incidents—for example, sales promotions.
- Intervention. A special predictor series used to account for one-time past incidents—for example, a power outage or employee strike.

The intervals can represent any unit of time, but the interval must be the same for all measurements. Moreover, any interval for which there is no measurement must be set to the missing value. Thus, the number of intervals with measurements (including those with missing values) defines the length of time of the historical span of the data.

- [Characteristics of time series](#)
- [Autocorrelation and partial autocorrelation functions](#)
- [Series transformations](#)

Characteristics of time series

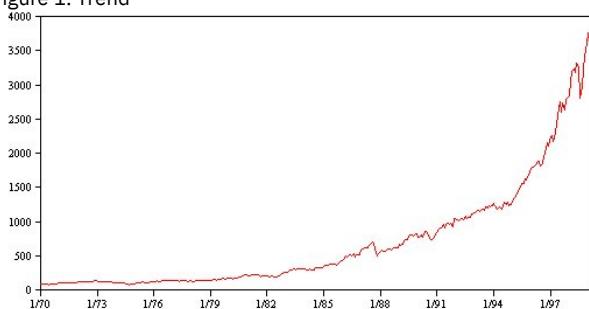

Studying the past behavior of a series will help you identify patterns and make better forecasts. When plotted, many time series exhibit one or more of the following features:

- Trends
 - Seasonal and nonseasonal cycles
 - Pulses and steps
 - Outliers
- [Trends](#)
 - [Seasonal cycles](#)
 - [Nonseasonal cycles](#)
 - [Pulses and steps](#)
 - [Outliers](#)

Trends

A **trend** is a gradual upward or downward shift in the level of the series or the tendency of the series values to increase or decrease over time.

Figure 1. Trend

Trends are either **local** or **global**, but a single series can exhibit both types. Historically, series plots of the stock market index show an upward global trend. Local downward trends have appeared in times of recession, and local upward trends have appeared in times of prosperity.

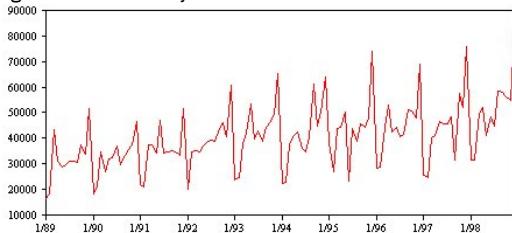

Trends can also be either **linear** or **nonlinear**. Linear trends are positive or negative additive increments to the level of the series, comparable to the effect of simple interest on principal. Nonlinear trends are often multiplicative, with increments that are proportional to the previous series value(s).

Global linear trends are fit and forecast well by both exponential smoothing and ARIMA models. In building ARIMA models, series showing trends are generally differenced to remove the effect of the trend.

Seasonal cycles

A **seasonal cycle** is a repetitive, predictable pattern in the series values.

Figure 1. Seasonal cycle

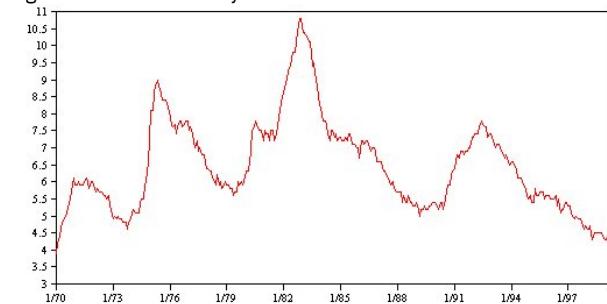

Seasonal cycles are tied to the interval of your series. For instance, monthly data typically cycles over quarters and years. A monthly series might show a significant quarterly cycle with a low in the first quarter or a yearly cycle with a peak every December. Series that show a seasonal cycle are said to exhibit **seasonality**.

Seasonal patterns are useful in obtaining good fits and forecasts, and there are exponential smoothing and ARIMA models that capture seasonality.

Nonseasonal cycles

A **nonseasonal cycle** is a repetitive, possibly unpredictable, pattern in the series values.

Figure 1. Nonseasonal cycle

Some series, such as unemployment rate, clearly display cyclical behavior; however, the periodicity of the cycle varies over time, making it difficult to predict when a high or low will occur. Other series may have predictable cycles but do not neatly fit into the Gregorian calendar or have cycles longer than a year. For example, the tides follow the lunar calendar, international travel and trade related to the Olympics swell every four years, and there are many religious holidays whose Gregorian dates change from year to year.

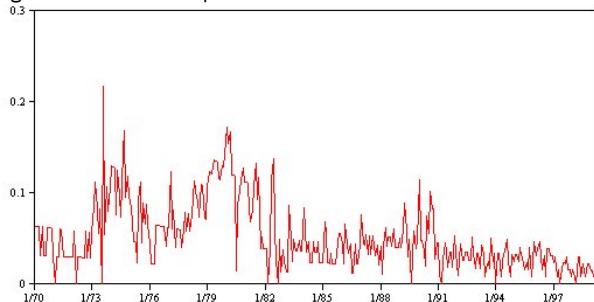

Nonseasonal cyclical patterns are difficult to model and generally increase uncertainty in forecasting. The stock market, for example, provides numerous instances of series that have defied the efforts of forecasters. All the same, nonseasonal patterns must be accounted for when they exist. In many cases, you can still identify a model that fits the historical data reasonably well, which gives you the best chance to minimize uncertainty in forecasting.

Pulses and steps

Many series experience abrupt changes in level. They generally come in two types:

- A sudden, *temporary* shift, or **pulse**, in the series level
- A sudden, *permanent* shift, or **step**, in the series level

Figure 1. Series with a pulse

When steps or pulses are observed, it is important to find a plausible explanation. Time series models are designed to account for gradual, not sudden, change. As a result, they tend to underestimate pulses and be ruined by steps, which lead to poor model fits and uncertain forecasts. (Some instances of seasonality may appear to exhibit sudden changes in level, but the level is constant from one seasonal period to the next.)

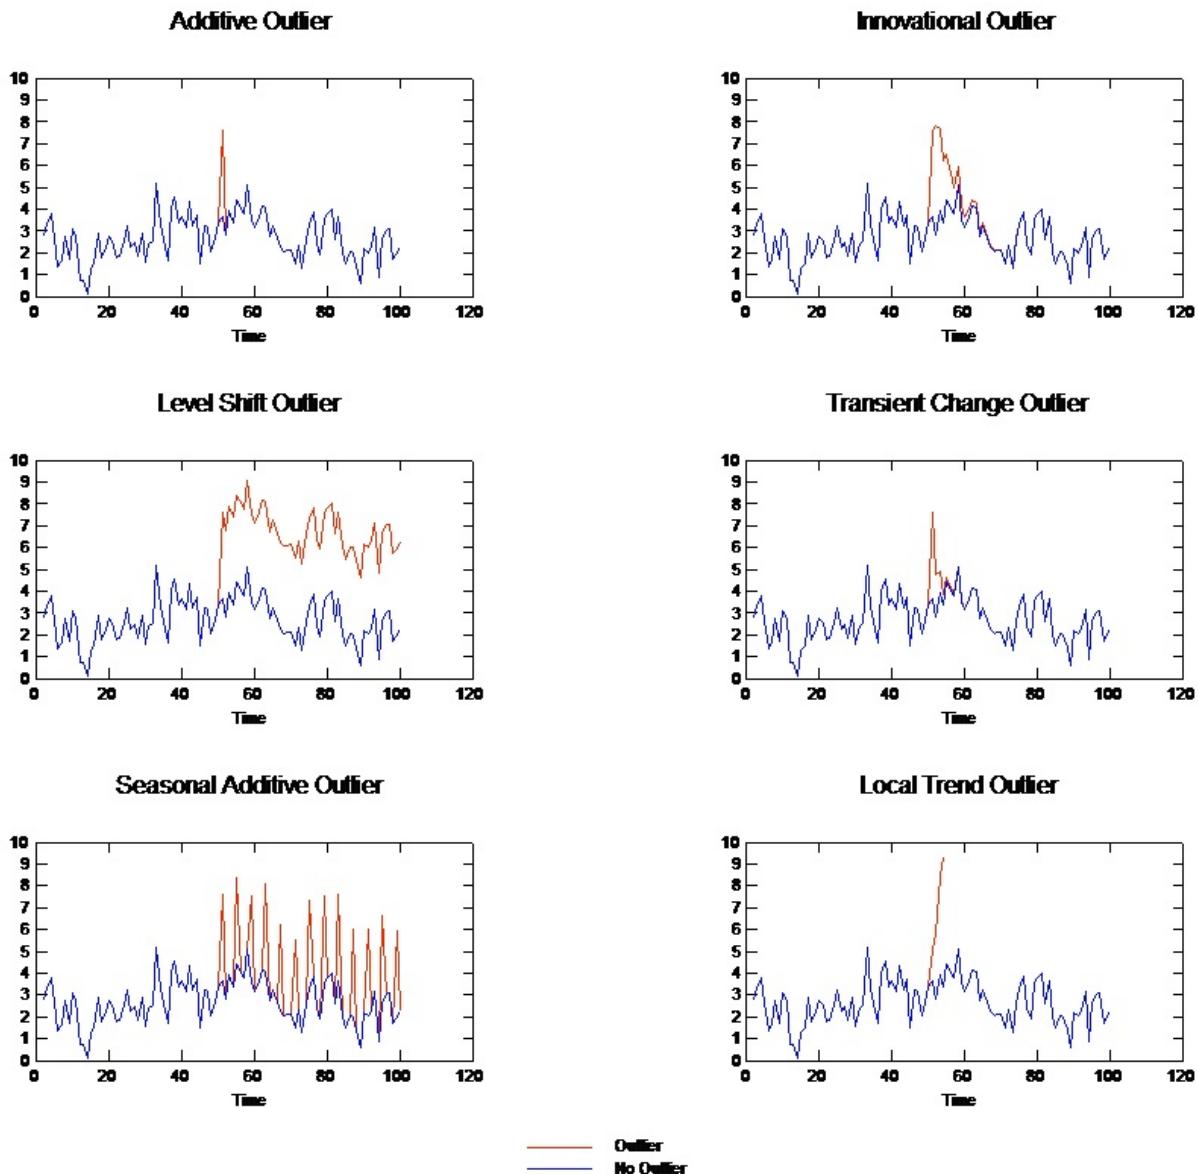

If a disturbance can be explained, it can be modeled using an **intervention** or **event**. For example, during August 1973, an oil embargo imposed by the Organization of Petroleum Exporting Countries (OPEC) caused a drastic change in the inflation rate, which then returned to normal levels in the ensuing months. By specifying a **point intervention** for the month of the embargo, you can improve the fit of your model, thus indirectly improving your forecasts. For example, a retail store might find that sales were much higher than usual on the day all items were marked 50% off. By specifying the 50%-off promotion as a recurring **event**, you can improve the fit of your model and estimate the effect of repeating the promotion on future dates.

Outliers

Shifts in the level of a time series that cannot be explained are referred to as **outliers**. These observations are inconsistent with the remainder of the series and can dramatically influence the analysis and, consequently, affect the forecasting ability of the time series model.

The following figure displays several types of outliers commonly occurring in time series. The blue lines represent a series without outliers. The red lines suggest a pattern that might be present if the series contained outliers. These outliers are all classified as **deterministic** because they affect only the mean level of the series.

Figure 1. Outlier types

- **Additive Outlier.** An additive outlier appears as a surprisingly large or small value occurring for a single observation. Subsequent observations are unaffected by an additive outlier. Consecutive additive outliers are typically referred to as **additive outlier patches**.
- **Innovational Outlier.** An innovational outlier is characterized by an initial impact with effects lingering over subsequent observations. The influence of the outliers may increase as time proceeds.
- **Level Shift Outlier.** For a level shift, all observations appearing after the outlier move to a new level. In contrast to additive outliers, a level shift outlier affects many observations and has a permanent effect.
- **Transient Change Outlier.** Transient change outliers are similar to level shift outliers, but the effect of the outlier diminishes exponentially over the subsequent observations. Eventually, the series returns to its normal level.
- **Seasonal Additive Outlier.** A seasonal additive outlier appears as a surprisingly large or small value occurring repeatedly at regular intervals.
- **Local Trend Outlier.** A local trend outlier yields a general drift in the series caused by a pattern in the outliers after the onset of the initial outlier.

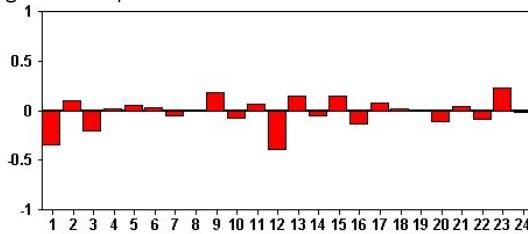

Outlier detection in time series involves determining the location, type, and magnitude of any outliers present. Tsay (1988) proposed an iterative procedure for detecting mean level change to identify deterministic outliers. This process involves comparing a time series model that assumes no outliers are present to another model that incorporates outliers. Differences between the models yield estimates of the effect of treating any given point as an outlier.

Autocorrelation and partial autocorrelation functions

Autocorrelation and partial autocorrelation are measures of association between current and past series values and indicate which past series values are most useful in predicting future values. With this knowledge, you can determine the order of processes in an ARIMA model. More specifically,

- Autocorrelation function (ACF). At lag k , this is the correlation between series values that are k intervals apart.
- Partial autocorrelation function (PACF). At lag k , this is the correlation between series values that are k intervals apart, accounting for the values of the intervals between.

Figure 1. ACF plot for a series

The x axis of the ACF plot indicates the lag at which the autocorrelation is computed; the y axis indicates the value of the correlation (between -1 and 1). For example, a spike at lag 1 in an ACF plot indicates a strong correlation between each series value and the preceding value, a spike at lag 2 indicates a strong correlation between each value and the value occurring two points previously, and so on.

- A positive correlation indicates that large current values correspond with large values at the specified lag; a negative correlation indicates that large current values correspond with small values at the specified lag.
- The absolute value of a correlation is a measure of the strength of the association, with larger absolute values indicating stronger relationships.

Series transformations

Transformations are often useful for stabilizing a series before estimating models. This is particularly important for ARIMA models, which require series to be **stationary** before models are estimated. A series is stationary if the global level (mean) and average deviation from the level (variance) are constant throughout the series.

While most interesting series are not stationary, ARIMA is effective as long as the series can be made stationary by applying transformations, such as the natural log, differencing, or seasonal differencing.

Variance stabilizing transformations. Series in which the variance changes over time can often be stabilized using a natural log or square root transformation. These are also called functional transformations.

- Natural log. The natural logarithm is applied to the series values.
- Square root. The square root function is applied to the series values.

Natural log and square root transformations cannot be used for series with negative values.

Level stabilizing transformations. A slow decline of the values in the ACF indicates that each series value is strongly correlated with the previous value. By analyzing the change in the series values, you obtain a stable level.

- Simple differencing. The differences between each value and the previous value in the series are computed, except the oldest value in the series. This means that the differenced series will have one less value than the original series.
- Seasonal differencing. Identical to simple differencing, except that the differences between each value and the previous seasonal value are computed.

When either simple or seasonal differencing is simultaneously in use with either the log or square root transformation, the variance stabilizing transformation is always applied first. When simple and seasonal differencing are both in use, the resulting series values are the same whether simple differencing or seasonal differencing is applied first.

Predictor series

Predictor series include related data that may help explain the behavior of the series to be forecast. For example, a Web- or catalog-based retailer might forecast sales based on the number of catalogs mailed, the number of phone lines open, or the number of hits to the company Web page.

Any series can be used as a predictor provided that the series extends as far into the future as you want to forecast and has complete data with no missing values.

Use care when adding predictors to a model. Adding large numbers of predictors will increase the time required to estimate models. While adding predictors may improve a model's ability to fit the historical data, it doesn't necessarily mean that the model does a better job of forecasting, so the added complexity may not be worth the trouble. Ideally, the goal should be to identify the simplest model that does a good job of forecasting.

As a general rule, it is recommended that the number of predictors should be less than the sample size divided by 15 (at most, one predictor per 15 cases).

Predictors with missing data. Predictors with incomplete or missing data cannot be used in forecasting. This applies to both historical data and future values. In some cases, you can avoid this limitation by setting the model's estimation span to exclude the oldest data when estimating models.

Spatio-Temporal Prediction modeling node

Spatio-Temporal prediction (STP) has many potential applications such as energy management for buildings or facilities, performance analysis and forecasting for mechanical service engineers, or public transport planning. In these applications measurements such as energy usage are often taken over space and time. Questions that might be relevant to the recording of these measurements include what factors will affect future observations, what can be done to effect a wanted change, or to better manage the system? To address these questions, you can use statistical techniques that can forecast future values at different locations, and can explicitly model adjustable factors to perform what-if analysis.

STP analysis uses data that contains location data, input fields for prediction (predictors), a time field, and a target field. Each location has numerous rows in the data that represent the values of each predictor at each time of measurement. After the data is analyzed, it can be used to predict target values at any location within the shape data that is used in the analysis. It can also forecast when input data for the future points in time are known.

Note: The STP node does not support the Model Evaluation or Champion Challenger steps in IBM® SPSS® Collaboration and Deployment Services. A stream that shows a worked example of using STP, named stp_server_demo.str, and which references the data files room_data.csv and score_data.csv is available from the Demos directory of your IBM SPSS Modeler installation. You can access the Demos directory from the IBM SPSS Modeler program group on the Windows Start menu. The stp_server_demo.str file is in the streams directory.

Spatio-Temporal Prediction - Fields Options

On the Fields tab, you choose whether you want to use the field role settings that are already defined in upstream nodes, or make the field assignments manually.

Use predefined roles

This option uses the role settings (targets and predictors only) from an upstream Type node (or the Types tab of an upstream source node).

Use custom field assignments

To assign targets, predictors, and other roles manually on this screen, select this option.

Fields

Displays all of the fields in the data that can be selected. Use the arrow buttons to assign items manually from this list to the various boxes on the right of the screen. The icons indicate the valid measurement levels for each field.

Note: STP requires 1 record per location, per time interval to function correctly; therefore these are mandatory fields.

At the bottom of the Fields pane, either click the All button to select all fields, regardless of measurement level, or click an individual measurement level button to select all fields with that measurement level.

Target

Select one field as the target for the prediction.

Note: You can only select fields with a measurement level of continuous.

Location

Select the location type to be used in the model.

Note: You can only select fields with a measurement level of geospatial.

Location label

Shape data often includes a field that shows the names of the features in the layer, for example, this might be the names of states or counties. Use this field to associate a name, or label, with a location by selecting a categorical field to label the chosen Location field in your output.

Time Field

Select the time fields to use in your predictions.

Note: You can select only fields with a measurement level of continuous and a storage type of time, date, timestamp, or integer.

Predictors (Inputs)

Choose one or more fields as inputs for the prediction.

Note: You can select only fields with a measurement level of continuous.

-

Spatio-Temporal Prediction - Time Intervals

In the Time Intervals pane, you can select the options to set the time interval and any required aggregation over time.

Data preparation is required to convert time fields into an index before you can build an STP model; for conversion to be possible the time field must have a constant interval between records. If your data does not already contain this information, use the options in this pane to set this interval before you can use the modeling node.

Time interval Select the interval that you want the data set to be converted to. Available options depend on the storage type of the field that is chosen as the Time Field for the model on the Fields tab.

- Periods Only available for integer time fields; this is a series of intervals, with a uniform interval between each measurement, that does not match any of the other available intervals.
- Years Only available for Date or Timestamp time fields.
- Quarters Only available for Date or Timestamp time fields. If you choose this option, you are prompted to select the Start month of the first quarter.
- Months Only available for Date or Timestamp time fields.
- Weeks Only available for Date or Timestamp time fields.
- Days Only available for Date or Timestamp time fields.
- Hours Only available for Time or Timestamp time fields.
- Minutes Only available for Time or Timestamp time fields.
- Seconds Only available for Time or Timestamp time fields.

When you select the Time interval, you are prompted to complete further fields. The fields available depend on both the time interval and the storage type. The fields that might be displayed are shown in the following list.

- Number of days per week
- Number of hours in a day
- Week begins on The first day of the week
- Day begins at The time at which you consider a new day to start.
- Interval value You can choose one of the following options: 1, 2, 3, 4, 5, 6, 10, 12, 15, 20, or 30.
- Start month The month on which the financial year starts.
- Starting period If you are using Periods, select the starting period.

Data matches specified time interval settings If your data already contains the correct time intervals information and does not need to be converted, select this check box. When you select this box, the fields in the Aggregation area are unavailable.

Aggregation

Only available if you clear the Data matches specified time interval settings check box; specify the options for aggregating fields to match the specified interval. For example, if you have a mix of weekly and monthly data, you might aggregate, or "roll up", the weekly values to achieve a uniform monthly interval. Select the default settings to be used for aggregation of different field types and create any custom settings that you want for any specific fields.

- **Continuous** Set the default aggregation method to be applied to all continuous fields that are not individually specified. You can choose from several methods:
 - Sum
 - Mean
 - Minimum
 - Maximum
 - Median

- First quartile
- Third quartile

Custom settings for specified fields To apply a specific aggregation function to individual fields, select them in this table and choose the aggregation method.

- Field Use the Add field button to display the Select Fields dialog box and choose the required fields. The chosen fields are displayed in this column.
- Aggregation function From the drop-down list, select the aggregation function to convert the field to the specified time interval.

- [Spatio-Temporal Prediction - Output](#)
- [Spatio-Temporal Prediction - Model Options](#)

Spatio-Temporal Prediction - Basic Build Options

Use the settings in this dialog box to set the basic model building options.

Model Settings

Include intercept

Including the intercept (the constant term in the model) can increase the overall accuracy of the solution. If you can assume the data passes through the origin, you can exclude the intercept.

Maximum autoregressive order

Autoregressive orders specify which previous values are used to predict current values. Use this option to specify the number of previous records that are used to calculate a new value. You can choose any integer between 1 and 5.

Spatial Covariance

Estimation method

Select the estimation method to be used; you can choose either Parametric or Nonparametric. For the Parametric method you can choose from one of three Model types:

- Gaussian
- Exponential
- Powered Exponential If you select this option, you must also specify the Power level to be used. This level can be any value between 1 and 2, changed in 0.1 increments.

- [Spatio-Temporal Prediction - Model Options](#)

Spatio-Temporal Prediction - Advanced Build Options

Users with detailed knowledge of STP can use the following options to fine-tune the model building process.

Maximum percentage of missing values

Specify the maximum percentage of records that contain missing values that can be included in the model.

Significance level for hypotheses testing in model build

Specify the significance level value to be used for all tests of STP model estimation, including two Goodness of Fit tests, Effect F-tests and Coefficient T-tests. This level can be any value from 0 to 1, changed in 0.01 increments.

-

Spatio-Temporal Prediction - Output

Before you build the model, use the options on this pane to select the output that you want to include in the output viewer.

Model Information

Model specifications

Select this option to include model specification information in the model output.

Temporal information summary

Select this option to include a summary of temporal information in the model output.

Evaluation

Model quality

Select this option to include model quality in the model output.

Test of effects in mean structure model

Select this option to include test of effects information in the model output.

Interpretation

Mean structure model coefficients

Select this option to include mean structure model coefficients information in the model output.

Autoregressive coefficients

Select this option to include autoregressive coefficients information in the model output.

Tests of decay over space

Select this option to include test of spatial covariance, or decay over space, information in the model output.

Parametric spatial covariance model parameters plot

Select this option to include parametric spatial covariance model parameter plot information in the model output.

Note: This option is only available if you selected the Parametric estimation method on the Basics tab.

Correlations heat map

Select this option to include a map of the target values in the model output.

Note: If there are more than 500 locations in your model, the map output will not be created.

Correlations map

Select this option to include a map of correlations in the model output.

Note: If there are more than 500 locations in your model, the map output will not be created.

Location clusters

Select this option to include location clustering output in the model output. Only output which does not require access to map data is included as part of the cluster output.

Note: This output can only be created for a non-parametric spatial covariance model.

If you choose this option, you can set the following:

- Similarity threshold Select the threshold at which output clusters are to be considered as similar enough to be merged into a single cluster.
- Maximum number of clusters to display Set the upper limit for the number of clusters that can be included in the model output.

Spatio-Temporal Prediction Model Nugget

The Spatio-Temporal Prediction (STP) model nugget displays details of the model in the Model tab of the Output Viewer. For more information on using the viewer, see [Working with output](#).

The spatio-temporal prediction (STP) modeling operation creates a number of new fields with the prefix \$STP- as shown in the following table.

Table 1. New fields created by the STP modeling operation

Field name	Description
\$STP-<Time>	The time field created as part of the model build. The settings on the Time Intervals pane of the Build Options tab determine how this field is created. <Time> is the original name of the field selected as the Time Field on the Fields tab. Note: This field is only created if you converted the original Time Field as part of the model build.
\$STP-<Target>	This field contains the predictions for the target value. <Target> is the name of the original Target field for the model
\$STPVAR-<Target>	This field contains the VarianceOfPointPrediction values. <Target> is the name of the original Target field for the model
\$STPLCI-<Target>	This field contains the LowerOfPredictionInterval values; that is, the lower bound of confidence. <Target> is the name of the original Target field for the model
\$STPUCI-<Target>	This field contains the UpperOfPredictionInterval values; that is, the upper bound of confidence. <Target> is the name of the original Target field for the model

- [Spatio-Temporal Prediction Model Settings](#)

Spatio-Temporal Prediction Model Settings

Use the Settings tab to control the level of uncertainty that you deem acceptable in the modeling operation.

Uncertainty factor (%) Uncertainty factor is a percentage value that represents the growth in uncertainty when you forecast into the future. The upper and lower limit of forecast uncertainty increase by this percentage each step into the future. Set the uncertainty factor to be applied to your model outputs; this sets the upper and lower boundaries for the predicted values.

TCM Node

Use this node to create a temporal causal model (TCM).

 - [TCM Model Nugget](#)
 - [Temporal Causal Model Scenarios](#)
-

Temporal Causal Models

Temporal causal modeling attempts to discover key causal relationships in time series data. In temporal causal modeling, you specify a set of target series and a set of candidate inputs to those targets. The procedure then builds an autoregressive time series model for each target and includes only those inputs that have a causal relationship with the target. This approach differs from traditional time series modeling where you must explicitly specify the predictors for a target series. Since temporal causal modeling typically involves building models for multiple related time series, the result is referred to as a *model system*.

In the context of temporal causal modeling, the term *causal* refers to Granger causality. A time series X is said to "Granger cause" another time series Y if regressing for Y in terms of past values of both X and Y results in a better model for Y than regressing only on past values of Y.

Note: The Temporal causal modeling node does not support the Model Evaluation or Champion Challenger steps in IBM® SPSS® Collaboration and Deployment Services.

Examples

Business decision makers can use temporal causal modeling to uncover causal relationships within a large set of time-based metrics that describe the business. The analysis might reveal a few controllable inputs, which have the largest impact on key performance indicators.

Managers of large IT systems can use temporal causal modeling to detect anomalies in a large set of interrelated operational metrics. The causal model then allows going beyond anomaly detection and discovering the most likely root causes of the anomalies.

Field requirements

There must be at least one target. By default, fields with a predefined role of None are not used.

Data structure

Temporal causal modeling supports two types of data structures.

Column-based data

For column-based data, each time series field contains the data for a single time series. This structure is the traditional structure of time series data, as used by the Time Series Modeler.

Multidimensional data

For multidimensional data, each time series field contains the data for multiple time series. Separate time series, within a particular field, are then identified by a set of values of categorical fields referred to as *dimension* fields. For example, sales data for two different sales channels (retail and web) might be stored in a single *sales* field. A dimension field that is named *channel*, with values 'retail' and 'web', identifies the records that are associated with each of the two sales channels.

Note: To build a temporal causal model, you need enough data points. The product uses the constraint:

$m > (L + KL + 1)$

where m is the number of data points, L is the number of lags, and K is the number of predictors. Make sure your data set is big enough so that the number of data points (m) satisfies the condition.

-

Time Series to Model (Temporal Causal Modeling)

On the Fields tab, use the Time Series settings to specify the series to include in the model system.

Select the option for the data structure that applies to your data. For multidimensional data, click Select Dimensions to specify the dimension fields. The specified order of the dimension fields defines the order in which they appear in all subsequent dialogs and output. Use the up and down arrow buttons on the Select Dimensions subdialog to reorder the dimension fields.

For column-based data, the term *series* has the same meaning as the term *field*. For multidimensional data, fields that contain time series are referred to as *metric* fields. A time series, for multidimensional data, is defined by a metric field and a value for each of the dimension fields. The following considerations apply to both column-based and multidimensional data.

- Series that are specified as candidate inputs or as both target and input are considered for inclusion in the model for each target. The model for each target always includes lagged values of the target itself.
- Series that are specified as forced inputs are always included in the model for each target.
- At least one series must be specified as either a target or as both target and input.
- When Use predefined roles is selected, fields that have a role of Input are set as candidate inputs. No predefined role maps to a forced input. For more information, see the topic [Roles](#).

Multidimensional data

For multidimensional data, you specify metric fields and associated roles in a grid, where each row in the grid specifies a single metric and role. By default, the model system includes series for all combinations of the dimension fields for each row in the grid. For example, if there are dimensions for *region* and *brand* then, by default, specifying the metric *sales* as a target means that there is a separate sales target series for each combination of *region* and *brand*.

For each row in the grid, you can customize the set of values for any of the dimension fields by clicking the ellipsis button for a dimension. This action opens the Select Dimension Values subdialog. You can also add, delete, or copy grid rows.

The Series Count column displays the number of sets of dimension values that are currently specified for the associated metric. The displayed value can be larger than the actual number of series (one series per set). This condition occurs when some of the specified combinations of dimension values do not correspond to series contained by the associated metric.

- [Select Dimension Values \(Temporal Causal Modeling\)](#)

Select Dimension Values (Temporal Causal Modeling)

For multidimensional data, you can customize the analysis by specifying which dimension values apply to a particular metric field with a particular role. For example, if *sales* is a metric field and *channel* is a dimension with values 'retail' and 'web', you can specify that 'web' sales is an input and 'retail' sales is a target. You can also specify dimension subsets that apply to all metric fields used in the analysis. For example, if *region* is a dimension field that indicates geographical region, then you can limit the analysis to particular regions.

All values

Specifies that all values of the current dimension field are included. This option is the default.

Select values to include or exclude

Use this option to specify the set of values for the current dimension field. When Include is selected for the Mode, only values that are specified in the Selected values list are included. When Exclude is selected for the Mode, all values other than the values that are specified in the Selected values list are included.

You can filter the set of values from which to choose. Values that meet the filter condition appear in the Matched tab and values that do not meet the filter condition appear in the Unmatched tab of the Unselected values list. The All tab lists all unselected values, regardless of any filter condition.

- You can use asterisks (*) to indicate wildcard characters when you specify a filter.
- To clear the current filter, specify an empty value for the search term on the Filter Displayed Values dialog.

Observations (Temporal Causal Modeling)

On the Fields tab, use the Observations settings to specify the fields that define the observations.

Observations that are defined by date/times

You can specify that the observations are defined by a date, time, or timestamp field. In addition to the field that defines the observations, select the appropriate time interval that describes the observations. Depending on the specified time interval, you can also specify other settings, such as the interval between observations (increment) or the number of days per week. The following considerations apply to the time interval:

- Use the value Irregular when the observations are irregularly spaced in time, such as the time at which a sales order is processed. When Irregular is selected, you must specify the time interval that is used for the analysis, from the Time Interval settings on the

Data Specifications tab.

- When the observations represent a date and time and the time interval is hours, minutes, or seconds, then use Hours per day, Minutes per day, or Seconds per day. When the observations represent a time (duration) without reference to a date and the time interval is hours, minutes, or seconds, then use Hours (non-periodic), Minutes (non-periodic), or Seconds (non-periodic).
- Based on the selected time interval, the procedure can detect missing observations. Detecting missing observations is necessary since the procedure assumes that all observations are equally spaced in time and that there are no missing observations. For example, if the time interval is Days and the date 2014-10-27 is followed by 2014-10-29, then there is a missing observation for 2014-10-28. Values are imputed for any missing observations. Settings for handling missing values can be specified from the Data Specifications tab.
- The specified time interval allows the procedure to detect multiple observations in the same time interval that need to be aggregated together and to align observations on an interval boundary, such as the first of the month, to ensure that the observations are equally spaced. For example, if the time interval is Months, then multiple dates in the same month are aggregated together. This type of aggregation is referred to as *grouping*. By default, observations are summed when grouped. You can specify a different method for grouping, such as the mean of the observations, from the Aggregation and Distribution settings on the Data Specifications tab.
- For some time intervals, the additional settings can define breaks in the normal equally spaced intervals. For example, if the time interval is Days, but only weekdays are valid, you can specify that there are five days in a week, and the week begins on Monday.

Observations that are defined by periods or cyclic periods

Observations can be defined by one or more integer fields that represent periods or repeating cycles of periods, up to an arbitrary number of cycle levels. With this structure, you can describe series of observations that don't fit one of the standard time intervals. For example, a fiscal year with only 10 months can be described with a cycle field that represents years and a period field that represents months, where the length of one cycle is 10.

Fields that specify cyclic periods define a hierarchy of periodic levels, where the lowest level is defined by the Period field. The next highest level is specified by a cycle field whose level is 1, followed by a cycle field whose level is 2, and so on. Field values for each level, except the highest, must be periodic with respect to the next highest level. Values for the highest level cannot be periodic. For example, in the case of the 10-month fiscal year, months are periodic within years and years are not periodic.

- The length of a cycle at a particular level is the periodicity of the next lowest level. For the fiscal year example, there is only one cycle level and the cycle length is 10 since the next lowest level represents months and there are 10 months in the specified fiscal year.
- Specify the starting value for any periodic field that does not start from 1. This setting is necessary for detecting missing values. For example, if a periodic field starts from 2 but the starting value is specified as 1, then the procedure assumes that there is a missing value for the first period in each cycle of that field.

 - [Estimation Period \(Temporal Causal Modeling\)](#)
-

Time Interval for Analysis (Temporal Causal Modeling)

The time interval that is used for the analysis can differ from the time interval of the observations. For example, if the time interval of the observations is Days, you might choose Months for the time interval for analysis. The data are then aggregated from daily to monthly data before the model is built. You can also choose to distribute the data from a longer to a shorter time interval. For example, if the observations are quarterly then you can distribute the data from quarterly to monthly data.

The available choices for the time interval at which the analysis is done depend on how the observations are defined and the time interval of those observations. In particular, when the observations are defined by cyclic periods, then only aggregation is supported. In that case, the time interval of the analysis must be greater than or equal to the time interval of the observations.

The time interval for the analysis is specified from the Time Interval settings on the Data Specifications tab. The method by which the data are aggregated or distributed is specified from the Aggregation and Distribution settings on the Data Specifications tab.

 - [Aggregation and Distribution \(Temporal Causal Modeling\)](#)
 - [Estimation Period \(Temporal Causal Modeling\)](#)
-

Aggregation and Distribution (Temporal Causal Modeling)

Aggregation functions

When the time interval that is used for the analysis is longer than the time interval of the observations, the input data are aggregated. For example, aggregation is done when the time interval of the observations is Days and the time interval for analysis is Months. The following aggregation functions are available: mean, sum, mode, min, or max.

Distribution functions

When the time interval that is used for the analysis is shorter than the time interval of the observations, the input data are distributed. For example, distribution is done when the time interval of the observations is Quarters and the time interval for analysis is Months. The following distribution functions are available: mean or sum.

Grouping functions

Grouping is applied when observations are defined by date/times and multiple observations occur in the same time interval. For example, if the time interval of the observations is Months, then multiple dates in the same month are grouped and associated with the month in which they occur. The following grouping functions are available: mean, sum, mode, min, or max. Grouping is always done when the observations are defined by date/times and the time interval of the observations is specified as Irregular.

Note: Although grouping is a form of aggregation, it is done before any handling of missing values whereas formal aggregation is done after any missing values are handled. When the time interval of the observations is specified as Irregular, aggregation is done only with the grouping function.

Aggregate cross-day observations to previous day

Specifies whether observations with times that cross a day boundary are aggregated to the values for the previous day. For example, for hourly observations with an eight-hour day that starts at 20:00, this setting specifies whether observations between 00:00 and 04:00 are included in the aggregated results for the previous day. This setting applies only if the time interval of the observations is Hours per day, Minutes per day or Seconds per day and the time interval for analysis is Days.

Custom settings for specified fields

You can specify aggregation, distribution, and grouping functions on a field by field basis. These settings override the default settings for the aggregation, distribution, and grouping functions.

Related information

 - [Time Interval for Analysis \(Temporal Causal Modeling\)](#)
 - [Missing Values \(Temporal Causal Modeling\)](#)
-

Missing Values (Temporal Causal Modeling)

Missing values in the input data are replaced with an imputed value. The following replacement methods are available:

Linear interpolation

Replaces missing values by using a linear interpolation. The last valid value before the missing value and the first valid value after the missing value are used for the interpolation. If the first or last observation in the series has a missing value, then the two nearest non-missing values at the beginning or end of the series are used.

Series mean

Replaces missing values with the mean for the entire series.

Mean of nearby points

Replaces missing values with the mean of valid surrounding values. The span of nearby points is the number of valid values before and after the missing value that are used to compute the mean.

Median of nearby points

Replaces missing values with the median of valid surrounding values. The span of nearby points is the number of valid values before and after the missing value that are used to compute the median.

Linear trend

This option uses all non-missing observations in the series to fit a simple linear regression model, which is then used to impute the missing values.

Other settings:

Maximum percentage of missing values (%)

Specifies the maximum percentage of missing values that are allowed for any series. Series with more missing values than the specified maximum are excluded from the analysis.

General Data Options (Temporal Causal Modeling)

Maximum number of distinct values per dimension field

This setting applies to multidimensional data and specifies the maximum number of distinct values that are allowed for any one dimension field. By default, this limit is set to 10000 but it can be increased to an arbitrarily large number.

General Build Options (Temporal Causal Modeling)

Confidence interval width (%)

This setting controls the confidence intervals for both forecasts and model parameters. You can specify any positive value less than 100. By default, a 95% confidence interval is used.

Maximum number of inputs for each target

This setting specifies the maximum number of inputs that are allowed in the model for each target. You can specify an integer in the range 1 - 20. The model for each target always includes lagged values of itself, so setting this value to 1 specifies that the only input is the target itself.

Model tolerance

This setting controls the iterative process that is used for determining the best set of inputs for each target. You can specify any value that is greater than zero. The default is 0.001. Model tolerance is a stop criterion for predictor selection. It can affect the number of predictors that are included in the final model. But if a target can predict itself very well, other predictors may not be included in the final model.

Some trial and error may be required (for example, if you have this value set to high, you can try setting it to a smaller value to see if other predictors can be included or not).

Outlier threshold (%)

An observation is flagged as an outlier if the probability, as calculated from the model, that it is an outlier exceeds this threshold. You can specify a value in the range 50 - 100.

Number of Lags for Each Input

This setting specifies the number of lag terms for each input in the model for each target. By default, the number of lag terms is automatically determined from the time interval that is used for the analysis. For example, if the time interval is months (with an increment of one month) then the number of lags is 12. Optionally, you can explicitly specify the number of lags. The specified value must be an integer in the range 1 - 20.

Continue estimation using existing models

If you already generated a temporal causal model, select this option to reuse the criteria settings that are specified for that model, rather than building a new model. In this way, you can save time by reestimating and producing a new forecast that is based on the same model settings as before but using more recent data.

Series to Display (Temporal Causal Modeling)

These options specify the series (targets or inputs) for which output is displayed. The content of the output for the specified series is determined by the Output Options settings.

Display targets associated with best-fitting models

By default, output is displayed for the targets that are associated with the 10 best-fitting models, as determined by the R square value. You can specify a different fixed number of best-fitting models or you can specify a percentage of best-fitting models. You can also choose from the following goodness of fit measures:

R square

Goodness-of-fit measure of a linear model, sometimes called the coefficient of determination. It is the proportion of variation in the target variable explained by the model. It ranges in value from 0 to 1. Small values indicate that the model does not fit the data well.

Root mean square percentage error

A measure of how much the model-predicted values differ from the observed values of the series. It is independent of the units that are used and can therefore be used to compare series with different units.

Root mean square error

The square root of mean square error. A measure of how much a dependent series varies from its model-predicted level, expressed in the same units as the dependent series.

BIC

Bayesian Information Criterion. A measure for selecting and comparing models based on the -2 reduced log likelihood. Smaller values indicate better models. The BIC also "penalizes" overparameterized models (complex models with a large number of inputs, for example), but more strictly than the AIC.

AIC

Akaike Information Criterion. A measure for selecting and comparing models based on the -2 reduced log likelihood. Smaller values indicate better models. The AIC "penalizes" overparameterized models (complex models with a large number of inputs, for example).

Specify Individual Series

You can specify individual series for which you want output.

- For column-based data, you specify the fields that contain the series that you want. The order of the specified fields defines the order in which they appear in the output.
- For multidimensional data, you specify a particular series by adding an entry to the grid for the metric field that contains the series. You then specify the values of the dimension fields that define the series.

- You can enter the value for each dimension field directly into the grid or you can select from the list of available dimension values. To select from the list of available dimension values, click the ellipsis button in the cell for the dimension that you want. This action opens the Select Dimension Value subdialog.
- You can search the list of dimension values, on the Select Dimension Value subdialog, by clicking the binoculars icon and specifying a search term. Spaces are treated as part of the search term. Asterisks (*) in the search term do not indicate wildcard characters.
- The order of the series in the grid defines the order in which they appear in the output.

For both column-based data and multidimensional data, output is limited to 30 series. This limit includes individual series (inputs or targets) that you specify and targets that are associated with best-fitting models. Individually specified series take precedence over targets that are associated with best-fitting models.

Related information

- [Output Options \(Temporal Causal Modeling\)](#)
-

Output Options (Temporal Causal Modeling)

These options specify the content of the output. Options in the Output for targets group generate output for the targets that are associated with the best-fitting models on the Series to Display settings. Options in the Output for series group generate output for the individual series that are specified on the Series to Display settings.

Overall model system

Displays a graphical representation of the causal relations between series in the model system. Tables of both model fit statistics and outliers for the displayed targets are included as part of the output item. When this option is selected in the Output for series group, a separate output item is created for each individual series that is specified on the Series to Display settings.

Causal relations between series have an associated significance level, where a smaller significance level indicates a more significant connection. You can choose to hide relations with a significance level that is greater than a specified value.

Model fit statistics and outliers

Tables of model fit statistics and outliers for the target series that are selected for display. These tables contain the same information as the tables in the Overall Model System visualization. These tables support all standard features for pivoting and editing tables.

Model effects and model parameters

Tables of model effects tests and model parameters for the target series that are selected for display. Model effects tests include the F statistic and associated significance value for each input included in the model.

Impact diagram

Displays a graphical representation of the causal relations between a series of interest and other series that it affects or that affect it. Series that affect the series of interest are referred to as *causes*. Selecting Effects generates an impact diagram that is initialized to display effects. Selecting Causes generates an impact diagram that is initialized to display causes. Selecting Both causes and effects generates two separate impact diagrams, one that is initialized to causes and one that is initialized to effects. You can interactively toggle between causes and effects in the output item that displays the impact diagram.

You can specify the number of levels of causes or effects to display, where the first level is just the series of interest. Each additional level shows more indirect causes or effects of the series of interest. For example, the third level in the display of effects consists of the series that contain series in the second level as a direct input. Series in the third level are then indirectly affected by the series of interest since the series of interest is a direct input to the series in the second level.

Series plot

Plots of observed and predicted values for the target series that are selected for display. When forecasts are requested, the plot also shows the forecasted values and the confidence intervals for the forecasts.

Residuals plot

Plots of the model residuals for the target series that are selected for display.

Top inputs

Plots of each displayed target, over time, along with the top 3 inputs for the target. The top inputs are the inputs with the lowest significance value. To accommodate different scales for the inputs and target, the y axis represents the z score for each series.

Forecast table

Tables of forecasted values and confidence intervals of those forecasts for the target series that are selected for display.

Outlier root cause analysis

Determines which series are most likely to be the cause of each outlier in a series of interest. Outlier root cause analysis is done for each target series that is included in the list of individual series on the Series to Display settings.

Output

Interactive outliers table and chart

Table and chart of outliers and root causes of those outliers for each series of interest. The table contains a single row for each outlier. The chart is an impact diagram. Selecting a row in the table highlights the path, in the impact diagram, from the

series of interest to the series that most likely causes the associated outlier.

Pivot table of outliers

Table of outliers and root causes of those outliers for each series of interest. This table contains the same information as the table in the interactive display. This table supports all standard features for pivoting and editing tables.

Causal levels

You can specify the number of levels to include in the search for the root causes. The concept of levels that is used here is the same as described for impact diagrams.

Model fit across all models

Histogram of model fit for all models and for selected fit statistics. The following fit statistics are available:

R square

Goodness-of-fit measure of a linear model, sometimes called the coefficient of determination. It is the proportion of variation in the target variable explained by the model. It ranges in value from 0 to 1. Small values indicate that the model does not fit the data well.

Root mean square percentage error

A measure of how much the model-predicted values differ from the observed values of the series. It is independent of the units that are used and can therefore be used to compare series with different units.

Root mean square error

The square root of mean square error. A measure of how much a dependent series varies from its model-predicted level, expressed in the same units as the dependent series.

BIC

Bayesian Information Criterion. A measure for selecting and comparing models based on the -2 reduced log likelihood. Smaller values indicate better models. The BIC also "penalizes" overparameterized models (complex models with a large number of inputs, for example), but more strictly than the AIC.

AIC

Akaike Information Criterion. A measure for selecting and comparing models based on the -2 reduced log likelihood. Smaller values indicate better models. The AIC "penalizes" overparameterized models (complex models with a large number of inputs, for example).

Outliers over time

Bar chart of the number of outliers, across all targets, for each time interval in the estimation period.

Series transformations

Table of any transformations that were applied to the series in the model system. The possible transformations are missing value imputation, aggregation, and distribution.

Related information

- [Interactive Output \(Temporal Causal Modeling\)](#)
 - [Series to Display \(Temporal Causal Modeling\)](#)
-

Estimation Period (Temporal Causal Modeling)

By default, the estimation period starts at the time of the earliest observation and ends at the time of the latest observation across all series.

By start and end times

You can specify both the start and end of the estimation period or you can specify just the start or just the end. If you omit the start or the end of the estimation period, the default value is used.

- If the observations are defined by a date/time field, then enter values for start and end in the same format that is used for the date/time field.
- For observations that are defined by cyclic periods, specify a value for each of the cyclic periods fields. Each field is displayed in a separate column.

By latest or earliest time intervals

Defines the estimation period as a specified number of time intervals that start at the earliest time interval or end at the latest time interval in the data, with an optional offset. In this context, the time interval refers to the time interval of the analysis. For example, assume that the observations are monthly but the time interval of the analysis is quarters. Specifying Latest and a value of 24 for the Number of time intervals means the latest 24 quarters.

Optionally, you can exclude a specified number of time intervals. For example, specifying the latest 24 time intervals and 1 for the number to exclude means that the estimation period consists of the 24 intervals that precede the last one.

Model Options (Temporal Causal Modeling)

Model Name

You can specify a custom name for the model or accept the automatically generated name, which is *TCM*.

Forecast

The option to Extend records into the future sets the number of time intervals to forecast beyond the end of the estimation period. The time interval in this case is the time interval of the analysis, which is specified on the Data Specifications tab. When forecasts are requested, autoregressive models are automatically built for any input series that are not also targets. These models are then used to generate values for those input series in the forecast period. There is no maximum limit for this setting.

Interactive Output (Temporal Causal Modeling)

The output from temporal causal modeling includes a number of interactive output objects. Interactive features are available by activating (double-clicking) the object in the Output Viewer.

Overall model system

Displays the causal relations between series in the model system. All lines that connect a particular target to its inputs have the same color. The thickness of the line indicates the significance of the causal connection, where thicker lines represent a more significant connection. Inputs that are not also targets are indicated with a black square.

- You can display relations for top models, a specified series, all series, or models with no inputs. The top models are the models that meet the criteria that were specified for best-fitting models on the Series to Display settings.
- You can generate impact diagrams for one or more series by selecting the series names in the chart, right-clicking, and then choosing Create Impact Diagram from the context menu.
- You can choose to hide causal relations that have a significance level that is greater than a specified value. Smaller significance levels indicate a more significant causal relation.
- You can display relations for a particular series by selecting the series name in the chart, right-clicking, and then choosing Highlight relations for series from the context menu.

Impact diagram

Displays a graphical representation of the causal relations between a series of interest and other series that it affects or that affect it. Series that affect the series of interest are referred to as *causes*.

- You can change the series of interest by specifying the name of the series that you want. Double-clicking any node in the impact diagram changes the series of interest to the series associated with that node.
- You can toggle the display between causes and effects and you can change the number of levels of causes or effects to display.
- Single-clicking any node opens a detailed sequence diagram for the series that is associated with the node.

Outlier root cause analysis

Determines which series are most likely to be the cause of each outlier in a series of interest.

- You can display the root cause for any outlier by selecting the row for the outlier in the Outliers table. You can also display the root cause by clicking the icon for the outlier in the sequence chart.
- Single-clicking any node opens a detailed sequence diagram for the series that is associated with the node.

Overall model quality

Histogram of model fit for all models, for a particular fit statistic. Clicking a bar in the bar chart filters the dot plot so that it displays only the models that are associated with the selected bar. You can find the model for a particular target series in the dot plot by specifying the series name.

Outlier distribution

Bar chart of the number of outliers, across all targets, for each time interval in the estimation period. Clicking a bar in the bar chart filters the dot plot so that it displays only the outliers that are associated with the selected bar.

Related information

- [Interactive output](#)
- [Output Options \(Temporal Causal Modeling\)](#)

TCM Model Nugget

The TCM modeling operation creates a number of new fields with the prefix \$TCM- as shown in the following table.

Table 1. New fields created by the TCM modeling operation

Field name	Description
\$TCM-colname	The value forecasted by the model for each target series.

\$TCMLCI-colname	The lower confidence intervals for each forecasted series.
\$TSUCI-colname	The upper confidence intervals for each forecasted series.
\$TCMResidual-colname	The noise residual value for each column of the generated model data.

- [TCM Model Nugget Settings](#)

TCM Model Nugget Settings

The Settings tab provides additional options for the TCM model nugget.

Forecast

The option to Extend records into the future sets the number of time intervals to forecast beyond the end of the estimation period. The time interval in this case is the time interval of the analysis, which is specified on the Data Specifications tab of the TCM node. When forecasts are requested, autoregressive models are automatically built for any input series that are not also targets. These models are then used to generate values for those input series in the forecast period.

Make available for scoring

Create new fields for each model to be scored. Enables you to specify the new fields to create for each model to be scored.

- Noises Residuals. If selected, creates a new field (with the default prefix \$TCM-) for the model residuals for each target field, together with a total of these values.
- Upper and lower confidence limits. If selected, creates new fields (with the default prefix \$TCM-) for the lower and upper confidence intervals, respectively, for each target field, together with totals of these values.

Targets included for scoring. Select available targets to include in the model score.

Temporal Causal Model Scenarios

The Temporal Causal Model Scenarios procedure runs user-defined scenarios for a temporal causal model system, with the data from the active dataset. A *scenario* is defined by a time series, that is referred to as the *root series*, and a set of user-defined values for that series over a specified time range. The specified values are then used to generate predictions for the time series that are affected by the root series. The procedure requires a model system file that was created by the Temporal Causal Modeling procedure. It is assumed that the active dataset is the same data as was used to create the model system file.

Example

Using the Temporal Causal Modeling procedure, a business decision maker discovered a key metric that affects a number of important performance indicators. The metric is controllable, so the decision maker wants to investigate the effect of various sets of values for the metric over the next quarter. The investigation is easily done by loading the model system file into the Temporal Causal Model Scenarios procedure and specifying the sets of values for the key metric.

- [Defining the Scenario Period \(Temporal Causal Model Scenarios\)](#)
- [Adding Scenarios and Scenario Groups \(Temporal Causal Model Scenarios\)](#)
- [Options \(Temporal Causal Model Scenarios\)](#)

Related information

- [Temporal Causal Models](#)

Defining the Scenario Period (Temporal Causal Model Scenarios)

The scenario period is the period over which you specify the values that are used to run your scenarios. It can start before or after the end of the estimation period. You can optionally specify to predict beyond the end of the scenario period. By default, predictions are generated through the end of the scenario period. All scenarios use the same scenario period and specifications for how far to predict.

Note: Predictions start at the first time period after the beginning of the scenario period. For example, if the scenario period starts on 2014-11-01 and the time interval is months, then the first prediction is for 2014-12-01.

Specify by start, end and predict through times

- If the observations are defined by a date/time field, then enter values for start, end, and predict through in the same format that is used for the date/time field. Values for date/time fields are aligned to the beginning of the associated time interval. For example, if the time interval of the analysis is months, then the value 10/10/2014 is adjusted to 10/01/2014, which is the beginning of the month.
- For observations that are defined by cyclic periods, specify a value for each of the cyclic periods fields. Each field is displayed in a separate column.

Specify by time intervals relative to end of estimation period

Defines start and end in terms of the number of time intervals relative to the end of the estimation period, where the time interval is the time interval of the analysis. The end of the estimation period is defined as time interval 0. Time intervals before the end of the estimation period have negative values and intervals after the end of the estimation period have positive values. You can also specify how many intervals to predict beyond the end of the scenario period. The default is 0.

For example, assume that the time interval of the analysis is months and that you specify 1 for starting interval, 3 for ending interval, and 1 for how far to predict beyond that. The scenario period is then the 3 months that follow the end of the estimation period. Predictions are generated for the second and third month of the scenario period and for 1 more month past the end of the scenario period.

Related information

- [Observations \(Temporal Causal Modeling\)](#)
 - [Time Interval for Analysis \(Temporal Causal Modeling\)](#)
-

Adding Scenarios and Scenario Groups (Temporal Causal Model Scenarios)

The Scenarios tab specifies the scenarios that are to be run. To define scenarios, you must first define the scenario period by clicking Define Scenario Period. Scenarios and scenario groups (applies only to multidimensional data) are created by clicking the associated Add Scenario or Add Scenario Group button. By selecting a particular scenario or scenario group in the associated grid, you can edit it, make a copy of it, or delete it.

Column-based data

The Root field column in the grid specifies the time series field whose values are replaced with the scenario values. The Scenario values column displays the specified scenario values in the order of earliest to latest. If the scenario values are defined by an expression, then the column displays the expression.

Multidimensional data

Individual Scenarios

Each row in the Individual Scenarios grid specifies a time series whose values are replaced by the specified scenario values. The series is defined by the combination of the field that is specified in the Root Metric column and the specified value for each of the dimension fields.

The content of the Scenario values column is the same as for column-based data.

Scenario Groups

A *scenario group* defines a set of scenarios that are based on a single root metric field and multiple sets of dimension values. Each set of dimension values (one value per dimension field), for the specified metric field, defines a time series. An individual scenario is then generated for each such time series, whose values are then replaced by the scenario values. Scenario values for a scenario group are specified by an expression, which is then applied to each time series in the group.

The Series Count column displays the number of sets of dimension values that are associated with a scenario group. The displayed value can be larger than the actual number of time series that are associated with the scenario group (one series per set). This condition occurs when some of the specified combinations of dimension values do not correspond to series contained by the root metric for the group.

As an example of a scenario group, consider a metric field *advertising* and two dimension fields *region* and *brand*. You can define a scenario group that is based on *advertising* as the root metric and that includes all combinations of *region* and *brand*. You might then specify *advertising*1.2* as the expression to investigate the effect of increasing *advertising* by 20 percent for each of the time series that are associated with the *advertising* field. If there are 4 values of *region* and 2 values of *brand*, then there are 8 such time series and thus 8 scenarios defined by the group.

- [Scenario Definition \(Temporal Causal Model Scenarios\)](#)
- [Scenario Group Definition \(Temporal Causal Model Scenarios\)](#)

Related information

- [Defining the Scenario Period \(Temporal Causal Model Scenarios\)](#)

Scenario Definition (Temporal Causal Model Scenarios)

Settings for defining a scenario depend on whether your data are column-based or multidimensional.

Root series

Specifies the root series for the scenario. Each scenario is based on a single root series. For column-based data, you select the field that defines the root series. For multidimensional data, you specify the root series by adding an entry to the grid for the metric field that contains the series. You then specify the values of the dimension fields that define the root series. The following apply to specifying the dimension values:

- You can enter the value for each dimension field directly into the grid or you can select from the list of available dimension values. To select from the list of available dimension values, click the ellipsis button in the cell for the dimension that you want. This action opens the Select Dimension Value subdialog.
- You can search the list of dimension values, on the Select Dimension Value subdialog, by clicking the binoculars icon and specifying a search term. Spaces are treated as part of the search term. Asterisks (*) in the search term do not indicate wildcard characters.

Specify affected targets

Use this option when you know specific targets that are affected by the root series and you want to investigate the effects on those targets only. By default, targets that are affected by the root series are automatically determined. You can specify the breadth of the series that are affected by the scenario with settings on the Options tab.

For column-based data, select the targets that you want. For multidimensional data, you specify target series by adding an entry to the grid for the target metric field that contains the series. By default, all series that are contained in the specified metric field are included. You can customize the set of included series by customizing the included values for one or more of the dimension fields. To customize the dimension values that are included, click the ellipsis button for the dimension that you want. This action opens the Select Dimension Values dialog.

The Series Count column (for multidimensional data) displays the number of sets of dimension values that are currently specified for the associated target metric. The displayed value can be larger than the actual number of affected target series (one series per set). This condition occurs when some of the specified combinations of dimension values do not correspond to series contained by the associated target metric.

Scenario ID

Each scenario must have a unique identifier. The identifier is displayed in output that is associated with the scenario. There are no restrictions, other than uniqueness, on the value of the identifier.

Specify scenario values for root series

Use this option to specify explicit values for the root series in the scenario period. You must specify a numeric value for each time interval that is listed in the grid. You can obtain the values of the root series (actual or forecasted) for each interval in the scenario period by clicking Read, Forecast, or Read\Forecast.

Specify expression for scenario values for root series

You can define an expression for computing the values of the root series in the scenario period. You can enter the expression directly or click the calculator button and create the expression from the Scenario Values Expression Builder.

- The expression can contain any target or input in the model system.
- When the scenario period extends beyond the existing data, the expression is applied to forecasted values of the fields in the expression.
- For multidimensional data, each field in the expression specifies a time series that is defined by the field and the dimension values that were specified for the root metric. It is those time series that are used to evaluate the expression.

As an example, assume that the root field is *advertising* and the expression is *advertising*1.2*. The values for *advertising* that are used in the scenario represent a 20 percent increase over the existing values.

Note: Scenarios are created by clicking Add Scenario on the Scenarios tab.

- [Select Dimension Values \(Temporal Causal Model Scenarios\)](#)

Select Dimension Values (Temporal Causal Model Scenarios)

For multidimensional data, you can customize the dimension values that define the targets that are affected by a scenario or scenario group. You can also customize the dimension values that define the set of root series for a scenario group.

All values

Specifies that all values of the current dimension field are included. This option is the default.

Select values

Use this option to specify the set of values for the current dimension field. You can filter the set of values from which to choose. Values that meet the filter condition appear in the Matched tab and values that do not meet the filter condition appear in the Unmatched tab of the Unselected values list. The All tab lists all unselected values, regardless of any filter condition.

- You can use asterisks (*) to indicate wildcard characters when you specify a filter.
- To clear the current filter, specify an empty value for the search term on the Filter Displayed Values dialog.

To customize dimension values for affected targets:

1. From the Scenario Definition or Scenario Group Definition dialog, select the target metric for which you want to customize dimension values.
2. Click the ellipsis button in the column for the dimension that you want to customize.

To customize dimension values for the root series of a scenario group:

1. From the Scenario Group Definition dialog, click the ellipsis button (in the root series grid) for the dimension that you want to customize.

Related information

- [Scenario Group Definition \(Temporal Causal Model Scenarios\)](#).

Scenario Group Definition (Temporal Causal Model Scenarios)

Root Series

Specifies the set of root series for the scenario group. An individual scenario is generated for each time series in the set. You specify the root series by adding an entry to the grid for the metric field that contains the series that you want. You then specify the values of the dimension fields that define the set. By default, all series that are contained in the specified root metric field are included. You can customize the set of included series by customizing the included values for one or more of the dimension fields. To customize the dimension values that are included, click the ellipsis button for a dimension. This action opens the Select Dimension Values dialog. The Series Count column displays the number of sets of dimension values that are currently included for the associated root metric. The displayed value can be larger than the actual number of root series for the scenario group (one series per set). This condition occurs when some of the specified combinations of dimension values do not correspond to series contained by the root metric.

Specify affected target series

Use this option when you know specific targets that are affected by the set of root series and you want to investigate the effects on those targets only. By default, targets that are affected by each root series are automatically determined. You can specify the breadth of the series that are affected by each individual scenario with settings on the Options tab.

You specify target series by adding an entry to the grid for the metric field that contains the series. By default, all series that are contained in the specified metric field are included. You can customize the set of included series by customizing the included values for one or more of the dimension fields. To customize the dimension values that are included, click the ellipsis button for the dimension that you want. This action opens the Select Dimension Values dialog.

The Series Count column displays the number of sets of dimension values that are currently specified for the associated target metric. The displayed value can be larger than the actual number of affected target series (one series per set). This condition occurs when some of the specified combinations of dimension values do not correspond to series contained by the associated target metric.

Scenario ID prefix

Each scenario group must have a unique prefix. The prefix is used to construct an identifier that is displayed in output that is associated with each individual scenario in the scenario group. The identifier for an individual scenario is the prefix, followed by an underscore, followed by the value of each dimension field that identifies the root series. The dimension values are separated by underscores. There are no restrictions, other than uniqueness, on the value of the prefix.

Expression for scenario values for root series

Scenario values for a scenario group are specified by an expression, which is then used to compute the values for each of the root series in the group. You can enter an expression directly or click the calculator button and create the expression from the Scenario Values Expression Builder.

- The expression can contain any target or input in the model system.
- When the scenario period extends beyond the existing data, the expression is applied to forecasted values of the fields in the expression.
- For each root series in the group, the fields in the expression specify time series that are defined by those fields and the dimension values that define the root series. It is those time series that are used to evaluate the expression. For example, if a root series is defined by `region='north'` and `brand='X'`, then the time series that are used in the expression are defined by those same dimension values.

As an example, assume that the root metric field is `advertising` and that there are two dimension fields `region` and `brand`. Also, assume that the scenario group includes all combinations of the dimension field values. You might then specify `advertising*1.2` as the expression to investigate the effect of increasing `advertising` by 20 percent for each of the time series that are associated with the `advertising` field.

Options (Temporal Causal Model Scenarios)

Maximum level for affected targets

Specifies the maximum number of levels of affected targets. Each successive level, up to the maximum of 5, includes targets that are more indirectly affected by the root series. Specifically, the first level includes targets that have the root series as a direct input. Targets in the second level have targets in the first level as a direct input, and so on. Increasing the value of this setting increases the complexity of the computation and might affect performance.

Maximum auto-detected targets

Specifies the maximum number of affected targets that are automatically detected for each root series. Increasing the value of this setting increases the complexity of the computation and might affect performance.

Impact diagram

Displays a graphical representation of the causal relations between the root series for each scenario and the target series that it affects.

Tables of both the scenario values and the predicted values for the affected targets are included as part of the output item. The graph includes plots of the predicted values of the affected targets. Single-clicking any node in the impact diagram opens a detailed sequence diagram for the series that is associated with the node. A separate impact diagram is generated for each scenario.

Series plots

Generates series plots of the predicted values for each of the affected targets in each scenario.

Forecast and scenario tables

Tables of predicted values and scenario values for each scenario. These tables contain the same information as the tables in the impact diagram. These tables support all standard features for pivoting and editing tables.

Include confidence intervals in plots and tables

Specifies whether confidence intervals for scenario predictions are included in both chart and table output.

Confidence interval width (%)

This setting controls the confidence intervals for the scenario predictions. You can specify any positive value less than 100. By default, a 95% confidence interval is used.

Time Series node

The Time Series node can be used with data in either a local or distributed environment; in a distributed environment you can harness the power of IBM® SPSS® Analytic Server. With this node, you can choose to estimate and build exponential smoothing, univariate Autoregressive Integrated Moving Average (ARIMA), or multivariate ARIMA (or transfer function) models for time series, and produce forecasts based on the time series data.

Exponential smoothing is a method of forecasting that uses weighted values of previous series observations to predict future values. As such, exponential smoothing is not based on a theoretical understanding of the data. It forecasts one point at a time, adjusting its forecasts as new data come in. The technique is useful for forecasting series that exhibit trend, seasonality, or both. You can choose from various exponential smoothing models that differ in their treatment of trend and seasonality.

ARIMA models provide more sophisticated methods for modeling trend and seasonal components than do exponential smoothing models, and, in particular, they allow the added benefit of including independent (predictor) variables in the model. This involves explicitly specifying autoregressive and moving average orders as well as the degree of differencing. You can include predictor variables and define transfer functions for any or all of them, as well as specify automatic detection of outliers or an explicit set of outliers.

Note: In practical terms, ARIMA models are most useful if you want to include predictors that might help to explain the behavior of the series that is being forecast, such as the number of catalogs that are mailed or the number of hits to a company web page. Exponential smoothing models describe the behavior of the time series without attempting to understand why it behaves as it does. For example, a series that historically peaks every 12 months will probably continue to do so even if you don't know why.

An Expert Modeler option is also available, which attempts to automatically identify and estimate the best-fitting ARIMA or exponential smoothing model for one or more target variables, thus eliminating the need to identify an appropriate model through trial and error. If in doubt, use the Expert Modeler option.

If predictor variables are specified, the Expert Modeler selects those variables that have a statistically significant relationship with the dependent series for inclusion in ARIMA models. Model variables are transformed where appropriate using differencing and/or a square root or natural log transformation. By default, the Expert Modeler considers all exponential smoothing models and all ARIMA models and picks the best model among them for each target field. You can, however, limit the Expert Modeler only to pick the best of the exponential smoothing models or only to pick the best of the ARIMA models. You can also specify automatic detection of outliers.

- [Time Series node - field options](#)
- [Time Series node - data specification options](#)
- [Time Series node - build options](#)
- [Time Series node - model options](#)
- [Time Series model nugget](#)

Time Series node - field options

On the Fields tab, you choose whether you want to use the field role settings already defined in upstream nodes, or make the field assignments manually.

Use predefined roles This option uses the role settings (targets, predictors and so on) from an upstream Type node (or the Types tab of an upstream source node).

Use custom field assignments. To manually assign targets, predictors and other roles, select this option.

Fields. Use the arrow buttons to assign items manually from this list to the various role fields on the right of the screen. The icons indicate the valid measurement levels for each role field.

To select all the fields in the list, click the All button, or click an individual measurement level button to select all fields with that measurement level.

Targets. Select one or more of the fields as your target for the prediction.

Candidate inputs. Select one or more fields as inputs for the prediction. You can select only fields with a measurement level of continuous.

Events and Interventions. Use this area to designate certain input fields as event or intervention fields. This designation identifies a field as containing time series data that can be affected by events (predictable recurring situations; for example, sales promotions) or interventions (one-time incidents; for example, power outage or employee strike). The fields you select must be flags that have integer storage.

Time Series node - data specification options

The Data Specifications tab is where you set all the options for the data to be included in your model. As long as you specify both a Date/time field and Time interval, you can click the Run button to build a model with all the default options, but normally you will want to customize the build for your own purposes.

The tab contains several different panes on which you set the customizations that are specific to your model.

- [Time Series node - observations](#)
- [Time Series node - time interval for analysis](#)
- [Time Series node - aggregation and distribution options](#)
- [Time Series node - missing value options](#)
- [Time Series node - estimation period](#)

Time Series node - observations

Use the settings in this pane to specify the fields that define the observations.

Observations that are specified by a date/time field

You can specify that the observations are defined by a date, time, or timestamp field. In addition to the field that defines the observations, select the appropriate time interval that describes the observations. Depending on the specified time interval, you can also specify other settings, such as the interval between observations (increment) or the number of days per week. The following considerations apply to the time interval:

- Use the value Irregular when the observations are irregularly spaced in time, such as the time at which a sales order is processed. When Irregular is selected, you must specify the time interval that is used for the analysis, from the Time Interval settings on the Data Specifications tab.
- When the observations represent a date and time and the time interval is hours, minutes, or seconds, then use Hours per day, Minutes per day, or Seconds per day. When the observations represent a time (duration) without reference to a date and the time interval is hours, minutes, or seconds, then use Hours (non-periodic), Minutes (non-periodic), or Seconds (non-periodic).
- Based on the selected time interval, the procedure can detect missing observations. Detecting missing observations is necessary since the procedure assumes that all observations are equally spaced in time and that no observations are missing. For example, if the time interval is Days and the date 2015-10-27 is followed by 2015-10-29, then an observation is missing for 2015-10-28. Values are imputed for any missing observations; use the Missing Value Handling area of the Data Specifications tab to specify settings for handling missing values.
- The specified time interval allows the procedure to detect multiple observations in the same time interval that need to be aggregated together and to align observations on an interval boundary, such as the first of the month, to ensure that the observations are equally spaced. For example, if the time interval is Months, then multiple dates in the same month are aggregated together. This type of aggregation is referred to as *grouping*. By default, observations are summed when grouped. You can specify a different method for grouping, such as the mean of the observations, from the Aggregation and Distribution settings on the Data Specifications tab.

- For some time intervals, the additional settings can define breaks in the normal equally spaced intervals. For example, if the time interval is Days, but only weekdays are valid, you can specify that there are five days in a week, and the week begins on Monday.

Observations that are defined as periods or cyclic periods

Observations can be defined by one or more integer fields that represent periods or repeating cycles of periods, up to an arbitrary number of cycle levels. With this structure, you can describe series of observations that don't fit one of the standard time intervals. For example, a fiscal year with only 10 months can be described with a cycle field that represents years and a period field that represents months, where the length of one cycle is 10.

Fields that specify cyclic periods define a hierarchy of periodic levels, where the lowest level is defined by the Period field. The next highest level is specified by a cycle field whose level is 1, followed by a cycle field whose level is 2, and so on. Field values for each level, except the highest, must be periodic with respect to the next highest level. Values for the highest level cannot be periodic. For example, in the case of the 10-month fiscal year, months are periodic within years and years are not periodic.

- The length of a cycle at a particular level is the periodicity of the next lowest level. For the fiscal year example, there is only one cycle level and the cycle length is 10 since the next lowest level represents months and there are 10 months in the specified fiscal year.
- Specify the starting value for any periodic field that does not start from 1. This setting is necessary for detecting missing values. For example, if a periodic field starts from 2 but the starting value is specified as 1, then the procedure assumes that there is a missing value for the first period in each cycle of that field.

Time Series node - time interval for analysis

The time interval that you use for analysis can differ from the time interval of the observations. For example, if the time interval of the observations is Days, you might choose Months for the time interval for analysis. The data is then aggregated from daily to monthly data before the model is built. You can also choose to distribute the data from a longer to a shorter time interval. For example, if the observations are quarterly then you can distribute the data from quarterly to monthly data.

Use the settings in this pane to specify the time interval for the analysis. The method by which the data is aggregated or distributed is specified from the Aggregation and Distribution settings on the Data Specifications tab.

The available choices for the time interval at which the analysis is done depend on how the observations are defined and the time interval of those observations. In particular, when the observations are defined by cyclic periods, only aggregation is supported. In that case, the time interval of the analysis must be greater than or equal to the time interval of the observations.

Time Series node - aggregation and distribution options

Use the settings in this pane to specify settings for aggregating or distributing the input data with respect to the time intervals of the observations.

Aggregation functions

When the time interval that is used for the analysis is longer than the time interval of the observations, the input data are aggregated. For example, aggregation is done when the time interval of the observations is Days and the time interval for analysis is Months. The following aggregation functions are available: mean, sum, mode, min, or max.

Distribution functions

When the time interval that is used for the analysis is shorter than the time interval of the observations, the input data are distributed. For example, distribution is done when the time interval of the observations is Quarters and the time interval for analysis is Months. The following distribution functions are available: mean or sum.

Grouping functions

Grouping is applied when observations are defined by date/times and multiple observations occur in the same time interval. For example, if the time interval of the observations is Months, then multiple dates in the same month are grouped and associated with the month in which they occur. The following grouping functions are available: mean, sum, mode, min, or max. Grouping is always done when the observations are defined by date/times and the time interval of the observations is specified as Irregular.

Note: Although grouping is a form of aggregation, it is done before any handling of missing values whereas formal aggregation is done after any missing values are handled. When the time interval of the observations is specified as Irregular, aggregation is done only with the grouping function.

Aggregate cross-day observations to previous day

Specifies whether observations with times that cross a day boundary are aggregated to the values for the previous day. For example, for hourly observations with an eight-hour day that starts at 20:00, this setting specifies whether observations between 00:00 and 04:00 are included in the aggregated results for the previous day. This setting applies only if the time interval of the observations is Hours per day, Minutes per day or Seconds per day and the time interval for analysis is Days.

Custom settings for specified fields

You can specify aggregation, distribution, and grouping functions on a field by field basis. These settings override the default settings for the aggregation, distribution, and grouping functions.

Time Series node - missing value options

Use the settings in this pane to specify how any missing values in the input data are to be replaced with an imputed value. The following replacement methods are available:

Linear interpolation

Replaces missing values by using a linear interpolation. The last valid value before the missing value and the first valid value after the missing value are used for the interpolation. If the first or last observation in the series has a missing value, then the two nearest non-missing values at the beginning or end of the series are used.

Replaces missing values by using a linear interpolation.

- For non-seasonal data, the last valid value before the missing value and the first valid value after the missing value are used for the interpolation. If missing values are at the beginning or the end of a time series, then a linear extrapolation method is used based on the two nearest valid values.
- For seasonal data, a missing value is linearly interpolated using the last valid value of the same period before the missing value and the first valid value of the same period after the missing value. If one of the two values of the same period can't be found for the missing value, then the data will be regarded as non-seasonal data and linear interpolation of non-seasonal data is used to impute the missing value.

Series mean

Replaces missing values with the mean for the entire series.

Mean of nearby points

Replaces missing values with the mean of valid surrounding values. The span of nearby points is the number of valid values before and after the missing value that are used to compute the mean.

Median of nearby points

Replaces missing values with the median of valid surrounding values. The span of nearby points is the number of valid values before and after the missing value that are used to compute the median.

Linear trend

This option uses all non-missing observations in the series to fit a simple linear regression model, which is then used to impute the missing values.

Other settings:

Lowest data quality score (%)

Computes data quality measures for the time variable and for input data corresponding to each time series. If the data quality score is lower than this threshold, the corresponding time series will be discarded.

Time Series node - estimation period

In the Estimation Period pane, you can specify the range of records to be used in model estimation. By default, the estimation period starts at the time of the earliest observation and ends at the time of the latest observation across all series.

By start and end times

You can specify both the start and end of the estimation period or you can specify just the start or just the end. If you omit the start or the end of the estimation period, the default value is used.

- If the observations are defined by a date/time field, enter values for start and end in the same format that is used for the date/time field.
- For observations that are defined by cyclic periods, specify a value for each of the cyclic periods fields. Each field is displayed in a separate column.

By latest or earliest time intervals

Defines the estimation period as a specified number of time intervals that start at the earliest time interval or end at the latest time interval in the data, with an optional offset. In this context, the time interval refers to the time interval of the analysis. For example, assume that the observations are monthly but the time interval of the analysis is quarters. Specifying Latest and a value of 24 for the Number of time intervals means the latest 24 quarters.

Optionally, you can exclude a specified number of time intervals. For example, specifying the latest 24 time intervals and 1 for the number to exclude means that the estimation period consists of the 24 intervals that precede the last one.

Time Series node - build options

The Build Options tab is where you set all the options for building your model. You can, of course, just click the Run button to build a model with all the default options, but normally you will want to customize the build for your own purposes.

The tab contains two different panes on which you set the customizations that are specific to your model.

- [Time Series node - general build options](#)
- [Time Series node - build output options](#)

Time Series node - general build options

The options available on this pane depend on which of the following three settings you choose from the Method list:

- Expert Modeler. Choose this option to use the Expert Modeler, which automatically finds the best-fitting model for each dependent series.
- Exponential Smoothing. Use this option to specify a custom exponential smoothing model.
- ARIMA. Use this option to specify a custom ARIMA model.

Expert Modeler

Under Model Type, select the type of models you want to build:

- All models. The Expert Modeler considers both ARIMA and exponential smoothing models.
- Exponential smoothing models only. The Expert Modeler considers only exponential smoothing models.
- ARIMA models only. The Expert Modeler considers only ARIMA models.

Expert Modeler considers seasonal models. This option is only enabled if a periodicity is defined for the active dataset. When this option is selected, the Expert Modeler considers both seasonal and nonseasonal models. If this option is not selected, the Expert Modeler considers only nonseasonal models.

Expert Modeler considers sophisticated exponential smoothing models. When this option is selected, the Expert Modeler searches a total of 13 exponential smoothing models (7 of them existed in the original Time Series node, and 6 of them were added in version 18.1). If this option is not selected, the Expert Modeler only searches the original 7 exponential smoothing models.

Under Outliers, select from the following options

Detect outliers automatically. By default, automatic detection of outliers is not performed. Select this option to perform automatic detection of outliers, then select the desired outlier types.

For more information, see [Outliers](#).

Input fields must have a measurement level of *Flag*, *Nominal*, or *Ordinal* and must be numeric (for example, 1/0, not True/False, for a flag field), before they are included in this list.

For more information, see [Pulses and steps](#).

The Expert Modeler considers only simple regression and not arbitrary transfer functions for inputs that are identified as event or intervention fields on the Fields tab.

Exponential Smoothing

Model Type. Exponential smoothing models are classified as either seasonal or nonseasonal.¹ Seasonal models are only available if the periodicity defined by using the Time Intervals pane on the Data Specifications tab is seasonal. The seasonal periodicities are: cyclic periods, years, quarters, months, days per week, hours per day, minutes per day, and seconds per day. The following model types are available:

- Simple. This model is appropriate for a series in which there is no trend or seasonality. Its only relevant smoothing parameter is level. Simple exponential smoothing is most similar to an ARIMA with zero orders of autoregression, one order of differencing, one order of moving average, and no constant.
- Holt's linear trend. This model is appropriate for a series in which there is a linear trend and no seasonality. Its relevant smoothing parameters are level and trend, and, in this model, they are not constrained by each other's values. Holt's model is more general than Brown's model but may take longer to compute estimates for large series. Holt's exponential smoothing is most similar to an ARIMA with zero orders of autoregression, two orders of differencing, and two orders of moving average.
- Damped trend. This model is appropriate for a series in which there is a linear trend that is dying out and no seasonality. Its relevant smoothing parameters are level, trend, and damping trend. Damped exponential smoothing is most similar to an ARIMA with one order of autoregression, one order of differencing, and two orders of moving average.
- Multiplicative trend. This model is appropriate for a series in which there is a trend that changes with the magnitude of the series and no seasonality. Its relevant smoothing parameters are level and trend. Multiplicative trend exponential smoothing is not similar to any ARIMA model.
- Brown's linear trend. This model is appropriate for a series in which there is a linear trend and no seasonality. Its relevant smoothing parameters are level and trend, but, in this model, they are assumed to be equal. Brown's model is therefore a special case of Holt's

model. Brown's exponential smoothing is most similar to an ARIMA with zero orders of autoregression, two orders of differencing, and two orders of moving average, with the coefficient for the second order of moving average equal to one half of the coefficient for the first order squared.

- Simple seasonal. This model is appropriate for a series in which there is no trend and a seasonal effect that is constant over time. Its relevant smoothing parameters are level and season. Seasonal exponential smoothing is most similar to an ARIMA with zero orders of autoregression; one order of differencing; one order of seasonal differencing; and orders 1, p , and $p+1$ of moving average, where p is the number of periods in a seasonal interval. For monthly data, $p = 12$.
- Winters' additive. This model is appropriate for a series in which there is a linear trend and a seasonal effect that is constant over time. Its relevant smoothing parameters are level, trend, and season. Winters' additive exponential smoothing is most similar to an ARIMA with zero orders of autoregression; one order of differencing; one order of seasonal differencing; and $p+1$ orders of moving average, where p is the number of periods in a seasonal interval. For monthly data, $p=12$.
- Damped trend with additive seasonal. This model is appropriate for a series in which there is a linear trend that is dying out and a seasonal effect that is constant over time. Its relevant smoothing parameters are level, trend, damping trend, and season. Damped trend and additive seasonal exponential smoothing is not similar to any ARIMA model.
- Multiplicative trend with additive seasonal. This model is appropriate for a series in which there is a trend that changes with the magnitude of the series and a seasonal effect that is constant over time. Its relevant smoothing parameters are level, trend, and season. Multiplicative trend and additive seasonal exponential smoothing is not similar to any ARIMA model.
- Multiplicative seasonal. This model is appropriate for a series in which there is no trend and a seasonal effect that changes with the magnitude of the series. Its relevant smoothing parameters are level and season. Multiplicative seasonal exponential smoothing is not similar to any ARIMA model.
- Winters' multiplicative. This model is appropriate for a series in which there is a linear trend and a seasonal effect that changes with the magnitude of the series. Its relevant smoothing parameters are level, trend, and season. Winters' multiplicative exponential smoothing is not similar to any ARIMA model.
- Damped trend with multiplicative seasonal. This model is appropriate for a series in which there is a linear trend that is dying out and a seasonal effect that changes with the magnitude of the series. Its relevant smoothing parameters are level, trend, damping trend, and season. Damped trend and multiplicative seasonal exponential smoothing is not similar to any ARIMA model.
- Multiplicative trend with multiplicative seasonal. This model is appropriate for a series in which there are a trend and a seasonal effect that both change with the magnitude of the series. Its relevant smoothing parameters are level, trend, and season. Multiplicative trend and multiplicative seasonal exponential smoothing is not similar to any ARIMA model.

Target Transformation. You can specify a transformation to be performed on each dependent variable before it is modeled.

For more information, see [Series transformations](#).

- None. No transformation is performed.
- Square root. Square root transformation is performed.
- Natural log. Natural log transformation is performed.

ARIMA

Specify the structure of a custom ARIMA model.

ARIMA Orders. Enter values for the various ARIMA components of your model into the corresponding cells of the grid. All values must be non-negative integers. For autoregressive and moving average components, the value represents the maximum order. All positive lower orders are included in the model. For example, if you specify 2, the model includes orders 2 and 1. Cells in the Seasonal column are only enabled if a periodicity is defined for the active dataset.

- Autoregressive (p). The number of autoregressive orders in the model. Autoregressive orders specify which previous values from the series are used to predict current values. For example, an autoregressive order of 2 specifies that the value of the series two time periods in the past is used to predict the current value.
- Difference (d). Specifies the order of differencing applied to the series before estimating models. Differencing is necessary when trends are present (series with trends are typically nonstationary and ARIMA modeling assumes stationarity) and is used to remove their effect. The order of differencing corresponds to the degree of series trend; first-order differencing accounts for linear trends, second-order differencing accounts for quadratic trends, and so on.
- Moving Average (q). The number of moving average orders in the model. Moving average orders specify how deviations from the series mean for previous values are used to predict current values. For example, moving-average orders of 1 and 2 specify that deviations from the mean value of the series from each of the last two time periods be considered when predicting current values of the series.

Seasonal. Seasonal autoregressive, moving average, and differencing components play the same roles as their nonseasonal counterparts. For seasonal orders, however, current series values are affected by previous series values that are separated by one or more seasonal periods. For example, for monthly data (seasonal period of 12), a seasonal order of 1 means that the current series value is affected by the series value 12 periods before the current one. A seasonal order of 1, for monthly data, is then the same as specifying a nonseasonal order of 12.

Detect outliers automatically. Select this option to perform automatic detection of outliers, and select one or more of the outlier types available.

Type of Outliers to Detect. Select the outlier type(s) you want to detect. The supported types are:

- Additive (default)
- Level shift (default)
- Innovational

- Transient
- Seasonal additive
- Local trend
- Additive patch

Transfer Function Orders and Transformations. To specify transformations and to define transfer functions for any or all of the input fields in your ARIMA model, click Set; a separate dialog box is displayed in which you enter the transfer and transformation details.

Include constant in model. Inclusion of a constant is standard unless you are sure that the overall mean series value is 0. Excluding the constant is recommended when differencing is applied.

Further details

- For more information on types of outliers, see [Outliers](#).
- For more information on transfer and transformation functions, see [Transfer and transformation functions](#).
- [Transfer and transformation functions](#)

¹ Gardner, E. S. 1985. Exponential smoothing: The state of the art. *Journal of Forecasting*, 4, 1-28.

Transfer and transformation functions

Use the Transfer Function Orders and Transformations dialog box to specify transformations and to define transfer functions for any or all of the input fields in your ARIMA model.

Target Transformations. In this pane you can specify a transformation to be performed on each target variable before it is modeled.

- None. No transformation is performed.
- Square root. Square root transformation is performed.
- Natural log. Natural log transformation is performed.

For more information, see [Series transformations](#).

Candidate Inputs Transfer functions and Transformation. You use transfer functions to specify the manner in which past values of the input fields are used to forecast future values of the target series. The list on the left hand side of the pane shows all input fields. The remaining information in this pane is specific to the input field you select.

Transfer Function Orders. Enter values for the various components of the transfer function into the corresponding cells of the Structure grid. All values must be non-negative integers. For numerator and denominator components, the value represents the maximum order. All positive lower orders are included in the model. In addition, order 0 is always included for numerator components. For example, if you specify 2 for numerator, the model includes orders 2, 1, and 0. If you specify 3 for denominator, the model includes orders 3, 2, and 1. Cells in the Seasonal column are only enabled if a periodicity is defined for the active dataset.

Numerator. The numerator order of the transfer function specifies which previous values from the selected independent (predictor) series are used to predict current values of the dependent series. For example, a numerator order of 1 specifies that the value of an independent series one time period in the past, in addition to the current value of the independent series, is used to predict the current value of each dependent series.

Denominator. The denominator order of the transfer function specifies how deviations from the series mean, for previous values of the selected independent (predictor) series, are used to predict current values of the dependent series. For example, a denominator order of 1 specifies that deviations from the mean value of an independent series one time period in the past is considered when predicting the current value of each dependent series.

Difference. Specifies the order of differencing applied to the selected independent (predictor) series before estimating models. Differencing is necessary when trends are present and is used to remove their effect.

Seasonal. Seasonal numerator, denominator, and differencing components play the same roles as their nonseasonal counterparts. For seasonal orders, however, current series values are affected by previous series values that are separated by one or more seasonal periods. For example, for monthly data (seasonal period of 12), a seasonal order of 1 means that the current series value is affected by the series value 12 periods prior to the current one. A seasonal order of 1, for monthly data, is then the same as specifying a nonseasonal order of 12.

Delay. Setting a delay causes the input field's influence to be delayed by the number of intervals specified. For example, if the delay is set to 5, the value of the input field at time t doesn't affect forecasts until five periods have elapsed ($t + 5$).

Transformation. Specification of a transfer function for a set of independent variables also includes an optional transformation to be performed on those variables.

- None. No transformation is performed.
- Square root. Square root transformation is performed.
- Natural log. Natural log transformation is performed.

Time Series node - build output options

Maximum number of lags in ACF and PACF output. Autocorrelation (ACF) and partial autocorrelation (PACF) are measures of association between current and past series values and indicate which past series values are most useful in predicting future values. You can set the maximum number of lags that are shown in tables and plots of autocorrelations and partial autocorrelations.

For more information, see [Autocorrelation and partial autocorrelation functions](#).

Calculate predictor importance. For models that produce an appropriate measure of importance, you can display a chart that indicates the relative importance of each predictor in estimating the model. Typically you want to focus your modeling efforts on the predictors that matter most, and consider dropping or ignoring the predictors that matter least. Predictor importance can take longer to calculate for some models, particularly when you are working with large datasets, and is off by default for some models as a result.

For more information, see [Predictor Importance](#).

Time Series node - model options

Model name. You can generate the model name automatically based on the target or ID field (or model type in cases where no such field is specified) or specify a custom name.

Confidence limit width (%). Confidence intervals are computed for the model predictions and residual autocorrelations. You can specify any positive value less than 100. By default, a 95% confidence interval is used.

Continue estimation using existing model(s). If you already generated a time series model, select this option to reuse the criteria settings that are specified for that model and generate a new model node in the Models palette, rather than building a new model from the beginning. In this way, you can save time by re-estimating and producing a new forecast that is based on the same model settings as before but using more recent data. Thus, for example, if the original model for a particular time series was Holt's linear trend, the same type of model is used for reestimating and forecasting for that data. The system does not reattempt to find the best model type for the new data.

Build scoring model only. To reduce the amount of data that is stored in the model, check this box. Using this option can improve performance when building models with large numbers of time series (tens of thousands). You can still score the data in the usual way.

Extend records into the future. Enables the following Future Values to Use in Forecasting section, where you can set the number of time intervals to forecast beyond the end of the estimation period. The time interval in this case is the time interval of the analysis, which you specify on the Data Specifications tab. There is no maximum limit for this setting. Using the following options, you can automatically compute future values of inputs, or you can manually specify forecasting values for one or more predictors.

Future Values to Use in Forecasting

- Compute future values of inputs If you select this option, the forecast values for predictors, noise predictions, variance estimation, and future time values are calculated automatically. When forecasts are requested, autoregressive models are automatically built for any input series that are not also targets. These models are then used to generate values for those input series in the forecast period.
 - Select fields whose values you wish to add to the data. For each record that you want to forecast (excluding holdouts), if you are using predictor fields (with the role set to **Input**), you can specify estimated values for the forecast period for each predictor. You can either specify values manually, or choose from a list.
 - Field. Click the field selector button and choose any fields that may be used as predictors. Note that fields selected here may or may not be used in modeling; to actually use a field as a predictor, it must be selected in a downstream modeling node. This dialog box simply gives you a convenient place to specify future values so they can be shared by multiple downstream modeling nodes without specifying them separately in each node. Also note that the list of available fields may be constrained by selections on the Build Options tab.
Note that if future values are specified for a field that is no longer available in the stream (because it has been dropped or because of updated selections made on the Build Options tab), the field is shown in red.
 - Values. For each field, you can choose from a list of functions, or click Specify to either enter values manually or choose from a list of predefined values. If the predictor fields relate to items that are under your control, or which are otherwise knowable in advance, you should enter values manually. For example, if you are forecasting next month's revenues for a hotel based on the number of room reservations, you could specify the number of reservations you actually have for that period. Conversely, if a predictor field relates to something outside your control, such as a stock price, you could use a function such as the most recent value or the mean of recent points.
- The available functions depend on the measurement level of the field.

Table 1. Functions available for measurement levels

Measurement level	Functions
-------------------	-----------

Measurement level	Functions
Continuous or Nominal field	Blank Mean of recent points Most recent value Specify
Flag field	Blank Most recent value True False Specify

Mean of recent points calculates the future value from the mean of the last three data points.

Most recent value sets the future value to that of the most recent data point.

True/False sets the future value of a flag field to True or False as specified.

Specify opens a dialog box for specifying future values manually, or choosing them from a predefined list.

Make Available for Scoring

You can set the default values here for the scoring options that appear on the dialog box for the model nugget.

- Calculate upper and lower confidence limits. If selected, this option creates new fields (with the default prefixes \$TSLCI- and \$TSUCI-) for the lower and upper confidence intervals, for each target field.
- Calculate noise residuals. If selected, this option creates a new field (with the default prefix \$TSResidual-) for the model residuals for each target field, together with a total of these values.

Model Settings

Maximum number of models to be displayed in output. Specify the maximum number of models you want to include in the output. Note that if the number of models built exceeds this threshold, the models are not shown in the output but they're still available for scoring. Default value is 10. Displaying a large number of models may result in poor performance or instability.

Time Series model nugget

- [Time Series model nugget output](#)
- [Time Series model nugget settings](#)

Time Series model nugget output

After you create a Time Series model, the following information is available in the Output viewer. Note that there's a limit of 10 models that can be displayed in the Output viewer for Time Series models.

Temporal Information Summary

The summary shows the following information:

- The Time field
- The increment
- The start and end point
- The number of unique points

The summary applies to all targets.

Model information table

Repeated for each target, the Model information table provides key information about the model. The table always includes the following high-level model settings:

- The name of the target field that is selected in either the Type node or the Time Series node Fields tab.
- The model building method - for example, Exponential Smoothing, or ARIMA.
- The number of predictors input into the model.

- The number of records that were used to fit the model type. Examples of the different types of models might include: RMSE, MAE, AIC, BIC, and R Square.

In addition, the Ljung-Box Q statistic might also be shown if your data meets the required conditions. This statistic is **not** available under the following conditions:

- If the number of non-missing data points is less than or equal to the number of summation terms desired (fixed at 18).
- If the number of parameters is greater than or equal to the number of summation terms desired.
- If the number of summation terms that are computed is less than the smallest acceptable k value (fixed at 7).
- If the table repeats for each target.

Predictor Importance

Repeated for each target, the Predictor Importance graph shows the importance of the top 10 inputs (predictors) in the model as a bar chart.

If there are more than 10 fields in the chart, you can change the selection of predictors that are included in the chart by using the slider beneath the chart. The indicator marks on the slider are a fixed width, and each mark on the slider represents 10 fields. You can move the indicator marks along the slider to display the next or previous 10 fields, ordered by predictor importance.

You can double-click the chart to open a separate dialog box in which you can edit the graph settings. For example, you can amend items such as the size of the graph, and the size and color of the fonts used. When you close this separate editing dialog box, the changes are applied to the chart that is displayed in the Output tab.

Correlogram

A correlogram, or autocorrelation plot, is shown for each target and shows the autocorrelation function (ACF), or partial autocorrelation function (PACF), of the residuals (the differences between expected and actual values) versus the time lags. The confidence interval is shown as a highlight across the chart.

Parameter Estimates

Repeated for each target, the Parameter Estimates table shows (where applicable) the following details:

- Target name
- The transformation applied
- The lags used for this parameter in the model (ARIMA)
- The coefficient value
- The standard error of the parameter estimate
- The value of the parameter estimate divided by the standard error
- The significance level for the parameter estimate.

Time Series model nugget settings

The Settings tab provides additional options for the Time Series model nugget.

Forecast

The option to Extend records into the future. sets the number of time intervals to forecast beyond the end of the estimation period. The time interval in this case is the time interval of the analysis, which is specified on the Data Specifications tab of the Time Series node. When forecasts are requested, autoregressive models are automatically built for any input series that are not also targets. These models are then used to generate values for those input series in the forecast period.

Compute future values of inputs. If you select this option, the forecast values for predictors, noise predictions, variance estimation, and future time values are calculated.

Future Values to Use in Forecasting

- Compute future values of inputs If you select this option, the forecast values for predictors, noise predictions, variance estimation, and future time values are calculated automatically. When forecasts are requested, autoregressive models are automatically built for any input series that are not also targets. These models are then used to generate values for those input series in the forecast period.
- Select fields whose values you wish to add to the data. For each record that you want to forecast (excluding holdouts), if you are using predictor fields (with the role set to **Input**), you can specify estimated values for the forecast period for each predictor. You can either specify values manually, or choose from a list.

- Field. Click the field selector button and choose any fields that may be used as predictors. Note that fields selected here may or may not be used in modeling; to actually use a field as a predictor, it must be selected in a downstream modeling node. This dialog box simply gives you a convenient place to specify future values so they can be shared by multiple downstream modeling nodes without specifying them separately in each node. Also note that the list of available fields may be constrained by selections on the Build Options tab.
Note that if future values are specified for a field that is no longer available in the stream (because it has been dropped or because of updated selections made on the Build Options tab), the field is shown in red.
- Values. For each field, you can choose from a list of functions, or click Specify to either enter values manually or choose from a list of predefined values. If the predictor fields relate to items that are under your control, or which are otherwise knowable in advance, you should enter values manually. For example, if you are forecasting next month's revenues for a hotel based on the number of room reservations, you could specify the number of reservations you actually have for that period. Conversely, if a predictor field relates to something outside your control, such as a stock price, you could use a function such as the most recent value or the mean of recent points.
The available functions depend on the measurement level of the field.

Table 1. Functions available for measurement levels

Measurement level	Functions
Continuous or Nominal field	Blank Mean of recent points Most recent value Specify
Flag field	Blank Most recent value True False Specify

Mean of recent points calculates the future value from the mean of the last three data points.

Most recent value sets the future value to that of the most recent data point.

True/False sets the future value of a flag field to True or False as specified.

Specify opens a dialog box for specifying future values manually, or choosing them from a predefined list.

Make available for scoring

Create new fields for each model to be scored. Enables you to specify the new fields to create for each model to be scored.

- Noises Residuals. If selected, creates a new field (with the default prefix \$TSResidual-) for the model residuals for each target field, together with a total of these values.
- Upper and lower confidence limits. If selected, this option creates new fields (with the default prefixes \$TSLCI- and \$TSUCI-) for the lower and upper confidence intervals respectively, for each target field, together with totals of these values.

Targets included for scoring. Select available targets to include in the model score.

Self-Learning Response Node Models

- [SLRM node](#)
- [SLRM Model Nuggets](#)

SLRM node

The Self-Learning Response Model (SLRM) node enables you to build a model that you can continually update, or reestimate, as a dataset grows without having to rebuild the model every time using the complete dataset. For example, this is useful when you have several products and you want to identify which product a customer is most likely to buy if you offer it to them. This model allows you to predict which offers are most appropriate for customers and the probability of their acceptance.

The model can initially be built using a small dataset with randomly made offers and the responses to those offers. As the dataset grows, the model can be updated and therefore becomes more able to predict the most suitable offers for customers and the probability of their acceptance based upon other input fields such as age, gender, job, and income. The offers available can be changed by adding or removing them from within the node dialog box, instead of having to change the target field of the dataset.

When coupled with IBM® SPSS® Collaboration and Deployment Services, you can set up automatic regular updates to the model. This process, without the need for human oversight or action, provides a flexible and low-cost solution for organizations and applications where custom intervention by a data miner is not possible or necessary.

Example. A financial institution wants to achieve more profitable results by matching the offer that is most likely to be accepted to each customer. You can use a self-learning model to identify the characteristics of customers most likely to respond favorably based on previous promotions and to update the model in real time based on the latest customer responses.

- [SLRM Node Fields Options](#)
 - [SLRM Node Model Options](#)
 - [SLRM Node Settings Options](#)
-

SLRM Node Fields Options

Before executing an SLRM node, you must specify both the target and target response fields on the Fields tab of the node.

Target field. Select the target field from the list; for example, a nominal (set) field containing the different products you want to offer to customers.

Note: The target field must have string storage, not numeric.

Target response field. Select the target response field from the list. For example, Accepted or Rejected.

Note: This field must be a Flag. The true value of the flag indicates offer acceptance and the false value indicates offer refusal.

The remaining fields in this dialog box are the standard ones used throughout IBM® SPSS® Modeler. See the topic [Modeling Node Fields Options](#) for more information.

Note: If the source data includes ranges that are to be used as continuous (numeric range) input fields, you must ensure that the metadata includes both the minimum and maximum details for each range.

SLRM Node Model Options

Model name. You can generate the model name automatically based on the target or ID field (or model type in cases where no such field is specified) or specify a custom name.

Use partitioned data. If a partition field is defined, this option ensures that data from only the training partition is used to build the model.

Continue training existing model. By default, a completely new model is created each time a modeling node is executed. If this option is selected, training continues with the last model successfully produced by the node. This makes it possible to update or refresh an existing model without having to access the original data and may result in significantly faster performance since *only* the new or updated records are fed into the stream. Details on the previous model are stored with the modeling node, making it possible to use this option even if the previous model nugget is no longer available in the stream or Models palette.

Target field values By default this is set to Use all, which means that a model will be built that contains every offer associated with the selected target field value. If you want to generate a model that contains only some of the target field's offers, click Specify and use the Add, Edit, and Delete buttons to enter or amend the names of the offers for which you want to build a model. For example, if you chose a target that lists all of the products you supply, you can use this field to limit the offered products to just a few that you enter here.

Model Assessment. The fields in this panel are independent from the model in that they don't affect the scoring. Instead they enable you to create a visual representation of how well the model will predict results.

Note: To display the model assessment results in the model nugget you must also select the Display model evaluation box.

- **Include model assessment.** Select this box to create graphs that show the model's predicted accuracy for each selected offer.
- **Set random seed.** When estimating the accuracy of a model based on a random percentage, this option allows you to duplicate the same results in another session. By specifying the starting value used by the random number generator, you can ensure the same records are

assigned each time the node is executed. Enter the desired seed value. If this option is not selected, a different sample will be generated each time the node is executed.

- **Simulated sample size.** Specify the number of records to be used in the sample when assessing the model. The default is 100.
- **Number of iterations.** This enables you to stop building the model assessment after the number of iterations specified. Specify the maximum number of iterations; the default is 20.

Note: Bear in mind that large sample sizes and high numbers of iterations will increase the amount of time it takes to build the model.

Display model evaluation. Select this option to display a graphical representation of the results in the model nugget.

-

SLRM Node Settings Options

The node settings options allow you to fine-tune the model-building process.

Maximum number of predictions per record. This option allows you to limit the number of predictions made for each record in the dataset. The default is 3.

For example, you may have six offers (such as savings, mortgage, car loan, pension, credit card, and insurance), but you only want to know the best two to recommend; in this case you would set this field to 2. When you build the model and attach it to a table, you would see two prediction columns (and the associated confidence in the probability of the offer being accepted) per record. The predictions could be made up of any of the six possible offers.

Level of randomization. To prevent any bias—for example, in a small or incomplete dataset—and treat all potential offers equally, you can add a level of randomization to the selection of offers and the probability of their being included as recommended offers. Randomization is expressed as a percentage, shown as decimal values between 0.0 (no randomization) and 1.0 (completely random). The default is 0.0.

Set random seed. When adding a level of randomization to selection of an offer, this option allows you to duplicate the same results in another session. By specifying the starting value used by the random number generator, you can ensure the same records are assigned each time the node is executed. Enter the desired seed value. If this option is not selected, a different sample will be generated each time the node is executed.

Note: When using the Set random seed option with records read from a database, a Sort node may be required prior to sampling in order to ensure the same result each time the node is executed. This is because the random seed depends on the order of records, which is not guaranteed to stay the same in a relational database.

Sort order. Select the order in which offers are to be displayed in the built model:

- Descending. The model displays offers with the highest scores first. These are the offers that have the greatest probability of being accepted.
- Ascending. The model displays offers with the lowest scores first. These are the offers that have the greatest probability of being rejected. For example, this may be useful when deciding which customers to remove from a marketing campaign for a specific offer.

Preferences for target fields. When building a model, there may be certain aspects of the data that you want to actively promote or remove. For example, if building a model that selects the best financial offer to promote to a customer, you may want to ensure that one particular offer is always included regardless of how well it scores against each customer.

To include an offer in this panel and edit its preferences, click Add, type the offer's name (for example, Savings or Mortgage), and click OK.

- Value. This shows the name of the offer that you added.
- Preference. Specify the level of preference to be applied to the offer. Preference is expressed as a percentage, shown as decimal values between 0.0 (not preferred) and 1.0 (most preferred). The default is 0.0.
- Always include. To ensure that a specific offer is always included in the predictions, select this box.
Note: If the Preference is set to 0.0, the Always include setting is ignored.

Take account of model reliability. A well-structured, data-rich model that has been fine-tuned through several regenerations should always produce more accurate results compared to a brand new model with little data. To take advantage of the more mature model's increased reliability, select this box.

-

SLRM Model Nuggets

Note: Results are only shown on this tab if you select both Include model assessment and Display model evaluation on the Model options tab.

When you run a stream containing an SLRM model, the node estimates the accuracy of the predictions for each target field value (offer) and the importance of each predictor used.

Note: If you selected Continue training existing model on the modeling node Model tab, the information shown on the model nugget is updated each time you regenerate the model.

For models built using IBM® SPSS® Modeler 12.0 or later, the model nugget Model tab is divided into two columns:

Left column.

- **View.** When you have more than one offer, select the one for which you want to display results.
- **Model Performance.** This shows the estimated model accuracy of each offer. The test set is generated through simulation.

Right column.

- **View.** Select whether you want to display Association with Response or Variable Importance details.
- **Association with Response.** Displays the association (correlation) of each predictor with the target variable.
- **Predictor Importance.** Indicates the relative importance of each predictor in estimating the model. Typically you will want to focus your modeling efforts on the predictors that matter most and consider dropping or ignoring those that matter least. This chart can be interpreted in the same manner as for other models that display predictor importance, though in the case of SLRM the graph is generated through simulation by the SLRM algorithm. This is done by removing each predictor in turn from the model and seeing how this affects the model's accuracy. See the topic [Predictor Importance](#) for more information.

SLRM Model Settings

The Settings tab for a SLRM model nugget specifies options for modifying the built model. For example, you may use the SLRM node to build several different models using the same data and settings, then use this tab in each model to slightly modify the settings to see how that affects the results.

Note: This tab is only available after the model nugget has been added to a stream.

Maximum number of predictions per record. This option allows you to limit the number of predictions made for each record in the dataset. The default is 3.

For example, you may have six offers (such as savings, mortgage, car loan, pension, credit card, and insurance), but you only want to know the best two to recommend; in this case you would set this field to 2. When you build the model and attach it to a table, you would see two prediction columns (and the associated confidence in the probability of the offer being accepted) per record. The predictions could be made up of any of the six possible offers.

Level of randomization. To prevent any bias—for example, in a small or incomplete dataset—and treat all potential offers equally, you can add a level of randomization to the selection of offers and the probability of their being included as recommended offers. Randomization is expressed as a percentage, shown as decimal values between 0.0 (no randomization) and 1.0 (completely random). The default is 0.0.

Set random seed. When adding a level of randomization to selection of an offer, this option allows you to duplicate the same results in another session. By specifying the starting value used by the random number generator, you can ensure the same records are assigned each time the node is executed. Enter the desired seed value. If this option is not selected, a different sample will be generated each time the node is executed.

Note: When using the Set random seed option with records read from a database, a Sort node may be required prior to sampling in order to ensure the same result each time the node is executed. This is because the random seed depends on the order of records, which is not

guaranteed to stay the same in a relational database.

Sort order. Select the order in which offers are to be displayed in the built model:

- Descending. The model displays offers with the highest scores first. These are the offers that have the greatest probability of being accepted.
- Ascending. The model displays offers with the lowest scores first. These are the offers that have the greatest probability of being rejected. For example, this may be useful when deciding which customers to remove from a marketing campaign for a specific offer.

Preferences for target fields. When building a model, there may be certain aspects of the data that you want to actively promote or remove. For example, if building a model that selects the best financial offer to promote to a customer, you may want to ensure that one particular offer is always included regardless of how well it scores against each customer.

To include an offer in this panel and edit its preferences, click Add, type the offer's name (for example, Savings or Mortgage), and click OK.

- Value. This shows the name of the offer that you added.
- Preference. Specify the level of preference to be applied to the offer. Preference is expressed as a percentage, shown as decimal values between 0.0 (not preferred) and 1.0 (most preferred). The default is 0.0.
- Always include. To ensure that a specific offer is always included in the predictions, select this box.
Note: If the Preference is set to 0.0, the Always include setting is ignored.

Take account of model reliability. A well-structured, data-rich model that has been fine-tuned through several regenerations should always produce more accurate results compared to a brand new model with little data. To take advantage of the more mature model's increased reliability, select this box.

Generate SQL for this model When using data from a database, SQL code can be pushed back to the database for execution, providing superior performance for many operations.

Select one of the following options to specify how SQL generation is performed.

- Default: Score using Server Scoring Adapter (if installed) otherwise in process If connected to a database with a scoring adapter installed, generates SQL using the scoring adapter and associated user defined functions (UDF) and scores your model within the database. When no scoring adapter is available, this option fetches your data back from the database and scores it in SPSS® Modeler.
- Score outside of the Database If selected, this option fetches your data back from the database and scores it in SPSS Modeler.

- [LSVM Node](#)
- [LSVM Model Nugget \(interactive output\)](#)

About SVM

Support Vector Machine (SVM) is a robust classification and regression technique that maximizes the predictive accuracy of a model without overfitting the training data. SVM is particularly suited to analyzing data with very large numbers (for example, thousands) of predictor fields.

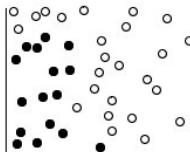

SVM has applications in many disciplines, including customer relationship management (CRM), facial and other image recognition, bioinformatics, text mining concept extraction, intrusion detection, protein structure prediction, and voice and speech recognition.

How SVM Works

SVM works by mapping data to a high-dimensional feature space so that data points can be categorized, even when the data are not otherwise linearly separable. A separator between the categories is found, then the data are transformed in such a way that the separator could be drawn as a hyperplane. Following this, characteristics of new data can be used to predict the group to which a new record should belong.

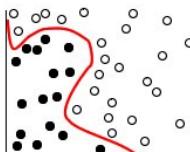

For example, consider the following figure, in which the data points fall into two different categories.

Figure 1. Original dataset

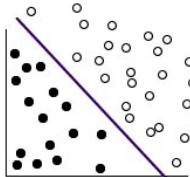

The two categories can be separated with a curve, as shown in the following figure.

Figure 2. Data with separator added

After the transformation, the boundary between the two categories can be defined by a hyperplane, as shown in the following figure.

Figure 3. Transformed data

The mathematical function used for the transformation is known as the **kernel** function. SVM in IBM® SPSS® Modeler supports the following kernel types:

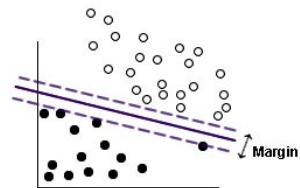

- Linear
- Polynomial
- Radial basis function (RBF)
- Sigmoid

A linear kernel function is recommended when linear separation of the data is straightforward. In other cases, one of the other functions should be used. You will need to experiment with the different functions to obtain the best model in each case, as they each use different algorithms and parameters.

Tuning an SVM Model

Besides the separating line between the categories, a classification SVM model also finds marginal lines that define the space between the two categories.

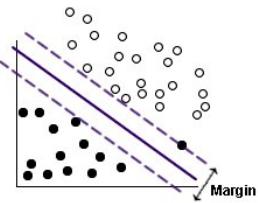

Figure 1. Data with a preliminary model

The data points that lie on the margins are known as the **support vectors**.

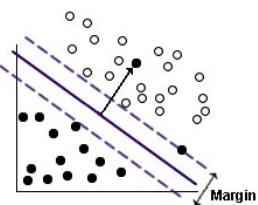

The wider the margin between the two categories, the better the model will be at predicting the category for new records. In the previous example, the margin is not very wide, and the model is said to be **overfitted**. A small amount of misclassification can be accepted in order to widen the margin; an example of this is shown in the following figure.

Figure 2. Data with an improved model

In some cases, linear separation is more difficult; an example of this is shown in the following figure.

Figure 3. A problem for linear separation

In a case like this, the goal is to find the optimum balance between a wide margin and a small number of misclassified data points. The kernel function has a **regularization parameter** (known as C) which controls the trade-off between these two values. You will probably need to experiment with different values of this and other kernel parameters in order to find the best model.

SVM node

The SVM node enables you to use a support vector machine to classify data. SVM is particularly suited for use with wide datasets, that is, those with a large number of predictor fields. You can use the default settings on the node to produce a basic model relatively quickly, or you can use the Expert settings to experiment with different types of SVM model.

When the model has been built, you can:

- Browse the model nugget to display the relative importance of the input fields in building the model.
- Append a Table node to the model nugget to view the model output.

Example. A medical researcher has obtained a dataset containing characteristics of a number of human cell samples extracted from patients who were believed to be at risk of developing cancer. Analysis of the original data showed that many of the characteristics differed significantly between benign and malignant samples. The researcher wants to develop an SVM model that can use the values of similar cell characteristics in samples from other patients to give an early indication of whether their samples might be benign or malignant.

- [SVM Node Model Options](#)
- [SVM Node Expert Options](#)

SVM Node Model Options

Model name. You can generate the model name automatically based on the target or ID field (or model type in cases where no such field is specified) or specify a custom name.

Use partitioned data. If a partition field is defined, this option ensures that data from only the training partition is used to build the model.

Create split models. Builds a separate model for each possible value of input fields that are specified as split fields. See [Building Split Models](#) for more information.

SVM Node Expert Options

If you have detailed knowledge of support vector machines, expert options allow you to fine-tune the training process. To access the expert options, set Mode to Expert on the Expert tab.

Append all probabilities (valid only for categorical targets). If selected (checked), specifies that probabilities for each possible value of a nominal or flag target field are displayed for each record processed by the node. If this option is not selected, the probability of only the predicted value is displayed for nominal or flag target fields. The setting of this check box determines the default state of the corresponding check box on the model nugget display.

Stopping criteria. Determines when to stop the optimization algorithm. Values range from 1.0E-1 to 1.0E-6; default is 1.0E-3. Reducing the value results in a more accurate model, but the model will take longer to train.

Regularization parameter (C). Controls the trade-off between maximizing the margin and minimizing the training error term. Value should normally be between 1 and 10 inclusive; default is 10. Increasing the value improves the classification accuracy (or reduces the regression error) for the training data, but this can also lead to overfitting.

Regression precision (epsilon). Used only if the measurement level of the target field is *Continuous*. Causes errors to be accepted provided that they are less than the value specified here. Increasing the value may result in faster modeling, but at the expense of accuracy.

Kernel type. Determines the type of kernel function used for the transformation. Different kernel types cause the separator to be calculated in different ways, so it is advisable to experiment with the various options. Default is RBF (Radial Basis Function).

RBF gamma. Enabled only if the kernel type is set to RBF. Value should normally be between $3/k$ and $6/k$, where k is the number of input fields. For example, if there are 12 input fields, values between 0.25 and 0.5 would be worth trying. Increasing the value improves the classification accuracy (or reduces the regression error) for the training data, but this can also lead to overfitting.

Gamma. Enabled only if the kernel type is set to Polynomial or Sigmoid. Increasing the value improves the classification accuracy (or reduces the regression error) for the training data, but this can also lead to overfitting.

Bias. Enabled only if the kernel type is set to Polynomial or Sigmoid. Sets the `coef0` value in the kernel function. The default value 0 is suitable in most cases.

Degree. Enabled only if Kernel type is set to Polynomial. Controls the complexity (dimension) of the mapping space. Normally you would not use a value greater than 10.

SVM Model Nugget

The SVM model creates a number of new fields. The most important of these is the `$S-fieldname` field, which shows the target field value predicted by the model.

The number and names of the new fields created by the model depend on the measurement level of the target field (this field is indicated in the following tables by *fieldname*).

To see these fields and their values, add a Table node to the SVM model nugget and execute the Table node.

Table 1. Target field measurement level is 'Nominal' or 'Flag'

New field name	Description
<code>\$S-fieldname</code>	Predicted value of target field.
<code>\$SP-fieldname</code>	Probability of predicted value.
<code>\$SP-value</code>	Probability of each possible value of nominal or flag (displayed only if Append all probabilities is checked on the Settings tab of the model nugget).
<code>\$SRP-value</code>	(Flag targets only) Raw (SRP) and adjusted (SAP) propensity scores, indicating the likelihood of a "true" outcome for the target field. These scores are displayed only if the corresponding check boxes are selected on the Analyze tab of the SVM modeling node before the model is generated. See the topic Modeling Node Analyze Options for more information.
<code>\$SAP-value</code>	

Table 2. Target field measurement level is
'Continuous'

New field name	Description
<code>\$S-fieldname</code>	Predicted value of target field.

Predictor Importance

Optionally, a chart that indicates the relative importance of each predictor in estimating the model may also be displayed on the Model tab. Typically you will want to focus your modeling efforts on the predictors that matter most and consider dropping or ignoring those that matter least. Note this chart is only available if Calculate predictor importance is selected on the Analyze tab before generating the model. See the topic [Predictor Importance](#) for more information.

Note: Predictor importance may take longer to calculate for SVM than for other types of models, and is not selected on the Analyze tab by default. Selecting this option may slow performance, particularly with large datasets.

- [SVM Model Settings](#)

SVM Model Settings

The Settings tab enables you to specify extra fields to be displayed when viewing the results (for example by executing a Table node attached to the nugget). You can see the effect of each of these options by selecting them and clicking the Preview button--scroll to the right of the Preview output to see the extra fields.

Append all probabilities (valid only for categorical targets). If this option is checked, probabilities for each possible value of a nominal or flag target field are displayed for each record processed by the node. If this option is unchecked, only the predicted value and its probability are displayed for nominal or flag target fields.

The default setting of this check box is determined by the corresponding check box on the modeling node.

Calculate raw propensity scores. For models with a flag target (which return a yes or no prediction), you can request propensity scores that indicate the likelihood of the true outcome specified for the target field. These are in addition to other prediction and confidence values that may be generated during scoring.

Calculate adjusted propensity scores. Raw propensity scores are based only on the training data and may be overly optimistic due to the tendency of many models to overfit this data. Adjusted propensities attempt to compensate by evaluating model performance against a test or validation partition. This option requires that a partition field be defined in the stream and adjusted propensity scores be enabled in the modeling node before generating the model.

Generate SQL for this model When using data from a database, SQL code can be pushed back to the database for execution, providing superior performance for many operations.

Select one of the following options to specify how SQL generation is performed.

- Default: Score using Server Scoring Adapter (if installed) otherwise in process If connected to a database with a scoring adapter installed, generates SQL using the scoring adapter and associated user defined functions (UDF) and scores your model within the database. When no scoring adapter is available, this option fetches your data back from the database and scores it in SPSS® Modeler.
- Score outside of the Database If selected, this option fetches your data back from the database and scores it in SPSS Modeler.

LSVM Node

The LSVM node enables you to use a linear support vector machine to classify data. LSVM is particularly suited for use with wide datasets, that is, those with a large number of predictor fields. You can use the default settings on the node to produce a basic model relatively quickly, or you can use the build options to experiment with different settings.

The LSVM node is similar to the SVM node, but it is linear and is better at handling a large number of records.

When the model has been built, you can:

- Browse the model nugget to display the relative importance of the input fields in building the model.
- Append a Table node to the model nugget to view the model output.

Example. A medical researcher has obtained a dataset containing characteristics of a number of human cell samples extracted from patients who were believed to be at risk of developing cancer. Analysis of the original data showed that many of the characteristics differed significantly between benign and malignant samples. The researcher wants to develop an LSVM model that can use the values of similar cell characteristics in samples from other patients to give an early indication of whether their samples might be benign or malignant.

-

LSVM Node Model Options

Model name. You can generate the model name automatically based on the target or ID field (or model type in cases where no such field is specified) or specify a custom name.

Calculate predictor importance. For models that produce an appropriate measure of importance, you can display a chart that indicates the relative importance of each predictor in estimating the model. Typically you will want to focus your modeling efforts on the predictors that matter most, and consider dropping or ignoring those that matter least. Note that predictor importance may take longer to calculate for some models, particularly when working with large datasets, and is off by default for some models as a result. Predictor importance is not available for decision list models. See [Predictor Importance](#) for more information.

LSVM Build Options

Model Settings

Include intercept. Including the intercept (the constant term in the model) can increase the overall accuracy of the solution. If you can assume the data passes through the origin, you can exclude the intercept.

Sorting order for categorical target. Specifies the sorting order for the categorical target. This setting is ignored for continuous targets.

Regression precision (epsilon). Used only if the measurement level of the target field is *Continuous*. Causes errors to be accepted provided that they are less than the value specified here. Increasing the value may result in faster modeling, but at the expense of accuracy.

Exclude records with any missing values. When set to True, a record is excluded if any single value is missing.

Penalty Settings

Penalty function. Specifies the type of penalty function that is used to reduce the likelihood of overfitting. The options are either L1 or L2.

L1 and L2 reduce the chance of overfitting by adding a penalty on the coefficients. The difference between them is that when there is a large number of features, L1 uses feature selection by setting some coefficients to 0 during model building. L2 does not have this ability so should not be used when you have a large number of features.

Penalty parameter (lambda). Specifies the penalty (regularization) parameter. This setting is enabled if the Penalty function is set.

 - [Tuning an SVM Model](#)
-

LSVM Model Nugget (interactive output)

After running an LSVM model, the following output is available.

Model Information

The Model Information view provides key information about the model. The table identifies some high-level model settings, such as:

- The name of the target specified on the Fields tab
- The model building method specified on the [Model Selection](#) settings

- The number of predictors input
- The number of predictors in the final model
- The regularization type (L1 or L2)
- The penalty parameter (lambda). This is the regularization parameter.
- The regression precision (epsilon). Errors are accepted if they are less than this value. A higher value may result in faster modeling, but at the expense of accuracy. It is only used only if the measurement level of the target field is *Continuous*.
- The classification accuracy percentage. This is only applicable for Classification.
- The average squared error. This is only applicable for Regression.

Records Summary

The Records Summary view provides information about the number and percentage of records (cases) included and excluded from the model.

Predictor Importance

Typically, you will want to focus your modeling efforts on the predictor fields that matter most and consider dropping or ignoring those that matter least. The predictor importance chart helps you do this by indicating the relative importance of each predictor in estimating the model. Since the values are relative, the sum of the values for all predictors on the display is 1.0. Predictor importance does not relate to model accuracy. It just relates to the importance of each predictor in making a prediction, not whether or not the prediction is accurate.

Predicted by Observed

This displays a binned scatterplot of the predicted values on the vertical axis by the observed values on the horizontal axis. Ideally, the points should lie on a 45-degree line; this view can tell you whether any records are predicted particularly badly by the model.

Note: Predictor importance may take longer to calculate for LSVM and SVM than for other types of models. Selecting this option may slow performance, particularly with large datasets.

Confusion Matrix

The confusion matrix, sometimes referred to as the summary table, shows the number of cases correctly and incorrectly assigned to each of the groups based on the LSVM analysis.

- [LSVM Model Settings](#)

- [LSVM Model Settings](#)

LSVM Model Settings

On the Settings tab for an SVLM model nugget, you specify options for raw propensity and for SQL generation during model scoring. This tab is available only after the model nugget is added to a stream.

Calculate raw propensity scores For models with flag targets only, you can request raw propensity scores that indicate the likelihood of the true outcome specified for the target field. These are in addition to standard prediction and confidence values. Adjusted propensity scores are not available.

Generate SQL for this model When using data from a database, SQL code can be pushed back to the database for execution, providing superior performance for many operations.

Select one of the following options to specify how SQL is generated.

- Default: Score using Server Scoring Adapter (if installed) otherwise in process. If connected to a database with a scoring adapter installed, generates SQL using the scoring adapter and associated user defined functions (UDF) and scores your model within the database. When no scoring adapter is available, this option fetches your data back from the database and scores it in SPSS® Modeler.
- Score outside of the Database. If selected, this option fetches your data back from the database and scores it in SPSS Modeler.

Nearest Neighbor Models

- [KNN node](#)
 - [KNN Model Nugget](#)
-

KNN node

Nearest Neighbor Analysis is a method for classifying cases based on their similarity to other cases. In machine learning, it was developed as a way to recognize patterns of data without requiring an exact match to any stored patterns, or cases. Similar cases are near each other and dissimilar cases are distant from each other. Thus, the distance between two cases is a measure of their dissimilarity.

Cases that are near each other are said to be “neighbors.” When a new case (holdout) is presented, its distance from each of the cases in the model is computed. The classifications of the most similar cases – the nearest neighbors – are tallied and the new case is placed into the category that contains the greatest number of nearest neighbors.

You can specify the number of nearest neighbors to examine; this value is called k . The pictures show how a new case would be classified using two different values of k . When $k = 5$, the new case is placed in category 1 because a majority of the nearest neighbors belong to category 1. However, when $k = 9$, the new case is placed in category 0 because a majority of the nearest neighbors belong to category 0.

Nearest neighbor analysis can also be used to compute values for a continuous target. In this situation, the average or median target value of the nearest neighbors is used to obtain the predicted value for the new case.

- [KNN Node Objectives Options](#)
 - [KNN Node Settings](#)
-

KNN Node Objectives Options

The Objectives tab is where you can choose either to build a model that predicts the value of a target field in your input data based on the values of its nearest neighbors, or to simply find which are the nearest neighbors for a particular case of interest.

What type of analysis do you want to perform?

Predict a target field. Choose this option if you want to predict the value of a target field based on the values of its nearest neighbors.

Only identify the nearest neighbors. Choose this option if you only want to see which are the nearest neighbors for a particular input field.

If you choose to identify only the nearest neighbors, the remaining options on this tab relating to accuracy and speed are disabled as they are relevant only for predicting targets.

What is your objective?

When predicting a target field, this group of options lets you decide whether speed, accuracy, or a blend of both, are the most important factors when predicting a target field. Alternatively you can choose to customize settings yourself.

If you choose the Balance, Speed, or Accuracy option, the algorithm preselects the most appropriate combination of settings for that option. Advanced users may wish to override these selections; this can be done on the various panels of the Settings tab.

Balance speed and accuracy. Selects the best number of neighbors within a small range.

Speed. Finds a fixed number of neighbors.

Accuracy. Selects the best number of neighbors within a larger range, and uses predictor importance when calculating distances.

Custom analysis. Choose this option to fine-tune the algorithm on the Settings tab.

Note: The size of the resulting KNN model, unlike most other models, increases linearly with the quantity of training data. If, when trying to build a KNN model, you see an error reporting an “out of memory” error, try increasing the maximum system memory used by IBM® SPSS® Modeler. To do so, choose

Tools > Options > System Options

and enter the new size in the Maximum memory field. Changes made in the System Options dialog do not take effect until you restart IBM SPSS Modeler.

- [Analyze](#)

Model

The Model panel provides options that control how the model is to be built, for example, whether to use partitioning or split models, whether to transform numeric input fields so that they all fall within the same range, and how to manage cases of interest. You can also choose a custom name for the model.

Note: The Use partitioned data and Use case labels can not use the same field.

Model name. You can generate the model name automatically based on the target or ID field (or model type in cases where no such field is specified) or specify a custom name.

Use partitioned data. If a partition field is defined, this option ensures that data from only the training partition is used to build the model.

Create split models. Builds a separate model for each possible value of input fields that are specified as split fields. See [Building Split Models](#) for more information.

To select fields manually... By default, the node uses the partition and split field settings (if any) from the Type node, but you can override those settings here. To activate the Partition and Splits fields, select the Fields tab and choose Use Custom Settings, then return here.

- Partition. This field allows you to specify a field used to partition the data into separate samples for the training, testing, and validation stages of model building. By using one sample to generate the model and a different sample to test it, you can get a good indication of how well the model will generalize to larger datasets that are similar to the current data. If multiple partition fields have been defined by using Type or Partition nodes, a single partition field must be selected on the Fields tab in each modeling node that uses partitioning. (If only one partition is present, it is automatically used whenever partitioning is enabled.) Also note that to apply the selected partition in your analysis, partitioning must also be enabled in the Model Options tab for the node. (Deselecting this option makes it possible to disable partitioning without changing field settings.)
- Splits. For split models, select the split field or fields. This is similar to setting the field role to *Split* in a Type node. You can designate only fields of type Flag, Nominal or Ordinal as split fields. Fields chosen as split fields cannot be used as target, input, partition, frequency or weight fields. See the topic [Building Split Models](#) for more information.

Normalize range inputs. Check this box to normalize the values for continuous input fields. Normalized features have the same range of values, which can improve the performance of the estimation algorithm. Adjusted normalization, $[2*(x-\min)/(max-\min)]-1$, is used. Adjusted normalized values fall between -1 and 1.

Use case labels. Check this box to enable the drop-down list, from where you can choose a field whose values will be used as labels to identify the cases of interest in the predictor space chart, peers chart, and quadrant map in the model viewer. You can choose any field with a measurement level of *Nominal*, *Ordinal*, or *Flag* to use as the labeling field. If you do not choose a field here, records are displayed in the model viewer charts with nearest neighbors being identified by row number in the source data. If you will be manipulating the data at all after building the model, use case labels to avoid having to refer back to the source data each time to identify the cases in the display.

Identify focal record. Check this box to enable the drop-down list, which allows you to mark an input field of particular interest (for flag fields only). If you specify a field here, the points representing that field are initially selected in the model viewer when the model is built. Selecting a focal record here is optional; any point can temporarily become a focal record when selected manually in the model viewer.

Related information

- [KNN node](#)
 - [Neighbors](#)
 - [Feature Selection](#)
 - [Cross-Validation](#)
 - [Analyze](#)
-

Neighbors

The Neighbors panel has a set of options that control how the number of nearest neighbors is calculated.

Number of Nearest Neighbors (k). Specify the number of nearest neighbors for a particular case. Note that using a greater number of neighbors will not necessarily result in a more accurate model.

If the objective is to predict a target, you have two choices:

- **Specify fixed k.** Use this option if you want to specify a fixed number of nearest neighbors to find.
- **Automatically select k.** You can alternatively use the Minimum and Maximum fields to specify a range of values and allow the procedure to choose the "best" number of neighbors within that range. The method for determining the number of nearest neighbors depends upon whether feature selection is requested on the Feature Selection panel:
If feature selection is in effect, then feature selection is performed for each value of k in the requested range, and the k , and accompanying feature set, with the lowest error rate (or the lowest sum-of-squares error if the target is continuous) is selected.

If feature selection is not in effect, then V-fold cross-validation is used to select the "best" number of neighbors. See the Cross-validation panel for control over assignment of folds.

Distance Computation. This is the metric used to specify the distance metric used to measure the similarity of cases.

- **Euclidean metric.** The distance between two cases, x and y , is the square root of the sum, over all dimensions, of the squared differences between the values for the cases.
- **City Block metric.** The distance between two cases is the sum, over all dimensions, of the absolute differences between the values for the cases. Also called Manhattan distance.

Optionally, if the objective is to predict a target, you can choose to weight features by their normalized importance when computing distances. Feature importance for a predictor is calculated by the ratio of the error rate or sum-of-squares error of the model with the predictor removed from the model, to the error rate or sum-of-squares error for the full model. Normalized importance is calculated by reweighting the feature importance values so that they sum to 1.

Weight features by importance when computing distances. (Displayed only if the objective is to predict a target.) Check this box to cause predictor importance to be used when calculating the distances between neighbors. Predictor importance will then be displayed in the model nugget, and used in predictions (and so will affect scoring). See the topic [Predictor Importance](#) for more information.

Predictions for Range Target. (Displayed only if the objective is to predict a target.) If a continuous (numeric range) target is specified, this defines whether the predicted value is computed based upon the mean or the median value of the nearest neighbors.

Related information

- [KNN node](#)
 - [Model](#)
 - [Feature Selection](#)
 - [Cross-Validation](#)
 - [Analyze](#)
-

Feature Selection

This panel is activated only if the objective is to predict a target. It allows you to request and specify options for feature selection. By default, all features are considered for feature selection, but you can optionally select a subset of features to force into the model.

Perform feature selection. Check this box to enable the feature selection options.

- **Forced entry.** Click the field chooser button next to this box and choose one or more features to force into the model.

Stopping Criterion. At each step, the feature whose addition to the model results in the smallest error (computed as the error rate for a categorical target and sum of squares error for a continuous target) is considered for inclusion in the model set. Forward selection continues until the specified condition is met.

- **Stop when the specified number of features have been selected.** The algorithm adds a fixed number of features in addition to those forced into the model. Specify a positive integer. Decreasing values of the number to select creates a more parsimonious model, at the risk of missing important features. Increasing values of the number to select will capture all the important features, at the risk of eventually adding features that actually increase the model error.
- **Stop when the change in the absolute error ratio is less than or equal to the minimum.** The algorithm stops when the change in the absolute error ratio indicates that the model cannot be further improved by adding more features. Specify a positive number. Decreasing values of the minimum change will tend to include more features, at the risk of including features that do not add much value to the model. Increasing the value of the minimum change will tend to exclude more features, at the risk of losing features that are important to the model. The "optimal" value of the minimum change will depend upon your data and application. See the Feature Selection Error Log in the output to help you assess which features are most important. See the topic [Predictor selection error log \(Nearest Neighbor Analysis\)](#) for more information.

Related information

- [KNN node](#)
- [Model](#)
- [Neighbors](#)
- [Cross-Validation](#)
- [Analyze](#)

Cross-Validation

This panel is activated only if the objective is to predict a target. The options on this panel control whether to use cross-validation when calculating the nearest neighbors.

Cross-validation divides the sample into a number of subsamples, or **folds**. Nearest neighbor models are then generated, excluding the data from each subsample in turn. The first model is based on all of the cases except those in the first sample fold, the second model is based on all of the cases except those in the second sample fold, and so on. For each model, the error is estimated by applying the model to the subsample excluded in generating it. The "best" number of nearest neighbors is the one which produces the lowest error across folds.

Cross-Validation Folds. V-fold cross-validation is used to determine the "best" number of neighbors. It is not available in conjunction with feature selection for performance reasons.

- **Randomly assign cases to folds.** Specify the number of folds that should be used for cross-validation. The procedure randomly assigns cases to folds, numbered from 1 to V, the number of folds.
- **Set random seed.** When estimating the accuracy of a model based on a random percentage, this option allows you to duplicate the same results in another session. By specifying the starting value used by the random number generator, you can ensure the same records are assigned each time the node is executed. Enter the desired seed value. If this option is not selected, a different sample will be generated each time the node is executed.
- **Use field to assign cases.** Specify a numeric field that assigns each case in the active dataset to a fold. The field must be numeric and take values from 1 to V. If any values in this range are missing, and on any split fields if split models are in effect, this will cause an error.

Related information

- [KNN node](#)
- [Model](#)
- [Neighbors](#)
- [Feature Selection](#)
- [Analyze](#)

Analyze

The Analyze panel is activated only if the objective is to predict a target. You can use it to specify whether the model is to include additional variables to contain:

- probabilities for each possible target field value
- distances between a case and its nearest neighbors
- raw and adjusted propensity scores (for flag targets only)

Append all probabilities. If this option is checked, probabilities for each possible value of a nominal or flag target field are displayed for each record processed by the node. If this option is unchecked, only the predicted value and its probability are displayed for nominal or flag target fields.

Save distances between cases and k nearest neighbors. For each focal record, a separate variable is created for each of the focal record's k nearest neighbors (from the training sample) and the corresponding k nearest distances.

Propensity Scores

Propensity scores can be enabled in the modeling node, and on the Settings tab in the model nugget. This functionality is available only when the selected target is a flag field. See the topic [Propensity Scores](#) for more information.

Calculate raw propensity scores. Raw propensity scores are derived from the model based on the training data only. If the model predicts the true value (will respond), then the propensity is the same as P , where P is the probability of the prediction. If the model predicts the false value, then the propensity is calculated as $(1 - P)$.

- If you choose this option when building the model, propensity scores will be enabled in the model nugget by default. However, you can always choose to enable raw propensity scores in the model nugget whether or not you select them in the modeling node.
- When scoring the model, raw propensity scores will be added in a field with the letters RP appended to the standard prefix. For example, if the predictions are in a field named $\$R\text{-churn}$, the name of the propensity score field will be $\$RRP\text{-churn}$.

Calculate adjusted propensity scores. Raw propensities are based purely on estimates given by the model, which may be overfitted, leading to over-optimistic estimates of propensity. Adjusted propensities attempt to compensate by looking at how the model performs on the test or validation partitions and adjusting the propensities to give a better estimate accordingly.

- This setting requires that a valid partition field is present in the stream.
- Unlike raw confidence scores, adjusted propensity scores must be calculated when building the model; otherwise, they will not be available when scoring the model nugget.
- When scoring the model, adjusted propensity scores will be added in a field with the letters AP appended to the standard prefix. For example, if the predictions are in a field named $\$R\text{-churn}$, the name of the propensity score field will be $\$RAP\text{-churn}$. Adjusted propensity scores are not available for logistic regression models.
- When calculating the adjusted propensity scores, the test or validation partition used for the calculation must not have been balanced. To avoid this, be sure the Only balance training data option is selected in any upstream Balance nodes. In addition, if a complex sample has been taken upstream this will invalidate the adjusted propensity scores.
- Adjusted propensity scores are not available for "boosted" tree and rule set models. See the topic [Boosted C5.0 Models](#) for more information.

-

Predictor Space (Nearest Neighbor Analysis)

The predictor space chart is an interactive graph of the predictor space (or a subspace, if there are more than 3 predictors). Each axis represents a predictor in the model, and the location of points in the chart show the values of these predictors for cases in the training and holdout partitions.

Keys. In addition to the predictor values, points in the plot convey other information.

- Shape indicates the partition to which a point belongs, either Training or Holdout.
- The color/shading of a point indicates the value of the target for that case; with distinct color values equal to the categories of a categorical target, and shades indicating the range of values of a continuous target. The indicated value for the training partition is the observed value; for the holdout partition, it is the predicted value. If no target is specified, this key is not shown.
- Heavier outlines indicate a case is focal. Focal records are shown linked to their k nearest neighbors.

Controls and Interactivity. A number of controls in the chart allow you explore the predictor space.

- You can choose which subset of predictors to show in the chart and change which predictors are represented on the dimensions.
 - “Focal records” are simply points selected in the Predictor Space chart. If you specified a focal record variable, the points representing the focal records will initially be selected. However, any point can temporarily become a focal record if you select it. The “usual” controls for point selection apply; clicking on a point selects that point and deselects all others; Control-clicking on a point adds it to the set of selected points. Linked views, such as the Peers Chart, will automatically update based upon the cases selected in the Predictor Space.
 - You can change the number of nearest neighbors (k) to display for focal records.
 - Hovering over a point in the chart displays a tooltip with the value of the case label, or case number if case labels are not defined, and the observed and predicted target values.
 - A “Reset” button allows you to return the Predictor Space to its original state.
 - [Changing the axes on the Predictor Space chart](#)
-

Changing the axes on the Predictor Space chart

You can control which features are displayed on the axes of the Predictor Space chart.

To change the axis settings:

1. Click the Edit Mode button (paintbrush icon) in the left-hand panel to select Edit mode for the Predictor Space.

2. Change the view (to anything) on the right-hand panel. The Show zones panel appears between the two main panels.
3. Click the Show zones check box.
4. Click any data point in the Predictor Space.
5. To replace an axis with a predictor of the same data type:
 - Drag the new predictor over the zone label (the one with the small X button) of the one you want to replace.
6. To replace an axis with a predictor of a different data type:
 - On the zone label of the predictor you want to replace, click the small X button. The predictor space changes to a two-dimensional view.
 - Drag the new predictor over the Add dimension zone label.
7. Click the Explore Mode button (arrowhead icon) in the left-hand panel to exit from Edit mode.

Predictor Importance (Nearest Neighbor Analysis)

Typically, you will want to focus your modeling efforts on the predictor fields that matter most and consider dropping or ignoring those that matter least. The predictor importance chart helps you do this by indicating the relative importance of each predictor in estimating the model. Since the values are relative, the sum of the values for all predictors on the display is 1.0. Predictor importance does not relate to model accuracy. It just relates to the importance of each predictor in making a prediction, not whether or not the prediction is accurate.

Nearest Neighbor Distances (Nearest Neighbor Analysis)

This table displays the k nearest neighbors and distances for focal records only. It is available if a focal record identifier is specified on the modeling node, and only displays focal records identified by this variable.

Each row of:

- The Focal Record column contains the value of the case labeling variable for the focal record; if case labels are not defined, this column contains the case number of the focal record.
- The i th column under the Nearest Neighbors group contains the value of the case labeling variable for the i th nearest neighbor of the focal record; if case labels are not defined, this column contains the case number of the i th nearest neighbor of the focal record.
- The i th column under the Nearest Distances group contains the distance of the i th nearest neighbor to the focal record

Peers (Nearest Neighbor Analysis)

This chart displays the focal cases and their k nearest neighbors on each predictor and on the target. It is available if a focal case is selected in the Predictor Space.

The Peers chart is linked to the Predictor Space in two ways.

- Cases selected (focal) in the Predictor Space are displayed in the Peers chart, along with their k nearest neighbors.
- The value of k selected in the Predictor Space is used in the Peers chart.

Select Predictors. Enables you to select the predictors to display in the Peers chart.

Quadrant Map (Nearest Neighbor Analysis)

This chart displays the focal cases and their k nearest neighbors on a scatterplot (or dotplot, depending upon the measurement level of the target) with the target on the y -axis and a scale predictor on the x -axis, paneled by predictors. It is available if there is a target and if a focal case is selected in the Predictor Space.

- Reference lines are drawn for continuous variables, at the variable means in the training partition.

Select Predictors. Enables you to select the predictors to display in the Quadrant Map.

Predictor selection error log (Nearest Neighbor Analysis)

Points on the chart display the error (either the error rate or sum-of-squares error, depending upon the measurement level of the target) on the y -axis for the model with the predictor listed on the x -axis (plus all features to the left on the x -axis). This chart is available if there is a target and

feature selection is in effect.

Classification Table (Nearest Neighbor Analysis)

This table displays the cross-classification of observed versus predicted values of the target, by partition. It is available if there is a target and it is categorical (flag, nominal, or ordinal).

- The (Missing) row in the Holdout partition contains holdout cases with missing values on the target. These cases contribute to the Holdout Sample: Overall Percent values but not to the Percent Correct values.

Error Summary (Nearest Neighbor Analysis)

This table is available if there is a target variable. It displays the error associated with the model; sum-of-squares for a continuous target and the error rate (100% – overall percent correct) for a categorical target.

KNN Model Settings

The Settings tab enables you to specify extra fields to be displayed when viewing the results (for example by executing a Table node attached to the nugget). You can see the effect of each of these options by selecting them and clicking the Preview button--scroll to the right of the Preview output to see the extra fields.

Append all probabilities (valid only for categorical targets). If this option is checked, probabilities for each possible value of a nominal or flag target field are displayed for each record processed by the node. If this option is unchecked, only the predicted value and its probability are displayed for nominal or flag target fields.

The default setting of this check box is determined by the corresponding check box on the modeling node.

Calculate raw propensity scores. For models with a flag target (which return a yes or no prediction), you can request propensity scores that indicate the likelihood of the true outcome specified for the target field. These are in addition to other prediction and confidence values that may be generated during scoring.

Calculate adjusted propensity scores. Raw propensity scores are based only on the training data and may be overly optimistic due to the tendency of many models to overfit this data. Adjusted propensities attempt to compensate by evaluating model performance against a test or validation partition. This option requires that a partition field be defined in the stream and adjusted propensity scores be enabled in the modeling node before generating the model.

Display nearest. If you set this value to n , where n is a non-zero positive integer, the n nearest neighbors to the focal record are included in the model, together with their relative distances from the focal record.

Glossary

A

AICC

A measure for selecting and comparing mixed models based on the -2 (Restricted) log likelihood. Smaller values indicate better models. The AICC "corrects" the AIC for small sample sizes. As the sample size increases, the AICC converges to the AIC.

B

Bayesian Information Criterion (BIC)

A measure for selecting and comparing models based on the -2 log likelihood. Smaller values indicate better models. The BIC also "penalizes" overparameterized models (complex models with a large number of inputs, for example), but more strictly than the AIC.

Box's M test

A test for the equality of the group covariance matrices. For sufficiently large samples, a nonsignificant p value means there is insufficient evidence that the matrices differ. The test is sensitive to departures from multivariate normality.

C

Cases

Codes for actual group, predicted group, posterior probabilities, and discriminant scores are displayed for each case.

Classification Results

The number of cases correctly and incorrectly assigned to each of the groups based on the discriminant analysis. Sometimes called the "Confusion Matrix."

Combined-Groups Plots

Creates an all-groups scatterplot of the first two discriminant function values. If there is only one function, a histogram is displayed instead.

Covariance

An unstandardized measure of association between two variables, equal to the cross-product deviation divided by N-1.

F

Fisher's

Displays Fisher's classification function coefficients that can be used directly for classification. A separate set of classification function coefficients is obtained for each group, and a case is assigned to the group for which it has the largest discriminant score (classification function value).

H

Hazard Plot

Displays the cumulative hazard function on a linear scale.

K

Kurtosis

A measure of the extent to which there are outliers. For a normal distribution, the value of the kurtosis statistic is zero. Positive kurtosis indicates that the data exhibit more extreme outliers than a normal distribution. Negative kurtosis indicates that the data exhibit less extreme outliers than a normal distribution.

L

Leave-one-out Classification

Each case in the analysis is classified by the functions derived from all cases other than that case. It is also known as the "U-method."

M

MAE

Mean absolute error. Measures how much the series varies from its model-predicted level. MAE is reported in the original series units.

Mahalanobis Distance

A measure of how much a case's values on the independent variables differ from the average of all cases. A large Mahalanobis distance identifies a case as having extreme values on one or more of the independent variables.

MAPE

Mean Absolute Percentage Error. A measure of how much a dependent series varies from its model-predicted level. It is independent of the units used and can therefore be used to compare series with different units.

MaxAE

Maximum Absolute Error. The largest forecasted error, expressed in the same units as the dependent series. Like MaxAPE, it is useful for imagining the worst-case scenario for your forecasts. Maximum absolute error and maximum absolute percentage error may occur at different series points--for example, when the absolute error for a large series value is slightly larger than the absolute error for a small series value. In

that case, the maximum absolute error will occur at the larger series value and the maximum absolute percentage error will occur at the smaller series value.

MaxAPE

Maximum Absolute Percentage Error. The largest forecasted error, expressed as a percentage. This measure is useful for imagining a worst-case scenario for your forecasts.

Maximizing the Smallest F Ratio Method of Entry

A method of variable selection in stepwise analysis based on maximizing an F ratio computed from the Mahalanobis distance between groups.

Maximum

The largest value of a numeric variable.

Mean

A measure of central tendency. The arithmetic average, the sum divided by the number of cases.

Means

Displays total and group means, as well as standard deviations for the independent variables.

Median

The value above and below which half of the cases fall, the 50th percentile. If there is an even number of cases, the median is the average of the two middle cases when they are sorted in ascending or descending order. The median is a measure of central tendency not sensitive to outlying values (unlike the mean, which can be affected by a few extremely high or low values).

Minimize Wilks' Lambda

A variable selection method for stepwise discriminant analysis that chooses variables for entry into the equation on the basis of how much they lower Wilks' lambda. At each step, the variable that minimizes the overall Wilks' lambda is entered.

Minimum

The smallest value of a numeric variable.

Mode

The most frequently occurring value. If several values share the greatest frequency of occurrence, each of them is a mode.

N

Normalized BIC

Normalized Bayesian Information Criterion. A general measure of the overall fit of a model that attempts to account for model complexity. It is a score based upon the mean square error and includes a penalty for the number of parameters in the model and the length of the series. The penalty removes the advantage of models with more parameters, making the statistic easy to compare across different models for the same series.

O

One Minus Survival

Plots one-minus the survival function on a linear scale.

R

Range

The difference between the largest and smallest values of a numeric variable, the maximum minus the minimum.

Rao's V (Discriminant Analysis)

A measure of the differences between group means. Also called the Lawley-Hotelling trace. At each step, the variable that maximizes the increase in Rao's V is entered. After selecting this option, enter the minimum value a variable must have to enter the analysis.

RMSE

Root Mean Square Error. The square root of mean square error. A measure of how much a dependent series varies from its model-predicted level, expressed in the same units as the dependent series.

R-Squared

Goodness-of-fit measure of a linear model, sometimes called the coefficient of determination. It is the proportion of variation in the dependent variable explained by the regression model. It ranges in value from 0 to 1. Small values indicate that the model does not fit the data well.

S

Separate-Groups

Separate-groups covariance matrices are used for classification. Because classification is based on the discriminant functions (not based on the original variables), this option is not always equivalent to quadratic discrimination.

Separate-Groups Covariance

Displays separate covariance matrices for each group.

Separate-Groups Plots

Creates separate-group scatterplots of the first two discriminant function values. If there is only one function, histograms are displayed instead.

Sequential Bonferroni

This is a sequentially step-down rejective Bonferroni procedure that is much less conservative in terms of rejecting individual hypotheses but maintains the same overall significance level.

Sequential Sidak

This is a sequentially step-down rejective Sidak procedure that is much less conservative in terms of rejecting individual hypotheses but maintains the same overall significance level.

Skewness

A measure of the asymmetry of a distribution. The normal distribution is symmetric and has a skewness value of 0. A distribution with a significant positive skewness has a long right tail. A distribution with a significant negative skewness has a long left tail. As a guideline, a skewness value more than twice its standard error is taken to indicate a departure from symmetry.

standard deviation

A measure of dispersion around the mean, equal to the square root of the variance. The standard deviation is measured in the same units as the original variable.

Standard Deviation

A measure of dispersion around the mean. In a normal distribution, 68% of cases fall within one standard deviation of the mean and 95% of cases fall within two standard deviations. For example, if the mean age is 45, with a standard deviation of 10, 95% of the cases would be between 25 and 65 in a normal distribution.

Standard Error

A measure of how much the value of a test statistic varies from sample to sample. It is the standard deviation of the sampling distribution for a statistic. For example, the standard error of the mean is the standard deviation of the sample means.

Standard Error of Kurtosis

The ratio of kurtosis to its standard error can be used as a test of normality (that is, you can reject normality if the ratio is less than -2 or greater than +2). A large positive value for kurtosis indicates that the tails of the distribution are longer than those of a normal distribution; a negative value for kurtosis indicates shorter tails (becoming like those of a box-shaped uniform distribution).

Standard Error of Mean

A measure of how much the value of the mean may vary from sample to sample taken from the same distribution. It can be used to roughly compare the observed mean to a hypothesized value (that is, you can conclude the two values are different if the ratio of the difference to the standard error is less than -2 or greater than +2).

Standard Error of Skewness

The ratio of skewness to its standard error can be used as a test of normality (that is, you can reject normality if the ratio is less than -2 or greater than +2). A large positive value for skewness indicates a long right tail; an extreme negative value indicates a long left tail.

Stationary R-squared

A measure that compares the stationary part of the model to a simple mean model. This measure is preferable to ordinary R-squared when there is a trend or seasonal pattern. Stationary R-squared can be negative with a range of negative infinity to 1. Negative values mean that the model under consideration is worse than the baseline model. Positive values mean that the model under consideration is better than the baseline model.

Sum

The sum or total of the values, across all cases with nonmissing values.

Survival Plot

Displays the cumulative survival function on a linear scale.

T

Territorial Map

A plot of the boundaries used to classify cases into groups based on function values. The numbers correspond to groups into which cases are classified. The mean for each group is indicated by an asterisk within its boundaries. The map is not displayed if there is only one discriminant function.

Total Covariance

Displays a covariance matrix from all cases as if they were from a single sample.

U

Unexplained Variance

At each step, the variable that minimizes the sum of the unexplained variation between groups is entered.

Unique

Evaluates all effects simultaneously, adjusting each effect for all other effects of any type.

Univariate ANOVAs

Performs a one-way analysis-of-variance test for equality of group means for each independent variable.

Unstandardized

Displays the unstandardized discriminant function coefficients.

Use F Value

A variable is entered into the model if its F value is greater than the Entry value and is removed if the F value is less than the Removal value. Entry must be greater than Removal, and both values must be positive. To enter more variables into the model, lower the Entry value. To remove more variables from the model, increase the Removal value.

Use Probability of F

A variable is entered into the model if the significance level of its F value is less than the Entry value and is removed if the significance level is greater than the Removal value. Entry must be less than Removal, and both values must be positive. To enter more variables into the model, increase the Entry value. To remove more variables from the model, lower the Removal value.

V

Valid

Valid cases having neither the system-missing value, nor a value defined as user-missing.

Variance

A measure of dispersion around the mean, equal to the sum of squared deviations from the mean divided by one less than the number of cases. The variance is measured in units that are the square of those of the variable itself.

W

Within-Groups

The pooled within-groups covariance matrix is used to classify cases.

Within-Groups Correlation

Displays a pooled within-groups correlation matrix that is obtained by averaging the separate covariance matrices for all groups before computing the correlations.

Within-Groups Covariance

Displays a pooled within-groups covariance matrix, which may differ from the total covariance matrix. The matrix is obtained by averaging the separate covariance matrices for all groups.

Python nodes

SPSS® Modeler offers nodes for using Python native algorithms. The Python tab on the [Nodes Palette](#) contains the following nodes you can use to run Python algorithms. These nodes are supported on Windows 64, Linux64, and Mac.

	The Synthetic Minority Over-sampling Technique (SMOTE) node provides an over-sampling algorithm to deal with imbalanced data sets. It provides an advanced method for balancing data. The SMOTE process node in SPSS Modeler is implemented in Python and requires the imbalanced-learn® Python library.
	XGBoost Linear® is an advanced implementation of a gradient boosting algorithm with a linear model as the base model. Boosting algorithms iteratively learn weak classifiers and then add them to a final strong classifier. The XGBoost Linear node in SPSS Modeler is implemented in Python.
	XGBoost Tree® is an advanced implementation of a gradient boosting algorithm with a tree model as the base model. Boosting algorithms iteratively learn weak classifiers and then add them to a final strong classifier. XGBoost Tree is very flexible and provides many parameters that can be overwhelming to most users, so the XGBoost Tree node in SPSS Modeler exposes the core features and commonly used parameters. The node is implemented in Python.
	t-Distributed Stochastic Neighbor Embedding (t-SNE) is a tool for visualizing high-dimensional data. It converts affinities of data points to probabilities. This t-SNE node in SPSS Modeler is implemented in Python and requires the scikit-learn® Python library.
	A Gaussian Mixture® model is a probabilistic model that assumes all the data points are generated from a mixture of a finite number of Gaussian distributions with unknown parameters. One can think of mixture models as generalizing k-means clustering to incorporate information about the covariance structure of the data as well as the centers of the latent Gaussians. The Gaussian Mixture node in SPSS Modeler exposes the core features and commonly used parameters of the Gaussian Mixture library. The node is implemented in Python.
	Kernel Density Estimation (KDE)® uses the Ball Tree or KD Tree algorithms for efficient queries, and combines concepts from unsupervised learning, feature engineering, and data modeling. Neighbor-based approaches such as KDE are some of the most popular and useful density estimation techniques. The KDE Modeling and KDE Simulation nodes in SPSS Modeler expose the core features and commonly used parameters of the KDE library. The nodes are implemented in Python.
	The Random Forest node uses an advanced implementation of a bagging algorithm with a tree model as the base model. This Random Forest modeling node in SPSS Modeler is implemented in Python and requires the scikit-learn® Python library.
	Hierarchical Density-Based Spatial Clustering (HDBSCAN)® uses unsupervised learning to find clusters, or dense regions, of a data set. The HDBSCAN node in SPSS Modeler exposes the core features and commonly used parameters of the HDBSCAN library. The node is implemented in Python, and you can use it to cluster your dataset into distinct groups when you don't know what those groups are at first.
	The One-Class SVM node uses an unsupervised learning algorithm. The node can be used for novelty detection. It will detect the soft boundary of a given set of samples, to then classify new points as belonging to that set or not. This One-Class SVM modeling node in SPSS Modeler is implemented in Python and requires the scikit-learn® Python library.

SMOTE node

The Synthetic Minority Over-sampling Technique (SMOTE) node provides an over-sampling algorithm to deal with imbalanced data sets. It provides an advanced method for balancing data. The SMOTE process node in SPSS Modeler is implemented in Python and requires the imbalanced-learn®

Python library. For details about the imbalanced-learn library, see <https://imbalanced-learn.org/stable/>¹.

The Python tab on the Nodes Palette contains the SMOTE node and other Python nodes.

¹Lemaître, Nogueira, Aridas. "Imbalanced-learn: A Python Toolbox to Tackle the Curse of Imbalanced Datasets in Machine Learning." *Journal of Machine Learning Research*, vol. 18, no. 17, 2017, pp. 1-5. (<http://jmlr.org/papers/v18/16-365.html>)

- [SMOTE node Settings](#)
- [SMOTE node Settings](#)

SMOTE node Settings

Define the following settings on the SMOTE node's Settings tab.

Target Setting

Target Field. Select the target field. All flag, nominal, ordinal, and discrete measurement types are supported. If the Use partitioned data option is selected in the Partition section, only training data will be over-sampled.

Over Sample Ratio

Select Auto to automatically select an over-sample ratio, or select Set Ratio (minority over majority) to set a custom ratio value. The ratio is the number of samples in the minority class over the number of samples in the majority class. The value must be greater than 0 and less than or equal to 1.

Random Seed

Set random seed. Select this option and click Generate to generate the seed used by the random number generator.

Methods

Algorithm Kind. Select the type of SMOTE algorithm you wish to use.

Samples Rules

K Neighbours. Specify the number of the nearest neighbors to use for constructing synthetic samples

M Neighbours. Specify the number of nearest neighbors to use for determining if a minority sample is in danger. This will only be used if the Borderline1 or Borderline2 SMOTE algorithm type is selected.

Partition

Use partitioned data. Select this option if you only want training data to be over-sampled.

The SMOTE node requires the imbalanced-learn® Python library. The following table shows the relationship between the settings in the SPSS® Modeler SMOTE node dialog and the Python algorithm.

Table 1. Node properties mapped to Python library parameters

SPSS Modeler setting	Script name (property name)	Python API parameter name
Over sample ratio (number input control)	sample_ratio_value	ratio
Random seed	random_seed	random_state
K_Neighbours	k_neighbours	k
M_Neighbours	m_neighbours	m
Algorithm kind	algorithm_kind	kind

XGBoost Linear node

XGBoost Linear® is an advanced implementation of a gradient boosting algorithm with a linear model as the base model. Boosting algorithms iteratively learn weak classifiers and then add them to a final strong classifier. The XGBoost Linear node in SPSS® Modeler is implemented in Python.

For more information about boosting algorithms, see the XGBoost Tutorials available at <http://xgboost.readthedocs.io/en/latest/tutorials/index.html>.¹

Note that the XGBoost cross-validation function is not supported in SPSS Modeler. You can use the SPSS Modeler Partition node for this functionality. Also note that XGBoost in SPSS Modeler performs one-hot encoding automatically for categorical variables.

 - [XGBoost Linear node Build Options](#)
 - [XGBoost Linear node Model Options](#)
-

XGBoost Linear node Fields

The Fields tab specifies which fields are used in the analysis.

Use predefined roles. This option uses the role settings (targets, predictors and so on) from an upstream Type node (or the Types tab of an upstream source node).

Use custom field assignments. To manually assign a target and predictors, select this option.

Fields. Use the arrow buttons to assign items manually from this list to the Target and Predictors role fields on the right of the screen. The icons indicate the valid measurement levels for each role field. To select all the fields in the list, click the All button, or click an individual measurement level button to select all fields with that measurement level.

Target. Select a field to use as the target for the prediction.

Predictors. Select one or more fields as inputs for the prediction.

XGBoost Linear node Build Options

Use the Build Options tab to specify build options for the XGBoost Linear node, including basic options such as linear boost parameters and model building, and learning task options for objectives. For additional information about these options, see the following online resources:

- [XGBoost Parameter Reference](#)¹
- [XGBoost Python API](#)²
- [XGBoost Home Page](#)³

Basic

Hyper-Parameter Optimization (Based on Rbfopt). Select this option to enable Hyper-Parameter Optimization based on Rbfopt, which automatically discovers the optimal combination of parameters so that the model will achieve the expected or lower error rate on the samples. For details about Rbfopt, see http://rbfopt.readthedocs.io/en/latest/rbfopt_settings.html.

Alpha. L1 regularization term on weights. Increasing this value will make model more conservative.

Lambda. L2 regularization term on weights. Increasing this value will make the model more conservative.

Lambda bias. L2 regularization term on bias. (There is no L1 regularization term on bias because it is not important.)

Number boost round. The number of boosting iterations.

Learning Task

Objective. Select from the following learning task objective types: reg:linear, reg:logistic, reg:gamma, reg:tweedie, count:poisson, rank:pairwise, binary:logistic, or multi.

Random Seed. You can click Generate to generate the seed used by the random number generator.

The following table shows the relationship between the settings in the SPSS® Modeler XGBoost Linear node dialog and the Python XGBoost library parameters.

Table 1. Node properties mapped to Python library parameters

SPSS Modeler setting	Script name (property name)	XGBoost parameter
Target	TargetField	

SPSS Modeler setting	Script name (property name)	XGBoost parameter
Predictors	InputFields	
Lambda	lambda	lambda
Alpha	alpha	alpha
Lambda bias	lambdaBias	lambda_bias
Num boost round	numBoostRound	num_boost_round
Objective	objectiveType	objective
Random Seed	random_seed	seed

³ "Scalable and Flexible Gradient Boosting." Web. © 2015-2016 DMLC.

XGBoost Linear node Model Options

Model name. You can generate the model name automatically based on the target or ID field (or model type in cases where no such field is specified) or specify a custom name.

XGBoost Tree node

XGBoost Tree[©] is an advanced implementation of a gradient boosting algorithm with a tree model as the base model. Boosting algorithms iteratively learn weak classifiers and then add them to a final strong classifier. XGBoost Tree is very flexible and provides many parameters that can be overwhelming to most users, so the XGBoost Tree node in SPSS® Modeler exposes the core features and commonly used parameters. The node is implemented in Python.

For more information about boosting algorithms, see the XGBoost Tutorials available at

<http://xgboost.readthedocs.io/en/latest/tutorials/index.html>.¹

Note that the XGBoost cross-validation function is not supported in SPSS Modeler. You can use the SPSS Modeler Partition node for this functionality. Also note that XGBoost in SPSS Modeler performs one-hot encoding automatically for categorical variables.

- [XGBoost Tree node Fields](#)
- [XGBoost Tree node Build Options](#)
- [XGBoost Tree node Model Options](#)

XGBoost Tree node Fields

The Fields tab specifies which fields are used in the analysis.

Use predefined roles. This option uses the role settings (targets, predictors and so on) from an upstream Type node (or the Types tab of an upstream source node).

Use custom field assignments. To manually assign a target and predictors, select this option.

Fields. Use the arrow buttons to assign items manually from this list to the Target and Predictors role fields on the right of the screen. The icons indicate the valid measurement levels for each role field. To select all the fields in the list, click the All button, or click an individual measurement level button to select all fields with that measurement level.

Target. Select a field to use as the target for the prediction.

Predictors. Select one or more fields as inputs for the prediction.

XGBoost Tree node Build Options

Use the Build Options tab to specify build options for the XGBoost Tree node, including basic options for model building and tree growth, learning task options for objectives, and advanced options for control overfitting and handling of imbalanced datasets. For additional information about these options, see the following online resources:

- [XGBoost Parameter Reference](#)¹
- [XGBoost Python API](#)²
- [XGBoost Home Page](#)³

Basic

Hyper-Parameter Optimization (Based on Rbfopt). Select this option to enable Hyper-Parameter Optimization based on Rbfopt, which automatically discovers the optimal combination of parameters so that the model will achieve the expected or lower error rate on the samples. For details about Rbfopt, see http://rbfopt.readthedocs.io/en/latest/rbfopt_settings.html.

Tree method. Select the XGBoost tree construction algorithm to use.

Num boost round. Specify the number of boosting iterations.

Max depth. Specify the maximum depth for trees. Increasing this value will make the model more complex and likely to be overfitting.

Min child weight. Specify the minimum sum of instance weight (hessian) needed in a child. If the tree partition step results in a leaf node with the sum of instance weight less than this Min child weight, then the building process will stop further partitioning. In linear regression mode, this simply corresponds to minimum number of instances needed in each node. The larger the weight, the more conservative the algorithm will be.

Max delta step. Specify the maximum delta step to allow for each tree's weight estimation. If set to 0, there is no constraint. If set to a positive value, it can help the update step be more conservative. Usually this parameter is not needed, but it may help in logistic regression when a class is extremely imbalanced.

Learning Task

Objective. Select from the following learning task objective types: reg:linear, reg:logistic, reg:gamma, reg:tweedie, count:poisson, rank:pairwise, binary:logistic, or multi.

Early stopping. Select this option if you want to use the early stopping function. For the stopping rounds, validation errors must decrease at least every early stopping round(s) to continue training. The Evaluation data ratio is the ratio of input data used for validation errors.

Random Seed. You can click Generate to generate the seed used by the random number generator.

Advanced

Sub sample. Sub sample is the ratio of the training instance. For example, if you set this to 0.5, XGBoost will randomly collect half the data instances to grow trees and this will prevent overfitting.

Eta. The step size shrinkage used during the update step to prevent overfitting. After each boosting step, the weights of new features can be obtained directly. Eta also shrinks the feature weights to make the boosting process more conservative.

Gamma. The minimum loss reduction required to make a further partition on a leaf node of the tree. The larger the gamma setting, the more conservative the algorithm will be.

Colsample by tree. Sub sample ratio of columns when constructing each tree.

Colsample by level. Sub sample ratio of columns for each split, in each level.

Lambda. L2 regularization term on weights. Increasing this value will make the model more conservative.

Alpha. L1 regularization term on weights. Increasing this value will make model more conservative.

Scale pos weight. Control the balance of positive and negative weights. This is useful for unbalanced classes.

The following table shows the relationship between the settings in the SPSS® Modeler XGBoost Tree node dialog and the Python XGBoost library parameters.

Table 1. Node properties mapped to Python library parameters

SPSS Modeler setting	Script name (property name)	XGBoost parameter
Target	TargetField	
Predictors	InputFields	
Tree method	treeMethod	tree_method
Num boost round	numBoostRound	num_boost_round
Max depth	maxDepth	max_depth
Min child weight	minChildWeight	min_child_weight

SPSS Modeler setting	Script name (property name)	XGBoost parameter
Max delta step	maxDeltaStep	max_delta_step
Objective	objectiveType	objective
Early stopping	earlyStopping	early_stopping_rounds
stopping rounds	stoppingRounds	
Evaluation data ratio	evaluationDataRatio	
Random Seed	random_seed	seed
Sub sample	sampleSize	subsample
Eta	eta	eta
Gamma	gamma	gamma
Colsample by tree	colSampleRatio	colsample_bytree
Colsample by level	colSampleLevel	colsample_bylevel
Lambda	lambda	lambda
Alpha	alpha	alpha

XGBoost Tree node Model Options

Model name. You can generate the model name automatically based on the target or ID field (or model type in cases where no such field is specified) or specify a custom name.

t-SNE node

t-Distributed Stochastic Neighbor Embedding (t-SNE)© is a tool for visualizing high-dimensional data. It converts affinities of data points to probabilities. The affinities in the original space are represented by Gaussian joint probabilities and the affinities in the embedded space are represented by Student's t-distributions. This allows t-SNE to be particularly sensitive to local structure and has a few other advantages over existing techniques:¹

- Revealing the structure at many scales on a single map
- Revealing data that lie in multiple, different, manifolds, or clusters
- Reducing the tendency to crowd points together at the center

The t-SNE node in SPSS® Modeler is implemented in Python and requires the scikit-learn© Python library. For details about t-SNE and the scikit-learn library, see:

- <https://scikit-learn.org/stable/modules/generated/sklearn.manifold.TSNE.html#sklearn.manifold.TSNE>
- <https://scikit-learn.org/stable/modules/manifold.html#t-sne>

The Python tab on the Nodes Palette contains this node and other Python nodes. The t-SNE node is also available on the Graphs tab.

t-SNE node Expert options

Choose Simple mode or Expert mode depending on which options you want to set for the t-SNE node.

Visualization type. Select 2D or 3D to specify whether to draw the graph as two-dimensional or three-dimensional.

Method. Select Barnes Hut or Exact. By default, the gradient calculation algorithm uses Barnes-Hut approximation which runs much faster than the Exact method. Barnes-Hut approximation allows the t-SNE technique to be applied to large, real-world datasets. The Exact algorithm will do a better job of avoiding nearest-neighbor errors.

Init. Select Random or PCA for the initialization of embedding.

Target Field. Select the target field to show as a colormap on the output graph. The graph will use one color if no target field is specified here.

Optimization

Perplexity. The perplexity is related to the number of nearest neighbors that are used in other manifold learning algorithms. Larger datasets usually require a larger perplexity. Consider selecting a value between 5 and 50. Default is 30, and the range is 2 - 9999999.

Early exaggeration. This setting controls how tight natural clusters in the original space will be in the embedded space, and how much space will be between them. Default is 12, and the range is 2 - 9999999.

Learning rate. If the learning rate is too high, the data might look like a "ball" with any point approximately equidistant from its nearest neighbors. If the learning rate is too low, most points may look compressed in a dense cloud with few outliers. If the cost function gets stuck in a bad local minimum, increasing the learning rate may help. Default is 200, and the range is 0 - 9999999.

Max iterations. The maximum number of iterations for the optimization. Default is 1000, and the range is 250 - 9999999.

Angular size. The angular size of a distant node as measured from a point. Enter a value between 0 and 1. Default is 0.5.

Random seed

Set random seed. Select this option and click Generate to generate the seed used by the random number generator.

Optimization stop condition

Max iterations without progress. The maximum number of iterations without progress to perform before stopping the optimization, used after 250 initial iterations with early exaggeration. Note that progress is only checked every 50 iterations, so this value is rounded to the next multiple of 50. Default is 300, and the range is 0 - 9999999.

Min gradient norm. If the gradient norm is below this minimum threshold, the optimization will stop. Default is 1.0E-7.

Metric. The metric to use when calculating distance between instances in a feature array. If the metric is a string, it must be one of the options allowed by `scipy.spatial.distance.pdist` for its metric parameter, or a metric listed in `pairwise.PAIRWISE_DISTANCE_FUNCTIONS`. Select one of the available metric types. Default is euclidean.

When number of records greater than. Specify a method for plotting large datasets. You can specify a maximum dataset size or use the default 2,000 points. Performance is enhanced for large datasets when you select the Bin or Sample options. Alternatively, you can choose to plot all data points by selecting Use all data, but you should note that this may dramatically decrease the performance of the software.

- Bin. Select to enable binning when the dataset contains more than the specified number of records. Binning divides the graph into fine grids before actually plotting and counts the number of connections that would appear in each of the grid cells. In the final graph, one connection is used per cell at the bin centroid (average of all connection points in the bin).
- Sample. Select to randomly sample the data to the specified number of records.

The following table shows the relationship between the settings on the Expert tab of the SPSS® Modeler t-SNE node dialog and the Python t-SNE library parameters.

Table 1. Node properties mapped to Python library parameters

SPSS Modeler setting	Script name (property name)	Python t-SNE parameter
Mode	<code>mode_type</code>	
Visualization type	<code>n_components</code>	<code>n_components</code>
Method	<code>method</code>	<code>method</code>
Initialization of embedding	<code>init</code>	<code>init</code>
Target	<code>target_field</code>	<code>target_field</code>
Perplexity	<code>perplexity</code>	<code>perplexity</code>
Early exaggeration	<code>early_exaggeration</code>	<code>early_exaggeration</code>

SPSS Modeler setting	Script name (property name)	Python t-SNE parameter
Learning rate	learning_rate	learning_rate
Max iterations	n_iter	n_iter
Angular size	angle	angle
Set random seed	enable_random_seed	
Random seed	random_seed	random_state
Max iterations without progress	n_iter_without_progress	n_iter_without_progress
Min gradient norm	min_grad_norm	min_grad_norm
Perform t-SNE with multiple perplexities	isGridSearch	

t-SNE node Output options

Specify options for the t-SNE node output on the Output tab.

Output name. Specify the name of the output that is produced when the node runs. If you select Auto, the name of the output is automatically set.

Output to screen. Select this option to generate and display the output in a new window. The output is also added to the Output manager.

Output to file. Select this option to save the output to a file. Doing so enables the File name and File type fields. The t-SNE node requires access to this output file if you want to create plots using other fields for comparison purposes – or to use its output as predictors in classification or regression models. The t-SNE model creates a result file of x, y (and z) coordinate fields that is most easily accessed using a Fixed File source node.

t-SNE model nuggets

t-SNE model nuggets contain all of the information captured by the t-SNE model. The following tabs are available.

Graph

The Graph tab displays chart output for the t-SNE node. A pyplot scatter chart shows the low dimensions result. If you didn't select the Perform t-SNE with multiple perplexities option on the [Expert](#) tab of the t-SNE node, only one graph is included rather than six graphs with different perplexities.

Text output

The Text output tab displays the results of the t-SNE algorithm. If you chose the 2D visualization type on the [Expert](#) tab of the t-SNE node, the result here is the point value in two dimensions. If you chose 3D, the result is the point value in three dimensions.

Gaussian Mixture node

A Gaussian Mixture© model is a probabilistic model that assumes all the data points are generated from a mixture of a finite number of Gaussian distributions with unknown parameters. One can think of mixture models as generalizing k-means clustering to incorporate information about the covariance structure of the data as well as the centers of the latent Gaussians.¹

The Gaussian Mixture node in SPSS® Modeler exposes the core features and commonly used parameters of the Gaussian Mixture library. The node is implemented in Python.

For more information about Gaussian Mixture modeling algorithms and parameters, see the Gaussian Mixture documentation available at <http://scikit-learn.org/stable/modules/mixture.html> and <https://scikit-learn.org/stable/modules/generated/sklearn.mixture.GaussianMixture.html>.²

- [Gaussian Mixture node Build Options](#)
- [Gaussian Mixture node Model Options](#)

Gaussian Mixture node Fields

The Fields tab specifies which fields are used in the analysis.

Use predefined roles. This option uses the input settings from an upstream Type node (or the Types tab of an upstream source node).

Use custom field assignments. To manually assign inputs, select this option.

Fields. Use the arrow buttons to assign items manually from this list to the Predictors list on the right of the screen. The icons indicate the valid measurement levels for each field. To select all the fields in the list, click the All button, or click an individual measurement level button to select all fields with that measurement level.

Predictors. Select one or more fields as predictors.

Gaussian Mixture node Build Options

Use the Build Options tab to specify build options for the Gaussian Mixture node, including basic options and advanced options. For details about these options not covered in this section, see the following online resources:

- [Gaussian mixture parameter reference](#)¹
- [Gaussian mixture node user guide](#)²

Basic

Covariance type. Select one of the following covariance matrices:

- Full. Each component has its own general covariance matrix.
- Tied. All components share the same general covariance matrix.
- Diag. Each component has its own diagonal covariance matrix.
- Spherical. Each component has its own single variance.

Number of components. Specify the number of mixture components to use when building the model.

Cluster Label. Specify whether the cluster label is a number or a string. If you choose String, specify a prefix for the cluster label (for example, the default prefix is `cluster`, which results in cluster labels such as `cluster-1`, `cluster-2`, etc.).

Random Seed. Select this option and click Generate to generate the seed used by the random number generator.

Advanced

Tolerance. Specify the convergence threshold. Default value is 0.001.

Number of iterations. Specify the maximum number of iterations to perform. Default value is 100.

Init parameters. Select the initialization parameter Kmeans (responsibilities are initialized using k-means) or Random (responsibilities are initialized randomly).

Warm start. If you select True, the solution of the last fitting will be used as the initialization for the next fitting. This can speed up convergence when fitting is called several times on similar problems.

The following table shows the relationship between the settings in the SPSS® Modeler Gaussian Mixture node dialog and the Python Gaussian Mixture library parameters.

Table 1. Node properties mapped to Python library parameters

SPSS Modeler setting	Script name (property name)	Gaussian Mixture parameter
Use predefined roles / Use custom field assignments	<code>role_use</code>	
Inputs	<code>predictors</code>	
Use partitioned data	<code>use_partition</code>	
Covariance type	<code>covariance_type</code>	<code>covariance_type</code>
Number of components	<code>number_component</code>	<code>n_components</code>
Cluster Label	<code>component_label</code>	
Label Prefix	<code>label_prefix</code>	
Set random seed	<code>enable_random_seed</code>	
Random Seed	<code>random_seed</code>	<code>random_state</code>

SPSS Modeler setting	Script name (property name)	Gaussian Mixture parameter
Tolerance	<code>tol</code>	<code>tol</code>

Gaussian Mixture node Model Options

Model name. You can generate the model name automatically based on the target or ID field (or model type in cases where no such field is specified) or specify a custom name.

KDE nodes

Kernel Density Estimation (KDE)© uses the Ball Tree or KD Tree algorithms for efficient queries, and walks the line between unsupervised learning, feature engineering, and data modeling. Neighbor-based approaches such as KDE are some of the most popular and useful density estimation techniques. KDE can be performed in any number of dimensions, though in practice high dimensionality can cause a degradation of performance. The KDE Modeling and KDE Simulation nodes in SPSS® Modeler expose the core features and commonly used parameters of the KDE library. The nodes are implemented in Python.¹

To use a KDE node, you must set up an upstream Type node. The KDE node will read input values from the Type node (or the Types tab of an upstream source node).

The KDE Modeling node is available on SPSS Modeler's Modeling tab and Python tab. The KDE Modeling node generates a model nugget, and the nugget's scored values are kernel density values from the input data.

The KDE Simulation node is available on the Output tab and the Python tab. The KDE Simulation node generates a KDE Gen source node that can create some records that have the same distribution as the input data. The KDE Gen node includes a Settings tab where you can specify how many records the node will create (default is 1) and generate a random seed.

For more information about KDE, including examples, see the KDE documentation available at <http://scikit-learn.org/stable/modules/density.html#kernel-density-estimation>.¹

¹ "User Guide." Kernel Density Estimation. Web. © 2007-2018, scikit-learn developers.

KDE Modeling node and KDE Simulation node Fields

The Fields tab specifies which fields are used in the analysis.

Use predefined roles. This option uses the input settings from an upstream Type node (or the Types tab of an upstream source node).

Use custom field assignments. To manually assign inputs, select this option.

Fields. Use the arrow buttons to assign items manually from this list to the Inputs list on the right of the screen. The icons indicate the valid measurement levels for each field. To select all the fields in the list, click the All button, or click an individual measurement level button to select all fields with that measurement level.

Inputs. Select one or more fields as inputs for clustering. KDE can only deal with continuous fields.

KDE nodes Build Options

Use the Build Options tab to specify build options for the KDE nodes, including basic options for kernel density parameters and cluster labels, and advanced options such as tolerance, leaf size, and whether to use a breadth-first approach. For additional information about these options, see the following online resources:

- [Kernel Density Estimation Python API Parameter Reference](#)¹
- [Kernel Density Estimation User Guide](#)²

Basic

Bandwidth. Specify the bandwidth of the kernel.

Kernel. Select the kernel to use. Available kernels for the KDE Modeling node are Gaussian, Tophat, Epanechnikov, Exponential, Linear, or Cosine. Available kernels for the KDE Simulation node are Gaussian or Tophat. For details about these available kernels, see the [Kernel Density Estimation User Guide](#).²

Algorithm. Select Auto, Ball Tree or KD Tree for the tree algorithm to use. For more information, see [Ball Tree](#)³ and [KD Tree](#).⁴

Metric. Select a distance metric. Available metrics are Euclidean, Braycurtis, Chebyshev, Canberra, Cityblock, Dice, Hamming, Infinity, Jaccard, L1, L2, Matching, Manhattan, P, Rogerstanimoto, Russellrao, Sokalmichener, Sokalsneath, Kulsinski, or Minkowski. If you select Minkowski, set the P Value as desired.

The metrics available in this drop-down will vary depending on which algorithm you choose. Also note that the normalization of the density output is correct only for the Euclidean distance metric.

Advanced

Absolute Tolerance. Specify the desired absolute tolerance of the result. A larger tolerance will generally result in faster run time. Default is 0.0.

Relative Tolerance. Specify the desired relative tolerance of the result. A larger tolerance will generally result in faster run time. Default is 1E-8.

Leaf Size. Specify the leaf size of the underlying tree. Default is 40. Changing the leaf size may significantly impact performance and required memory. For more information about the Ball Tree and KD Tree algorithms, see [Ball Tree](#)³ and [KD Tree](#).⁴

Breadth first. Select True if you want to use a breadth-first approach or False to use a depth-first approach.

The following table shows the relationship between the settings in the SPSS® Modeler KDE node dialogs and the Python KDE library parameters.

Table 1. Node properties mapped to Python library parameters

SPSS Modeler setting	Script name (property name)	KDE parameter
Inputs	inputs	
Bandwidth	bandwidth	bandwidth
Kernel	kernel	kernel
Algorithm	algorithm	algorithm
Metric	metric	metric
P Value	pValue	pValue
Absolute Tolerance	atol	atol
Relative Tolerance	rtol	Rtol
Leaf Size	leafSize	leafSize
Breadth first	breadthFirst	breadthFirst

KDE Modeling node and KDE Simulation node Model Options

Model name. You can generate the model name automatically based on the target or ID field (or model type in cases where no such field is specified) or specify a custom name.

Random Forest node

Random Forest® is an advanced implementation of a bagging algorithm with a tree model as the base model. In random forests, each tree in the ensemble is built from a sample drawn with replacement (for example, a bootstrap sample) from the training set. When splitting a node during the construction of the tree, the split that is chosen is no longer the best split among all features. Instead, the split that is picked is the best split among a random subset of the features. Because of this randomness, the bias of the forest usually slightly increases (with respect to the bias of a single non-random tree) but, due to averaging, its variance also decreases, usually more than compensating for the increase in bias, hence yielding an overall better model.¹

The Random Forest node in SPSS® Modeler is implemented in Python. The Python tab on the Nodes Palette contains this node and other Python nodes.

For more information about random forest algorithms, see <https://scikit-learn.org/stable/modules/ensemble.html#forest>.

¹L. Breiman, "Random Forests," *Machine Learning*, 45(1), 5-32, 2001.

- [Random Forest node Fields](#)
- [Random Forest node Build Options](#)
- [Random Forest node Model Options](#)
- [Random Forest model nuggets](#)

Random Forest node Fields

The Fields tab specifies which fields are used in the analysis.

Use predefined roles. This option uses the role settings (targets, predictors and so on) from an upstream Type node (or the Types tab of an upstream source node).

Use custom field assignments. To manually assign a target and predictors, select this option.

Fields. Use the arrow buttons to assign items manually from this list to the Target and Predictors role fields on the right of the screen. The icons indicate the valid measurement levels for each role field. To select all the fields in the list, click the All button, or click an individual measurement level button to select all fields with that measurement level.

Target. Select a field to use as the target for the prediction.

Predictors. Select one or more fields as inputs for the prediction.

Random Forest node Build Options

Use the Build Options tab to specify build options for the Random Forest node, including basic options and advanced options. For more information about these options, see <https://scikit-learn.org/stable/modules/ensemble.html#forest>

Basic

Number of trees to build. Select the number of trees in the forest.

Specify max depth. If not selected, nodes are expanded until all leaves are pure or until all leaves contain less than `min_samples_split` samples.

Max depth. The maximum depth of the tree.

Minimum leaf node size. The minimum number of samples required to be at a leaf node.

Number of features to use for splitting. The number of features to consider when looking for the best split:

- If `auto`, then `max_features=sqrt(n_features)` for classifier and `max_features=n_features` for regression.
- If `sqrt`, then `max_features=sqrt(n_features)`.
- If `log2`, then `max_features=log2(n_features)`.

Advanced

Use bootstrap samples when building trees. If selected, bootstrap samples are used when building trees.

Use out-of-bag samples to estimate the generalization accuracy. If selected, out-of-bag samples are used to estimate the generalization accuracy.

Use extremely randomized trees. If selected, extremely randomized trees are used instead of general random forests. In extremely randomized trees, randomness goes one step further in the way splits are computed. As in random forests, a random subset of candidate features is used, but instead of looking for the most discriminative thresholds, thresholds are drawn at random for each candidate feature and the best of these randomly-generated thresholds is picked as the splitting rule. This usually allows the variance of the model to be reduced a bit more, at the expense of a slightly greater increase in bias.¹

Replicate results. If selected, the model building process is replicated to achieve the same scoring results.

Random seed. You can click Generate to generate the seed used by the random number generator.

Hyper-Parameter Optimization (Based on Rbfopt). Select this option to enable Hyper-Parameter Optimization based on Rbfopt, which automatically discovers the optimal combination of parameters so that the model will achieve the expected or lower error rate on the samples. For details about Rbfopt, see http://rbfopt.readthedocs.io/en/latest/rbfopt_settings.html.

Target. The objective function value (error rate of the model on the samples) you want to reach (i.e., the value of the unknown optimum). Set to an acceptable value such as 0.01.

Max iterations. The maximum number of iterations to try the model. Default is 1000.

Max evaluations. The maximum number of function evaluations in accurate mode, for trying the model. Default is 300.

The following table shows the relationship between the settings in the SPSS® Modeler Random Forest node dialog and the Python Random Forest library parameters.

Table 1. Node properties mapped to Python library parameters

SPSS Modeler setting	Script name (property name)	Random Forest parameter
Target	<code>target</code>	
Predictors	<code>inputs</code>	
Number of trees to build	<code>n_estimators</code>	<code>n_estimators</code>
Specify max depth	<code>specify_max_depth</code>	<code>specify_max_depth</code>
Max depth	<code>max_depth</code>	<code>max_depth</code>
Minimum leaf node size	<code>min_samples_leaf</code>	<code>min_samples_leaf</code>
Number of features to use for splitting	<code>max_features</code>	<code>max_features</code>
Use bootstrap samples when building trees	<code>bootstrap</code>	<code>bootstrap</code>
Use out-of-bag samples to estimate the generalization accuracy	<code>oob_score</code>	<code>oob_score</code>
Use extremely randomized trees	<code>extreme</code>	
Replicate results	<code>use_random_seed</code>	
Random seed	<code>random_seed</code>	<code>random_seed</code>
Hyper-Parameter Optimization (based on Rbfopt)	<code>enable_hpo</code>

Random Forest node Model Options

Model name. You can generate the model name automatically based on the target or ID field (or model type in cases where no such field is specified) or specify a custom name.

Random Forest model nuggets

Random Forest model nuggets contain all of the information captured by the random forest model. The following sections are available.

Model Information

This view provides key information about the model, including input fields, one-hot encoding values, and model parameters.

Predictor Importance

This view displays a chart that indicates the relative importance of each predictor in estimating the model. For more information, see [Predictor Importance](#).

HDBSCAN node

Hierarchical Density-Based Spatial Clustering (HDBSCAN)© uses unsupervised learning to find clusters, or dense regions, of a data set. The HDBSCAN node in SPSS® Modeler exposes the core features and commonly used parameters of the HDBSCAN library. The node is implemented in Python, and you can use it to cluster your dataset into distinct groups when you don't know what those groups are at first. Unlike most learning methods in SPSS Modeler, HDBSCAN models do *not* use a target field. This type of learning, with no target field, is called *unsupervised learning*. Rather than trying to predict an outcome, HDBSCAN tries to uncover patterns in the set of input fields. Records are grouped so that records within a group or cluster tend to be similar to each other, but records in different groups are dissimilar. The HDBSCAN algorithm views clusters as areas of high density separate by areas of low density. Due this rather generic view, clusters found by HDBSCAN can be any shape, as opposed to k-means which assumes that clusters are convex shaped. Outlier points that lie alone in low-density regions are also marked. HDBSCAN also supports scoring of new samples.¹

To use the HDBSCAN node, you must set up an upstream Type node. The HDBSCAN node will read input values from the Type node (or the Types tab of an upstream source node).

For more information about HDBSCAN clustering algorithms, see the HDBSCAN documentation available at <http://hdbSCAN.readthedocs.io/en/latest/>.¹

- [HDBSCAN node Fields](#)
 - [HDBSCAN node Build Options](#)
 - [HDBSCAN node Model Options](#)
-

HDBSCAN node Fields

The Fields tab specifies which fields are used in the analysis.

Important: To train an HDBSCAN model, you must use one or more fields with the role set to Input. Fields with the role set to Output, Both, or None are ignored.

Use predefined roles. This option uses the input settings from an upstream Type node (or the Types tab of an upstream source node).

Use custom field assignments. To manually assign inputs, select this option.

Fields. Use the arrow buttons to assign items manually from this list to the Inputs list on the right of the screen. The icons indicate the valid measurement levels for each field. To select all the fields in the list, click the All button, or click an individual measurement level button to select all fields with that measurement level.

Inputs. Select one or more fields as inputs for clustering.

HDBSCAN node Build Options

Use the Build Options tab to specify build options for the HDBSCAN node, including basic options for cluster parameters and cluster labels, and advanced options for advanced parameters and chart output options. For additional information about these options, see the following online resources:

- [HDBSCAN Python API Parameter Reference](#)¹
- [HDBSCAN Home Page](#)²

Basic

Hyper-Parameter Optimization (Based on Rbfopt). Select this option to enable Hyper-Parameter Optimization based on Rbfopt, which automatically discovers the optimal combination of parameters so that the model will achieve the expected or lower error rate on the samples. For details about Rbfopt, see http://rbfopt.readthedocs.io/en/latest/rbfopt_settings.html.

Min Cluster Size. Specify the minimum size of clusters. Single linkage splits that contain fewer points than the value specified here will be considered points "falling out" of a cluster rather than a cluster splitting into two new clusters.

Min Samples. Specify the minimum number of samples in a neighborhood for a point to be considered a core point. If set to 0, the default value is the minimum cluster size value.

Algorithm. Select the algorithm to use. HDBSCAN has variants that are specialized for different characteristics of the data. By default, BEST is used - which automatically chooses the best algorithm given the nature of the data. For details about these algorithm types, see the [HDBSCAN documentation](#).¹ Note that the algorithm you choose will impact performance. For example, for large data we recommend trying Boruvka KDTree or Boruvka BallTree.

Metric for Distance. Select the metric to use when calculating distance between instances in a feature array.

Cluster Label. Specify whether the cluster label is a number or a string. If you choose String, specify a prefix for the cluster label (for example, the default prefix is `cluster`, which results in cluster labels such as `cluster-1`, `cluster-2`, etc.).

Advanced

Approximate Minimum Spanning Tree. Select True if you want to accept an approximate minimum spanning tree. For some algorithms, this can improve performance, but the resulting clustering might be of marginally lower quality. If you are willing to sacrifice speed for correctness, you may want to try the False option. In most cases, True is recommended.

Method to Select Cluster. Select which method to use for selecting clusters from the condensed tree. The standard approach for HDBSCAN is to use an Excess of Mass (EOM) algorithm to find the most persistent clusters. Or you can select the clusters at the leaves of the tree, which provides the most fine-grained and homogeneous clusters.

Accept Single Cluster. Change this setting to True to allow single cluster results only if this is a valid result for your dataset.

P Value. If using the Minkowski metric for distance (under Basic build options), you can change this p value if desired.

Leaf Size. If using a space tree algorithm (Boruvka KDTree or Boruvka BallTree), this is the number of points in a leaf node of the tree. This setting doesn't alter the resulting clustering, but it may impact the run time of the algorithm.

Validity Index. Select this option to include the Validity Index chart in the model nugget output.

Condensed Tree. Select this option to include the Condensed Tree chart in the model nugget output.

Single Linkage Tree. Select this option to include the Single Linkage Tree chart in the model nugget output.

Min Span Tree. Select this option to include the Min Span Tree chart in the model nugget output.

The following table shows the relationship between the settings in the SPSS® Modeler HDBSCAN node dialog and the Python HDBSCAN library parameters.

Table 1. Node properties mapped to Python library parameters

SPSS Modeler setting	Script name (property name)	HDBSCAN parameter
Inputs	<code>inputs</code>	<code>inputs</code>
Hyper-Parameter Optimization	<code>useHPO</code>

HDBSCAN node Model Options

Model name. You can generate the model name automatically based on the target or ID field (or model type in cases where no such field is specified) or specify a custom name.

One-Class SVM node

The One-Class SVM[©] node uses an unsupervised learning algorithm. The node can be used for novelty detection. It will detect the soft boundary of a given set of samples, to then classify new points as belonging to that set or not. This One-Class SVM modeling node is implemented in Python and requires the scikit-learn[©] Python library. For details about the scikit-learn library, see <http://contrib.scikit-learn.org/imbalanced-learn/about.html>¹.

The Python tab on the Nodes Palette contains the One-Class SVM node and other Python nodes.

Note: One-Class SVM is used for unsupervised outlier and novelty detection. In most cases, we recommend using a known, "normal" dataset to build the model so the algorithm can set a correct boundary for the given samples. Parameters for the model – such as nu, gamma, and kernel – impact the result significantly. So you may need to experiment with these options until you find the optimal settings for your situation.

¹Smola, Schölkopf. "A Tutorial on Support Vector Regression." *Statistics and Computing Archive*, vol. 14, no. 3, August 2004, pp. 199-222. (<http://citeseerx.ist.psu.edu/viewdoc/summary?doi=10.1.1.114.4288>)

- [One-Class SVM node Fields](#)
- [One-Class SVM node Expert](#)
- [One-Class SVM node Options](#)

One-Class SVM node Fields

The Fields tab specifies which fields are used in the analysis.

Use predefined roles. Select this option to select all fields with a defined role of Input.

Use custom field assignments. To manually select fields, select this option and choose input fields and split fields:

Inputs. Select the input fields to use in the analysis. All storage types and measurement types are supported, except for typeless or unknown. If a field has a String storage type, the values of this field will be binarized in a one-vs-all fashion via a one-hot encoding algorithm.

Split. Select which field or fields to use as split fields. All flag, nominal, ordinal, and discrete measurement types are supported.

Use partitioned data If a partition field is defined, this option ensures that data from only the training partition is used to build the model.

One-Class SVM node Expert

On the Expert tab of the One-Class SVM node, you can choose from Simple mode or Expert mode. If you choose Simple, all parameters are set with the default values as shown below. If you select Expert, you can specify custom values for these parameters. For further detail about these options, see <http://scikit-learn.org/stable/modules/generated/sklearn.svm.OneClassSVM.html#sklearn.svm.OneClassSVM>.

Stopping criteria. Specify the tolerance for stopping criteria. Default is 1.0E-3 (0.001).

Regression precision (nu). Bound on the fraction of training errors and support vectors. Default is 0.1.

Kernel type. The kernel type to use in the algorithm. Options include RBF, Polynomial, Sigmoid, Linear, or Precomputed. Default is RBF.

Specify Gamma. Select this option to specify the Gamma. Otherwise, the auto gamma will be applied.

Gamma. The Gamma setting is only available for the RBF, Polynomial, and Sigmoid kernel types.

Coef0. Coef0 is only available for the Polynomial and Sigmoid kernel types.

Degree. Degree is only available for the Polynomial kernel type.

Use the shrinking heuristic. Select this option to use the shrinking heuristic. This option is deselected by default.

Specify the size of the kernel cache (in MB). Select this option to specify the size of the kernel cache. This option is deselected by default. When selected, the default value is 200 MB.

Hyper-Parameter Optimization (Based on Rbfopt). Select this option to enable Hyper-Parameter Optimization based on Rbfopt, which automatically discovers the optimal combination of parameters so that the model will achieve the expected or lower error rate on the samples. For details about Rbfopt, see http://rbfopt.readthedocs.io/en/latest/rbfopt_settings.html.

Target. The objective function value (error rate of the model on the samples) we want to reach (for example, the value of the unknown optimum). Set to an acceptable value such as 0.01.

Max Iterations. Maximum number of iterations for trying the model. Default is 1000.

Max Evaluations. Maximum number of function evaluations for trying the model, where the focus is accuracy over speed. Default is 300.

The One-Class SVM node requires the scikit-learn® Python library. The following table shows the relationship between the settings in the SPSS® Modeler SMOTE node dialog and the Python algorithm.

Table 1. Node properties mapped to Python library parameters

Parameter name	Script name (property name)	Python API parameter name
Stopping criteria	<code>stopping_criteria</code>	<code>tol</code>
Regression precision	<code>precision</code>	<code>nu</code>
Kernel type	<code>kernel</code>	<code>kernel</code>
Gamma	<code>gamma</code>	<code>gamma</code>
Coef0	<code>coef0</code>	<code>coef0</code>
Degree	<code>degree</code>	<code>degree</code>
Use the shrinking heuristic	<code>shrinking</code>	<code>shrinking</code>
Specify the size of the kernel cache (number input box)	<code>cache_size</code>	<code>cache_size</code>
Random seed	<code>random_seed</code>	<code>random_state</code>

One-Class SVM node Options

On the Options tab of the One-Class SVM node, you can set the following options.

Type of Parallel Coordinates graphic. SPSS® Modeler draws parallel coordinates graphics to present the built model. Sometimes, the values for some data columns/features will be displayed much larger than others, which can make some other portions of the graph hard to see. For cases like this, you can choose the Independent vertical axes option to give all vertical axes a standalone axis scale, or select General vertical axes to force all vertical axes to share the same axes scale.

Maximum lines on the graphic. Specify the maximum number of data rows (lines) to display in graph output. The default is 100. For performance reasons, a maximum of 20 fields will be displayed.

Draw all input fields on the graphic. Select this option to show all input fields in the graph output. By default, each data field will be drawn as a vertical axis. For performance reasons, a maximum of 30 fields will be displayed.

Custom fields to be drawn on the graphic. Rather than showing all input fields in the graph output, you can select this option and choose a subset of fields to show. This can improve performance. For performance reasons, a maximum of 20 fields will be displayed.

Spark nodes

SPSS® Modeler offers nodes for using Spark native algorithms. The Spark tab on the [Nodes Palette](#) contains the following nodes you can use to run Spark algorithms. These nodes are supported on Windows 64, Mac 64, and Linux 64. Note that these nodes don't support specifying an integer/double column as Flag/Nominal for building a model. To do this, you must convert the column value to 0/1 or 0,1,2,3,4...

	Isotonic Regression belongs to the family of regression algorithms. The Isotonic-AS node in SPSS Modeler is implemented in Spark. For details about Isotonic Regression algorithms, see https://spark.apache.org/docs/2.2.0/mllib-isotonic-regression.html .
	XGBoost® is an advanced implementation of a gradient boosting algorithm. Boosting algorithms iteratively learn weak classifiers and then add them to a final strong classifier. XGBoost is very flexible and provides many parameters that can be overwhelming to most users, so the XGBoost-AS node in SPSS Modeler exposes the core features and commonly used parameters. The XGBoost-AS node is implemented in Spark.
	K-Means is one of the most commonly used clustering algorithms. It clusters data points into a predefined number of clusters. The K-Means-AS node in SPSS Modeler is implemented in Spark. For details about K-Means algorithms, see https://spark.apache.org/docs/2.2.0/ml-clustering.html . Note that the K-Means-AS node performs one-hot encoding automatically for categorical variables.
	Multilayer perceptron is a classifier based on the feedforward artificial neural network and consists of multiple layers. Each layer is fully connected to the next layer in the network. The MultiLayerPerceptron-AS node in SPSS Modeler is implemented in Spark. For details about the multilayer perceptron classifier (MLPC), see https://spark.apache.org/docs/latest/ml-classification-regression.html#multilayer-perceptron-classifier .

Isotonic-AS node Fields

The Fields tab specifies which fields are used in the analysis.

Fields. Lists all fields in the data source. Use the arrow buttons to assign items manually from this list to the Target, Input, and Weight fields on the right of the screen. The icons indicate the valid measurement levels for each role field. To select all the fields in the list, click the All button, or click an individual measurement level button to select all fields with that measurement level.

Target. Select a field to use as the target.

Input. Select the input field or fields.

Weight. Select a weight field for exponential weight. If not set, the default weight value of 1 will be used.

Isotonic-AS node Build Options

Use the Build Options tab to specify build options for the Isotonic-AS node, including the feature index and isotonic type. For more information, see <http://spark.apache.org/docs/latest/api/java/org/apache/spark/ml/regression/IsotonicRegression.html>.¹

Input Fields Index. Specify the index of the input fields. Default is 0.

Isotonic Type. This setting determines whether the output sequence should be isotonic/increasing or antitonic/decreasing. Default is Isotonic.

¹ "Class IsotonicRegression." *Apache Spark. JavaDoc*. Web. 3 Oct 2017.

Isotonic-AS model nuggets

Isotonic-AS model nuggets contain all of the information captured by the isotonic regression model. The following sections are available.

Model Summary

This view provides key information about the model, including input fields, target field, and model building options.

Model Chart

This view displays a scatter diagram.

XGBoost-AS node

XGBoost® is an advanced implementation of a gradient boosting algorithm. Boosting algorithms iteratively learn weak classifiers and then add them to a final strong classifier. XGBoost is very flexible and provides many parameters that can be overwhelming to most users, so the XGBoost-AS node in SPSS® Modeler exposes the core features and commonly used parameters. The XGBoost-AS node is implemented in Spark.

For more information about boosting algorithms, see the XGBoost Tutorials available at <http://xgboost.readthedocs.io/en/latest/tutorials/index.html>.¹

Note that the XGBoost cross-validation function is not supported in SPSS Modeler. You can use the SPSS Modeler Partition node for this functionality. Also note that XGBoost in SPSS Modeler performs one-hot encoding automatically for categorical variables.

Note: On Mac, version 10.12.3 or higher is required for building XGBoost-AS models.

XGBoost-AS node Fields

The Fields tab specifies which fields are used in the analysis.

Use predefined roles. This option uses the role settings (targets, predictors and so on) from an upstream Type node (or the Types tab of an upstream source node).

Use custom field assignments. To manually assign a target and predictors, select this option.

Fields. Use the arrow buttons to assign items manually from this list to the Target and Predictors role fields on the right of the screen. The icons indicate the valid measurement levels for each role field. To select all the fields in the list, click the All button, or click an individual measurement level button to select all fields with that measurement level.

Target. Select a field to use as the target for the prediction.

Predictors. Select one or more fields as inputs for the prediction.

XGBoost-AS node Build Options

Use the Build Options tab to specify build options for the XGBoost-AS node, including general options for model building and handling imbalanced datasets, learning task options for objectives and evaluation metrics, and booster parameters for specific boosters. For more information about these options, see the following online resources:

- [XGBoost Home Page](#)¹
- [XGBoost Parameter Reference](#)²
- [XGBoost Spark API](#)³

General

Number of Workers. Number of workers used to train the XGBoost model.

Number of Threads. Number of threads used per worker.

Use External Memory. Whether to use external memory as cache.

Booster Type. The booster to use (gbtree, gblinear, or dart).

Booster Rounds Number. The number of rounds for boosting.

Scale pos weight. This setting controls the balance of positive and negative weights, and is useful for unbalanced classes.

Random Seed. Click Generate to generate the seed used by the random number generator.

Learning Task

Objective. Select from the following learning task objective types: reg:linear, reg:logistic, reg:gamma, reg:tweedie, rank:pairwise, binary:logistic, or multi.

Evaluation Metrics. Evaluation metrics for validation data. A default metric will be assigned according to the objective (rmse for regression, error for classification, or mean average precision for ranking). Available options are rmse, mae, logloss, error, merror, mlogloss, uac, ndcg, map, or gamma-deviance (default is rmse).

Booster Parameters

Lambda. L2 regularization term on weights. Increasing this value will make the model more conservative.

Alpha. L1 regularization term on weights. Increasing this value will make model more conservative.

Lambda bias. L2 regularization term on bias. (There is no L1 regularization term on bias because it is not important.)

Tree method. Select the XGBoost tree construction algorithm to use.

Max depth. Specify the maximum depth for trees. Increasing this value will make the model more complex and likely to be overfitting.

Min child weight. Specify the minimum sum of instance weight (hessian) needed in a child. If the tree partition step results in a leaf node with the sum of instance weight less than this Min child weight, then the building process will stop further partitioning. In linear regression mode, this simply corresponds to minimum number of instances needed in each node. The larger the weight, the more conservative the algorithm will be.

Max delta step. Specify the maximum delta step to allow for each tree's weight estimation. If set to 0, there is no constraint. If set to a positive value, it can help the update step be more conservative. Usually this parameter is not needed, but it may help in logistic regression when a class is extremely imbalanced.

Sub sample. Sub sample is the ratio of the training instance. For example, if you set this to 0.5, XGBoost will randomly collect half the data instances to grow trees and this will prevent overfitting.

Eta. The step size shrinkage used during the update step to prevent overfitting. After each boosting step, the weights of new features can be obtained directly. Eta also shrinks the feature weights to make the boosting process more conservative.

Gamma. The minimum loss reduction required to make a further partition on a leaf node of the tree. The larger the gamma setting, the more conservative the algorithm will be.

Colsample by tree. Sub sample ratio of columns when constructing each tree.

Colsample by level. Sub sample ratio of columns for each split, in each level.

Normalization Algorithm. The normalization algorithm to use when the dart booster type is selected under General options. Available options are tree or forest (default is tree).

Sampling Algorithm. The sampling algorithm to use when the dart booster type is selected under General options. The uniform algorithm uniformly selects dropped trees. The weighted algorithm selects dropped trees in proportion to weight. The default is uniform.

Dropout Rate. The dropout rate to use when the dart booster type is selected under General options.

Probability of Skip Dropout. The skip dropout probability to use when the dart booster type is selected under General options. If a dropout is skipped, new trees are added in the same manner as gbtree.

The following table shows the relationship between the settings in the SPSS® Modeler XGBoost-AS node dialog and the XGBoost Spark parameters.

Table 1. Node properties mapped to Spark parameters

SPSS Modeler setting	Script name (property name)	XGBoost Spark parameter
Target	target_fields	
Predictors	input_fields	
Lambda	lambda	lambda
Number of Workers	nWorkers	nWorkers
Number of Threads	numThreadPerTask	numThreadPerTask

XGBoost-AS node Model Options

Model name. You can generate the model name automatically based on the target or ID field (or model type in cases where no such field is specified) or specify a custom name.

K-Means-AS node

K-Means is one of the most commonly used clustering algorithms. It clusters data points into a predefined number of clusters.¹ The K-Means-AS node in SPSS® Modeler is implemented in Spark.

For details about K-Means algorithms, see <https://spark.apache.org/docs/2.2.0/ml-clustering.html>.

Note that the K-Means-AS node performs one-hot encoding automatically for categorical variables.

¹ "Clustering." *Apache Spark*. MLlib: Main Guide. Web. 3 Oct 2017.

- [K-Means-AS node Fields](#)
- [K-Means-AS node Build Options](#)
- [K-Means-AS node Fields](#)
- [K-Means-AS node Build Options](#)

K-Means-AS node Fields

The Fields tab specifies which fields are used in the analysis.

Use predefined roles. This option tells the node to use field information from an upstream Type node. It's selected by default.

Use custom field assignments. If you want to manually assign input fields, select this option and then select the input field or fields. Using this option is similar to setting the field role in Input in a Type node.

K-Means-AS node Build Options

Use the Build Options tab to specify build options for the K-Means-AS node, including regular options for model building, initialization options for initializing cluster centers, and advanced options for the computing iteration and random seed. For more information, see the [JavaDoc for K-Means on SparkML](#).¹

Regular

Model Name. The name of the field generated after scoring to a specific cluster. Select Auto (default) or select Custom and type a name.

Number of Clusters. Specify the number of clusters to generate. The default is 5 and the minimum is 2.

Initialization

Initialization Mode. Specify the method for initializing the cluster centers. K-Means|| is the default. For details about these two methods, see [Scalable K-Means++](#).²

Initialization Steps. If the K-Means|| initialization mode is selected, specify the number of initialization steps. 2 is the default.

Advanced

Advanced Settings. Select this option if you want to set advanced options as follows.

Max Iteration. Specify the maximum number of iterations to perform when searching cluster centers. 20 is the default.

Tolerance. Specify the convergence tolerance for iterative algorithms. 1.0E-4 is the default.

Set Random Seed. Select this option and click Generate to generate the seed used by the random number generator.

Display

Display Graph. Select this option if you want a graph to be included in the output.

The following table shows the relationship between the settings in the SPSS® Modeler K-Means-AS node and the K-Means Spark parameters.

Table 1. Node properties mapped to Spark parameters

SPSS Modeler setting	Script name (property name)	K-Means SparkML parameter
Input Fields	features	
Number of Clusters	clustersNum	k
Initialization Mode	initMode	initMode
Initialization Steps	initSteps	initSteps
Max Iteration	maxIter	maxIter
Toleration	toleration	tol
Random Seed	randomSeed	seed

MultiLayerPerceptron-AS node

Multilayer perceptron is a classifier based on the feedforward artificial neural network and consists of multiple layers. Each layer is fully connected to the next layer in the network. For details about the multilayer perceptron classifier (MLPC), see

<https://spark.apache.org/docs/latest/ml-classification-regression.html#multilayer-perceptron-classifier>.¹

The MultiLayerPerceptron-AS node in SPSS® Modeler is implemented in Spark. To use a this node, you must set up an upstream Type node. The MultiLayerPerceptron-AS node will read input values from the Type node (or the Types tab of an upstream source node).

¹ "Multilayer perceptron classifier." *Apache Spark*. MLlib: Main Guide. Web. 5 Oct 2018.

- [MultiLayerPerceptron-AS node Fields](#)
- [MultiLayerPerceptron-AS node Build Options](#)
- [MultiLayerPerceptron node Model Options](#)

MultiLayerPerceptron-AS node Fields

The Fields tab specifies which fields are used in the analysis.

Use predefined roles. This option tells the node to use field information from an upstream Type node. This is the default.

Use custom field assignments. To manually assign target and predictors, select this option.

Target. Select a field to use as the target for the prediction.

Predictors. Select one or more fields to use as inputs for the prediction.

MultiLayerPerceptron-AS node Build Options

Use the Build Options tab to specify build options for the MultiLayerPerceptron-AS node, including performance, modeling building, and expert options. For more information about these options, see

<http://spark.apache.org/docs/latest/api/java/org/apache/spark/ml/classification/MultilayerPerceptronClassifier.html>.¹

Performance

Perceptrons Layer. Use this setting to define the number of perceptron layers to include. This value must be larger than the number of perceptron fields. The default value is 1.

Hidden Layers. Specify the number of hidden layers. Use a comma between multiple hidden layers. The default value is 1.

Output Layer. Specify the number of output layers. The default value is 1.

Random Seed. Click Generate if you want to generate the seed used by the random number generator.

Model Building

Max iterations. Specify the maximum number of iterations to perform. The default value is 10.

Expert Only

BlockSize. Select the Expert Mode option in the Model Building section if you want to specify the block size for stacking input data in matrices. This can speed up the computation. The default block size is 128.

The following table shows the relationship between the settings in the SPSS® Modeler MultiLayerPerceptron-AS node dialogs and the Spark KDE library parameters.

Table 1. Node properties mapped to Spark parameters

SPSS Modeler setting	Script name (property name)	Spark parameter
Predictors	<code>features</code>	
Target	<code>label</code>	
Perceptrons Layer	<code>layers[0]</code>	<code>layers[0]</code>
Hidden Layers	<code>layers[1...<latest-1>]</code>	<code>layers[1...<latest-1>]</code>
Output Layer	<code>layers[<latest>]</code>	<code>layers[<latest>]</code>
Random Seed	<code>seed</code>	<code>seed</code>
Max iterations	<code>maxiter</code>	<code>maxiter</code>

MultiLayerPerceptron node Model Options

Model name. You can generate the model name automatically based on the target or ID field (or model type in cases where no such field is specified) or specify a custom name.

Scripting and the Scripting Language

- [Scripting overview](#)
- [Types of Scripts](#)
- [Stream Scripts](#)
- [Standalone Scripts](#)
- [SuperNode Scripts](#)
- [Looping and conditional execution in streams](#)
- [Executing and interrupting scripts](#)

Scripting overview

Scripting in IBM® SPSS® Modeler is a powerful tool for automating processes in the user interface. Scripts can perform the same types of actions that you perform with a mouse or a keyboard, and you can use them to automate tasks that would be highly repetitive or time consuming to perform manually.

You can use scripts to:

- Impose a specific order for node executions in a stream.
- Set properties for a node as well as perform derivations using a subset of CLEM (Control Language for Expression Manipulation).
- Specify an automatic sequence of actions that normally involves user interaction--for example, you can build a model and then test it.
- Set up complex processes that require substantial user interaction--for example, cross-validation procedures that require repeated model generation and testing.
- Set up processes that manipulate streams—for example, you can take a model training stream, run it, and produce the corresponding model-testing stream automatically.

This section provides high-level descriptions and examples of stream-level scripts, standalone scripts, and scripts within SuperNodes in the IBM SPSS Modeler interface. More information on scripting language, syntax, and commands is provided in the sections that follow.

Note:

You cannot import and run scripts created in IBM SPSS Statistics within IBM SPSS Modeler.

Related information

- [Types of Scripts](#)
- [Stream Scripts](#)
- [Stream script example: Training a neural net](#)
- [Standalone Scripts](#)
- [SuperNode Scripts](#)
- [CLEM Reference Overview](#)

Types of Scripts

IBM® SPSS® Modeler uses three types of scripts:

- **Stream scripts** are stored as a stream property and are therefore saved and loaded with a specific stream. For example, you can write a stream script that automates the process of training and applying a model nugget. You can also specify that whenever a particular stream is executed, the script should be run instead of the stream's canvas content. See the topic [Stream Scripts](#) for more information.
- **Standalone scripts** are not associated with any particular stream and are saved in external text files. You might use a standalone script, for example, to manipulate multiple streams together. See the topic [Standalone Scripts](#) for more information.
- **SuperNode scripts** are stored as a SuperNode stream property. SuperNode scripts are only available in terminal SuperNodes. You might use a SuperNode script to control the execution sequence of the SuperNode contents. For nonterminal (source or process) SuperNodes, you can define properties for the SuperNode or the nodes it contains in your stream script directly. See the topic [SuperNode Scripts](#) for more information.

Related information

- [Scripting overview](#)
- [Stream Scripts](#)
- [Stream script example: Training a neural net](#)
- [Standalone Scripts](#)
- [SuperNode Scripts](#)

Stream Scripts

Scripts can be used to customize operations within a particular stream, and they are saved with that stream. Stream scripts can be used to specify a particular execution order for the terminal nodes within a stream. You use the stream script dialog box to edit the script that is saved with the current stream.

To access the stream script tab in the Stream Properties dialog box:

- From the Tools menu, choose:
Stream Properties > Execution
- Click the Execution tab to work with scripts for the current stream.

Use the toolbar icons at the top of the stream script dialog box for the following operations:

- Import the contents of a preexisting stand-alone script into the window.
- Save a script as a text file.
- Print a script.
- Append default script.
- Edit a script (undo, cut, copy, paste, and other common edit functions).
- Execute the entire current script.
- Execute selected lines from a script.
- Stop a script during execution. (This icon is only enabled when a script is running.)
- Check the syntax of the script and, if any errors are found, display them for review in the lower pane of the dialog box.

Note: From version 16.0 onwards, SPSS® Modeler uses the Python scripting language. All versions before 16.0 used a scripting language unique to SPSS Modeler, now referred to as Legacy scripting. Depending on the type of script you are working with, on the Execution tab select the Default (optional script) execution mode and then select either Python or Legacy.

You can specify whether a script is or is not run when the stream is executed. To run the script each time the stream is executed, respecting the execution order of the script, select Run this script. This setting provides automation at the stream level for quicker model building. However, the default setting is to ignore this script during stream execution. Even if you select the option Ignore this script, you can always run the script directly from this dialog box.

The script editor includes the following features that help with script authoring:

- Syntax highlighting; keywords, literal values (such as strings and numbers), and comments are highlighted.
- Line numbering.
- Block matching; when the cursor is placed by the start of a program block, the corresponding end block is also highlighted.
- Suggested auto-completion.

The colors and text styles that are used by the syntax highlighter can be customized by using the IBM® SPSS Modeler display preferences. To access the display preferences, choose Tools > Options > User Options and select the Syntax tab.

A list of suggested syntax completions can be accessed by selecting Auto-Suggest from the context menu, or pressing Ctrl + Space. Use the cursor keys to move up and down the list, then press Enter to insert the selected text. To exit from auto-suggest mode without modifying the existing text, press Esc.

The Debug tab displays debugging messages and can be used to evaluate script state once the script is executed. The Debug tab consists of a read-only text area and a single-line input text field. The text area displays text that is sent to either standard output or standard error by the scripts, for example through error message text. The input text field takes input from the user. This input is then evaluated within the context of the script that was most recently executed within the dialog (known as the *scripting context*). The text area contains the command and resulting output so that the user can see a trace of commands. The text input field always contains the command prompt (→ for Legacy scripting).

A new scripting context is created in the following circumstances:

- A script is executed by using either Run this script or Run selected lines.
- The scripting language is changed.

If a new scripting context is created, the text area is cleared.

Note: Executing a stream outside of the script pane does not modify the script context of the script pane. The values of any variables that are created as part of that execution are not visible within the script dialog box.

Stream script example: Training a neural net

A stream can be used to train a neural network model when executed. Normally, to test the model, you might run the modeling node to add the model to the stream, make the appropriate connections, and execute an Analysis node.

Using an IBM® SPSS® Modeler script, you can automate the process of testing the model nugget after you have created it. For example, the following stream script to test the demo stream druglearn.str (available in the /Demos/streams/ folder under your IBM SPSS Modeler installation) could be run from the Stream Properties dialog (Tools > Stream Properties > Script):

```
stream = modeler.script.stream()
neuralnetnode = stream.findByName("neuralnetwork", None)
results = []
neuralnetnode.run(results)
appliernode = stream.createModelApplierAt(results[0], "Drug", 594, 187)
analysisnode = stream.createAt("analysis", "Drug", 688, 187)
typenode = stream.findByName("type", None)
stream.linkBetween(appliernode, typenode, analysisnode)
analysisnode.run([])
```

The following bullets describe each line in this script example.

- The first line defines a variable that points to the current stream.
- In line 2, the script finds the Neural Net builder node.
- In line 3, the script creates a list where the execution results can be stored.
- In line 4, the Neural Net model nugget is created. This is stored in the list defined on line 3.
- In line 5, a model apply node is created for the model nugget and placed on the stream canvas.
- In line 6, an analysis node called **Drug** is created.
- In line 7, the script finds the Type node.
- In line 8, the script connects the model apply node created in line 5 between the Type node and the Analysis node.
- Finally, the Analysis node is executed to produce the Analysis report.

It is possible to use a script to build and run a stream from scratch, starting with a blank canvas.

Jython code size limits

Jython compiles each script to Java bytecode, which is then executed by the Java Virtual Machine (JVM). However, Java imposes a limit on the size of a single bytecode file. So when Jython attempts to load the bytecode, it can cause the JVM to crash. IBM® SPSS® Modeler is unable to prevent this from happening.

Ensure that you write your Jython scripts using good coding practices (such as minimizing duplicated code by using variables or functions to compute common intermediate values). If necessary, you may need to split your code over several source files or define it using modules as these are compiled into bytecode files.

Standalone Scripts

The Standalone Script dialog box is used to create or edit a script that is saved as a text file. It displays the name of the file and provides facilities for loading, saving, importing, and executing scripts.

To access the standalone script dialog box:

From the main menu, choose:

Tools > Standalone Script

The same toolbar and script syntax-checking options are available for standalone scripts as for stream scripts. See the topic [Stream Scripts](#) for more information.

- [Standalone script example: Saving and loading a model](#)
- [Standalone script example: Generating a Feature Selection model](#)

Standalone script example: Saving and loading a model

Standalone scripts are useful for stream manipulation. Suppose that you have two streams—one that creates a model and another that uses graphs to explore the generated rule set from the first stream with existing data fields. A standalone script for this scenario might look something like this:

```
taskrunner = modeler.script.session().getTaskRunner()

# Modify this to the correct Modeler installation Demos folder.
# Note use of forward slash and trailing slash.
installation = "C:/Program Files/IBM/SPSS/Modeler/19/Demos/"

# First load the model builder stream from file and build a model
druglearn_stream = taskrunner.openStreamFromFile(installation + "streams/druglearn.str", True)
results = []
druglearn_stream.findByType("c50", None).run(results)

# Save the model to file
taskrunner.saveModelToFile(results[0], "rule.gm")

# Now load the plot stream, read the model from file and insert it into the stream
drugplot_stream = taskrunner.openStreamFromFile(installation + "streams/drugplot.str", True)
model = taskrunner.openModelFromFile("rule.gm", True)
modelapplier = drugplot_stream.createModelApplier(model, "Drug")

# Now find the plot node, disconnect it and connect the
# model applier node between the derive node and the plot node
derivenode = drugplot_stream.findByType("derive", None)
plotnode = drugplot_stream.findByType("plot", None)
drugplot_stream.disconnect(plotnode)
modelapplier.setPositionBetween(derivenode, plotnode)
drugplot_stream.linkBetween(modelapplier, derivenode, plotnode)
plotnode.setPropertyValue("color_field", "$C-Drug")
plotnode.run([])
```

Note: To learn more about scripting language in general, see [Scripting language overview](#).

Standalone script example: Generating a Feature Selection model

Starting with a blank canvas, this example builds a stream that generates a Feature Selection model, applies the model, and creates a table that lists the 15 most important fields relative to the specified target.

```
stream = modeler.script.session().createProcessorStream("featureselection", True)

statisticsimportnode = stream.createAt("statisticsimport", "Statistics File", 150, 97)
statisticsimportnode.setPropertyValue("full_filename", "$CLEO_DEMOS/customer_dbase.sav")

typenode = stream.createAt("type", "Type", 258, 97)
typenode.setKeyedPropertyValue("direction", "response_01", "Target")

featureselectionnode = stream.createAt("featureselection", "Feature Selection", 366, 97)
featureselectionnode.setPropertyValue("top_n", 15)
featureselectionnode.setPropertyValue("max_missing_values", 80.0)
featureselectionnode.setPropertyValue("selection_mode", "TopN")
featureselectionnode.setPropertyValue("important_label", "Check Me Out!")
featureselectionnode.setPropertyValue("criteria", "Likelihood")

stream.link(statisticsimportnode, typenode)
stream.link(typenode, featureselectionnode)
models = []
featureselectionnode.run(models)

# Assumes the stream automatically places model apply nodes in the stream
applynode = stream.findByType("applyfeatureselection", None)
tablenode = stream.createAt("table", "Table", applynode.getXPosition() + 96, applynode.getYPosition())
stream.link(applynode, tablenode)
tablenode.run([])
```

The script creates a source node to read in the data, uses a Type node to set the role (direction) for the `response_01` field to `Target`, and then creates and executes a Feature Selection node. The script also connects the nodes and positions each on the stream canvas to produce a readable layout. The resulting model nugget is then connected to a Table node, which lists the 15 most important fields as determined by the `selection_mode` and `top_n` properties. See the topic [featureselectionnode.properties](#) for more information.

SuperNode Scripts

You can create and save scripts within any terminal SuperNodes using the IBM® SPSS® Modeler scripting language. These scripts are only available for terminal SuperNodes and are often used when creating template streams or to impose a special execution order for the SuperNode contents. SuperNode scripts also enable you to have more than one script running within a stream.

For example, let's say you needed to specify the order of execution for a complex stream, and your SuperNode contains several nodes including a SetGlobals node, which needs to be executed before deriving a new field used in a Plot node. In this case, you can create a SuperNode script that executes the SetGlobals node first. Values calculated by this node, such as the average or standard deviation, can then be used when the Plot node is executed.

Within a SuperNode script, you can specify node properties in the same manner as other scripts. Alternatively, you can change and define the properties for any SuperNode or its encapsulated nodes directly from a stream script. See the topic [SuperNode properties](#) for more information. This method works for source and process SuperNodes as well as terminal SuperNodes.

Note: Since only terminal SuperNodes can execute their own scripts, the Scripts tab of the SuperNode dialog box is available only for terminal SuperNodes.

To open the SuperNode script dialog box from the main canvas:

Select a terminal SuperNode on the stream canvas and, from the SuperNode menu, choose:

SuperNode Script...

To open the SuperNode script dialog box from the zoomed-in SuperNode canvas:

Right-click the SuperNode canvas, and from the context menu, choose:

SuperNode Script...

SuperNode Script Example

The following SuperNode script declares the order in which the terminal nodes inside the SuperNode should be executed. This order ensures that the Set Globals node is executed first so that the values calculated by this node can then be used when another node is executed.

```
execute 'Set Globals'  
execute 'gains'  
execute 'profit'  
execute 'age v. $CC-pep'  
execute 'Table'
```

Locking and unlocking SuperNodes

The following example illustrates how you can lock and unlock a SuperNode:

```
stream = modeler.script.stream()  
superNode=stream.findByID('id854RNTSD5MB')
```

```

# unlock one super node
print 'unlock the super node with password abcd'
if superNode.unlock('abcd'):
    print 'unlocked.'
else:
    print 'invalid password.'
# lock one super node
print 'lock the super node with password abcd'
superNode.lock('abcd')

```

Looping and conditional execution in streams

From version 16.0 onwards, SPSS® Modeler enables you to create some basic scripts from within a stream by selecting values within various dialog boxes instead of having to write instructions directly in the scripting language. The two main types of scripts you can create in this way are simple loops and a way to execute nodes if a condition has been met.

You can combine both looping and conditional execution rules within a stream. For example, you may have data relating to sales of cars from manufacturers worldwide. You could set up a loop to process the data in a stream, identifying details by the country of manufacture, and output the data to different graphs showing details such as sales volume by model, emissions levels by both manufacturer and engine size, and so on. If you were interested in analyzing European information only, you could also add conditions to the looping that prevented graphs being created for manufacturers based in America and Asia.

Note: Because both looping and conditional execution are based on background scripts they are only applied to a whole stream when it is run.

- **Looping** You can use looping to automate repetitive tasks. For example, this might mean adding a given number of nodes to a stream and changing one node parameter each time. Alternatively, you could control the running of a stream or branch again and again for a given number of times, as in the following examples:
 - Run the stream a given number of times and change the source each time.
 - Run the stream a given number of times, changing the value of a variable each time.
 - Run the stream a given number of times, entering one extra field on each execution.
 - Build a model a given number of times and change a model setting each time.
- **Conditional Execution** You can use this to control how terminal nodes are run, based on conditions that you predefine, examples may include the following:
 - Based on whether a given value is true or false, control if a node will be run.
 - Define whether looping of nodes will be run in parallel or sequentially.

Both looping and conditional execution are set up on the Execution tab within the Stream Properties dialog box. Any nodes that are used in conditional or looping requirements are shown with an additional symbol attached to them on the stream canvas to indicate that they are taking part in looping and conditional execution.

You can access the Execution tab in one of 3 ways:

- Using the menus at the top of the main dialog box:
 1. From the Tools menu, choose:
[Stream Properties](#) > [Execution](#)
 2. Click the Execution tab to work with scripts for the current stream.
- From within a stream:
 1. Right-click on a node and choose Looping/Conditional Execution.
 2. Select the relevant submenu option.
- From the graphic toolbar at the top of the main dialog box, click the stream properties icon.

If this is the first time you have set up either looping or conditional execution details, on the Execution tab select the Looping/Conditional Execution execution mode and then select either the Conditional or Looping subtab.

- [Looping in streams](#)
- [Conditional execution in streams](#)

Related information

-

Looping in streams

With looping you can automate repetitive tasks in streams; examples may include the following:

- Run the stream a given number of times and change the source each time.
- Run the stream a given number of times, changing the value of a variable each time.
- Run the stream a given number of times, entering one extra field on each execution.
- Build a model a given number of times and change a model setting each time.

You set up the conditions to be met on the Looping subtab of the stream Execution tab. To display the subtab, select the Looping/Conditional Execution execution mode.

Any looping requirements that you define will take effect when you run the stream, if the Looping/Conditional Execution execution mode has been set. Optionally, you can generate the script code for your looping requirements and paste it into the script editor by clicking Paste... in the bottom right corner of the Looping subtab; the main Execution tab display changes to show the Default (optional script) execution mode with the script in the top part of the tab. This means that you can define a looping structure using the various looping dialog box options before generating a script that you can customize further in the script editor. Note that when you click Paste... any conditional execution requirements you have defined will also be displayed in the generated script.

Important: The looping variables that you set in a SPSS® Modeler stream may be overridden if you run the stream in a IBM® SPSS Collaboration and Deployment Services job. This is because the IBM SPSS Collaboration and Deployment Services job editor entry overrides the SPSS Modeler entry. For example, if you set a looping variable in the stream to create a different output file name for each loop, the files are correctly named in SPSS Modeler but are overridden by the fixed entry entered on the Result tab of the IBM SPSS Collaboration and Deployment Services Deployment Manager.

To set up a loop

1. Create an iteration key to define the main looping structure to be carried out in a stream. See [Create an iteration key](#) for more information.
 2. Where needed, define one or more iteration variables. See [Create an iteration variable](#) for more information.
 3. The iterations and any variables you created are shown in the main body of the subtab. By default, iterations are executed in the order they appear; to move an iteration up or down the list, click on it to select it then use the up or down arrow in the right hand column of the subtab to change the order.

Creating an iteration key for looping in streams

You use an iteration key to define the main looping structure to be carried out in a stream. For example, if you are analyzing car sales, you could create a stream parameter *Country of manufacture* and use this as the iteration key; when the stream is run this key is set to each different country value in your data during each iteration. Use the Define Iteration Key dialog box to set up the key.

To open the dialog box, either select the Iteration Key... button in the bottom left corner of the Looping subtab, or right click on any node in the stream and select either Looping/Conditional Execution > Define Iteration Key (Fields) or Looping/Conditional Execution > Define Iteration Key (Values). If you open the dialog box from the stream, some of the fields may be completed automatically for you, such as the name of the node.

To set up an iteration key, complete the following fields:

Iterate on. You can select from one of the following options:

- Stream Parameter - Fields. Use this option to create a loop that sets the value of an existing stream parameter to each specified field in turn.
- Stream Parameter - Values. Use this option to create a loop that sets the value of an existing stream parameter to each specified value in turn.
- Node Property - Fields. Use this option to create a loop that sets the value of a node property to each specified field in turn.
- Node Property - Values. Use this option to create a loop that sets the value of a node property to each specified value in turn.

What to Set. Choose the item that will have its value set each time the loop is executed. You can select from one of the following options:

- Parameter. Only available if you select either Stream Parameter - Fields or Stream Parameter - Values. Select the required parameter from the available list.
- Node. Only available if you select either Node Property - Fields or Node Property - Values. Select the node for which you want to set up a loop. Click the browse button to open the Select Node dialog and choose the node you want; if there are too many nodes listed you can filter the display to only show certain types of nodes by selecting one of the following categories: Source, Process, Graph, Modeling, Output, Export, or Apply Model nodes.
- Property. Only available if you select either Node Property - Fields or Node Property - Values. Select the property of the node from the available list.

Fields to Use. Only available if you select either Stream Parameter - Fields or Node Property - Fields. Choose the field, or fields, within a node to use to provide the iteration values. You can select from one of the following options:

- Node. Only available if you select Stream Parameter - Fields. Select the node that contains the details for which you want to set up a loop. Click the browse button to open the Select Node dialog and choose the node you want; if there are too many nodes listed you can filter the display to only show certain types of nodes by selecting one of the following categories: Source, Process, Graph, Modeling, Output, Export, or Apply Model nodes.
- Field List. Click the list button in the right column to display the Select Fields dialog box, within which you select the fields in the node to provide the iteration data. See [Selecting fields for iterations](#) for more information.

Values to Use. Only available if you select either Stream Parameter - Values or Node Property - Values. Choose the value, or values, within the selected field to use as iteration values. You can select from one of the following options:

- Node. Only available if you select Stream Parameter - Values. Select the node that contains the details for which you want to set up a loop. Click the browse button to open the Select Node dialog and choose the node you want; if there are too many nodes listed you can filter the display to only show certain types of nodes by selecting one of the following categories: Source, Process, Graph, Modeling, Output, Export, or Apply Model nodes.
- Field List. Select the field in the node to provide the iteration data.
- Value List. Click the list button in the right column to display the Select Values dialog box, within which you select the values in the field to provide the iteration data.

Related information

Creating an iteration variable for looping in streams

You can use iteration variables to change the values of stream parameters or properties of selected nodes within a stream each time a loop is executed. For example, if your stream loop is analyzing car sales data and using *Country of manufacture* as the iteration key, you may have one graph output showing sales by model and another graph output showing exhaust emissions information. In these cases you could create iteration variables that create new titles for the resultant graphs, such as *Swedish vehicle emissions* and *Japanese car sales by model*. Use the Define Iteration Variable dialog box to set up any variables that you require.

To open the dialog box, either select the Add Variable... button in the bottom left corner of the Looping subtab, or right click on any node in the stream and select:Looping/Conditional Execution > Define Iteration Variable.

To set up an iteration variable, complete the following fields:

Change. Select the type of attribute that you want to amend. You can choose from either Stream Parameter or Node Property.

- If you select Stream Parameter, choose the required parameter and then, by using one of the following options, if available in your stream, define what the value of that parameter should be set to with each iteration of the loop:
 - Global variable. Select the global variable that the stream parameter should be set to.

- Table output cell. To set a stream parameter to be the value in a table output cell, select the table from the list and enter the Row and Column to be used.
 - Enter manually. Select this if you want to manually enter a value for this parameter to take in each iteration. When you return to the Looping subtab a new column is created into which you enter the required text.
 - If you select Node Property, choose the required node and one of its properties and then set the value you want to use for that property. Set the new property value by using one of the following options:
 - Alone. The property value will use the iteration key value. See [Creating an iteration key for looping in streams](#) for more information.
 - As prefix to stem. Uses the iteration key value as a prefix to what you enter in the Stem field.
 - As suffix to stem. Uses the iteration key value as a suffix to what you enter in the Stem field
- If you select either the prefix or suffix option you are prompted to add the additional text to the Stem field. For example, if your iteration key value is *Country of manufacture*, and you select As prefix to stem, you might enter - *sales by model* in this field.

Selecting fields for iterations

When creating iterations you can select one or more fields using the Select Fields dialog box.

Sort by You can sort available fields for viewing by selecting one of the following options:

- Natural View the order of fields as they have been passed down the data stream into the current node.
- Name Use alphabetical order to sort fields for viewing.
- Type View fields sorted by their measurement level. This option is useful when selecting fields with a particular measurement level.

Select fields from the list one at a time or use the Shift-click and Ctrl-click methods to select multiple fields. You can also use the buttons below the list to select groups of fields based on their measurement level, or to select or deselect all fields in the table.

Note that the fields available for selection are filtered to show only the fields that are appropriate for the stream parameter or node property you are using. For example, if you are using a stream parameter that has a storage type of String, only fields that have a storage type of String are shown.

Related information

- [Scripting overview](#)

Conditional execution in streams

With conditional execution you can control how terminal nodes are run, based on the stream contents matching conditions that you define; examples may include the following:

- Based on whether a given value is true or false, control if a node will be run.
- Define whether looping of nodes will be run in parallel or sequentially.

You set up the conditions to be met on the Conditional subtab of the stream Execution tab. To display the subtab, select the Looping/Conditional Execution execution mode.

Any conditional execution requirements that you define will take effect when you run the stream, if the Looping/Conditional Execution execution mode has been set. Optionally, you can generate the script code for your conditional execution requirements and paste it into the script editor by clicking Paste... in the bottom right corner of the Conditional subtab; the main Execution tab display changes to show the Default (optional script) execution mode with the script in the top part of the tab. This means that you can define conditions using the various looping dialog box options before generating a script that you can customize further in the script editor. Note that when you click Paste... any looping requirements you have defined will also be displayed in the generated script.

To set up a condition:

1. In the right hand column of the Conditional subtab, click the Add New Condition button to open the Add Conditional Execution Statement dialog box. In this dialog you specify the condition that must be met in order for the node to be executed.
2. In the Add Conditional Execution Statement dialog box, specify the following:
 - a. **Node**. Select the node for which you want to set up conditional execution. Click the browse button to open the Select Node dialog and choose the node you want; if there are too many nodes listed you can filter the display to show nodes by one of the following categories: Export, Graph, Modeling, or Output node.
 - b. **Condition based on**. Specify the condition that must be met for the node to be executed. You can choose from one of four options: Stream parameter, Global variable, Table output cell, or Always true. The details you enter in the bottom half of the dialog box are controlled by the condition you choose.
 - **Stream parameter**. Select the parameter from the list available and then choose the Operator for that parameter; for example, the operator may be More than, Equals, Less than, Between, and so on. You then enter the Value, or minimum and maximum values, depending on the operator.
 - **Global variable**. Select the variable from the list available; for example, this might include: Mean, Sum, Minimum value, Maximum value, or Standard deviation. You then select the Operator and values required.
 - **Table output cell**. Select the table node from the list available and then choose the Row and Column in the table. You then select the Operator and values required.
 - **Always true**. Select this option if the node must always be executed. If you select this option, there are no further parameters to select.
3. Repeat steps 1 and 2 as often as required until you have set up all the conditions you require. The node you selected and the condition to be met before that node is executed are shown in the main body of the subtab in the Execute Node and If this condition is true columns respectively.
4. By default, nodes and conditions are executed in the order they appear; to move a node and condition up or down the list, click on it to select it then use the up or down arrow in the right hand column of the subtab to change the order.

In addition, you can set the following options at the bottom of the Conditional subtab:

- **Evaluate all in order**. Select this option to evaluate each condition in the order in which they are shown on the subtab. The nodes for which conditions have been found to be "True" will all be executed once all the conditions have been evaluated.
- **Execute one at a time**. Only available if **Evaluate all in order** is selected. Selecting this means that if a condition is evaluated as "True", the node associated with that condition is executed before the next condition is evaluated.
- **Evaluate until first hit**. Selecting this means that only the first node that returns a "True" evaluation from the conditions you specified will be run.

Executing and interrupting scripts

A number of ways of executing scripts are available. For example, on the stream script or standalone script dialog, the "Run this script" button executes the complete script:

Figure 1. Run This Script button

The "Run selected lines" button executes a single line, or a block of adjacent lines, that you have selected in the script:

Figure 2. Run Selected Lines button

You can execute a script using any of the following methods:

- Click the "Run this script" or "Run selected lines" button within a stream script or standalone script dialog box.
- Run a stream where Run this script is set as the default execution method.
- Use the `-execute` flag on startup in interactive mode. See the topic [Using command line arguments](#) for more information.

Note: A SuperNode script is executed when the SuperNode is executed as long as you have selected Run this script within the SuperNode script dialog box.

Interrupting script execution

Within the stream script dialog box, the red stop button is activated during script execution. Using this button, you can abandon the execution of the script and any current stream.

The Scripting Language

Scripting language overview

The scripting facility for IBM® SPSS® Modeler enables you to create scripts that operate on the SPSS Modeler user interface, manipulate output objects, and run command syntax. You can run scripts directly from within SPSS Modeler.

Scripts in IBM SPSS Modeler are written in the scripting language Python. The Java-based implementation of Python that is used by IBM SPSS Modeler is called Jython. The scripting language consists of the following features:

- A format for referencing nodes, streams, projects, output, and other IBM SPSS Modeler objects.
- A set of scripting statements or commands that can be used to manipulate these objects.
- A scripting expression language for setting the values of variables, parameters, and other objects.
- Support for comments, continuations, and blocks of literal text.

The following sections describe the Python scripting language, the Jython implementation of Python, and the basic syntax for getting started with scripting within IBM SPSS Modeler. Information about specific properties and commands is provided in the sections that follow.

Python and Jython

Jython is an implementation of the Python scripting language, which is written in the Java language and integrated with the Java platform. Python is a powerful object-oriented scripting language. Jython is useful because it provides the productivity features of a mature scripting language and, unlike Python, runs in any environment that supports a Java virtual machine (JVM). This means that the Java libraries on the JVM are available to use when you are writing programs. With Jython, you can take advantage of this difference, and use the syntax and most of the features of the Python language.

As a scripting language, Python (and its Jython implementation) is easy to learn and efficient to code, and has minimal required structure to create a running program. Code can be entered interactively, that is, one line at a time. Python is an interpreted scripting language; there is no precompile step, as there is in Java. Python programs are simply text files that are interpreted as they are input (after parsing for syntax errors). Simple expressions, like defined values, as well as more complex actions, such as function definitions, are immediately executed and available for use. Any changes that are made to the code can be tested quickly. Script interpretation does, however, have some disadvantages. For example, use of an undefined variable is not a compiler error, so it is detected only if (and when) the statement in which the variable is used is executed. In this case, the program can be edited and run to debug the error.

Python sees everything, including all data and code, as an object. You can, therefore, manipulate these objects with lines of code. Some select types, such as numbers and strings, are more conveniently considered as values, not objects; this is supported by Python. There is one null value that is supported. This null value has the reserved name **None**.

For a more in-depth introduction to Python and Jython scripting, and for some example scripts, see <http://www.ibm.com/developerworks/java/tutorials/j-jython1/j-jython1.html> and <http://www.ibm.com/developerworks/java/tutorials/j-jython2/j-jython2.html>.

Operations

Assignment is done using an equals sign (=). For example, to assign the value "3" to a variable called "x" you would use the following statement:

```
x = 3
```

The equals sign is also used to assign string type data to a variable. For example, to assign the value "a string value" to the variable "y" you would use the following statement:

```
y = "a string value"
```

The following table lists some commonly used comparison and numeric operations, and their descriptions.

Table 1. Common comparison and numeric operations

Operation	Description
<code>x < y</code>	Is <code>x</code> less than <code>y</code> ?
<code>x > y</code>	Is <code>x</code> greater than <code>y</code> ?
<code>x <= y</code>	Is <code>x</code> less than or equal to <code>y</code> ?
<code>x >= y</code>	Is <code>x</code> greater than or equal to <code>y</code> ?
<code>x == y</code>	Is <code>x</code> equal to <code>y</code> ?
<code>x != y</code>	Is <code>x</code> not equal to <code>y</code> ?
<code>x <> y</code>	Is <code>x</code> not equal to <code>y</code> ?

Operation	Description
<code>x + y</code>	Add <code>y</code> to <code>x</code>
<code>x - y</code>	Subtract <code>y</code> from <code>x</code>
<code>x * y</code>	Multiply <code>x</code> by <code>y</code>
<code>x / y</code>	Divide <code>x</code> by <code>y</code>
<code>x ** y</code>	Raise <code>x</code> to the <code>y</code> power

Lists

Lists are sequences of elements. A list can contain any number of elements, and the elements of the list can be any type of object. Lists can also be thought of as arrays. The number of elements in a list can increase or decrease as elements are added, removed, or replaced.

Examples

<code>[]</code>	Any empty list.
<code>[1]</code>	A list with a single element, an integer.
<code>["Mike", 10, "Don", 20]</code>	A list with four elements, two string elements and two integer elements.
<code>[[], [7], [8, 9]]</code>	A list of lists. Each sub-list is either an empty list or a list of integer elements.
<code>x = 7; y = 2; z = 3; [1, x, y, x + y]</code>	A list of integers. This example demonstrates the use of variables and expressions.

You can assign a list to a variable, for example:

```
mylist1 = ["one", "two", "three"]
```

You can then access specific elements of the list, for example:

```
mylist[0]
```

This will result in the following output:

```
one
```

The number in the brackets (`[]`) is known as an *index* and refers to a particular element of the list. The elements of a list are indexed starting from 0.

You can also select a range of elements of a list; this is called *slicing*. For example, `x[1:3]` selects the second and third elements of `x`. The end index is one past the selection.

Strings

A *string* is an immutable sequence of characters that is treated as a value. Strings support all of the immutable sequence functions and operators that result in a new string. For example, "`abcdef[1:4]`" results in the output "`bcd`".

In Python, characters are represented by strings of length one.

String literals are defined by the use of single or triple quoting. Strings that are defined using single quotes cannot span lines, while strings that are defined using triple quotes can. A string can be enclosed in single quotes ('') or double quotes (""). A quoting character may contain the other quoting character un-escaped or the quoting character escaped, that is preceded by the backslash (\) character.

Examples

```
"This is a string"
'This is also a string'
"It's a string"
'This book is called "Python Scripting and Automation Guide".'
"This is an escape quote (\") in a quoted string"
```

Multiple strings separated by white space are automatically concatenated by the Python parser. This makes it easier to enter long strings and to mix quote types in a single string, for example:

```
"This string uses ' and " that string uses ". '
```

This results in the following output:

```
This string uses ' and that string uses ".
```

Strings support several useful methods. Some of these methods are given in the following table.

Table 1. String methods

Method	Usage
<code>s.capitalize()</code>	Initial capitalize <code>s</code>
<code>s.count(ss [,start [,end]])</code>	Count the occurrences of <code>ss</code> in <code>s[start:end]</code>
<code>s.startswith(str [, start [, end]])</code>	Test to see if <code>s</code> starts with <code>str</code>
<code>s.endswith(str [, start [, end]])</code>	Test to see if <code>s</code> ends with <code>str</code>
<code>s.expandtabs({size})</code>	Replace tabs with spaces, default <code>size</code> is 8
<code>s.find(str [, start [, end]])</code>	Finds first index of <code>str</code> in <code>s</code> ; if not found, the result is -1. <code>rfind</code> searches right to left.
<code>s.index(str [, start [, end]])</code>	Finds first index of <code>str</code> in <code>s</code> ; if not found: raise <code>ValueError</code> . <code>rindex</code> searches right to left.
<code>s.isalnum</code>	Test to see if the string is alphanumeric
<code>s.isalpha</code>	Test to see if the string is alphabetic
<code>s.isnum</code>	Test to see if the string is numeric
<code>s.isupper</code>	Test to see if the string is all uppercase
<code>s.islower</code>	Test to see if the string is all lowercase
<code>s.isspace</code>	Test to see if the string is all whitespace
<code>s.istitle</code>	Test to see if the string is a sequence of initial cap alphanumeric strings
<code>s.lower()</code>	Convert to all lower case
<code>s.upper()</code>	Convert to all upper case
<code>s.swapcase()</code>	Convert to all opposite case
<code>s.title()</code>	Convert to all title case
<code>s.join(seq)</code>	Join the strings in <code>seq</code> with <code>s</code> as the separator
<code>s.splitlines({keep})</code>	Split <code>s</code> into lines, if <code>keep</code> is <code>true</code> , keep the new lines
<code>s.split({sep [, max]})</code>	Split <code>s</code> into "words" using <code>sep</code> (default <code>sep</code> is a white space) for up to <code>max</code> times
<code>s.ljust(width)</code>	Left justify the string in a field <code>width</code> wide
<code>s.rjust(width)</code>	Right justify the string in a field <code>width</code> wide
<code>s.center(width)</code>	center justify the string in a field <code>width</code> wide
<code>s.zfill(width)</code>	Fill with 0.
<code>s.lstrip()</code>	Remove leading white space
<code>s.rstrip()</code>	Remove trailing white space
<code>s.strip()</code>	Remove leading and trailing white space
<code>s.translate(str {,delc})</code>	Translate <code>s</code> using table, after removing any characters in <code>delc</code> . <code>str</code> should be a string with length == 256.
<code>s.replace(old, new [, max])</code>	Replaces all or <code>max</code> occurrences of string <code>old</code> with string <code>new</code>

Remarks

Remarks are comments that are introduced by the pound (or hash) sign (#). All text that follows the pound sign on the same line is considered part of the remark and is ignored. A remark can start in any column. The following example demonstrates the use of remarks:

```
#The HelloWorld application is one of the most simple
print 'Hello World' # print the Hello World line
```

Statement Syntax

The statement syntax for Python is very simple. In general, each source line is a single statement. Except for **expression** and **assignment** statements, each statement is introduced by a keyword name, such as **if** or **for**. Blank lines or remark lines can be inserted anywhere between any statements in the code. If there is more than one statement on a line, each statement must be separated by a semicolon (;).

Very long statements can continue on more than one line. In this case the statement that is to continue on to the next line must end with a backslash (\), for example:

```
x = "A loooooooooooooong string" + \
    "another loooooooooooooong string"
```

When a structure is enclosed by parentheses (()), brackets ([]), or curly braces ({ }), the statement can be continued on to a new line after any comma, without having to insert a backslash, for example:

```
x = (1, 2, 3, "hello",
      "goodbye", 4, 5, 6)
```

Identifiers

Identifiers are used to name variables, functions, classes and keywords. Identifiers can be any length, but must start with either an alphabetical character of upper or lower case, or the underscore character (_). Names that start with an underscore are generally reserved for internal or private names. After the first character, the identifier can contain any number and combination of alphabetical characters, numbers from 0-9, and the underscore character.

There are some reserved words in Jython that cannot be used to name variables, functions, or classes. They fall under the following categories:

- **Statement introducers:** assert, break, class, continue, def, del, elif, else, except, exec, finally, for, from, global, if, import, pass, print, raise, return, try, and while
- **Parameter introducers:** as, import, and in
- **Operators:** and, in, is, lambda, not, and or

Improper keyword use generally results in a SyntaxError.

Blocks of Code

Blocks of code are groups of statements that are used where single statements are expected. Blocks of code can follow any of the following statements: if, elif, else, for, while, try, except, def, and class. These statements introduce the block of code with the colon character (:), for example:

```
if x == 1:  
    y = 2  
    z = 3  
elif:  
    y = 4  
    z = 5
```

Indentation is used to delimit code blocks (rather than the curly braces that are used in Java). All lines in a block must be indented to the same position. This is because a change in the indentation indicates the end of a code block. It is usual to indent by four spaces per level. It is recommended that spaces are used to indent the lines, rather than tabs. Spaces and tabs must not be mixed. The lines in the outermost block of a module must start at column one, else a SyntaxError will occur.

The statements that make up a code block (and follow the colon) can also be on a single line, separated by semicolons, for example:

```
if x == 1: y = 2; z = 3;
```

Passing Arguments to a Script

Passing arguments to a script is useful as it means a script can be used repeatedly without modification. The arguments that are passed on the command line are passed as values in the list `sys.argv`. The number of values passed can be obtained by using the command `len(sys.argv)`. For example:

```
import sys
print "test1"
print sys.argv[0]
print sys.argv[1]
print len(sys.argv)
```

In this example, the `import` command imports the entire `sys` class so that the methods that exist for this class, such as `argv`, can be used.

The script in this example can be invoked using the following line:

```
/u/mjloos/test1 mike don
```

The result is the following output:

```
/u/mjloos/test1 mike don
test1
mike
don
3
```

Examples

The `print` keyword prints the arguments immediately following it. If the statement is followed by a comma, a new line is not included in the output. For example:

```
print "This demonstrates the use of a",
print " comma at the end of a print statement."
```

This will result in the following output:

```
This demonstrates the use of a comma at the end of a print statement.
```

The `for` statement is used to iterate through a block of code. For example:

```
mylist1 = ["one", "two", "three"]
for lv in mylist1:
    print lv
    continue
```

In this example, three strings are assigned to the list `mylist1`. The elements of the list are then printed, with one element of each line. This will result in the following output:

```
one
two
three
```

In this example, the iterator `lv` takes the value of each element in the list `mylist1` in turn as the for loop implements the code block for each element. An iterator can be any valid identifier of any length.

The `if` statement is a conditional statement. It evaluates the condition and returns either true or false, depending on the result of the evaluation. For example:

```

mylist1 = ["one", "two", "three"]
for lv in mylist1:
    if lv == "two":
        print "The value of lv is ", lv
    else
        print "The value of lv is not two, but ", lv
    continue

```

In this example, the value of the iterator `lv` is evaluated. If the value of `lv` is `two` a different string is returned to the string that is returned if the value of `lv` is not `two`. This results in the following output:

```

The value of lv is not two, but one
The value of lv is two
The value of lv is not two, but three

```

Mathematical Methods

From the `math` module you can access useful mathematical methods. Some of these methods are given in the following table. Unless specified otherwise, all values are returned as floats.

Table 1. Mathematical methods

Method	Usage
<code>math.ceil(x)</code>	Return the ceiling of <code>x</code> as a float, that is the smallest integer greater than or equal to <code>x</code>
<code>math.copysign(x, y)</code>	Return <code>x</code> with the sign of <code>y</code> . <code>copysign(1, -0.0)</code> returns <code>-1</code>
<code>math.fabs(x)</code>	Return the absolute value of <code>x</code>
<code>math.factorial(x)</code>	Return <code>x</code> factorial. If <code>x</code> is negative or not an integer, a <code>ValueError</code> is raised.
<code>math.floor(x)</code>	Return the floor of <code>x</code> as a float, that is the largest integer less than or equal to <code>x</code>
<code>math.frexp(x)</code>	Return the mantissa (<code>m</code>) and exponent (<code>e</code>) of <code>x</code> as the pair (<code>m, e</code>). <code>m</code> is a float and <code>e</code> is an integer, such that <code>x == m * 2**e</code> exactly. If <code>x</code> is zero, returns <code>(0.0, 0)</code> , otherwise <code>0.5 <= abs(m) < 1</code> .
<code>math.fsum(iterable)</code>	Return an accurate floating point sum of values in <code>iterable</code>
<code>math.isinf(x)</code>	Check if the float <code>x</code> is positive or negative infinitive
<code>math.isnan(x)</code>	Check if the float <code>x</code> is <code>NaN</code> (not a number)
<code>math.ldexp(x, i)</code>	Return <code>x * (2**i)</code> . This is essentially the inverse of the function <code>frexp</code> .
<code>math.modf(x)</code>	Return the fractional and integer parts of <code>x</code> . Both results carry the sign of <code>x</code> and are floats.
<code>math.trunc(x)</code>	Return the <code>Real</code> value <code>x</code> , that has been truncated to an <code>Integral</code> .
<code>math.exp(x)</code>	Return <code>e**x</code>
<code>math.log(x[, base])</code>	Return the logarithm of <code>x</code> to the given value of <code>base</code> . If <code>base</code> is not specified, the natural logarithm of <code>x</code> is returned.
<code>math.log1p(x)</code>	Return the natural logarithm of <code>1+x</code> (<code>base e</code>)
<code>math.log10(x)</code>	Return the base-10 logarithm of <code>x</code>
<code>math.pow(x, y)</code>	Return <code>x</code> raised to the power <code>y</code> . <code>pow(1.0, x)</code> and <code>pow(x, 0.0)</code> always return 1, even when <code>x</code> is zero or <code>NaN</code> .
<code>math.sqrt(x)</code>	Return the square root of <code>x</code>

In addition to the mathematical functions, there are some useful trigonometric methods. These methods are shown in the following table.

Table 2. Trigonometric methods

Method	Usage
<code>math.acos(x)</code>	Return the arc cosine of <code>x</code> in radians
<code>math.asin(x)</code>	Return the arc sine of <code>x</code> in radians
<code>math.atan(x)</code>	Return the arc tangent of <code>x</code> in radians
<code>math.atan2(y, x)</code>	Return <code>atan(y / x)</code> in radians.
<code>math.cos(x)</code>	Return the cosine of <code>x</code> in radians.
<code>math.hypot(x, y)</code>	Return the Euclidean norm <code>sqrt(x*x + y*y)</code> . This is the length of the vector from the origin to the point <code>(x, y)</code> .
<code>math.sin(x)</code>	Return the sine of <code>x</code> in radians
<code>math.tan(x)</code>	Return the tangent of <code>x</code> in radians
<code>math.degrees(x)</code>	Convert angle <code>x</code> from radians to degrees
<code>math.radians(x)</code>	Convert angle <code>x</code> from degrees to radians
<code>math.acosh(x)</code>	Return the inverse hyperbolic cosine of <code>x</code>
<code>math.asinh(x)</code>	Return the inverse hyperbolic sine of <code>x</code>
<code>math.atanh(x)</code>	Return the inverse hyperbolic tangent of <code>x</code>
<code>math.cosh(x)</code>	Return the hyperbolic cosine of <code>x</code>
<code>math.sinh(x)</code>	Return the hyperbolic sine of <code>x</code>
<code>math.tanh(x)</code>	Return the hyperbolic tangent of <code>x</code>

There are also two mathematical constants. The value of `math.pi` is the mathematical constant pi. The value of `math.e` is the mathematical constant e.

Using Non-ASCII characters

In order to use non-ASCII characters, Python requires explicit encoding and decoding of strings into Unicode. In IBM® SPSS® Modeler, Python scripts are assumed to be encoded in UTF-8, which is a standard Unicode encoding that supports non-ASCII characters. The following script will compile because the Python compiler has been set to UTF-8 by SPSS Modeler.

```
stream = modeler.script.stream()
filenode = stream.createAt("variablefile", "テストノード", 96, 64)
```

However, the resulting node will have an incorrect label.

Figure 1. Node label containing non-ASCII characters, displayed incorrectly

äfää,äf^äf äf%äf%

The label is incorrect because the string literal itself has been converted to an ASCII string by Python.

Python allows Unicode string literals to be specified by adding a `u` character prefix before the string literal:

```
stream = modeler.script.stream()
filenode = stream.createAt("variablefile", u"テストノード", 96, 64)
```

This will create a Unicode string and the label will appear correctly.

Figure 2. Node label containing non-ASCII characters, displayed correctly

テストノード

Using Python and Unicode is a large topic which is beyond the scope of this document. Many books and online resources are available that cover this topic in great detail.

Object-Oriented Programming

Object-oriented programming is based on the notion of creating a model of the target problem in your programs. Object-oriented programming reduces programming errors and promotes the reuse of code. Python is an object-oriented language. Objects defined in Python have the following features:

- **Identity.** Each object must be distinct, and this must be testable. The `is` and `is not` tests exist for this purpose.
- **State.** Each object must be able to store state. Attributes, such as fields and instance variables, exist for this purpose.
- **Behavior.** Each object must be able to manipulate its state. Methods exist for this purpose.

Python includes the following features for supporting object-oriented programming:

- **Class-based object creation.** Classes are templates for the creation of objects. Objects are data structures with associated behavior.
 - **Inheritance with polymorphism.** Python supports single and multiple inheritance. All Python instance methods are polymorphic and can be overridden by subclasses.
 - **Encapsulation with data hiding.** Python allows attributes to be hidden. When hidden, attributes can be accessed from outside the class only through methods of the class. Classes implement methods to modify the data.

Defining a Class

Within a Python class, both variables and methods can be defined. Unlike in Java, in Python you can define any number of public classes per source file (or *module*). Therefore, a module in Python can be thought of similar to a package in Java.

In Python, classes are defined using the `class` statement. The `class` statement has the following form:

```
class name (superclasses): statement
```

or

```
class name (superclasses):  
    assignment  
    .  
    .  
    function  
    .  
    .
```

When you define a class, you have the option to provide zero or more *assignment* statements. These create class attributes that are shared by all instances of the class. You can also provide zero or more *function* definitions. These function definitions create methods. The superclasses list is optional.

The class name should be unique in the same scope, that is within a module, function or class. You can define multiple variables to reference the same class.

Related information

 - [Hidden Variables](#)
 - [Inheritance](#)
-

Creating a Class Instance

Classes are used to hold class (or shared) attributes or to create class instances. To create an instance of a class, you call the class as if it were a function. For example, consider the following class:

```
class MyClass:  
    pass
```

Here, the `pass` statement is used because a statement is required to complete the class, but no action is required programmatically.

The following statement creates an instance of the class `MyClass`:

```
x = MyClass()
```

Related information

 - [Hidden Variables](#)
 - [Inheritance](#)
-

Adding Attributes to a Class Instance

Unlike in Java, in Python clients can add attributes to an instance of a class. Only the one instance is changed. For example, to add attributes to an instance `x`, set new values on that instance:

```
x.attr1 = 1  
x.attr2 = 2  
.  
. .  
x.attrN = n
```

Related information

- [Object-Oriented Programming](#)
 - [Defining a Class](#)
 - [Creating a Class Instance](#)
 - [Defining Class Attributes and Methods](#)
 - [Hidden Variables](#)
 - [Inheritance](#)
-

Defining Class Attributes and Methods

Any variable that is bound in a class is a *class attribute*. Any function defined within a class is a *method*. Methods receive an instance of the class, conventionally called `self`, as the first argument. For example, to define some class attributes and methods, you might enter the following code:

```
class MyClass
    attr1 = 10      #class attributes
    attr2 = "hello"

    def method1(self):
        print MyClass.attr1  #reference the class attribute

    def method2(self):
        print MyClass.attr2  #reference the class attribute

    def method3(self, text):
        self.text = text      #instance attribute
        print text, self.text  #print my argument and my attribute

    method4 = method3  #make an alias for method3
```

Inside a class, you should qualify all references to class attributes with the class name; for example, `MyClass.attr1`. All references to instance attributes should be qualified with the `self` variable; for example, `self.text`. Outside the class, you should qualify all references to class attributes with the class name (for example `MyClass.attr1`) or with an instance of the class (for example `x.attr1`, where `x` is an instance of the class). Outside the class, all references to instance variables should be qualified with an instance of the class; for example, `x.text`.

Related information

- [Object-Oriented Programming](#)
 - [Defining a Class](#)
 - [Creating a Class Instance](#)
 - [Adding Attributes to a Class Instance](#)
 - [Hidden Variables](#)
 - [Inheritance](#)
-

Hidden Variables

Data can be hidden by creating *Private* variables. Private variables can be accessed only by the class itself. If you declare names of the form `__xxx` or `__xxx_yyy`, that is with two preceding underscores, the Python parser will automatically add the class name to the declared name, creating hidden variables, for example:

```
class MyClass:
    __attr = 10  #private class attribute

    def method1(self):
        pass

    def method2(self, p1, p2):
        pass

    def __privateMethod(self, text):
        self.__text = text  #private attribute
```

Unlike in Java, in Python all references to instance variables must be qualified with `self`; there is no implied use of `this`.

Related information

- [Object-Oriented Programming](#)
 - [Defining a Class](#)
 - [Creating a Class Instance](#)
 - [Adding Attributes to a Class Instance](#)
 - [Defining Class Attributes and Methods](#)
 - [Inheritance](#)
-

Inheritance

The ability to inherit from classes is fundamental to object-oriented programming. Python supports both single and multiple inheritance. *Single inheritance* means that there can be only one superclass. *Multiple inheritance* means that there can be more than one superclass.

Inheritance is implemented by subclassing other classes. Any number of Python classes can be superclasses. In the Jython implementation of Python, only one Java class can be directly or indirectly inherited from. It is not required for a superclass to be supplied.

Any attribute or method in a superclass is also in any subclass and can be used by the class itself, or by any client as long as the attribute or method is not hidden. Any instance of a subclass can be used wherever and instance of a superclass can be used; this is an example of *polymorphism*. These features enable reuse and ease of extension.

Example

```
class Class1: pass      #no inheritance
class Class2: pass

Scripting in IBM® SPSS® Modeler

- [Types of scripts](#)
 - [Streams, SuperNode streams, and diagrams](#)
 - [Executing a stream](#)
 - [The scripting context](#)
 - [Referencing existing nodes](#)
 - [Creating nodes and modifying streams](#)
 - [Clearing, or removing, items](#)
 - [Getting information about nodes](#)
-

Types of scripts

In IBM® SPSS® Modeler there are three types of script:

- *Stream scripts* are used to control execution of a single stream and are stored within the stream.
- *SuperNode scripts* are used to control the behavior of SuperNodes.
- *Stand-alone or session scripts* can be used to coordinate execution across a number of different streams.

Various methods are available to be used in scripts in IBM SPSS Modeler with which you can access a wide range of SPSS Modeler functionality. These methods are also used in [The Scripting API](#) to create more advanced functions.

Related information

Streams, SuperNode streams, and diagrams

Most of the time, the term *stream* means the same thing, regardless of whether it is a stream that is loaded from a file or used within a SuperNode. It generally means a collection of nodes that are connected together and can be executed. In scripting, however, not all operations are supported in all places, meaning a script author should be aware of which stream variant they are using.

- [Streams](#)
- [SuperNode streams](#)
- [Diagrams](#)

Related information

- [Executing a stream](#)

- [Getting information about nodes](#)
- [Streams](#)
- [SuperNode streams](#)
- [Diagrams](#)

Streams

A stream is the main IBM® SPSS® Modeler document type. It can be saved, loaded, edited and executed. Streams can also have parameters, global values, a script, and other information associated with them.

Related information

- [Executing a stream](#)
- [The scripting context](#)
- [Referencing existing nodes](#)
- [Creating nodes and modifying streams](#)
- [Getting information about nodes](#)
- [Streams, SuperNode streams, and diagrams](#)

SuperNode streams

A *SuperNode stream* is the type of stream used within a SuperNode. Like a normal stream, it contains nodes which are linked together. SuperNode streams have a number of differences from a normal stream:

- Parameters and any scripts are associated with the SuperNode that owns the SuperNode stream, rather than with the SuperNode stream itself.
- SuperNode streams have additional input and output connector nodes, depending on the type of SuperNode. These connector nodes are used to flow information into and out of the SuperNode stream, and are created automatically when the SuperNode is created.

Related information

- [Executing a stream](#)
- [The scripting context](#)
- [Referencing existing nodes](#)
- [Creating nodes and modifying streams](#)
- [Getting information about nodes](#)
- [Streams, SuperNode streams, and diagrams](#)

Diagrams

The term *diagram* covers the functions that are supported by both normal streams and SuperNode streams, such as adding and removing nodes, and modifying connections between the nodes.

Related information

- [Executing a stream](#)
- [The scripting context](#)
- [Referencing existing nodes](#)
- [Creating nodes and modifying streams](#)
- [Getting information about nodes](#)
- [Streams, SuperNode streams, and diagrams](#)

Executing a stream

The following example runs all executable nodes in the stream, and is the simplest type of stream script:

```
modeler.script.stream().runAll(None)
```

The following example also runs all executable nodes in the stream:

```
stream = modeler.script.stream()
stream.runAll(None)
```

In this example, the stream is stored in a variable called `stream`. Storing the stream in a variable is useful because a script is typically used to modify either the stream or the nodes within a stream. Creating a variable that stores the stream results in a more concise script.

Related information

- [Types of scripts](#)
- [The scripting context](#)
- [Referencing existing nodes](#)
- [Creating nodes and modifying streams](#)
- [Getting information about nodes](#)

The scripting context

The `modeler.script` module provides the context in which a script is executed. The module is automatically imported into a SPSS® Modeler script at run time. The module defines four functions that provide a script with access to its execution environment:

- The `session()` function returns the session for the script. The session defines information such as the locale and the SPSS Modeler backend (either a local process or a networked SPSS Modeler Server) that is being used to run any streams.
- The `stream()` function can be used with stream and SuperNode scripts. This function returns the stream that owns either the stream script or the SuperNode script that is being run.
- The `diagram()` function can be used with SuperNode scripts. This function returns the diagram within the SuperNode. For other script types, this function returns the same as the `stream()` function.
- The `supernode()` function can be used with SuperNode scripts. This function returns the SuperNode that owns the script that is being run.

The four functions and their outputs are summarized in the following table.

Table 1. Summary of `modeler.script` functions

Script type	<code>session()</code>	<code>stream()</code>	<code>diagram()</code>	<code>supernode()</code>
Standalone	Returns a session	Returns the current managed stream at the time the script was invoked (for example, the stream passed via the batch mode <code>-stream</code> option), or <code>None</code> .	Same as for <code>stream()</code>	Not applicable
Stream	Returns a session	Returns a stream	Same as for <code>stream()</code>	Not applicable

Script type	session()	stream()	diagram()	supernode()
SuperNode	Returns a session	Returns a stream	Returns a SuperNode stream	Returns a SuperNode

The `modeler.script` module also defines a way of terminating the script with an exit code. The `exit(exit-code)` function stops the script from executing and returns the supplied integer exit code.

One of the methods that is defined for a stream is `runAll(List)`. This method runs all executable nodes. Any models or outputs that are generated by executing the nodes are added to the supplied list.

It is common for a stream execution to generate outputs such as models, graphs, and other output. To capture this output, a script can supply a variable that is initialized to a list, for example:

```
stream = modeler.script.stream()
results = []
stream.runAll(results)
```

When execution is complete, any objects that are generated by the execution can be accessed from the `results` list.

- [Getting information about nodes](#)

Referencing existing nodes

A stream is often pre-built with some parameters that must be modified before the stream is executed. Modifying these parameters involves the following tasks:

1. Locating the nodes in the relevant stream.
 2. Changing the node or stream settings (or both).
- [Finding nodes](#)
 - [Setting properties](#)

- [Getting information about nodes](#)

Finding nodes

Streams provide a number of ways of locating an existing node. These methods are summarized in the following table.

Table 1. Methods for locating an existing node

Method	Return type	Description
<code>s.findAll(type, label)</code>	Collection	Returns a list of all nodes with the specified type and label. Either the type or label can be <code>None</code> , in which case the other parameter is used.
<code>s.findAll(filter, recursive)</code>	Collection	Returns a collection of all nodes that are accepted by the specified filter. If the recursive flag is <code>True</code> , any SuperNodes within the specified stream are also searched.
<code>s.findById(id)</code>	Node	Returns the node with the supplied ID or <code>None</code> if no such node exists. The search is limited to the current stream.

Method	Return type	Description
<code>s.findByType(type, label)</code>	Node	Returns the node with the supplied type, label, or both. Either the type or name can be <code>None</code> , in which case the other parameter is used. If multiple nodes result in a match, then an arbitrary one is chosen and returned. If no nodes result in a match, then the return value is <code>None</code> .
<code>s.findDownstream(fromNodes)</code>	Collection	Searches from the supplied list of nodes and returns the set of nodes downstream of the supplied nodes. The returned list includes the originally supplied nodes.
<code>s.findUpstream(fromNodes)</code>	Collection	Searches from the supplied list of nodes and returns the set of nodes upstream of the supplied nodes. The returned list includes the originally supplied nodes.
<code>s.findProcessorForID(String id, boolean recursive)</code>	Node	Returns the node with the supplied ID or <code>None</code> if no such node exists. If the recursive flag is <code>true</code> , then any composite nodes within this diagram are also searched.

As an example, if a stream contained a single Filter node that the script needed to access, the Filter node can be found by using the following script:

```
stream = modeler.script.stream()
node = stream.findByType("filter", None)
...
```

Alternatively, if the ID of the node (as shown on the Annotations tab of the node dialog box) is known, the ID can be used to find the node, for example:

```
stream = modeler.script.stream()
node = stream.findById("id32FJT71G2") # the filter node ID
...
```

Setting properties

Nodes, streams, models, and outputs all have properties that can be accessed and, in most cases, set. Properties are typically used to modify the behavior or appearance of the object. The methods that are available for accessing and setting object properties are summarized in the following table.

Table 1. Methods for accessing and setting object properties

Method	Return type	Description
<code>p.getPropertyValue(propertyName)</code>	Object	Returns the value of the named property or <code>None</code> if no such property exists.
<code>p.setPropertyValue(propertyName, value)</code>	Not applicable	Sets the value of the named property.
<code>p.setPropertyValues(properties)</code>	Not applicable	Sets the values of the named properties. Each entry in the properties map consists of a key that represents the property name and the value that should be assigned to that property.
<code>p.getKeyedPropertyValue(propertyName, keyName)</code>	Object	Returns the value of the named property and associated key or <code>None</code> if no such property or key exists.
<code>p.setKeyedPropertyValue(propertyName, keyName, value)</code>	Not applicable	Sets the value of the named property and key.

For example, if you wanted to set the value of a Variable File node at the start of a stream, you can use the following script:

```
stream = modeler.script.stream()
node = stream.findByType("variablefile", None)
node.setPropertyValue("full_filename", "$CLEO/DEMOS/DRUG1n")
...
```

Alternatively, you might want to filter a field from a Filter node. In this case, the value is also keyed on the field name, for example:

```
stream = modeler.script.stream()
# Locate the filter node ...
node = stream.findByType("filter", None)
# ... and filter out the "Na" field
node.setKeyedPropertyValue("include", "Na", False)
```

Creating nodes and modifying streams

In some situations, you might want to add new nodes to existing streams. Adding nodes to existing streams typically involves the following tasks:

1. Creating the nodes.
 2. Linking the nodes into the existing stream flow.
- [Creating nodes](#)
 - [Linking and unlinking nodes](#)
 - [Importing, replacing, and deleting nodes](#)
 - [Traversing through nodes in a stream](#)

- [Referencing existing nodes](#)
- [Getting information about nodes](#)

Creating nodes

Streams provide a number of ways of creating nodes. These methods are summarized in the following table.

Table 1. Methods for creating nodes

Method	Return type	Description
<code>s.create(nodeType, name)</code>	Node	Creates a node of the specified type and adds it to the specified stream.
<code>s.createAt(nodeType, name, x, y)</code>	Node	Creates a node of the specified type and adds it to the specified stream at the specified location. If either x < 0 or y < 0, the location is not set.
<code>s.createModelApplier(modelOutput, name)</code>	Node	Creates a model applier node that is derived from the supplied model output object.

For example, to create a new Type node in a stream you can use the following script:

```
stream = modeler.script.stream()
# Create a new type node
node = stream.create("type", "My Type")
```

Related information

- [Creating nodes and modifying streams](#)
- [Linking and unlinking nodes](#)
- [Importing, replacing, and deleting nodes](#)
- [Traversing through nodes in a stream](#)

Linking and unlinking nodes

When a new node is created within a stream, it must be connected into a sequence of nodes before it can be used. Streams provide a number of methods for linking and unlinking nodes. These methods are summarized in the following table.

Table 1. Methods for linking and unlinking nodes

Method	Return type	Description
<code>s.link(source, target)</code>	Not applicable	Creates a new link between the source and the target nodes.
<code>s.link(source, targets)</code>	Not applicable	Creates new links between the source node and each target node in the supplied list.
<code>s.linkBetween(inserted, source, target)</code>	Not applicable	Connects a node between two other node instances (the source and target nodes) and sets the position of the inserted node to be between them. Any direct link between the source and target nodes is removed first.
<code>s.linkPath(path)</code>	Not applicable	Creates a new path between node instances. The first node is linked to the second, the second is linked to the third, and so on.

Method	Return type	Description
<code>s.unlink(source, target)</code>	Not applicable	Removes any direct link between the source and the target nodes.
<code>s.unlink(source, targets)</code>	Not applicable	Removes any direct links between the source node and each object in the targets list.
<code>s.unlinkPath(path)</code>	Not applicable	Removes any path that exists between node instances.
<code>s.disconnect(node)</code>	Not applicable	Removes any links between the supplied node and any other nodes in the specified stream.
<code>s.isValidLink(source, target)</code>	<code>boolean</code>	Returns <code>True</code> if it would be valid to create a link between the specified source and target nodes. This method checks that both objects belong to the specified stream, that the source node can supply a link and the target node can receive a link, and that creating such a link will not cause a circularity in the stream.

The example script that follows performs these five tasks:

1. Creates a Variable File input node, a Filter node, and a Table output node.
2. Connects the nodes together.
3. Sets the file name on the Variable File input node.
4. Filters the field "Drug" from the resulting output.
5. Executes the Table node.

```
stream = modeler.script.stream()
filenode = stream.createAt("variablefile", "My File Input ", 96, 64)
filternode = stream.createAt("filter", "Filter", 192, 64)
tablenode = stream.createAt("table", "Table", 288, 64)
stream.link(filenode, filternode)
stream.link(filternode, tablenode)
filenode.setPropertyValue("full_filename", "$CLEO_DEMOS/DRUG1n")
filternode.setKeyedPropertyValue("include", "Drug", False)
results = []
tablenode.run(results)
```

Importing, replacing, and deleting nodes

As well as creating and connecting nodes, it is often necessary to replace and delete nodes from the stream. The methods that are available for importing, replacing and deleting nodes are summarized in the following table.

Table 1. Methods for importing, replacing, and deleting nodes

Method	Return type	Description
<code>s.replace(originalNode, replacementNode, discardOriginal)</code>	Not applicable	Replaces the specified node from the specified stream. Both the original node and replacement node must be owned by the specified stream.
<code>s.insert(source, nodes, newIDs)</code>	List	Inserts copies of the nodes in the supplied list. It is assumed that all nodes in the supplied list are contained within the specified stream. The <code>newIDs</code> flag indicates whether new IDs should be generated for each node, or whether the existing ID should be copied and used. It is assumed that all nodes in a stream have a unique ID, so this flag must be set to <code>True</code> if the source stream is the same as the specified stream. The method returns the list of newly inserted nodes, where the order of the nodes is undefined (that is, the ordering is not necessarily the same as the order of the nodes in the input list).
<code>s.delete(node)</code>	Not applicable	Deletes the specified node from the specified stream. The node must be owned by the specified stream.
<code>s.deleteAll(nodes)</code>	Not applicable	Deletes all the specified nodes from the specified stream. All nodes in the collection must belong to the specified stream.
<code>s.clear()</code>	Not applicable	Deletes all nodes from the specified stream.

Traversing through nodes in a stream

A common requirement is to identify nodes that are either upstream or downstream of a particular node. The stream provides a number of methods that can be used to identify these nodes. These methods are summarized in the following table.

Table 1. Methods to identify upstream and downstream nodes

Method	Return type	Description
<code>s.iterator()</code>	Iterator	Returns an iterator over the node objects that are contained in the specified stream. If the stream is modified between calls of the <code>next()</code> function, the behavior of the iterator is undefined.
<code>s.predecessorAt(node, index)</code>	Node	Returns the specified immediate predecessor of the supplied node or <code>None</code> if the index is out of bounds.
<code>s.predecessorCount(node)</code>	<code>int</code>	Returns the number of immediate predecessors of the supplied node.
<code>s.predecessors(node)</code>	List	Returns the immediate predecessors of the supplied node.
<code>s.successorAt(node, index)</code>	Node	Returns the specified immediate successor of the supplied node or <code>None</code> if the index is out of bounds.
<code>s.successorCount(node)</code>	<code>int</code>	Returns the number of immediate successors of the supplied node.
<code>s.successors(node)</code>	List	Returns the immediate successors of the supplied node.

Clearing, or removing, items

Legacy scripting supports various uses of the `clear` command, for example:

- `clear outputs` To delete all output items from the manager palette.
- `clear generated palette` To clear all model nuggets from the Models palette.
- `clear stream` To remove the contents of a stream.

Python scripting supports a similar set of functions; the `removeAll()` command is used to clear the Streams, Outputs, and Models managers. For example:

- To clear the Streams manager:

```
session = modeler.script.session()
session.getStreamManager().removeAll()
```

- To clear the Outputs manager:

```
session = modeler.script.session()
session.getDocumentOutputManager().removeAll()
```

- To clear the Models manager:

```
session = modeler.script.session()
session.getModelOutputManager().removeAll()
```

Getting information about nodes

Nodes fall into a number of different categories such as data import and export nodes, model building nodes, and other types of nodes. Every node provides a number of methods that can be used to find out information about the node.

The methods that can be used to obtain the ID, name, and label of a node are summarized in the following table.

Table 1. Methods to obtain the ID, name, and label of a node

Method	Return type	Description
<code>n.getLabel()</code>	<code>string</code>	Returns the display label of the specified node. The label is the value of the property <code>custom_name</code> only if that property is a non-empty string and the <code>use_custom_name</code> property is not set; otherwise, the label is the value of <code>getName()</code> .

Method	Return type	Description
<code>n.setLabel(label)</code>	Not applicable	Sets the display label of the specified node. If the new label is a non-empty string it is assigned to the property <code>custom_name</code> , and <code>False</code> is assigned to the property <code>use_custom_name</code> so that the specified label takes precedence; otherwise, an empty string is assigned to the property <code>custom_name</code> and <code>True</code> is assigned to the property <code>use_custom_name</code> .
<code>n.getName()</code>	<code>string</code>	Returns the name of the specified node.
<code>n.getID()</code>	<code>string</code>	Returns the ID of the specified node. A new ID is created each time a new node is created. The ID is persisted with the node when it is saved as part of a stream so that when the stream is opened, the node IDs are preserved. However, if a saved node is inserted into a stream, the inserted node is considered to be a new object and will be allocated a new ID.

Methods that can be used to obtain other information about a node are summarized in the following table.

Table 2. Methods for obtaining information about a node

Method	Return type	Description
<code>n.getTypeName()</code>	<code>string</code>	Returns the scripting name of this node. This is the same name that could be used to create a new instance of this node.
<code>n.isInitial()</code>	<code>Boolean</code>	Returns <code>True</code> if this is an <i>initial</i> node, that is one that occurs at the start of a stream.
<code>n.isInline()</code>	<code>Boolean</code>	Returns <code>True</code> if this is an <i>in-line</i> node, that is one that occurs mid-stream.
<code>n.isTerminal()</code>	<code>Boolean</code>	Returns <code>True</code> if this is a <i>terminal</i> node, that is one that occurs at the end of a stream.
<code>n.getXPosition()</code>	<code>int</code>	Returns the x position offset of the node in the stream.
<code>n.getYPosition()</code>	<code>int</code>	Returns the y position offset of the node in the stream.
<code>n.setXYPosition(x, y)</code>	Not applicable	Sets the position of the node in the stream.
<code>n.setPositionBetween(source, target)</code>	Not applicable	Sets the position of the node in the stream so that it is positioned between the supplied nodes.
<code>n.isCacheEnabled()</code>	<code>Boolean</code>	Returns <code>True</code> if the cache is enabled; returns <code>False</code> otherwise.
<code>n.setCacheEnabled(val)</code>	Not applicable	Enables or disables the cache for this object. If the cache is full and the caching becomes disabled, the cache is flushed.
<code>n.isCacheFull()</code>	<code>Boolean</code>	Returns <code>True</code> if the cache is full; returns <code>False</code> otherwise.
<code>n.flushCache()</code>	Not applicable	Flushes the cache of this node. Has no affect if the cache is not enabled or is not full.

- [Global Values](#)
- [Working with Multiple Streams: Standalone Scripts](#)

Introduction to the Scripting API

The Scripting API provides access to a wide range of SPSS® Modeler functionality. All the methods described so far are part of the API and can be accessed implicitly within the script without further imports. However, if you want to reference the API classes, you must import the API explicitly with the following statement:

```
import modeler.api
```

This import statement is required by many of the Scripting API examples.

Related information

- [Example 1: searching for nodes using a custom filter](#)
 - [Metadata: Information about data](#)
 - [Accessing Generated Objects](#)
 - [Handling errors](#)
 - [Stream, Session, and SuperNode Parameters](#)
 - [Global Values](#)
 - [Working with Multiple Streams: Standalone Scripts](#)
-

Example 1: searching for nodes using a custom filter

The section [Finding nodes](#) included an example of searching for a node in a stream using the type name of the node as the search criterion. In some situations, a more generic search is required and this can be implemented using the `NodeFilter` class and the stream `findAll()` method. This kind of search involves the following two steps:

1. Creating a new class that extends `NodeFilter` and that implements a custom version of the `accept()` method.
2. Calling the stream `findAll()` method with an instance of this new class. This returns all nodes that meet the criteria defined in the `accept()` method.

The following example shows how to search for nodes in a stream that have the node cache enabled. The returned list of nodes could be used to either flush or disable the caches of these nodes.

```
import modeler.api

class CacheFilter(modeler.api.NodeFilter):
    """A node filter for nodes with caching enabled"""
    def accept(this, node):
        return node.isCacheEnabled()

cachingnodes = modeler.script.stream().findAll(CacheFilter(), False)
```

Example 2: allowing users to obtain directory or file information based on their privileges

To avoid the PSAPI being opened to users, a method called `session.getServerFileSystem()` can be used via calling the PSAPI function to create a file system object.

The following example shows how to allow a user to get directory or file information based on the privileges of the user that connects to the IBM® SPSS® Modeler Server.

```
import modeler.api
stream = modeler.script.stream()
sourceNode = stream.findByID('')
session = modeler.script.session()
fileSystem = session.getServerFileSystem()
parameter = stream.getParameterValue('VPATH')
serverDirectory = fileSystem.getServerFile(parameter)
files = fileSystem.GetFiles(serverDirectory)
for f in files:
    if f.isDirectory():
        print 'Directory:'
    else:
        print 'File:'
        sourceNode.setPropertyValue('full_filename',f.getPath())
        break
    print f.getName(),f.getPath()
stream.execute()
```

Metadata: Information about data

Because nodes are connected together in a stream, information about the columns or fields that are available at each node is available. For example, in the Modeler UI, this allows you to select which fields to sort or aggregate by. This information is called the data model.

Scripts can also access the data model by looking at the fields coming into or out of a node. For some nodes, the input and output data models are the same, for example a Sort node simply reorders the records but doesn't change the data model. Some, such as the Derive node, can add new fields. Others, such as the Filter node can rename or remove fields.

In the following example, the script takes the standard IBM® SPSS® Modeler druglearn.str stream, and for each field, builds a model with one of the input fields dropped. It does this by:

1. Accessing the output data model from the Type node.
2. Looping through each field in the output data model.
3. Modifying the Filter node for each input field.
4. Changing the name of the model being built.
5. Running the model build node.

Note: Before running the script in the druglean.str stream, remember to set the scripting language to Python (the stream was created in a previous version of IBM SPSS Modeler so the stream scripting language is set to Legacy).

```
import modeler.api

stream = modeler.script.stream()
filternode = stream.findByType("filter", None)
typenode = stream.findByType("type", None)
c50node = stream.findByType("c50", None)
# Always use a custom model name
c50node.setPropertyValue("use_model_name", True)

lastRemoved = None
fields = typenode.getOutputDataModel()
for field in fields:
    # If this is the target field then ignore it
    if field.getModelingRole() == modeler.api.ModelingRole.OUT:
        continue

    # Re-enable the field that was most recently removed
    if lastRemoved != None:
        filternode.setKeyedPropertyValue("include", lastRemoved, True)

    # Remove the field
    lastRemoved = field.getColumnName()
    filternode.setKeyedPropertyValue("include", lastRemoved, False)

    # Set the name of the new model then run the build
    c50node.setPropertyValue("model_name", "Exclude " + lastRemoved)
    c50node.run([])
```

The DataModel object provides a number of methods for accessing information about the fields or columns within the data model. These methods are summarized in the following table.

Table 1. DataModel object methods for accessing information about fields or columns

Method	Return type	Description
d.getColumnCount()	int	Returns the number of columns in the data model.
d.columnIterator()	Iterator	Returns an iterator that returns each column in the "natural" insert order. The iterator returns instances of Column.
d.nameIterator()	Iterator	Returns an iterator that returns the name of each column in the "natural" insert order.
d.contains(name)	Boolean	Returns True if a column with the supplied name exists in this DataModel, False otherwise.
d.getColumn(name)	Column	Returns the column with the specified name.
d.getColumnGroup(name)	ColumnGroup	Returns the named column group or None if no such column group exists.
d.getColumnGroupCount()	int	Returns the number of column groups in this data model.
d.columnGroupIterator()	Iterator	Returns an iterator that returns each column group in turn.
d.toArray()	Column[]	Returns the data model as an array of columns. The columns are ordered in their "natural" insert order.

Each field (Column object) includes a number of methods for accessing information about the column. The table below shows a selection of these.

Table 2. Column object methods for accessing information about the column

Method	Return type	Description
c.getColumnName()	string	Returns the name of the column.

Method	Return type	Description
<code>c.getColumnLabel()</code>	<code>string</code>	Returns the label of the column or an empty string if there is no label associated with the column.
<code>c.getMeasureType()</code>	<code>MeasureType</code>	Returns the measure type for the column.
<code>c.getStorageType()</code>	<code>StorageType</code>	Returns the storage type for the column.
<code>c.isMeasureDiscrete()</code>	<code>Boolean</code>	Returns <code>True</code> if the column is discrete. Columns that are either a set or a flag are considered discrete.
<code>c.isModelOutputColumn()</code>	<code>Boolean</code>	Returns <code>True</code> if the column is a model output column.
<code>c.isStorageDatetime()</code>	<code>Boolean</code>	Returns <code>True</code> if the column's storage is a time, date or timestamp value.
<code>c.isStorageNumeric()</code>	<code>Boolean</code>	Returns <code>True</code> if the column's storage is an integer or a real number.
<code>c.isValidValue(value)</code>	<code>Boolean</code>	Returns <code>True</code> if the specified value is valid for this storage, and <code>valid</code> when the valid column values are known.
<code>c.getModelingRole()</code>	<code>ModelingRole</code>	Returns the modeling role for the column.
<code>c.getSetValues()</code>	<code>Object[]</code>	Returns an array of valid values for the column, or <code>None</code> if either the values are not known or the column is not a set.
<code>c.getValueLabel(value)</code>	<code>string</code>	Returns the label for the value in the column, or an empty string if there is no label associated with the value.
<code>c.getFalseFlag()</code>	<code>Object</code>	Returns the "false" indicator value for the column, or <code>None</code> if either the value is not known or the column is not a flag.
<code>c.getTrueFlag()</code>	<code>Object</code>	Returns the "true" indicator value for the column, or <code>None</code> if either the value is not known or the column is not a flag.
<code>c.getLowerBound()</code>	<code>Object</code>	Returns the lower bound value for the values in the column, or <code>None</code> if either the value is not known or the column is not continuous.
<code>c.getUpperBound()</code>	<code>Object</code>	Returns the upper bound value for the values in the column, or <code>None</code> if either the value is not known or the column is not continuous.

Note that most of the methods that access information about a column have equivalent methods defined on the DataModel object itself. For example the two following statements are equivalent:

```
dataModel.getColumn("someName").getModelingRole()
dataModel.getModelingRole("someName")
```

Accessing Generated Objects

Executing a stream typically involves producing additional output objects. These additional objects might be a new model, or a piece of output that provides information to be used in subsequent executions.

In the example below, the druglearn.str stream is used again as the starting point for the stream. In this example, all nodes in the stream are executed and the results are stored in a list. The script then loops through the results, and any model outputs that result from the execution are saved as an IBM® SPSS® Modeler model (.gm) file, and the model is PMML exported.

```
import modeler.api

stream = modeler.script.stream()

# Set this to an existing folder on your system.
# Include a trailing directory separator
modelFolder = "C:/temp/models/"

# Execute the stream
models = []
stream.runAll(models)
```

```

# Save any models that were created
taskrunner = modeler.script.session().getTaskRunner()
for model in models:
    # If the stream execution built other outputs then ignore them
    if not(isinstance(model, modeler.api.ModelOutput)):
        continue

    label = model.getLabel()
    algorithm = model.getModelDetail().getAlgorithmName()

    # save each model...
    modelFile = modelFolder + label + algorithm + ".gm"
    taskrunner.saveModelToFile(model, modelFile)

    # ...and export each model PMML...
    modelFile = modelFolder + label + algorithm + ".xml"
    taskrunner.exportModelToFile(model, modelFile, modeler.api.FileFormat.XML)

```

The task runner class provides a convenient way running various common tasks. The methods that are available in this class are summarized in the following table.

Table 1. Methods of the task runner class for performing common tasks

Method	Return type	Description
t.createStream(name, autoConnect, autoManage)	Stream	Creates and returns a new stream. Note that code that must create streams privately without making them visible to the user should set the autoManage flag to False .
t.exportDocumentToFile(documentOutput, filename, fileFormat)	Not applicable	Exports the stream description to a file using the specified file format.
t.exportModelToFile(modelOutput, filename, fileFormat)	Not applicable	Exports the model to a file using the specified file format.
t.exportStreamToFile(stream, filename, fileFormat)	Not applicable	Exports the stream to a file using the specified file format.
t.insertNodeFromFile(fileName, diagram)	Node	Reads and returns a node from the specified file, inserting it into the supplied diagram. Note that this can be used to read both Node and SuperNode objects.
t.openDocumentFromFile(fileName, autoManage)	DocumentOutput	Reads and returns a document from the specified file.
t.openModelFromFile(fileName, autoManage)	ModelOutput	Reads and returns a model from the specified file.
t.openStreamFromFile(fileName, autoManage)	Stream	Reads and returns a stream from the specified file.
t.saveDocumentToFile(documentOutput, filename)	Not applicable	Saves the document to the specified file location.
t.saveModelToFile(modelOutput, filename)	Not applicable	Saves the model to the specified file location.
t.saveStreamToFile(stream, filename)	Not applicable	Saves the stream to the specified file location.

Handling errors

The Python language provides error handling via the `try...except` code block. This can be used within scripts to trap exceptions and handle problems that would otherwise cause the script to terminate.

In the example script below, an attempt is made to retrieve a model from a IBM® SPSS® Collaboration and Deployment Services Repository. This operation can cause an exception to be thrown, for example, the repository login credentials might not have been set up correctly, or the repository path is wrong. In the script, this may cause a `ModelerException` to be thrown (all exceptions that are generated by IBM SPSS Modeler are derived from `modeler.api.ModelerException`).

```

import modeler.api

session = modeler.script.session()
try:
    repo = session.getRepository()
    m = repo.retrieveModel("/some-non-existent-path", None, None, True)
    # print goes to the Modeler UI script panel Debug tab
    print "Everything OK"
except modeler.api.ModelerException, e:
    print "An error occurred:", e.getMessage()

```

Note: Some scripting operations may cause standard Java exceptions to be thrown; these are not derived from `ModelerException`. In order to catch these exceptions, an additional except block can be used to catch all Java exceptions, for example:

```

import modeler.api
import java.lang.Exception

session = modeler.script.session()
try:
    repo = session.getRepository()
    m = repo.retrieveModel("/some-non-existent-path", None, None, True)
    # print goes to the Modeler UI script panel Debug tab
    print "Everything OK"
except modeler.api.ModelerException, e:
    print "An error occurred:", e.getMessage()
except java.lang.Exception, e:
    print "A Java exception occurred:", e.getMessage()

```

Stream, Session, and SuperNode Parameters

Parameters provide a useful way of passing values at runtime, rather than hard coding them directly in a script. Parameters and their values are defined in the same as way for streams, that is, as entries in the parameters table of a stream or SuperNode, or as parameters on the command line. The Stream and SuperNode classes implement a set of functions defined by the ParameterProvider object as shown in the following table. Session provides a `getParameters()` call which returns an object that defines those functions.

Table 1. Functions defined by the ParameterProvider object

Method	Return type	Description
<code>p.getParameterIterator()</code>	Iterator	Returns an iterator of parameter names for this object.
<code>p.getParameterDefinition(parameterName)</code>	ParameterDefinition	Returns the parameter definition for the parameter with the specified name, or <code>None</code> if no such parameter exists in this provider. The result may be a snapshot of the definition at the time the method was called and need not reflect any subsequent modifications made to the parameter through this provider.
<code>p.getParameterLabel(parameterName)</code>	string	Returns the label of the named parameter, or <code>None</code> if no such parameter exists.
<code>p.setParameterLabel(parameterName, label)</code>	Not applicable	Sets the label of the named parameter.
<code>p.getParameterStorage(parameterName)</code>	ParameterStorage	Returns the storage of the named parameter, or <code>None</code> if no such parameter exists.
<code>p.setParameterStorage(parameterName, storage)</code>	Not applicable	Sets the storage of the named parameter.
<code>p.getParameterType(parameterName)</code>	ParameterType	Returns the type of the named parameter, or <code>None</code> if no such parameter exists.
<code>p.setParameterType(parameterName, type)</code>	Not applicable	Sets the type of the named parameter.
<code>p.getParameterValue(parameterName)</code>	Object	Returns the value of the named parameter, or <code>None</code> if no such parameter exists.
<code>p.setParameterValue(parameterName, value)</code>	Not applicable	Sets the value of the named parameter.

In the following example, the script aggregates some Telco data to find which region has the lowest average income data. A stream parameter is then set with this region. That stream parameter is then used in a Select node to exclude that region from the data, before a churn model is built on the remainder.

The example is artificial because the script generates the Select node itself and could therefore have generated the correct value directly into the Select node expression. However, streams are typically pre-built, so setting parameters in this way provides a useful example.

The first part of the example script creates the stream parameter that will contain the region with the lowest average income. The script also creates the nodes in the aggregation branch and the model building branch, and connects them together.

```

import modeler.api

stream = modeler.script.stream()

# Initialize a stream parameter
stream.setParameterStorage("LowestRegion", modeler.api.ParameterStorage.INTEGER)

# First create the aggregation branch to compute the average income per region
statisticsimportnode = stream.createAt("statisticsimport", "SPSS File", 114, 142)
statisticsimportnode.setPropertyValue("full_filename", "$CLEO_DEMOS/telco.sav")
statisticsimportnode.setPropertyValue("use_field_format_for_storage", True)

aggregatenode = modeler.script.stream().createAt("aggregate", "Aggregate", 294, 142)
aggregatenode.setPropertyValue("keys", ["region"])
aggregatenode.setKeyedPropertyValue("aggregates", "income", ["Mean"])

tablenode = modeler.script.stream().createAt("table", "Table", 462, 142)

stream.link(statisticsimportnode, aggregatenode)
stream.link(aggregatenode, tablenode)

selectnode = stream.createAt("select", "Select", 210, 232)
selectnode.setPropertyValue("mode", "Discard")
# Reference the stream parameter in the selection
selectnode.setPropertyValue("condition", "'region' = '$P-LowestRegion'")

typenode = stream.createAt("type", "Type", 366, 232)
typenode.setKeyedPropertyValue("direction", "churn", "Target")

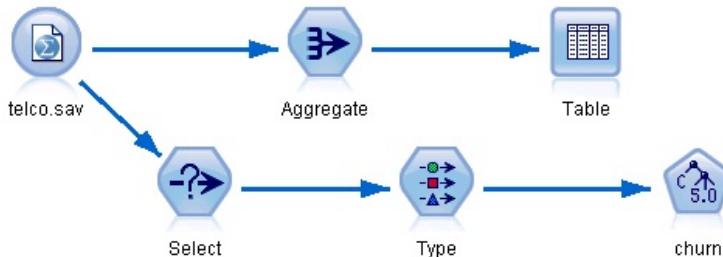

c50node = stream.createAt("c50", "C5.0", 534, 232)

stream.link(statisticsimportnode, selectnode)
stream.link(selectnode, typenode)
stream.link(typenode, c50node)

```

The example script creates the following stream.

Figure 1. Stream that results from the example script

The following part of the example script executes the Table node at the end of the aggregation branch.

```

# First execute the table node
results = []
tablenode.run(results)

```

The following part of the example script accesses the table output that was generated by the execution of the Table node. The script then iterates through rows in the table, looking for the region with the lowest average income.

```

# Running the table node should produce a single table as output
table = results[0]

# table output contains a RowSet so we can access values as rows and columns
rowset = table.getRowSet()
min_income = 1000000.0
min_region = None

# From the way the aggregate node is defined, the first column
# contains the region and the second contains the average income
row = 0
rowcount = rowset.getRowCount()
while row < rowcount:
    if rowset.getValueAt(row, 1) < min_income:
        min_income = rowset.getValueAt(row, 1)

```

```

        min_region = rowset.getValueAt(row, 0)
        row += 1

```

The following part of the script uses the region with the lowest average income to set the "LowestRegion" stream parameter that was created earlier. The script then runs the model builder with the specified region excluded from the training data.

```

# Check that a value was assigned
if min_region != None:
    stream.setParameterValue("LowestRegion", min_region)
else:
    stream.setParameterValue("LowestRegion", -1)

# Finally run the model builder with the selection criteria
c50node.run([])

```

The complete example script is shown below.

```

import modeler.api

stream = modeler.script.stream()

# Create a stream parameter
stream.setParameterStorage("LowestRegion", modeler.api.ParameterStorage.INTEGER)

# First create the aggregation branch to compute the average income per region
statisticsimportnode = stream.createAt("statisticsimport", "SPSS File", 114, 142)
statisticsimportnode.setPropertyValue("full_filename", "$CLEO_DEMOS/telco.sav")
statisticsimportnode.setPropertyValue("use_field_format_for_storage", True)

aggregatenode = modeler.script.stream().createAt("aggregate", "Aggregate", 294, 142)
aggregatenode.setPropertyValue("keys", ["region"])
aggregatenode.setKeyedPropertyValue("aggregates", "income", ["Mean"])

tablenode = modeler.script.stream().createAt("table", "Table", 462, 142)

stream.link(statisticsimportnode, aggregatenode)
stream.link(aggregatenode, tablenode)

selectnode = stream.createAt("select", "Select", 210, 232)
selectnode.setPropertyValue("mode", "Discard")
# Reference the stream parameter in the selection
selectnode.setPropertyValue("condition", "'region' = '$P-LowestRegion'")

typenode = stream.createAt("type", "Type", 366, 232)
typenode.setKeyedPropertyValue("direction", "churn", "Target")

c50node = stream.createAt("c50", "C5.0", 534, 232)

stream.link(statisticsimportnode, selectnode)
stream.link(selectnode, typenode)
stream.link(typenode, c50node)

# First execute the table node
results = []
tablenode.run(results)

# Running the table node should produce a single table as output
table = results[0]

# table output contains a RowSet so we can access values as rows and columns
rowset = table.getRowSet()
min_income = 1000000.0
min_region = None

# From the way the aggregate node is defined, the first column
# contains the region and the second contains the average income
row = 0
rowcount = rowset.getRowCount()
while row < rowcount:
    if rowset.getValueAt(row, 1) < min_income:
        min_income = rowset.getValueAt(row, 1)
        min_region = rowset.getValueAt(row, 0)
    row += 1

# Check that a value was assigned
if min_region != None:
    stream.setParameterValue("LowestRegion", min_region)
else:
    stream.setParameterValue("LowestRegion", -1)

```

```
# Finally run the model builder with the selection criteria
c50node.run([])
```

Global Values

Global values are used to compute various summary statistics for specified fields. These summary values can be accessed anywhere within the stream. Global values are similar to stream parameters in that they are accessed by name through the stream. They are different from stream parameters in that the associated values are updated automatically when a Set Globals node is run, rather than being assigned by scripting or from the command line. The global values for a stream are accessed by calling the stream's `getGlobalValues()` method.

The `GlobalValues` object defines the functions that are shown in the following table.

Table 1. Functions that are defined by the `GlobalValues` object

Method	Return type	Description
<code>g.fieldNameIterator()</code>	Iterator	Returns an iterator for each field name with at least one global value.
<code>g.getValue(type, fieldName)</code>	Object	Returns the global value for the specified type and field name, or <code>None</code> if no value can be located. The returned value is generally expected to be a number, although future functionality may return different value types.
<code>g.getValues(fieldName)</code>	Map	Returns a map containing the known entries for the specified field name, or <code>None</code> if there are no existing entries for the field.

`GlobalValues.Type` defines the type of summary statistics that are available. The following summary statistics are available:

- **MAX**: the maximum value of the field.
- **MEAN**: the mean value of the field.
- **MIN**: the minimum value of the field.
- **STDDEV**: the standard deviation of the field.
- **SUM**: the sum of the values in the field.

For example, the following script accesses the mean value of the "income" field, which is computed by a Set Globals node:

```
import modeler.api

globals = modeler.script.stream().getGlobalValues()
mean_income = globals.getValue(modeler.api.GlobalValues.Type.MEAN, "income")
```

Working with Multiple Streams: Standalone Scripts

To work with multiple streams, a standalone script must be used. The standalone script can be edited and run within the IBM® SPSS® Modeler UI or passed as a command line parameter in batch mode.

The following standalone script opens two streams. One of these streams builds a model, while the second stream plots the distribution of the predicted values.

```
# Change to the appropriate location for your system
demosDir = "C:/Program Files/IBM/SPSS/Modeler/18.4.0/DEMONS/streams/"

session = modeler.script.session()
tasks = session.getTaskRunner()

# Open the model build stream, locate the C5.0 node and run it
buildstream = tasks.openStreamFromFile(demosDir + "druglearn.str", True)
c50node = buildstream.findByName("c50", None)
results = []
c50node.run(results)
```

```

# Now open the plot stream, find the Na_to_K derive and the histogram
plotstream = tasks.openStreamFromFile(demosDir + "drugplot.str", True)
derivenode = plotstream.findByType("derive", None)
histogramnode = plotstream.findByType("histogram", None)

# Create a model applier node, insert it between the derive and histogram nodes
# then run the histogram
applyc50 = plotstream.createModelApplier(results[0], results[0].getName())
applyc50.setPositionBetween(derivenode, histogramnode)
plotstream.linkBetween(applyc50, derivenode, histogramnode)
histogramnode.setPropertyValue("color_field", "$C-Drug")
histogramnode.run([])

# Finally, tidy up the streams
buildstream.close()
plotstream.close()

```

The following example shows how you can also iterate over the open streams (all the streams open in the Streams tab). Note that this is only supported in standalone scripts.

```

for stream in modeler.script.streams():
    print stream.getName()

```

Scripting tips

This section provides an overview of tips and techniques for using scripts, including modifying stream execution, using an encoded password in a script, and accessing objects in the IBM® SPSS® Collaboration and Deployment Services Repository.

- [Modifying stream execution](#)
- [Looping through nodes](#)
- [Accessing Objects in the IBM SPSS Collaboration and Deployment Services Repository](#)
- [Generating an encoded password](#)
- [Script checking](#)
- [Scripting from the command line](#)
- [Compatibility with previous releases](#)
- [Accessing stream execution results](#)

Modifying stream execution

When a stream is run, its terminal nodes are executed in an order optimized for the default situation. In some cases, you may prefer a different execution order. To modify the execution order of a stream, complete the following steps from the Execution tab of the stream properties dialog box:

1. Begin with an empty script.
2. Click the Append default script button on the toolbar to add the default stream script.
3. Change the order of statements in the default stream script to the order in which you want statements to be executed.

Looping through nodes

You can use a `for` loop to loop through all of the nodes in a stream. For example, the following two script examples loop through all nodes and changes field names in any Filter nodes to upper case.

This scripts can be used in any stream that has a Filter node, even if no fields are actually filtered. Simply add a Filter node that passes all fields in order to change field names to upper case across the board.

```

# Alternative 1: using the data model nameIterator() function
stream = modeler.script.stream()
for node in stream.iterator():
    if (node.getTypeName() == "filter"):
        # nameIterator() returns the field names
        for field in node.getInputDataModel().nameIterator():
            newname = field.upper()
            node.setKeyedPropertyValue("new_name", field, newname)

# Alternative 2: using the data model iterator() function
stream = modeler.script.stream()
for node in stream.iterator():
    if (node.getTypeName() == "filter"):
        # iterator() returns the field objects so we need
        # to call getColumnNames() to get the name
        for field in node.getInputDataModel().iterator():
            newname = field.getColumnName().upper()
            node.setKeyedPropertyValue("new_name", field.getColumnName(), newname)

```

The script loops through all nodes in the current stream, and checks whether each node is a Filter. If so, the script loops through each field in the node and uses either the `field.upper()` or `field.getColumnName().upper()` function to change the name to upper case.

Accessing Objects in the IBM SPSS Collaboration and Deployment Services Repository

If you have a license for the IBM® SPSS® Collaboration and Deployment Services Repository, you can store and retrieve objects from the repository by using script commands. Use the repository to manage the lifecycle of data mining models and related predictive objects in the context of enterprise applications, tools, and solutions.

Connecting to the IBM SPSS Collaboration and Deployment Services Repository

To access the repository, you must first set up a valid connection to it, either through the Tools menu of the SPSS Modeler user interface or through the command line. For more information, see [IBM SPSS Collaboration and Deployment Services Repository Connection Arguments](#).

Getting access to the repository

The repository can be accessed from the session, for example:

```
repo = modeler.script.session().getRepository()
```

Retrieving objects from the repository

Within a script, use the `retrieve*` functions to access various objects, including streams, models, output, and nodes. A summary of the retrieval functions is shown in the following table.

Table 1. Retrieve scripting functions

Object Type	Repository Function
Stream	<code>repo.retrieveStream(String path, String version, String label, Boolean autoManage)</code>
Model	<code>repo.retrieveModel(String path, String version, String label, Boolean autoManage)</code>
Output	<code>repo.retrieveDocument(String path, String version, String label, Boolean autoManage)</code>
Node	<code>repo.retrieveProcessor(String path, String version, String label, ProcessorDiagram diagram)</code>

For example, you can retrieve a stream from the repository with the following function:

```
stream = repo.retrieveStream("/projects/retention/risk_score.str", None, "production", True)
```

This example retrieves the `risk_score.str` stream from the specified folder. The label `production` identifies which version of the stream to retrieve, and the last parameter specifies that SPSS Modeler is to manage the stream (for example, so the stream appears in the Streams tab if the SPSS Modeler user interface is visible). As an alternative, to use a specific, unlabeled version:

```
stream = repo.retrieveStream("/projects/retention/risk_score.str", "0:2015-10-12 14:15:41.281", None, True)
```

Note: If both the version and label parameters are `None`, then the latest version is returned.

Storing objects in the repository

To use scripting to store objects in the repository, use the `store*` functions. A summary of the store functions is shown in the following table.

Table 2. Store scripting functions

Object Type	Repository Function
Stream	repo.storeStream(ProcessorStream stream, String path, String label)
Model	repo.storeModel(ModelOutput modelOutput, String path, String label)
Output	repo.storeDocument(DocumentOutput documentOutput, String path, String label)
Node	repo.storeProcessor(Processor node, String path, String label)

For example, you can store a new version of the `risk_score.str` stream with the following function:

```
versionId = repo.storeStream(stream, "/projects/retention/risk_score.str", "test")
```

This example stores a new version of the stream, associates the "test" label with it, and returns the version marker for the newly created version.

Note: If you do not want to associate a label with the new version, pass `None` for the label.

Managing repository folders

By using folders within the repository, you can organize objects into logical groups and make it easier to see which objects are related. Create folders by using the `createFolder()` function, as in the following example:

```
newpath = repo.createFolder("/projects", "cross-sell")
```

This example creates a new folder that is called "cross-sell" in the "/projects" folder. The function returns the full path to the new folder.

To rename a folder, use the `renameFolder()` function:

```
repo.renameFolder("/projects/cross-sell", "cross-sell-Q1")
```

The first parameter is the full path to the folder to be renamed, and the second is the new name to give that folder.

To delete an empty folder, use the `deleteFolder()` function:

```
repo.deleteFolder("/projects/cross-sell")
```

Locking and unlocking objects

From a script, you can lock an object to prevent other users from updating any of its existing versions or creating new versions. You can also unlock an object that you have locked.

The syntax to lock and unlock an object is:

```
repo.lockFile(REPOSITORY_PATH)
repo.lockFile(URI)
```

```
repo.unlockFile(REPOSITORY_PATH)
repo.unlockFile(URI)
```

As with storing and retrieving objects, the `REPOSITORY_PATH` gives the location of the object in the repository. The path must be enclosed in quotation marks and use forward slashes as delimiters. It is not case sensitive.

```
repo.lockFile("/myfolder/Stream1.str")
repo.unlockFile("/myfolder/Stream1.str")
```

Alternatively, you can use a Uniform Resource Identifier (URI) rather than a repository path to give the location of the object. The URI must include the prefix `spsscr:` and must be fully enclosed in quotation marks. Only forward slashes are allowed as path delimiters, and spaces must be encoded. That is, use %20 instead of a space in the path. The URI is not case sensitive. Here are some examples:

```
repo.lockFile("spsscr:///myfolder/Stream1.str")
repo.unlockFile("spsscr:///myfolder/Stream1.str")
```

Note that object locking applies to all versions of an object - you cannot lock or unlock individual versions.

Related information

- [Scripting tips](#)
- [Modifying stream execution](#)
- [Looping through nodes](#)
- [Generating an encoded password](#)
- [Script checking](#)
- [Scripting from the command line](#)
- [Compatibility with previous releases](#)

Generating an encoded password

In certain cases, you may need to include a password in a script; for example, you may want to access a password-protected data source. Encoded passwords can be used in:

- Node properties for Database Source and Output nodes
- Command line arguments for logging into the server
- Database connection properties stored in a .par file (the parameter file generated from the Publish tab of an export node)

Through the user interface, a tool is available to generate encoded passwords based on the Blowfish algorithm (see <http://www.schneier.com/blowfish.html> for more information). Once encoded, you can copy and store the password to script files and command line arguments. The node property **epassword** used for **databasenode** and **databaseexportnode** stores the encoded password.

1. To generate an encoded password, from the Tools menu choose:
 Encode Password...
2. Specify a password in the Password text box.
3. Click Encode to generate a random encoding of your password.
4. Click the Copy button to copy the encoded password to the Clipboard.
5. Paste the password to the desired script or parameter.

Script checking

You can quickly check the syntax of all types of scripts by clicking the red check button on the toolbar of the Standalone Script dialog box.

Figure 1. Stream script toolbar icons

Script checking alerts you to any errors in your code and makes recommendations for improvement. To view the line with errors, click on the feedback in the lower half of the dialog box. This highlights the error in red.

Scripting from the command line

Scripting enables you to run operations typically performed in the user interface. Simply specify and run a standalone script on the command line when launching IBM® SPSS® Modeler. For example:

```
client -script scores.txt -execute
```

The **-script** flag loads the specified script, while the **-execute** flag executes all commands in the script file.

Compatibility with previous releases

Scripts created in previous releases of IBM® SPSS® Modeler should generally work unchanged in the current release. However, model nuggets may now be inserted in the stream automatically (this is the default setting), and may either replace or supplement an existing nugget of that type in the stream. Whether this actually happens depends on the settings of the Add model to stream and Replace previous model options (Tools > Options > User Options > Notifications). You may, for example, need to modify a script from a previous release in which nugget replacement is handled by deleting the existing nugget and inserting the new one.

Scripts created in the current release may not work in earlier releases.

If a script created in an older release uses a command that has since been replaced (or deprecated), the old form will still be supported, but a warning message will be displayed. For example, the old **generated** keyword has been replaced by **model**, and **clear generated** has been replaced by **clear generated palette**. Scripts that use the old forms will still run, but a warning will be displayed.

Accessing stream execution results

Many IBM® SPSS® Modeler nodes produce output objects such as models, charts, and tabular data. Many of these outputs contain useful values that can be used by scripts to guide subsequent runs. These values are grouped into content containers (referred to as simply containers) which

can be accessed using tags or IDs that identify each container. The way these values are accessed depends on the format or "content model" used by that container.

For example, many predictive model outputs use a variant of XML called PMML to represent information about the model such as which fields a decision tree uses at each split, or how the neurones in a neural network are connected and with what strengths. Model outputs that use PMML provide an XML Content Model that can be used to access that information. For example:

```
stream = modeler.script.stream()
# Assume the stream contains a single C5.0 model builder node
# and that the datasource, predictors and targets have already been
# set up
modelbuilder = stream.findByType("c50", None)
results = []
modelbuilder.run(results)
modeloutput = results[0]

# check how many contents are there and what are their names
tags = modeloutput.getContentModelTags()
print "Content Model Tags :" , tags

# Now that we have the C5.0 model output object, access the
# relevant content model
cm = modeloutput.getContentModel("PMML")
if (cm != None) :
    # The PMML content model is a generic XML-based content model that
    # uses XPath syntax. Use that to find the names of the data fields.
    # The call returns a list of strings match the XPath values
    dataFieldNames = cm.getStringValues("/PMML/DataDictionary/DataField", "name")
    print "Data Field Names:" , dataFieldNames
```

IBM SPSS Modeler supports the following content models in scripting:

- Table content model provides access to the simple tabular data represented as rows and columns.
- XML content model provides access to content stored in XML format.
- JSON content model provides access to content stored in JSON format.
- Column statistics content model provides access to summary statistics about a specific field.
- Pair-wise column statistics content model provides access to summary statistics between two fields or values between two separate fields.

Note that the following nodes don't contain these content models:

- Time Series
- Discriminant
- SLRM
- TCM
- All Python nodes
- All Spark nodes
- All Database Modeling nodes
- Extension Model
- STP
- [Table content model](#)
- [XML Content Model](#)
- [JSON Content Model](#)
- [Column statistics content model and pairwise statistics content model](#)

Table content model

The table content model provides a simple model for accessing simple row and column data. The values in a particular column must all have the same type of storage (for example, strings or integers).

API

Table 1. API

Return	Method	Description
int	<code>getRowCount()</code>	Returns the number of rows in this table.
int	<code>getColumnCount()</code>	Returns the number of columns in this table.
String	<code>getColumnName(int columnIndex)</code>	Returns the name of the column at the specified column index. The column index starts at 0.

Return	Method	Description
<code>StorageType</code>	<code>getStorageType(int columnIndex)</code>	Returns the storage type of the column at the specified index. The column index starts at 0.
<code>Object</code>	<code>getValueAt(int rowIndex, int columnIndex)</code>	Returns the value at the specified row and column index. The row and column indices start at 0.
<code>void</code>	<code>reset()</code>	Flushes any internal storage associated with this content model.

Nodes and outputs

This table lists nodes that build outputs which include this type of content model.

Table 2. Nodes and outputs

Node name	Output name	Container ID
<code>table</code>	<code>table</code>	"table"

Example script

```

stream = modeler.script.stream()
from modeler.api import StorageType

# Set up the variable file import node
varfilenode = stream.createAt("variablefile", "DRUG Data", 96, 96)
varfilenode.setPropertyValue("full_filename", "$CLEO_DEMOS/DRUG1n")

# Next create the aggregate node and connect it to the variable file node
aggregatenode = stream.createAt("aggregate", "Aggregate", 192, 96)
stream.link(varfilenode, aggregatenode)

# Configure the aggregate node
aggregatenode.setPropertyValue("keys", ["Drug"])
aggregatenode.setKeyedPropertyValue("aggregates", "Age", ["Min", "Max"])
aggregatenode.setKeyedPropertyValue("aggregates", "Na", ["Mean", "SD"])

# Then create the table output node and connect it to the aggregate node
tablenode = stream.createAt("table", "Table", 288, 96)
stream.link(aggregatenode, tablenode)

# Execute the table node and capture the resulting table output object
results = []
tablenode.run(results)
tableoutput = results[0]

# Access the table output's content model
tablecontent = tableoutput.getContentModel("table")

# For each column, print column name, type and the first row
# of values from the table content
col = 0
while col < tablecontent.getColumnCount():
    print tablecontent.getColumnName(col), \
        tablecontent.getStorageType(col), \
        tablecontent.getValueAt(0, col)
    col = col + 1

```

The output in the scripting Debug tab will look something like this:

```

Age_Min Integer 15
Age_Max Integer 74
Na_Mean Real 0.730851098901
Na_SDev Real 0.116669731242
Drug String drugY
Record_Count Integer 91

```

- [JSON Content Model](#)
- [Column statistics content model and pairwise statistics content model](#)

XML Content Model

The XML Content Model provides access to XML-based content.

The XML Content Model supports the ability to access components based on XPath expressions. XPath expressions are strings that define which elements or attributes are required by the caller. The XML Content Model hides the details of constructing various objects and compiling expressions that are typically required by XPath support. This makes it simpler to call from Python scripting.

The XML Content Model includes a function that returns the XML document as a string. This allows Python script users to use their preferred Python library to parse the XML.

API

Table 1. API

Return	Method	Description
<code>String</code>	<code>getXMLAsString()</code>	Returns the XML as a string.
<code>number</code>	<code>getNumericValue(String xpath)</code>	Returns the result of evaluating the path with return type of numeric (for example, count the number of elements that match the path expression).
<code>boolean</code>	<code>getBooleanValue(String xpath)</code>	Returns the boolean result of evaluating the specified path expression.
<code>String</code>	<code>getStringValue(String xpath, String attribute)</code>	Returns either the attribute value or XML node value that matches the specified path.
<code>List of strings</code>	<code>getStringValues(String xpath, String attribute)</code>	Returns a list of all attribute values or XML node values that match the specified path.
<code>List of lists of strings</code>	<code>getValuesList(String xpath, <List of strings> attributes, boolean includeValue)</code>	Returns a list of all attribute values that match the specified path along with the XML node value if required.
<code>Hash table (key:string, value:list of string)</code>	<code>getValuesMap(String xpath, String keyAttribute, <List of strings> attributes, boolean includeValue)</code>	Returns a hash table that uses either the key attribute or XML node value as key, and the list of specified attribute values as table values.
<code>boolean</code>	<code>isNamespaceAware()</code>	Returns whether the XML parsers should be aware of namespaces. Default is <code>False</code> .
<code>void</code>	<code>setNamespaceAware(boolean value)</code>	Sets whether the XML parsers should be aware of namespaces. This also calls <code>reset()</code> to ensure changes are picked up by subsequent calls.
<code>void</code>	<code>reset()</code>	Flushes any internal storage associated with this content model (for example, a cached DOM object).

Nodes and outputs

This table lists nodes that build outputs which include this type of content model.

Table 2. Nodes and outputs

Node name	Output name	Container ID
<code>Most model builders</code>	<code>Most generated models</code>	"PMML"
<code>"autodataprep"</code>	n/a	"PMML"

Example script

The Python scripting code to access the content might look like this:

```
results = []
modelbuilder.run(results)
modeloutput = results[0]
cm = modeloutput.getContentModel("PMML")

dataFieldNames = cm.getStringValues("/PMML/DataDictionary/DataField", "name")
predictedNames = cm.getStringValues("//MiningSchema/MiningField[@usageType='predicted']", "name")
```

- [Accessing stream execution results](#)
- [Table content model](#)
- [JSON Content Model](#)
- [Column statistics content model and pairwise statistics content model](#)

JSON Content Model

The JSON Content Model is used to provide support for JSON format content. This provides a basic API to allow callers to extract values on the assumption that they know which values are to be accessed.

API

Table 1. API

Return	Method	Description
<code>String</code>	<code>getJSONAsString()</code>	Returns the JSON content as a string.
<code>Object</code>	<code>getObjectAt(<List of objects> path, JSONArtifact artifact)</code> throws <code>Exception</code>	Returns the object at the specified path. The supplied root artifact may be null in which case the root of the content is used. The returned value may be a literal string, integer, real or boolean, or a JSON artifact (either a JSON object or a JSON array).
<code>Hash table<(key:object, value:object)></code>	<code>getChildValuesAt(<List of objects> path, JSONArtifact artifact)</code> throws <code>Exception</code>	Returns the child values of the specified path if the path leads to a JSON object or null otherwise. The keys in the table are strings while the associated value may be a literal string, integer, real or boolean, or a JSON artifact (either a JSON object or a JSON array).
<code>List of objects</code>	<code>getChildrenAt(<List of objects> path, JSONArtifact artifact)</code> throws <code>Exception</code>	Returns the list of objects at the specified path if the path leads to a JSON array or null otherwise. The returned values may be a literal string, integer, real or boolean, or a JSON artifact (either a JSON object or a JSON array).
<code>void</code>	<code>reset()</code>	Flushes any internal storage associated with this content model (for example, a cached DOM object).

Nodes and outputs

This table lists nodes that build outputs which include this type of content model.

Table 2. Nodes and outputs

Node name	Output name	Container ID
"applykmeansas"	n/a	"JSON_MV"
"applyxgboosttree"	n/a	"JSON_MV"

Example scripts

The following scripts retrieve JSON files:

```
applykmeansas = stream.findByName("applykmeansas",None)
mvjson = applykmeansas.getContentModel("JSON_MV")
print(mvjson.getJSONAsString())

applyxgboosttree = stream.findByName("applyxgboosttree",None)
mvjson = applyxgboosttree.getContentModel("JSON_MV")
print(mvjson.getJSONAsString())
```

Column statistics content model and pairwise statistics content model

The column statistics content model provides access to statistics that can be computed for each field (univariate statistics). The pairwise statistics content model provides access to statistics that can be computed between pairs of fields or values in a field.

The possible statistics measures are:

- `Count`
- `UniqueCount`
- `ValidCount`
- `Mean`
- `Sum`
- `Min`
- `Max`

- Range
- Variance
- StandardDeviation
- StandardErrorOfMean
- Skewness
- SkewnessStandardError
- Kurtosis
- KurtosisStandardError
- Median
- Mode
- Pearson
- Covariance
- TTest
- FTest

Some values are only appropriate from single column statistics while others are only appropriate for pairwise statistics.

Nodes that will produce these are:

- Statistics node produces column statistics and can produce pairwise statistics when correlation fields are specified
- Data Audit node produces column and can produce pairwise statistics when an overlay field is specified.
- Means node produces pairwise statistics when comparing pairs of fields or comparing a field's values with other field summaries.

Which content models and statistics are available will depend on both the particular node's capabilities and the settings within the node.

ColumnStatsContentModel API

Table 1. ColumnStatsContentModel API

Return	Method	Description
<code>List<StatisticType></code>	<code>getAvailableStatistics()</code>	Returns the available statistics in this model. Not all fields will necessarily have values for all statistics.
<code>List<String></code>	<code>getAvailableColumns()</code>	Returns the column names for which statistics were computed.
<code>Number</code>	<code>getStatistic(String column, StatisticType statistic)</code>	Returns the statistic values associated with the column.
<code>void</code>	<code>reset()</code>	Flushes any internal storage associated with this content model.

PairwiseStatsContentModel API

Table 2. PairwiseStatsContentModel API

Return	Method	Description
<code>List<StatisticType></code>	<code>getAvailableStatistics()</code>	Returns the available statistics in this model. Not all fields will necessarily have values for all statistics.
<code>List<String></code>	<code>getAvailablePrimaryColumns()</code>	Returns the primary column names for which statistics were computed.
<code>List<Object></code>	<code>getAvailablePrimaryValues()</code>	Returns the values of the primary column for which statistics were computed.
<code>List<String></code>	<code>getAvailableSecondaryColumns()</code>	Returns the secondary column names for which statistics were computed.
<code>Number</code>	<code>getStatistic(String primaryColumn, String secondaryColumn, StatisticType statistic)</code>	Returns the statistic values associated with the columns.
<code>Number</code>	<code>getStatistic(String primaryColumn, Object primaryValue, String secondaryColumn, StatisticType statistic)</code>	Returns the statistic values associated with the primary column value and the secondary column.
<code>void</code>	<code>reset()</code>	Flushes any internal storage associated with this content model.

Nodes and outputs

This table lists nodes that build outputs which include this type of content model.

Table 3. Nodes and outputs

Node name	Output name	Container ID	Notes
"means" (Means node)	"means"	"columnStatistics"	
"means" (Means node)	"means"	"pairwiseStatistics"	
"dataaudit" (Data Audit node)	"means"	"columnStatistics"	
"statistics" (Statistics node)	"statistics"	"columnStatistics"	Only generated when specific fields are examined.
"statistics" (Statistics node)	"statistics"	"pairwiseStatistics"	Only generated when fields are correlated.

Example script

```
from modeler.api import StatisticType
stream = modeler.script.stream()

# Set up the input data
varfile = stream.createAt("variablefile", "File", 96, 96)
varfile.setPropertyValue("full_filename", "$CLEO/DEMOS/DRUG1n")

# Now create the statistics node. This can produce both
# column statistics and pairwise statistics
statisticsnode = stream.createAt("statistics", "Stats", 192, 96)
statisticsnode.setPropertyValue("examine", ["Age", "Na", "K"])
statisticsnode.setPropertyValue("correlate", ["Age", "Na", "K"])
stream.link(varfile, statisticsnode)

results = []
statisticsnode.run(results)
statsoutput = results[0]
statscm = statsoutput.getContentModel("columnStatistics")
if (statscm != None):
    cols = statscm.getAvailableColumns()
    stats = statscm.getAvailableStatistics()
    print "Column stats:", cols[0], str(stats[0]), " = ", statscm.getStatistic(cols[0], stats[0])

statscm = statsoutput.getContentModel("pairwiseStatistics")
if (statscm != None):
    pcols = statscm.getAvailablePrimaryColumns()
    scols = statscm.getAvailableSecondaryColumns()
    stats = statscm.getAvailableStatistics()
    corr = statscm.getStatistic(pcols[0], scols[0], StatisticType.Pearson)
    print "Pairwise stats:", pcols[0], scols[0], " Pearson = ", corr
```

Command Line Arguments

- [Invoking the software](#)
- [Using command line arguments](#)

Invoking the software

Windows

You can use the command line of your operating system to launch IBM® SPSS® Modeler as follows:

1. On a computer where IBM SPSS Modeler is installed, open a DOS, or command-prompt, window.
2. To launch the IBM SPSS Modeler interface in interactive mode, type the `modelerclient` command followed by the required arguments; for example:

```
modelerclient -stream report.str -execute
```

The available arguments (flags) allow you to connect to a server, load streams, run scripts, or specify other parameters as needed.

Mac OS

1. Locate the Mac OS command path for IBM SPSS Modeler (for example, [Installpath]/IBM SPSS Modeler.app/Contents/MacOS).
2. To launch the IBM SPSS Modeler interface in interactive mode, run the `modeler` command followed by the required arguments; for example:

```
./modeler -stream report.str -execute
```

Using command line arguments

You can append command line arguments (also referred to as *flags*) to the initial `modelerclient` command to alter the invocation of IBM® SPSS® Modeler.

Several types of command line arguments are available, and are described later in this section.

Table 1. Types of command line arguments

Argument type	Where described
System arguments	See the topic System arguments for more information.
Parameter arguments	See the topic Parameter arguments for more information.
Server connection arguments	See the topic Server connection arguments for more information.
IBM SPSS Collaboration and Deployment Services Repository connection arguments	See the topic IBM SPSS Collaboration and Deployment Services Repository Connection Arguments for more information.
IBM SPSS Analytic Server connection arguments	See the topic IBM SPSS Analytic Server connection arguments for more information.

For example, you can use the `-server`, `-stream` and `-execute` flags to connect to a server and then load and run a stream, as follows:

```
modelerclient -server -hostname myserver -port 80 -username dminer  
-password 1234 -stream mystream.str -execute
```

Note that when running against a local client installation, the server connection arguments are not required.

Parameter values that contain spaces can be enclosed in double quotes—for example:

```
modelerclient -stream mystream.str -Pusername="Joe User" -execute
```

You can also execute IBM SPSS Modeler states and scripts in this manner, using the `-state` and `-script` flags, respectively.

Note: If you use a structured parameter in a command, you must precede quotation marks with a backslash. This prevents the quotation marks being removed during interpretation of the string.

Debugging command line arguments

To debug a command line, use the `modelerclient` command to launch IBM SPSS Modeler with the desired arguments. This enables you to verify that commands will execute as expected. You can also confirm the values of any parameters passed from the command line in the Session Parameters dialog box (Tools menu, Set Session Parameters).

- [System arguments](#)
- [Parameter arguments](#)
- [Server connection arguments](#)
- [IBM SPSS Collaboration and Deployment Services Repository Connection Arguments](#)
- [IBM SPSS Analytic Server connection arguments](#)
- [Combining Multiple Arguments](#)

System arguments

The following table describes system arguments available for command line invocation of the user interface.

Table 1. System arguments

Argument	Behavior/Description
@<commandFile>	The @ character followed by a filename specifies a command list. When <code>modelerclient</code> encounters an argument beginning with @, it operates on the commands in that file as if they had been on the command line. See the topic Combining Multiple Arguments for more information.
-directory <dir>	Sets the default working directory. In local mode, this directory is used for both data and output. Example: <code>-directory c:/</code> or <code>-directory c:\\</code>
-server_directory <dir>	Sets the default server directory for data. The working directory, specified by using the <code>-directory</code> flag, is used for output.
-execute	After starting, execute any stream, state, or script loaded at startup. If a script is loaded in addition to a stream or state, the script alone will be executed.

Argument	Behavior/Description
-stream <stream>	At startup, load the stream specified. Multiple streams can be specified, but the last stream specified will be set as the current stream.
-script <script>	At startup, load the standalone script specified. This can be specified in addition to a stream or state as described below, but only one script can be loaded at startup.
-model <model>	At startup, load the generated model (.gm format file) specified.
-state <state>	At startup, load the saved state specified.
-project <project>	Load the specified project. Only one project can be loaded at startup.
-output <output>	At startup, load the saved output object (.cou format file).
-help	Display a list of command line arguments. When this option is specified, all other arguments are ignored and the Help screen is displayed.
-P <name>=<value>	Used to set a startup parameter. Can also be used to set node properties (slot parameters).

Note: Default directories can also be set in the user interface. To access the options, from the File menu, choose Set Working Directory or Set Server Directory.

Loading multiple files

From the command line, you can load multiple streams, states, and outputs at startup by repeating the relevant argument for each object loaded. For example, to load and run two streams called report.str and train.str, you would use the following command:

```
modelerclient -stream report.str -stream train.str -execute
```

Loading objects from the IBM SPSS Collaboration and Deployment Services Repository

Because you can load certain objects from a file or from the IBM® SPSS® Collaboration and Deployment Services Repository (if licensed), the filename prefix **spsscr:** and, optionally, **file:** (for objects on disk) tells IBM SPSS Modeler where to look for the object. The prefix works with the following flags:

- **-stream**
- **-script**
- **-output**
- **-model**
- **-project**

You use the prefix to create a URI that specifies the location of the object—for example, **-stream**

"spsscr://folder_1/scoring_stream.str". The presence of the **spsscr:** prefix requires that a valid connection to the IBM SPSS Collaboration and Deployment Services Repository has been specified in the same command. So, for example, the full command would look like this:

```
modelerclient -spsscr_hostname myhost -spsscr_port 8080  
-spsscr_username myusername -spsscr_password mypassword  
-stream "spsscr://folder_1/scoring_stream.str" -execute
```

Note that from the command line, you *must* use a URI. The simpler **REPOSITORY_PATH** is not supported. (It works only within scripts.) For more details about URIs for objects in the IBM SPSS Collaboration and Deployment Services Repository, see the topic [Accessing Objects in the IBM SPSS Collaboration and Deployment Services Repository](#).

Parameter arguments

Parameters can be used as flags during command line execution of IBM® SPSS® Modeler. In command line arguments, the **-P** flag is used to denote a parameter of the form **-P <name>=<value>**.

Parameters can be any of the following:

- Simple parameters (or parameters used directly in CLEM expressions).
- Slot parameters, also referred to as node properties. These parameters are used to modify the settings of nodes in the stream. See the topic [Node properties overview](#) for more information.
- Command line parameters, used to alter the invocation of IBM SPSS Modeler.

For example, you can supply data source user names and passwords as a command line flag, as follows:

```
modelerclient -stream response.str -P:databasenode.datasource="{"ORA_10gR2",user1,mypsw,false}"
```

The format is the same as that of the **datasource** parameter of the **databasenode** node property. For more information, see: [databasenode properties](#).

The last parameter should be set to **true** if you're passing an encoded password. Also note that no leading spaces should be used in front of the database user name and password (unless, of course, your user name or password actually contains a leading space).

Note: If the node is named, you must surround the node name with double quotes and escape the quotes with a backslash. For example, if the data source node in the preceding example has the name **Source_ABC** the entry would be as follows:

```
modelerclient -stream response.str -P:databasenode.\\"Source_ABC\".datasource="{"ORA_10gR2",user1,mypsw,true}"
```

A backslash is also required in front of the quotes that identify a structured parameter, as in the following TM1 datasource example:

```
clemb -server -hostname 9.115.21.169 -port 28053 -username administrator  
-execute -stream C:\Share\TM1_Script.str -P:tm1import.pm_host="http://9.115.21.163:9510/pmhup/pm"  
-P:tm1import.tm1_connection={"SData","","","admin","\apple"}  
-P:tm1import.selected_view={"SalesPriorCube","\salesmargin%\"}
```

Note: If the database name (in the **datasource** property) contains one or more spaces, periods (also known as a "full stop"), or underscores, you can use the "backslash double quote" format to treat it as string. For example: `"\"db2v9.7.6_linux\""` or: `"\"TADATA_131\""`. In addition, always enclose **datasource** string values in double quotes and curly braces, as in the following example: `"\"SQL Server\",spssuser,abcd1234,false\""`.

Server connection arguments

The **-server** flag tells IBM® SPSS® Modeler that it should connect to a public server, and the flags **-hostname**, **-use_ssl**, **-port**, **-username**, **-password**, and **-domain** are used to tell IBM SPSS Modeler how to connect to the public server. If no **-server** argument is specified, the default or local server is used.

Examples

To connect to a public server:

```
modelerclient -server -hostname myserver -port 80 -username dminer  
-password 1234 -stream mystream.str -execute
```

To connect to a server cluster:

```
modelerclient -server -cluster "QA Machines" \  
-spsscrr_hostname pes_host -spsscrr_port 8080 \  
-spsscrr_username asmith -spsscrr_epassword xyz
```

Note that connecting to a server cluster requires the Coordinator of Processes through IBM SPSS Collaboration and Deployment Services, so the **-cluster** argument must be used in combination with the repository connection options (**spsscrr_***). See the topic [IBM SPSS Collaboration and Deployment Services Repository Connection Arguments](#) for more information.

Table 1. Server connection arguments

Argument	Behavior/Description
-server	Runs IBM SPSS Modeler in server mode, connecting to a public server using the flags -hostname , -port , -username , -password , and -domain .
-hostname <name>	The hostname of the server machine. Available in server mode only.
-use_ssl	Specifies that the connection should use SSL (secure socket layer). This flag is optional; the default setting is <i>not</i> to use SSL.
-port <number>	The port number of the specified server. Available in server mode only.
-cluster <name>	Specifies a connection to a server cluster rather than a named server; this argument is an alternative to the hostname , port and use_ssl arguments. The name is the cluster name, or a unique URI which identifies the cluster in the IBM SPSS Collaboration and Deployment Services Repository. The server cluster is managed by the Coordinator of Processes through IBM SPSS Collaboration and Deployment Services. See the topic IBM SPSS Collaboration and Deployment Services Repository Connection Arguments for more information.
-username <name>	The user name with which to log on to the server. Available in server mode only.
-password <password>	The password with which to log on to the server. Available in server mode only. Note: If the -password argument is not used, you will be prompted for a password.

Argument	Behavior/Description
-epassword <encodedpasswordstring>	The encoded password with which to log on to the server. Available in server mode only. Note: An encoded password can be generated from the Tools menu of the IBM SPSS Modeler application.
-domain <name>	The domain used to log on to the server. Available in server mode only.
-P <name>= <value>	Used to set a startup parameter. Can also be used to set node properties (slot parameters).

IBM SPSS Collaboration and Deployment Services Repository Connection Arguments

If you want to store or retrieve objects from IBM® SPSS® Collaboration and Deployment Services via the command line, you must specify a valid connection to the IBM SPSS Collaboration and Deployment Services Repository. For example:

```
modelerclient -spsscr_hostname myhost -spsscr_port 8080
-spsscr_username myusername -spsscr_password mypassword
-stream "spsscr:///folder_1/scoring_stream.str" -execute
```

The following table lists the arguments that can be used to set up the connection.

Table 1. IBM SPSS Collaboration and Deployment Services Repository connection arguments

Argument	Behavior/Description
-spsscr_hostname <hostname or IP address>	The hostname or IP address of the server on which the IBM SPSS Collaboration and Deployment Services Repository is installed.
-spsscr_port <number>	The port number on which the IBM SPSS Collaboration and Deployment Services Repository accepts connections (typically, 8080 by default).
-spsscr_use_ssl	Specifies that the connection should use SSL (secure socket layer). This flag is optional; the default setting is <i>not</i> to use SSL.
-spsscr_username <name>	The user name with which to log on to the IBM SPSS Collaboration and Deployment Services Repository.
-spsscr_password <password>	The password with which to log on to the IBM SPSS Collaboration and Deployment Services Repository.
-spsscr_epassword <encoded password>	The encoded password with which to log on to the IBM SPSS Collaboration and Deployment Services Repository.
-spsscr_providername <name>	The authentication provider used for logging on to the IBM SPSS Collaboration and Deployment Services Repository (Active Directory or LDAP). This is not required if using the native (Local Repository) provider.

For more information about storing and retrieving objects from the IBM SPSS Collaboration and Deployment Services Repository via the command line, see [System arguments](#).

IBM SPSS Analytic Server connection arguments

If you want to store or retrieve objects from IBM® SPSS® Analytic Server via the command line, you must specify a valid connection to IBM SPSS Analytic Server.

Note: The default location of Analytic Server is obtained from SPSS Modeler Server. Users can also define their own Analytic Server connections via Tools > Analytic Server Connections.

The following table lists the arguments that can be used to set up the connection.

Table 1. IBM SPSS Analytic Server connection arguments

Argument	Behavior/Description
-analytic_server_username	The user name with which to log on to IBM SPSS Analytic Server.
-analytic_server_password	The password with which to log on to IBM SPSS Analytic Server.
-analytic_server_epassword	The encoded password with which to log on to IBM SPSS Analytic Server.
-analytic_server_credential	The credentials used to log on to IBM SPSS Analytic Server.

Combining Multiple Arguments

Multiple arguments can be combined in a single command file specified at invocation by using the @ symbol followed by the filename. This enables you to shorten the command line invocation and overcome any operating system limitations on command length. For example, the following startup command uses the arguments specified in the file referenced by <commandFileName>.

```
modelerclient @<commandFileName>
```

Enclose the filename and path to the command file in quotation marks if spaces are required, as follows:

```
modelerclient @ "C:\Program Files\IBM\SPSS\Modeler\nn\scripts\my_command_file.txt"
```

The command file can contain all arguments previously specified individually at startup, with one argument per line. For example:

```
-stream report.str  
-Porder.full_filename=APR_orders.dat  
-Report.filename=APR_report.txt  
-execute
```

When writing and referencing command files, be sure to follow these constraints:

- Use only one command per line.
- Do not embed an @CommandFile argument within a command file.

Properties Reference

- [Properties reference overview](#)
- [Node properties overview](#)

Properties reference overview

You can specify a number of different properties for nodes, streams, projects, and SuperNodes. Some properties are common to all nodes, such as name, annotation, and ToolTip, while others are specific to certain types of nodes. Other properties refer to high-level stream operations, such as caching or SuperNode behavior. Properties can be accessed through the standard user interface (for example, when you open a dialog box to edit options for a node) and can also be used in a number of other ways.

- Properties can be modified through scripts, as described in this section. For more information, see [Syntax for properties](#).
- Node properties can be used in SuperNode parameters.
- Node properties can also be used as part of a command line option (using the -P flag) when starting IBM® SPSS® Modeler.

In the context of scripting within IBM SPSS Modeler, node and stream properties are often called **slot parameters**. In this guide, they are referred to as node or stream properties.

- [Syntax for properties](#)
- [Node and stream property examples](#)

Syntax for properties

Properties can be set using the following syntax

```
OBJECT.setPropertyValue(PROPERTY, VALUE)
```

or:

```
OBJECT.setKeyedPropertyValue(PROPERTY, KEY, VALUE)
```

The value of properties can be retrieved using the following syntax:

```
VARIABLE = OBJECT.getPropertyValue(PROPERTY)
```

or:

```
VARIABLE = OBJECT.getKeyedPropertyValue(PROPERTY, KEY)
```

where **OBJECT** is a node or output, **PROPERTY** is the name of the node property that your expression refers to, and **KEY** is the key value for keyed properties.. For example, the following syntax is used to find the filter node, and then set the default to include all fields and filter the **Age** field from downstream data:

```

filternode = modeler.script.stream().findByType("filter", None)
filternode.setPropertyValue("default_include", True)
filternode.setKeyedPropertyValue("include", "Age", False)

```

All nodes used in IBM® SPSS® Modeler can be located using the stream `findByType (TYPE, LABEL)` function. At least one of `TYPE` or `LABEL` must be specified.

- [Structured properties](#)
- [Abbreviations](#)

Structured properties

There are two ways in which scripting uses structured properties for increased clarity when parsing:

- To give structure to the names of properties for complex nodes, such as Type, Filter, or Balance nodes.
- To provide a format for specifying multiple properties at once.

Structuring for Complex Interfaces

The scripts for nodes with tables and other complex interfaces (for example, the Type, Filter, and Balance nodes) must follow a particular structure in order to parse correctly. These properties need a name that is more complex than the name for a single identifier, this name is called the key. For example, within a Filter node, each available field (on its upstream side) is switched on or off. In order to refer to this information, the Filter node stores one item of information per field (whether each field is true or false). This property may have (or be given) the value `True` or `False`. Suppose that a Filter node named `mynode` has (on its upstream side) a field called `Age`. To switch this to off, set the property `include`, with the key `Age`, to the value `False`, as follows:

```

mynode.setKeyedPropertyValue("include", "Age", False)

```

Structuring to Set Multiple Properties

For many nodes, you can assign more than one node or stream property at a time. This is referred to as the **multiset command** or **set block**.

In some cases, a structured property can be quite complex. An example is as follows:

```

sortnode.setPropertyValue("keys", [[{"K": "Descending"}, {"Age": "Ascending"}, {"Na": "Descending"}]])

```

Another advantage that structured properties have is their ability to set several properties on a node before the node is stable. By default, a multiset sets all properties in the block before taking any action based on an individual property setting. For example, when defining a Fixed File node, using two steps to set field properties would result in errors because the node is not consistent until both settings are valid. Defining properties as a multiset circumvents this problem by setting both properties before updating the data model.

Abbreviations

Standard abbreviations are used throughout the syntax for node properties. Learning the abbreviations is helpful in constructing scripts.

Table 1. Standard abbreviations used
throughout the syntax

Abbreviation	Meaning
abs	Absolute value
len	Length
min	Minimum
max	Maximum
correl	Correlation
covar	Covariance
num	Number or numeric
pct	Percent or percentage
transp	Transparency
xval	Cross-validation
var	Variance or variable (in source nodes)

Node and stream property examples

Node and stream properties can be used in a variety of ways with IBM® SPSS® Modeler. They are most commonly used as part of a script, either a **standalone script**, used to automate multiple streams or operations, or a **stream script**, used to automate processes within a single stream. You can also specify node parameters by using the node properties within the SuperNode. At the most basic level, properties can also be used as a command line option for starting IBM SPSS Modeler. Using the **-p** argument as part of command line invocation, you can use a stream property to change a setting in the stream.

Table 1. Node and stream property examples

Property	Meaning
<code>s.max_size</code>	Refers to the property <code>max_size</code> of the node named <code>s</code> .
<code>s:samplenode.max_size</code>	Refers to the property <code>max_size</code> of the node named <code>s</code> , which must be a Sample node.
<code>:samplenode.max_size</code>	Refers to the property <code>max_size</code> of the Sample node in the current stream (there must be only one Sample node).
<code>s:sample.max_size</code>	Refers to the property <code>max_size</code> of the node named <code>s</code> , which must be a Sample node.
<code>t.direction.Age</code>	Refers to the role of the field <code>Age</code> in the Type node <code>t</code> .
<code>:.max_size</code>	*** NOT LEGAL *** You must specify either the node name or the node type.

The example `s:sample.max_size` illustrates that you do not need to spell out node types in full.

The example `t.direction.Age` illustrates that some slot names can themselves be structured—in cases where the attributes of a node are more complex than simply individual slots with individual values. Such slots are called **structured** or **complex** properties.

Node properties overview

Each type of node has its own set of legal properties, and each property has a type. This type may be a general type—number, flag, or string—in which case settings for the property are coerced to the correct type. An error is raised if they cannot be coerced. Alternatively, the property reference may specify the range of legal values, such as `Discard`, `PairAndDiscard`, and `IncludeAsText`, in which case an error is raised if any other value is used. Flag properties should be read or set by using values of `true` and `false`. (Variations including `Off`, `OFF`, `off`, `No`, `NO`, `no`, `n`, `N`, `f`, `F`, `false`, `False`, `FALSE`, or `0` are also recognized when setting values but may cause errors when reading property values in some cases. All other values are regarded as true. Using `true` and `false` consistently will avoid any confusion.) In this guide's reference tables, the structured properties are indicated as such in the Property description column, and their usage formats are given.

- [Common Node Properties](#)

Common Node Properties

A number of properties are common to all nodes (including SuperNodes) in IBM® SPSS® Modeler.

Table 1. Common node properties

Property name	Data type	Property description
<code>use_custom_name</code>	<code>flag</code>	
<code>name</code>	<code>string</code>	Read-only property that reads the name (either auto or custom) for a node on the canvas.
<code>custom_name</code>	<code>string</code>	Specifies a custom name for the node.
<code>tooltip</code>	<code>string</code>	
<code>annotation</code>	<code>string</code>	
<code>keywords</code>	<code>string</code>	Structured slot that specifies a list of keywords associated with the object (for example, <code>["Keyword1", "Keyword2"]</code>).
<code>cache_enabled</code>	<code>flag</code>	
<code>node_type</code>	<code>source_supernode</code> <code>process_supernode</code> <code>terminal_supernode</code> all node names as specified for scripting	Read-only property used to refer to a node by type. For example, instead of referring to a node only by name, such as <code>real_income</code> , you can also specify the type, such as <code>userinputnode</code> or <code>filternode</code> .

Related information

- [Node properties overview](#)

Stream properties

A variety of stream properties can be controlled by scripting. To reference stream properties, you must set the execution method to use scripts:

```
stream = modeler.script.stream()
stream.setPropertyValue("execute_method", "Script")
```

Example

The node property is used to refer to the nodes in the current stream. The following stream script provides an example:

```
stream = modeler.script.stream()
annotation = stream.getPropertyValue("annotation")

annotation = annotation + "\n\nThis stream is called \"" + stream.getLabel() + "\" and
contains the following nodes:\n"

for node in stream.iterator():
    annotation = annotation + "\n" + node.getTypeName() + " node called \"" + node.getLabel()
    + "\""

stream.setPropertyValue("annotation", annotation)
```

The above example uses the node property to create a list of all nodes in the stream and write that list in the stream annotations. The annotation produced looks like this:

This stream is called "druglearn" and contains the following nodes:

```
type node called "Define Types"
derive node called "Na_to_K"
variablefile node called "DRUGin"
neuralnetwork node called "Drug"
c50 node called "Drug"
filter node called "Discard Fields"
```

Stream properties are described in the following table.

Table 1. Stream properties

Property name	Data type	Property description
execute_method	Normal Script	

Property name	Data type	Property description
date_baseline	number	
date_2digit_baseline	number	
time_format	"HHMMSS" "HHMM" "MMSS" "HH:MM:SS" "HH:MM" "MM:SS" "(H) H: (M) M: (S) S" "(H) H: (M) M" (M) M: (S) S" "HH.MM.SS" "HH.MM" "MM.SS" "(H) H. (M) M. (S) S" "(H) H. (M) M" "(M) M. (S) S"	
time_rollover	flag	
import_datetime_as_string	flag	
decimal_places	number	
decimal_symbol	Default Period Comma	
angles_in_radians	flag	
use_max_set_size	flag	
max_set_size	number	
ruleset_evaluation	Voting FirstHit	
refresh_source_nodes	flag	Use to refresh source nodes automatically upon stream execution.
script	string	
annotation	string	
name	string	Note: This property is read-only. If you want to change the name of a stream, you should save it with a different name.
parameters		Use this property to update stream parameters from within a stand-alone script.
nodes		See detailed information below.
encoding	SystemDefault "UTF-8"	
stream_rewriting	boolean	
stream_rewriting_maximize_sql	boolean	
stream_rewriting_optimize_clem_execution	boolean	
stream_rewriting_optimize_syntax_execution	boolean	
enable_parallelism	boolean	
sql_generation	boolean	
database_caching	boolean	
sql_logging	boolean	
sql_generation_logging	boolean	
sql_log_native	boolean	
sql_log_prettyprint	boolean	
record_count_suppress_input	boolean	
record_count_feedback_interval	integer	
use_stream_auto_create_node_settings	boolean	If true, then stream-specific settings are used, otherwise user preferences are used.
create_model_applier_for_new_models	boolean	If true, when a model builder creates a new model, and it has no active update links, a new model applier is added. Note: If you are using IBM® SPSS® Modeler Batch version 15 you must explicitly add the model applier within your script.

Property name	Data type	Property description
<code>create_model_applier_up_date_links</code>	<code>createEnabled</code> <code>createDisabled</code> <code>doNotCreate</code>	Defines the type of link created when a model applier node is added automatically.
<code>create_source_node_from_builders</code>	<code>boolean</code>	If true, when a source builder creates a new source output, and it has no active update links, a new source node is added.
<code>create_source_node_update_links</code>	<code>createEnabled</code> <code>createDisabled</code> <code>doNotCreate</code>	Defines the type of link created when a source node is added automatically.
<code>has_coordinate_system</code>	<code>boolean</code>	If true, applies a coordinate system to the entire stream.
<code>coordinate_system</code>	<code>string</code>	The name of the selected projected coordinate system.
<code>deployment_area</code>	<code>ModelRefresh</code> <code>Scoring</code> <code>None</code>	Choose how you want to deploy the stream. If this value is set to <code>None</code> , no other deployment entries are used.
<code>scoring_terminal_node_id</code>	<code>string</code>	Choose the scoring branch in the stream. It can be any terminal node in the stream.
<code>scoring_node_id</code>	<code>string</code>	Choose the nugget in the scoring branch.
<code>model_build_node_id</code>	<code>string</code>	Choose the modeling node in the stream.

- [xmlimportnode Properties](#)

Source node common properties

Properties that are common to all source nodes are listed below, with information on specific nodes in the topics that follow.

Example 1

```
varfilenode = modeler.script.stream().create("variablefile", "Var. File")
varfilenode.setPropertyValue("full_filename", "$CLEO_DEMOS/DRUG1n")
varfilenode.setKeyedPropertyValue("check", "Age", "None")
varfilenode.setKeyedPropertyValue("values", "Age", [1, 100])
varfilenode.setKeyedPropertyValue("type", "Age", "Range")
varfilenode.setKeyedPropertyValue("direction", "Age", "Input")
```

Example 2

This script assumes that the specified data file contains a field called `Region` that represents a multi-line string.

```
from modeler.api import StorageType
from modeler.api import MeasureType

# Create a Variable File node that reads the data set containing
# the "Region" field
varfilenode = modeler.script.stream().create("variablefile", "My Geo Data")
```

```

varfilenode.setPropertyValue("full_filename", "C:/mydata/mygeodata.csv")
varfilenode.setPropertyValue("treat_square_brackets_as_lists", True)

# Override the storage type to be a list...
varfilenode.setKeyedPropertyValue("custom_storage_type", "Region", StorageType.LIST)
# ...and specify the type if values in the list and the list depth
varfilenode.setKeyedPropertyValue("custom_list_storage_type", "Region", StorageType.INTEGER)
varfilenode.setKeyedPropertyValue("custom_list_depth", "Region", 2)

# Now change the measurement to indentify the field as a geospatial value...
varfilenode.setKeyedPropertyValue("measure_type", "Region", MeasureType.GEOSPATIAL)
# ...and finally specify the necessary information about the specific
# type of geospatial object
varfilenode.setKeyedPropertyValue("geo_type", "Region", "MultiLineString")
varfilenode.setKeyedPropertyValue("geo_coordinates", "Region", "2D")
varfilenode.setKeyedPropertyValue("has_coordinate_system", "Region", True)
varfilenode.setKeyedPropertyValue("coordinate_system", "Region",
                                "ETRS_1989_EPSG_Arctic_zone_5-47")

```

Table 1. Source node common properties

Property name	Data type	Property description
direction	Input Target Both None Partition Split Frequency RecordID	Keyed property for field roles. Usage format: NODE.direction.FIELDNAME Note: The values In and Out are now deprecated. Support for them may be withdrawn in a future release.
type	Range Flag Set Typeless Discrete Ordered Set Default	Type of field. Setting this property to Default will clear any values property setting, and if value_mode is set to Specify, it will be reset to Read. If value_mode is already set to Pass or Read, it will be unaffected by the type setting. Usage format: NODE.type.FIELDNAME
storage	Unknown String Integer Real Time Date Timestamp	Read-only keyed property for field storage type. Usage format: NODE.storage.FIELDNAME
check	None Nullify Coerce Discard Warn Abort	Keyed property for field type and range checking. Usage format: NODE.check.FIELDNAME
values	[value value]	For a continuous (range) field, the first value is the minimum, and the last value is the maximum. For nominal (set) fields, specify all values. For flag fields, the first value represents false, and the last value represents true. Setting this property automatically sets the value_mode property to Specify. The storage is determined based on the first value in the list, for example, if the first value is a string then the storage is set to String. Usage format: NODE.values.FIELDNAME
value_mode	Read Pass Read+ Current Specify	Determines how values are set for a field on the next data pass. Usage format: NODE.value_mode.FIELDNAME Note that you cannot set this property to Specify directly; to use specific values, set the values property.
default_value_mode	Read Pass	Specifies the default method for setting values for all fields. Usage format: NODE.default_value_mode This setting can be overridden for specific fields by using the value_mode property.
extend_values	flag	Applies when value_mode is set to Read. Set to T to add newly read values to any existing values for the field. Set to F to discard existing values in favor of the newly read values. Usage format: NODE.extend_values.FIELDNAME
value_labels	string	Used to specify a value label. Note that values must be specified first.
enable_missing	flag	When set to T, activates tracking of missing values for the field. Usage format: NODE.enable_missing.FIELDNAME
missing_values	[value value ...]	Specifies data values that denote missing data. Usage format: NODE.missing_values.FIELDNAME
range_missing	flag	When this property is set to T, specifies whether a missing-value (blank) range is defined for a field. Usage format: NODE.range_missing.FIELDNAME
missing_lower	string	When range_missing is true, specifies the lower bound of the missing-value range. Usage format: NODE.missing_lower.FIELDNAME
missing_upper	string	When range_missing is true, specifies the upper bound of the missing-value range. Usage format: NODE.missing_upper.FIELDNAME
null_missing	flag	When this property is set to T, nulls (undefined values that are displayed as \$null\$ in the software) are considered missing values. Usage format: NODE.null_missing.FIELDNAME
whitespace_missing	flag	When this property is set to T, values containing only white space (spaces, tabs, and new lines) are considered missing values. Usage format: NODE.whitespace_missing.FIELDNAME
description	string	Used to specify a field label or description.

Property name	Data type	Property description
<code>default_incl ude</code>	<code>flag</code>	Keyed property to specify whether the default behavior is to pass or filter fields: <code>NODE.default_include Example: set mynode:filternode.default_include = false</code>
<code>include</code>	<code>flag</code>	Keyed property used to determine whether individual fields are included or filtered: <code>NODE.include.FIELDNAME.</code>
<code>new_name</code>	<code>string</code>	
<code>measure_type</code>	<code>Range / MeasureType. RANGE Discrete / MeasureType. DISCRETE Flag / MeasureType. FLAG Set / MeasureType. SET OrderedSet / MeasureType. ORDERED_SET Typeless / MeasureType. TYPELESS Collection / MeasureType. COLLECTION Geospatial / MeasureType. GEOSPATIAL</code>	This keyed property is similar to <code>type</code> in that it can be used to define the measurement associated with the field. What is different is that in Python scripting, the setter function can also be passed one of the <code>MeasureType</code> values while the getter will always return on the <code>MeasureType</code> values.
<code>collection_m easure</code>	<code>Range / MeasureType. RANGE Flag / MeasureType. FLAG Set / MeasureType. SET OrderedSet / MeasureType. ORDERED_SET Typeless / MeasureType. TYPELESS</code>	For collection fields (lists with a depth of 0), this keyed property defines the measurement type associated with the underlying values.
<code>geo_type</code>	<code>Point MultiPoint LineString MultiLineStr ing Polygon MultiPolygon</code>	For geospatial fields, this keyed property defines the type of geospatial object represented by this field. This should be consistent with the list depth of the values.
<code>has_coordinate_system</code>	<code>boolean</code>	For geospatial fields, this property defines whether this field has a coordinate system
<code>coordinate_s ystem</code>	<code>string</code>	For geospatial fields, this keyed property defines the coordinate system for this field.

Property name	Data type	Property description
custom_storage_type	Unknown / MeasureType. UNKNOWN String / MeasureType. STRING Integer / MeasureType. INTEGER Real / MeasureType. REAL Time / MeasureType. TIME Date / MeasureType. DATE Timestamp / MeasureType. TIMESTAMP List / MeasureType. LIST	This keyed property is similar to <code>custom_storage</code> in that it can be used to define the override storage for the field. What is different is that in Python scripting, the setter function can also be passed one of the <code>StorageType</code> values while the getter will always return on the <code>StorageType</code> values.
custom_list_storage_type	String / MeasureType. STRING Integer / MeasureType. INTEGER Real / MeasureType. REAL Time / MeasureType. TIME Date / MeasureType. DATE Timestamp / MeasureType. TIMESTAMP	For list fields, this keyed property specifies the storage type of the underlying values.
custom_list_depth	integer	For list fields, this keyed property specifies the depth of the field
max_list_length	integer	Only available for data with a measurement level of either <i>Geospatial</i> or <i>Collection</i> . Set the maximum length of the list by specifying the number of elements the list can contain.
max_string_length	integer	Only available for <i>typeless</i> data and used when you are generating SQL to create a table. Enter the value of the largest string in your data; this generates a column in the table that is big enough to contain the string.

asimport Properties

The Analytic Server source enables you to run a stream on Hadoop Distributed File System (HDFS).

Example

```
node.setPropertyValue("use_default_as", False)
node.setPropertyValue("connection",
["false","9.119.141.141","9080","analyticserver","ibm","admin","admin","false","","","",""])

```

Table 1. asimport properties

asimport properties	Data type	Property description
data_source	string	The name of the data source.
use_default_as	boolean	If set to <code>True</code> , uses the default Analytic Server connection configured in the server options.cfg file. If set to <code>False</code> , uses the connection of this node.

asimport properties	Data type	Property description
connection	["string", "string", "string", "string", "string", "string", "string", "string"]	A list property containing the Analytic Server connection details. The format is: ["is_secure_connect", "server_url", "server_port", "context_root", "consumer", "user_name", "password", "use-kerberos-auth", "kerberos-krb5-config-file-path", "kerberos-jaas-config-file-path", "kerberos-krb5-service-principal-name", "enable-kerberos-debug"] Where: is_secure_connect: indicates whether secure connection is used, and is either true or false. use-kerberos-auth: indicates whether kerberos authentication is used, and is either true or false. enable-kerberos-debug: indicates whether the debug mode of kerberos authentication is used, and is either true or false.

cognosimport Node Properties

The IBM Cognos source node imports data from Cognos Analytics databases.

Example

```
node = stream.create("cognosimport", "My node")
node.setPropertyValue("cognos_connection", ["http://mycogsrv1:9300/p2pd/servlet/dispatch",
    True, "", "", ""])
node.setPropertyValue("cognos_package_name", "/Public Folders/GOSALES")
node.setPropertyValue("cognos_items", "[GreatOutdoors].[BRANCH].[BRANCH_CODE]", "[GreatOutdoors].[BRANCH].[COUNTRY_CODE]"])
```

Table 1. cognosimport node properties

cognosimport node properties	Data type	Property description
mode	Data Report	Specifies whether to import Cognos data (default) or reports.
cognos_connection	["string", "flag", "string", "string", "string"]	A list property containing the connection details for the Cognos server. The format is: ["Cognos_server_URL", login_mode, namespace, username, password] where: Cognos_server_URL is the URL of the Cognos server containing the source. login_mode indicates whether anonymous login is used, and is either true or false; if set to true, the following fields should be set to "". namespace specifies the security authentication provider used to log on to the server. username and password are those used to log on to the Cognos server. Instead of login_mode, the following modes are also available: <ul style="list-style-type: none"> anonymousMode. For example: ['Cognos_server_url', 'anonymousMode', 'namespace', 'username', 'password'] credentialMode. For example: ['Cognos_server_url', 'credentialMode', 'namespace', 'username', 'password'] storedCredentialMode. For example: ['Cognos_server_url', 'storedCredentialMode', 'stored_credential_name'] Where stored_credential_name is the name of a Cognos credential in the repository.
cognos_package_name	string	The path and name of the Cognos package from which you are importing data objects, for example: /Public Folders/GOSALES Note: Only forward slashes are valid.
cognos_items	["field", "field", ..., "field"]	The name of one or more data objects to be imported. The format of field is [namespace].[query_subject].[query_item]
cognos_filters	field	The name of one or more filters to apply before importing data.
cognos_data_parameters	list	Values for prompt parameters for data. Name-and-value pairs are enclosed in square brackets, and multiple pairs are separated by commas and the whole string enclosed in square brackets. Format: [{"param1", "value"}, ..., {"paramN", "value"}]]
cognos_report_directory	field	The Cognos path of a folder or package from which to import reports, for example: /Public Folders/GOSALES Note: Only forward slashes are valid.
cognos_report_name	field	The path and name within the report location of a report to import.
cognos_report_parameters	list	Values for report parameters. Name-and-value pairs are enclosed in square brackets, and multiple pairs are separated by commas and the whole string enclosed in square brackets. Format: [{"param1", "value"}, ..., {"paramN", "value"}]]

databasenode properties

You can use the Database node to import data from a variety of other packages using ODBC (Open Database Connectivity), including Microsoft SQL Server, Db2, Oracle, and others.

Example

```
import modeler.api
stream = modeler.script.stream()
node = stream.create("database", "My node")
node.setPropertyValue("mode", "Table")
node.setPropertyValue("query", "SELECT * FROM drug1n")
node.setPropertyValue("datasource", "Drug1n_db")
node.setPropertyValue("username", "spss")
node.setPropertyValue("password", "spss")
node.setPropertyValue("tablename", ".Drug1n")
```

Table 1. databasenode properties

databasenode properties	Data type	Property description
mode	Table Query	Specify <i>Table</i> to connect to a database table by using dialog box controls, or specify <i>Query</i> to query the selected database by using SQL.
datasource	string	Database name (see also note below).
username	string	Database connection details (see also note below).
password	string	
credential	string	Name of credential stored in IBM® SPSS® Collaboration and Deployment Services. This can be used instead of the username and password properties. The credential's user name and password must match the user name and password required to access the database
use_credential		Set to True or False .
epassword	string	Specifies an encoded password as an alternative to hard-coding a password in a script. See the topic Generating an encoded password for more information. This property is read-only during execution.
tablename	string	Name of the table you want to access.
strip_spaces	None Left Right Both	Options for discarding leading and trailing spaces in strings.
use_quotes	AsNeeded Always Never	Specify whether table and column names are enclosed in quotation marks when queries are sent to the database (for example, if they contain spaces or punctuation).
query	string	Specifies the SQL code for the query you want to submit.

Note: If the database name (in the **datasource** property) contains spaces, then instead of individual properties for **datasource**, **username** and **password**, you can also use a single **datasource** property in the following format:

Table 2. databasenode properties - datasource specific

databasenode properties	Data type	Property description
datasource	string	Format: [database_name , username , password [, true false]] The last parameter is for use with encrypted passwords. If this is set to true , the password will be decrypted before use.

Use this format also if you are changing the data source; however, if you just want to change the **username** or **password**, you can use the **username** or **password** properties.

datacollectionimportnode Properties

The Data Collection Data Import node imports survey data based on the Data Collection Data Model used by market research products. The Data Collection Data Library must be installed to use this node.

Example

```
node = stream.create("datacollectionimport", "My node")
node.setPropertyValue("metadata_name", "mrQvDsc")

```

Table 1. datacollectionimportnode properties

datacollectionimportnode properties	Data type	Property description
<code>metadata_name</code>	<code>string</code>	The name of the MDSC. The special value <code>DimensionsMDD</code> indicates that the standard Data Collection metadata document should be used. Other possible values include: <code>mrADODsc mrI2dDsc mrLogDsc mrQdiDrsDsc mrQvDsc mrSampleReportingMDSC mrSavDsc mrSCDsc mrScriptMDSC</code> The special value <code>none</code> indicates that there is no MDSC.
<code>metadata_file</code>	<code>string</code>	Name of the file where the metadata is stored.
<code>casedata_name</code>	<code>string</code>	The name of the CDSC. Possible values include: <code>mrADODsc mrI2dDsc mrLogDsc mrPunchDSC mrQdiDrsDsc mrQvDsc mrRdbDsc2 mrSavDsc mrScDSC mrXmlDsc</code> The special value <code>none</code> indicates that there is no CDSC.
<code>casedata_source_type</code>	<code>Unknown File Folder UDL DSN</code>	Indicates the source type of the CDSC.
<code>casedata_file</code>	<code>string</code>	When <code>casedata_source_type</code> is <code>File</code> , specifies the file containing the case data.
<code>casedata_folder</code>	<code>string</code>	When <code>casedata_source_type</code> is <code>Folder</code> , specifies the folder containing the case data.
<code>casedata_udl_string</code>	<code>string</code>	When <code>casedata_source_type</code> is <code>UDL</code> , specifies the OLD-DB connection string for the data source containing the case data.
<code>casedata_dsn_string</code>	<code>string</code>	When <code>casedata_source_type</code> is <code>DSN</code> , specifies the ODBC connection string for the data source.
<code>casedata_project</code>	<code>string</code>	When reading case data from a Data Collection database, you can enter the name of the project. For all other case data types, this setting should be left blank.
<code>version_import_mode</code>	<code>All Latest Specify</code>	Defines how versions should be handled.
<code>specific_version</code>	<code>string</code>	When <code>version_import_mode</code> is <code>Specify</code> , defines the version of the case data to be imported.
<code>use_language</code>	<code>string</code>	Defines whether labels of a specific language should be used.
<code>language</code>	<code>string</code>	If <code>use_language</code> is true, defines the language code to use on import. The language code should be one of those available in the case data.
<code>use_context</code>	<code>string</code>	Defines whether a specific context should be imported. Contexts are used to vary the description associated with responses.
<code>context</code>	<code>string</code>	If <code>use_context</code> is true, defines the context to import. The context should be one of those available in the case data.
<code>use_label_type</code>	<code>string</code>	Defines whether a specific type of label should be imported.
<code>label_type</code>	<code>string</code>	If <code>use_label_type</code> is true, defines the label type to import. The label type should be one of those available in the case data.
<code>user_id</code>	<code>string</code>	For databases requiring an explicit login, you can provide a user ID and password to access the data source.
<code>password</code>	<code>string</code>	
<code>import_system_variables</code>	<code>Common None All</code>	Specifies which system variables are imported.
<code>import_codes_variables</code>	<code>flag</code>	
<code>import_sourcefile_variables</code>	<code>flag</code>	
<code>import_multiresponse</code>	<code>MultipleFlags Single</code>

excelimportnode Properties

The Excel Import node imports data from Microsoft Excel in the .xlsx file format. An ODBC data source is not required.

Examples

```
#To use a named range:  
node = stream.create("excelimport", "My node")  
node.setPropertyValue("excel_file_type", "Excel2007")  
node.setPropertyValue("full_filename", "C:/drug.xlsx")  
node.setPropertyValue("use_named_range", True)  
node.setPropertyValue("named_range", "DRUG")  
node.setPropertyValue("read_field_names", True)  
  
#To use an explicit range:  
node = stream.create("excelimport", "My node")  
node.setPropertyValue("excel_file_type", "Excel2007")  
node.setPropertyValue("full_filename", "C:/drug.xlsx")  
node.setPropertyValue("worksheet_mode", "Name")  
node.setPropertyValue("worksheet_name", "Drug")  
node.setPropertyValue("explicit_range_start", "A1")  
node.setPropertyValue("explicit_range_end", "F300")
```

Table 1. excelimportnode properties

excelimportnode properties	Data type	Property description
excel_file_type	Excel2007	
full_filename	string	The complete filename, including path.
use_named_range	Boolean	Whether to use a named range. If true, the named_range property is used to specify the range to read, and other worksheet and data range settings are ignored.
named_range	string	
worksheet_mode	Index Name	Specifies whether the worksheet is defined by index or name.
worksheet_index	integer	Index of the worksheet to be read, beginning with 0 for the first worksheet, 1 for the second, and so on.
worksheet_name	string	Name of the worksheet to be read.
data_range_mode	FirstNonBlank ExplicitRange	Specifies how the range should be determined.
blank_rows	StopReading ReturnBlankRows	When data_range_mode is <i>FirstNonBlank</i> , specifies how blank rows should be treated.
explicit_range_start	string	When data_range_mode is <i>ExplicitRange</i> , specifies the starting point of the range to read.
explicit_range_end	string	
read_field_names	Boolean	Specifies whether the first row in the specified range should be used as field (column) names.
scanLineCount	integer	Specifies the number of rows to scan for the column and storage type. Default is 200.

extensionimportnode properties

With the Extension Import node, you can run R or Python for Spark scripts to import data.

Python for Spark example

```
##### Script example for Python for Spark  
import modeler.api  
stream = modeler.script.stream()  
node = stream.create("extension_importer", "extension_importer")  
node.setPropertyValue("syntax_type", "Python")
```

```

python_script = """

"""

node.setPropertyValue("r_syntax", R_script)

```

Table 1. extensionimportnode properties

extensionimportnode properties	Data type	Property description
syntax_type	R Python	Specify which script runs – R or Python (R is the default).
r_syntax	string	The R scripting syntax to run.
python_syntax	string	The Python scripting syntax to run.

fixedfilenode Properties

The Fixed File node imports data from fixed-field text files—that is, files whose fields are not delimited but start at the same position and are of a fixed length. Machine-generated or legacy data are frequently stored in fixed-field format.

Example

```

node = stream.create("fixedfile", "My node")
node.setPropertyValue("full_filename", "$CLEO_DEMOS/DRUG1n")
node.setPropertyValue("record_len", 32)
node.setPropertyValue("skip_header", 1)
node.setPropertyValue("fields", [[{"Age", 1, 3}, {"Sex", 5, 7}, {"BP", 9, 10}, {"Cholesterol", 12, 22}, {"Na", 24, 25}, {"K", 27, 27}, {"Drug", 29, 32}]])

```

```

node.setPropertyValue("decimal_symbol", "Period")
node.setPropertyValue("lines_to_scan", 30)

```

Table 1. fixedfilenode properties

fixedfilenode properties	Data type	Property description
record_len	number	Specifies the number of characters in each record.
line_oriented	flag	Skips the new-line character at the end of each record.
decimal_symbol	Default Comma Period	The type of decimal separator used in your data source.
skip_header	number	Specifies the number of lines to ignore at the beginning of the first record. Useful for ignoring column headers.
auto_recognize_datetime	flag	Specifies whether dates or times are automatically identified in the source data.
lines_to_scan	number	
fields	list	Structured property.
full_filename	string	Full name of file to read, including directory.
strip_spaces	None Left Right Both	Discards leading and trailing spaces in strings on import.
invalid_char_mode	Discard Replace	Removes invalid characters (null, 0, or any character non-existent in current encoding) from the data input or replaces invalid characters with the specified one-character symbol.
invalid_char_replacement	string	
use_custom_values	flag	
custom_storage	Unknown String Integer Real Time Date Timestamp	
custom_date_format	"DDMMYY" "MMDDYY" "YYMMDD" "YYYYMMDD" "YYYYDDD" DAY MONTH "DD-MM-YY" "DD-MM-YYYY" "MM-DD-YY" "MM-DD-YYYY" "DD-MON-YY" "DD-MON-YYYY" "YYYY-MM-DD" "DD.MM.YY" "DD.MM.YYYY" "MM.DD.YY" "MM.DD.YYYY" "DD.MON.YY" "DD.MON.YYYY"	This property is applicable only if a custom storage has been specified.
	"DD/MM/YY" "DD/MM/YYYY" "MM/DD/YY" "MM/DD/YYYY" "DD/MON/YY" "DD/MON/YYYY" MON YYYY q Q YYYY ww WK YYYY	
custom_time_format	"HHMMSS" "HHMM" "MMSS" "HH:MM:SS" "HH:MM" "MM:SS" " (H) H: (M) M: (S) S" "(H) H: (M) M" "(M) M: (S) S" "HH.MM.SS" "HH.MM" "MM.SS" "(H) H. (M) M. (S) S" "(H) H. (M) M" "(M) M. (S) S"	This property is applicable only if a custom storage has been specified.
custom_decimal_symbol	field	Applicable only if a custom storage has been specified.
encoding	StreamDefault SystemDefault "UTF-8"	Specifies the text-encoding method.

gsdata_import Node Properties

Use the Geospatial source node to bring map or spatial data into your data mining session.

Table 1. gsdata_import node properties

gsdata_import node properties	Data type	Property description
full_filename	string	Enter the file path to the .shp file you want to load.
map_service_URL	string	Enter the map service URL to connect to.
map_name	string	Only if map_service_URL is used; this contains the top level folder structure of the map service.

jsonimportnode Properties

The JSON source node imports data from a JSON file. See [JSON Source node](#) for more information.

Table 1. jsonimportnode properties

jsonimportnode properties	Data type	Property description
<code>full_filename</code>	<code>string</code>	The complete filename, including path.
<code>string_format</code>	<code>records values</code>	Specify the format of the JSON string. Default is <code>records</code> .
<code>auto_label</code>		Added in version 18.2.1.1.

sasimportnode Properties

The SAS Import node imports SAS data into IBM® SPSS® Modeler.

Example

```
node = stream.create("sasimport", "My node")
node.setPropertyValue("format", "Windows")
node.setPropertyValue("full_filename", "C:/data/retail.sas7bdat")
node.setPropertyValue("member_name", "Test")
node.setPropertyValue("read_formats", False)
node.setPropertyValue("full_format_filename", "Test")
node.setPropertyValue("import_names", True)
```

Table 1. sasimportnode properties

sasimportnode properties	Data type	Property description
<code>format</code>	<code>Windows UNIX Transport SAS7 SAS8 SAS9</code>	Format of the file to be imported.
<code>full_filename</code>	<code>string</code>	The complete filename that you enter, including its path.
<code>member_name</code>	<code>string</code>	Specify the member to import from the specified SAS transport file.
<code>read_formats</code>	<code>flag</code>	Reads data formats (such as variable labels) from the specified format file.
<code>full_format_filename</code>	<code>string</code>	
<code>import_names</code>	<code>NamesAndLabels LabelsasNames</code>	Specifies the method for mapping variable names and labels on import.

simgennode properties

The Simulation Generate node provides an easy way to generate simulated data—either from scratch using user specified statistical distributions or automatically using the distributions obtained from running a Simulation Fitting node on existing historical data. This is useful when you want to evaluate the outcome of a predictive model in the presence of uncertainty in the model inputs.

Table 1. simgennode properties

simgennode properties	Data type	Property description
fields	Structured property	See example
correlations	Structured property	See example
keep_min_max_setting	<i>boolean</i>	
refit_correlations	<i>boolean</i>	
max_cases	<i>integer</i>	Minimum value is 1000, maximum value is 2,147,483,647
create_iteration_field	<i>boolean</i>	
iteration_field_name	<i>string</i>	
replicate_results	<i>boolean</i>	
random_seed	<i>integer</i>	
parameter_xml	<i>string</i>	Returns the parameter Xml as a string

fields example

This is a structured slot parameter with the following syntax:

```
simgennode.setPropertyValue("fields", [
    [field1, storage, locked, [distribution1], min, max],
    [field2, storage, locked, [distribution2], min, max],
    [field3, storage, locked, [distribution3], min, max]
])
```

distribution is a declaration of the distribution name followed by a list containing pairs of attribute names and values. Each distribution is defined in the following way:

```
[distributionname, [[par1], [par2], [par3]]]

simgennode = modeler.script.stream().createAt("simgen", u"Sim Gen", 726, 322)
simgennode.setPropertyValue("fields", [{"Age": "integer", "False": ["Uniform", [{"min": "1"}, {"max": "2"}]], "", ""}])
```

For example, to create a node that generates a single field with a Binomial distribution, you might use the following script:

```
simgen_node1 = modeler.script.stream().createAt("simgen", u"Sim Gen", 200, 200)
simgen_node1.setPropertyValue("fields", [{"Education": "Real", "False": ["Binomial", [{"n": 32}, {"prob": 0.7}]], "", ""}])
```

The Binomial distribution takes 2 parameters: **n** and **prob**. Since Binomial does not support minimum and maximum values, these are supplied as an empty string.

Note: You cannot set the **distribution** directly; you use it in conjunction with the **fields** property.

The following examples show all the possible distribution types. Note that the threshold is entered as **thresh** in both **NegativeBinomialFailures** and **NegativeBinomialTrial**.

```
stream = modeler.script.stream()

simgennode = stream.createAt("simgen", u"Sim Gen", 200, 200)

beta_dist = ["Field1", "Real", False, ["Beta", [{"shape1": "1"}, {"shape2": "2"}]], "", ""]
binomial_dist = ["Field2", "Real", False, ["Binomial", [{"n": "1"}, {"prob": "1"}]], "", ""]
categorical_dist = ["Field3", "String", False, ["Categorical", [{"A": "0.3"}, {"B": "0.5"}, {"C": "0.2"}]], "", ""]
dice_dist = ["Field4", "Real", False, ["Dice", [{"1": "0.5"}, {"2": "0.5"}]], "", ""]
exponential_dist = ["Field5", "Real", False, ["Exponential", [{"scale": "1"}]], "", ""]
```

```

fixed_dist = ["Field6", "Real", False, ["Fixed", [[{"value","1"}]], "", ""]
gamma_dist = ["Field7", "Real", False, ["Gamma", [{"scale","1"}, {"shape","1"}]], "", ""]
lognormal_dist = ["Field8", "Real", False, ["Lognormal", [{"a","1"}, {"b","1"}]], "", ""]
negbinomialfailures_dist = ["Field9", "Real", False, ["NegativeBinomialFailures", [{"prob","0.5"}, {"thresh","1"}]], "", ""]
negbinomialtrial_dist = ["Field10", "Real", False, ["NegativeBinomialTrials", [{"prob","0.2"}, {"thresh","1"}]], "", ""]
normal_dist = ["Field11", "Real", False, ["Normal", [{"mean","1"}, {"stddev","2"}]], "", ""]
poisson_dist = ["Field12", "Real", False, ["Poisson", [{"mean","1"}]], "", ""]
range_dist = ["Field13", "Real", False, ["Range", [{"BEGIN","[1,3]"}, {"END","[2,4]"}, {"PROB","[[0.5, 0.5]]"}]], "", ""]
triangular_dist = ["Field14", "Real", False, ["Triangular", [{"min","0"}, {"max","1"}, {"mode","1"}]], "", ""]
uniform_dist = ["Field15", "Real", False, ["Uniform", [{"min","1"}, {"max","2"}]], "", ""]
weibull_dist = ["Field16", "Real", False, ["Weibull", [{"a","0"}, {"b","1"}, {"c","1"}]], "", ""]

simgennode.setPropertyValue("fields", [
beta_dist, \
binomial_dist, \
categorical_dist, \
dice_dist, \
exponential_dist, \
fixed_dist, \
gamma_dist, \
lognormal_dist, \
negbinomialfailures_dist, \
negbinomialtrial_dist, \
normal_dist, \
poisson_dist, \
range_dist, \
triangular_dist, \
uniform_dist, \
weibull_dist
])

```

correlations example

This is a structured slot parameter with the following syntax:

```

simgennode.setPropertyValue("correlations", [
    [field1, field2, correlation],
    [field1, field3, correlation],
    [field2, field3, correlation]
])

```

Correlation can be any number between +1 and -1. You can specify as many or as few correlations as you like. Any unspecified correlations are set to zero. If any fields are unknown, the correlation value should be set on the correlation matrix (or table) and is shown in red text. When there are unknown fields, it is not possible to execute the node.

statisticsimportnode Properties

The IBM® SPSS® Statistics File node reads data from the .sav file format used by IBM SPSS Statistics, as well as cache files saved in IBM SPSS Modeler, which also use the same format.

The properties for this node are described under [statisticsimportnode Properties](#).

tm1odataimport Node Properties

The IBM Cognos TM1 source node imports data from Cognos TM1 databases.

Table 1. tm1odataimport node properties

tm1odataimport node properties	Data type	Property description
credential_type	inputCredential or storedCredential	Used to indicate the credential type.

tm1odataimport rt node properties	Data type	Property description
input_credential	<i>list</i>	When the credential_type is inputCredential ; specify the domain, user name and password.
stored_credential_name	<i>string</i>	When the credential_type is storedCredential ; specify the name of credential on the C&DS server.
selected_view	<i>["field" "field"]</i>	A list property containing the details of the selected TM1 cube and the name of the cube view from where data will be imported into SPSS. For example: <code>TM1_import.setPropertyValue("selected_view", ['plan_BudgetPlan', 'Goal Input'])</code>
is_private_view	<i>flag</i>	Specifies whether the selected_view is a private view. Default value is false .
selected_columns	<i>["field"]</i>	Specify the selected column; only one item can be specified. For example: <code>setPropertyValue("selected_columns", ["Measures"])</code>
selected_rows	<i>["field" "field"]</i>	Specify the selected rows. For example: <code>setPropertyValue("selected_rows", ["Dimension_1_1", "Dimension_2_1", "Dimension_3_1", "Periods"])</code>
connection_type	AdminServer TM1Server	Indicates the connection type. Default is AdminServer .
admin_host	<i>string</i>	The URL for the host name of the REST API. Required if the connection_type is AdminServer .
server_name	<i>string</i>	The name of the TM1 server selected from the admin_host . Required if the connection_type is AdminServer .
server_url	<i>string</i>	The URL for the TM1 Server REST API. Required if the connection_type is TM1Server .

tm1import Node Properties (deprecated)

The IBM Cognos TM1 source node imports data from Cognos TM1 databases.

Note: This node was deprecated in Modeler 18.0. The replacement node script name is *tm1odataimport*.

Table 1. tm1import node properties

tm1import node properties	Data type	Property description
pm_host	<i>string</i>	Note: Only for version 16.0 and 17.0 The host name. For example: <code>TM1_import.setPropertyValue("pm_host", 'http://9.191.86.82:9510/pmhub/pm')</code>
tm1_connection	<i>["field","field", ... , "field"]</i>	Note: Only for version 16.0 and 17.0 A list property containing the connection details for the TM1 server. The format is: ["TM1_Server_Name", "tm1_username", "tm1_password"] For example: <code>TM1_import.setPropertyValue("tm1_connection", ['Planning Sample', 'admin', 'apple'])</code>
selected_view	<i>["field" "field"]</i>	A list property containing the details of the selected TM1 cube and the name of the cube view from where data will be imported into SPSS. For example: <code>TM1_import.setPropertyValue("selected_view", ['plan_BudgetPlan', 'Goal Input'])</code>
selected_columns	<i>["field"]</i>	Specify the selected column; only one item can be specified. For example: <code>setPropertyValue("selected_columns", ["Measures"])</code>
selected_rows	<i>["field" "field"]</i>	Specify the selected rows. For example: <code>setPropertyValue("selected_rows", ["Dimension_1_1", "Dimension_2_1", "Dimension_3_1", "Periods"])</code>

twcimport node properties

The TWC source node imports weather data from The Weather Company, an IBM Business. You can use it to obtain historical or forecast weather data for a location. This can help you develop weather-driven business solutions for better decision-making using the most accurate and precise weather data available.

Table 1. twcimport node properties

twcimport node properties	Data type	Property description
TWCDataImport.latitude	Real	Specifies a latitude value in the format [-90.090.0]
TWCDataImport.longitude	Real	Specifies a longitude value in the format [-180.0180.0].
TWCDataImport.licenseKey	string	Specifies the license key obtained from The Weather Company.
TWCDataImport.measurementUnit	English Metric Hybrid	Specifies the measurement unit. Possible values are English, Metric, or Hybrid. Metric is the default.
TWCDataImport.dataType	Historical Forecast	Specifies the type of weather data to input. Possible values are Historical or Forecast. Historical is the default.
TWCDataImport.startDate	Integer	If Historical is specified for <code>TWCDataImport.dataType</code> , specify a start date in the format yyyyMMdd.
TWCDataImport.endDate	Integer	If Historical is specified for <code>TWCDataImport.dataType</code> , specify an end date in the format yyyyMMdd.
TWCDataImport.forecastHour	6 12 24 48	If Forecast is specified for <code>TWCDataImport.dataType</code> , specify 6, 12, 24, or 48 for the hour.

userinputnode properties

The User Input node provides an easy way to create synthetic data—either from scratch or by altering existing data. This is useful, for example, when you want to create a test dataset for modeling.

Example

```
node = stream.create("userinput", "My node")
node.setPropertyValue("names", ["test1", "test2"])
node.setKeyedPropertyValue("data", "test1", "2, 4, 8")
node.setKeyedPropertyValue("custom_storage", "test1", "Integer")
node.setPropertyValue("data_mode", "Ordered")
```

Table 1. userinputnode properties

userinputnode properties	Data type	Property description
data		
names		Structured slot that sets or returns a list of field names generated by the node.
custom_storage	Unknown String Integer Real Time Date Timestamp	Keyed slot that sets or returns the storage for a field.
data_mode	Combined Ordered	If <code>Combined</code> is specified, records are generated for each combination of set values and min/max values. The number of records generated is equal to the product of the number of values in each field. If <code>Ordered</code> is specified, one value is taken from each column for each record in order to generate a row of data. The number of records generated is equal to the largest number values associated with a field. Any fields with fewer data values will be padded with null values.
values		Note: This property has been deprecated in favor of <code>userinputnode.data</code> and should no longer be used.

variablefilenode Properties

The Variable File node reads data from free-field text files—that is, files whose records contain a constant number of fields but a varied number of characters. This node is also useful for files with fixed-length header text and certain types of annotations.

Example

```

node = stream.create("variablefile", "My node")
node.setPropertyValue("full_filename", "$CLEO_DEMOS/DRUG1n")
node.setPropertyValue("read_field_names", True)
node.setPropertyValue("delimit_other", True)
node.setPropertyValue("other", ",")
node.setPropertyValue("quotes_1", "Discard")
node.setPropertyValue("decimal_symbol", "Comma")
node.setPropertyValue("invalid_char_mode", "Replace")
node.setPropertyValue("invalid_char_replacement", "|")
node.setKeyedPropertyValue("use_custom_values", "Age", True)
node.setKeyedPropertyValue("direction", "Age", "Input")
node.setKeyedPropertyValue("type", "Age", "Range")
node.setKeyedPropertyValue("values", "Age", [1, 100])

```

Table 1. variablefilenode properties

variablefile node properties	Data type	Property description
skip_header	number	Specifies the number of characters to ignore at the beginning of the first record.
num_fields_auto	flag	Determines the number of fields in each record automatically. Records must be terminated with a new-line character.
num_fields	number	Manually specifies the number of fields in each record.
delimit_space	flag	Specifies the character used to delimit field boundaries in the file.
delimit_tab	flag	
delimit_new_line	flag	
delimit_non_printing	flag	
delimit_comma	flag	In cases where the comma is both the field delimiter and the decimal separator for streams, set delimit_other to <i>true</i> , and specify a comma as the delimiter by using the other property.
delimit_other	flag	Allows you to specify a custom delimiter using the other property.
other	string	Specifies the delimiter used when delimit_other is <i>true</i> .
decimal_symbol	Default Comma Period	Specifies the decimal separator used in the data source.
multi_blank	flag	Treats multiple adjacent blank delimiter characters as a single delimiter.
read_field_names	flag	Treats the first row in the data file as labels for the column.
strip_spaces	None Left Right Both	Discards leading and trailing spaces in strings on import.
invalid_char_mode	Discard Replace	Removes invalid characters (null, 0, or any character non-existent in current encoding) from the data input or replaces invalid characters with the specified one-character symbol.
invalid_char_replacement	string	
break_case_by_newline	flag	Specifies that the line delimiter is the newline character.
lines_to_scan	number	Specifies how many lines to scan for specified data types.
auto_recognize_datetime	flag	Specifies whether dates or times are automatically identified in the source data.
quotes_1	Discard PairAndDiscard IncludeAsText	Specifies how single quotation marks are treated upon import.
quotes_2	Discard PairAndDiscard IncludeAsText	Specifies how double quotation marks are treated upon import.

variablefile node properties	Data type	Property description
full_filename	string	Full name of file to be read, including directory.
use_custom_values	flag	
custom_storage	Unknown String Integer Real Time Date Timestamp	
custom_date_format	"DDMMYY" "MMDDYY" "YYMMDD" "YYYYMMDD" "YYYYDDD" DAY MONTH "DD-MM-YY" "DD-MM-YYYY" "MM-DD-YY" "MM-DD-YYYY" "DD-MON-YY" "DD-MON-YYYY" "YYYY-MM-DD" "DD.MM.YY" "DD.MM.YYYY" "MM.DD.YY" "MM.DD.YYYY" "DD.MON.YY" "DD.MON.YYYY"	Applicable only if a custom storage has been specified.
	"DD/MM/YY" "DD/MM/YYYY" "MM/DD/YY" "MM/DD/YYYY" "DD/MON/YY" "DD/MON/YYYY" MON YYYY q Q YYYY ww WK YYYY	
custom_time_format	"HHMMSS" "HHMM" "MMSS" "HH:MM:SS" "HH:MM" "MM:SS" "(H) H: (M) M: (S) S" "(H) H: (M) M" "(M) M: (S) S" "HH.MM.SS" "HH.MM" "MM.SS" "(H) H. (M) M. (S) S" "(H) H. (M) M" "(M) M. (S) S"	Applicable only if a custom storage has been specified.
custom_decimal_symbol	field	Applicable only if a custom storage has been specified.
encoding	StreamDefault SystemDefault "UTF-8"	Specifies the text-encoding method.

xmlimportnode Properties

The XML source node imports data in XML format into the stream. You can import a single file, or all files in a directory. You can optionally specify a schema file from which to read the XML structure.

Example

```
node = stream.create("xmlimport", "My node")
node.setPropertyValue("full_filename", "c:/import/ebooks.xml")
node.setPropertyValue("records", "/author/name")
```

Table 1. xmlimportnode properties

xmlimportnode properties	Data type	Property description
read	single directory	Reads a single data file (default), or all XML files in a directory.
recurse	flag	Specifies whether to additionally read XML files from all the subdirectories of the specified directory.
full_filename	string	(required) Full path and file name of XML file to import (if read = single).
directory_name	string	(required) Full path and name of directory from which to import XML files (if read = directory).
full_schema_filename	string	Full path and file name of XSD or DTD file from which to read the XML structure. If you omit this parameter, structure is read from the XML source file.
records	string	XPath expression (e.g. /author/name) to define the record boundary. Each time this element is encountered in the source file, a new record is created.
mode	read specify	Read all data (default), or specify which items to read.
fields		List of items (elements and attributes) to import. Each item in the list is an XPath expression.

appendnode properties

The Append node concatenates sets of records. It is useful for combining datasets with similar structures but different data.

Example

```
node = stream.create("append", "My node")
node.setPropertyValue("match_by", "Name")
node.setPropertyValue("match_case", True)
node.setPropertyValue("include_fields_from", "All")
node.setPropertyValue("create_tag_field", True)
node.setPropertyValue("tag_field_name", "Append_Flag")
```

Table 1. appendnode properties

appendnode properties	Data type	Property description
match_by	Position Name	You can append datasets based on the position of fields in the main data source or the name of fields in the input datasets.
match_case	flag	Enables case sensitivity when matching field names.
include_fields_from	Main All	
create_tag_field	flag	
tag_field_name	string	

aggregatenode properties

The Aggregate node replaces a sequence of input records with summarized, aggregated output records.

Example

```
node = stream.create("aggregate", "My node")
# dbnode is a configured database import node
stream.link(dbnode, node)
node.setPropertyValue("contiguous", True)
node.setPropertyValue("keys", ["Drug"])
node.setKeyedPropertyValue("aggregates", "Age", ["Sum", "Mean"])
node.setPropertyValue("inc_record_count", True)
node.setPropertyValue("count_field", "index")
node.setPropertyValue("extension", "Aggregated_")
node.setPropertyValue("add_as", "Prefix")
```

Table 1. aggregatenode properties

aggregatenode properties	Data type	Property description
--------------------------	-----------	----------------------

aggregatenode properties	Data type	Property description
keys	<i>list</i>	Lists fields that can be used as keys for aggregation. For example, if Sex and Region are your key fields, each unique combination of M and F with regions N and S (four unique combinations) will have an aggregated record.
contiguous	<i>flag</i>	Select this option if you know that all records with the same key values are grouped together in the input (for example, if the input is sorted on the key fields). Doing so can improve performance.
aggregates		Structured property listing the numeric fields whose values will be aggregated, as well as the selected modes of aggregation.
aggregate_exprs		Keyed property which keys the derived field name with the aggregate expression used to compute it. For example: <code>aggregatenode.setKeyedPropertyValue("aggregate_exprs", "Na_MAX", "MAX('Na')")</code>
extension	<i>string</i>	Specify a prefix or suffix for duplicate aggregated fields (sample below).
add_as	<i>Suffix Prefix</i>	
inc_record_count	<i>flag</i>	Creates an extra field that specifies how many input records were aggregated to form each aggregate record.
count_field	<i>string</i>	Specifies the name of the record count field.
allow_approximation	<i>Boolean</i>	Allows approximation of order statistics when aggregation is performed in Analytic Server
bin_count	<i>integer</i>	Specifies the number of bins to use in approximation

balancenode properties

	The Balance node corrects imbalances in a dataset, so it conforms to a specified condition. The balancing directive adjusts the proportion of records where a condition is true by the factor specified.
---	--

Example

```
node = stream.create("balance", "My node")
node.setPropertyValue("training_data_only", True)
node.setPropertyValue("directives", [[1.3, "Age > 60"], [1.5, "Na > 0.5"]])
```

Table 1. balancenode properties

balancenode properties	Data type	Property description
directives		Structured property to balance proportion of field values based on number specified (see example below).
training_data_only	<i>flag</i>	Specifies that only training data should be balanced. If no partition field is present in the stream, then this option is ignored.

This node property uses the format:

`[[number, string] \ [number, string] \ ... [number, string]]`.

Note: If strings (using double quotation marks) are embedded in the expression, they must be preceded by the escape character `" \ "`. The `" \ "` character is also the line continuation character, which you can use to align the arguments for clarity.

cplexoptnode properties

	The CPLEX Optimization node provides the ability to use complex mathematical (CPLEX) based optimization via an Optimization Programming Language (OPL) model file. This functionality was available in the IBM® Analytical Decision Management product, which is no longer supported. But you can also use the CPLEX node in SPSS® Modeler without requiring IBM Analytical Decision Management.
---	--

Table 1. cplexoptnode properties

cplexoptnode properties	Data type	Property description
opl_model_text	<i>string</i>	The OPL (Optimization Programming Language) script program that the CPLEX Optimization node will run and then generate the optimization result.
opl_tuple_set_name	<i>string</i>	The tuple set name in the OPL model that corresponds to the incoming data. This is not required and is normally not set via script. It should only be used for editing field mappings of a selected data source.

cplexoptnode properties	Data type	Property description
<code>data_input_map</code>	<i>List of structured properties</i>	The input field mappings for a data source. This is not required and is normally not set via script. It should only be used for editing field mappings of a selected data source.
<code>md_data_input_map</code>	<i>List of structured properties</i>	<p>The field mappings between each tuple defined in the OPL, with each corresponding field data source (incoming data). Users can edit them each individually per data source. With this script, you can set the property directly to set all mappings at once. This setting is not shown in the user interface.</p> <p>Each entity in the list is structured data:</p> <p>Data Source Tag. The tag of the data source, which can be found in the data source drop-down. For example, for <code>0_Products_Type</code> the tag is <code>0</code>.</p> <p>Data Source Index. The physical sequence (index) of the data source. This is determined by the connection order.</p> <p>Source Node. The source node (annotation) of the data source. This can be found in the data source drop-down. For example, for <code>0_Products_Type</code> the source node is <code>Products</code>.</p> <p>Connected Node. The prior node (annotation) that connects the current CPLEX optimization node. This can be found in the data source drop-down. For example, for <code>0_Products_Type</code> the connected node is <code>Type</code>.</p> <p>Tuple Set Name. The tuple set name of the data source. It must match what's defined in the OPL.</p> <p>Tuple Field Name. The tuple set field name of the data source. It must match what's defined in the OPL tuple set definition.</p> <p>Storage Type. The field storage type. Possible values are <code>int</code>, <code>float</code>, or <code>string</code>.</p>
		<p>Data Field Name. The field name of the data source.</p> <p>Example:</p> <pre>[[0,0,'Product','Type','Products','prod_id_tup','int','prod_id'], [0,0,'Product','Type','Products','prod_name_tup','string', 'prod_name'],[1,1,'Components','Type','Components', 'comp_id_tup','int','comp_id'],[1,1,'Components','Type', 'Components','comp_name_tup','string','comp_name']]</pre>
<code>opl_data_text</code>	<code>string</code>	The definition of some variables or data used for the OPL.
<code>output_value_mode</code>	<code>string</code>	Possible values are <code>raw</code> or <code>dvar</code> . If <code>dvar</code> is specified, on the Output tab the user must specify the object function variable name in OPL for the output. If <code>raw</code> is specified, the objective function will be output directly, regardless of name.
<code>decision_variable_name</code>	<code>string</code>	The objective function variable name in defined in the OPL. This is enabled only when the <code>output_value_mode</code> property is set to <code>dvar</code> .
<code>objective_function_value_fieldname</code>	<code>string</code>	The field name for the objective function value to use in the output. Default is <code>_OBJECTIVE</code> .
<code>output_tuple_set_names</code>	<code>string</code>	<p>The name of the predefined tuples from the incoming data. This acts as the indexes of the decision variable and is expected to be output with the Variable Outputs. The Output Tuple must be consistent with the decision variable definition in the OPL. If there are multiple indexes, the tuple names must be joined by a comma (,).</p> <p>An example for a single tuple is <code>Products</code>, with the corresponding OPL definition being <code>dvar float+ Production[Products];</code></p> <p>An example for multiple tuples is <code>Products,Components</code>, with the corresponding OPL definition being <code>dvar float+ Production[Products] [Components];</code></p>
<code>decision_output_map</code>	<i>List of structured properties</i>	<p>The field mapping between variables defined in the OPL that will be output and the output fields. Each entity in the list is structured data:</p> <p>Variable Name. The variable name in the OPL to output.</p> <p>Storage Type. Possible values are <code>int</code>, <code>float</code>, or <code>string</code>.</p> <p>Output Field Name. The expected field name in the results (output or export).</p> <p>Example:</p> <pre>[['Production','int','res'], ['Remark','string','res_1'],['Cost', 'float','res_2']]</pre>

derive_stbnode properties

The Space-Time-Boxes node derives Space-Time-Boxes from latitude, longitude and timestamp fields. You can also identify frequent Space-Time-Boxes as hangouts.

Example

```
node = modeler.script.stream().createAt("derive_stb", "My node", 96, 96)

# Individual Records mode
node.setPropertyValue("mode", "IndividualRecords")
node.setPropertyValue("latitude_field", "Latitude")
node.setPropertyValue("longitude_field", "Longitude")
node.setPropertyValue("timestamp_field", "OccurredAt")
node.setPropertyValue("densities", ["STB_GH7_1HOUR", "STB_GH7_30MINS"])
node.setPropertyValue("add_extension_as", "Prefix")
node.setPropertyValue("name_extension", "stb_")

# Hangouts mode
node.setPropertyValue("mode", "Hangouts")
node.setPropertyValue("hangout_density", "STB_GH7_30MINS")
node.setPropertyValue("id_field", "Event")
node.setPropertyValue("qualifying_duration", "30MINUTES")
node.setPropertyValue("min_events", 4)
node.setPropertyValue("qualifying_pct", 65)
```

Table 1. Space-Time-Boxes node properties

derive_stbnode properties	Data type	Property description
mode	IndividualRecords Hangouts	
latitude_field	field	
longitude_field	field	
timestamp_field	field	
hangout_density	density	A single density. See densities for valid density values.
densities	[density,density,..,density]	Each density is a string, for example STB_GH8_1DAY . Note: There are limits to which densities are valid. For the geohash, values from GH1 to GH15 can be used. For the temporal part, the following values can be used: EVER 1YEAR 1MONTH 1DAY 12HOURS 8HOURS 6HOURS 4HOURS 3HOURS 2HOURS 1HOUR 30MINS 15MINS 10MINS 5MINS 2MINS 1MIN 30SECS 15SECS 10SECS 5SECS 2SECS 1SEC
id_field	field	

derive_stbnode_properties	Data type	Property description
qualifying_duration	1DAY 12HOURS 8HOURS 6HOURS 4HOURS 3HOURS 2Hours 1HOUR 30MIN 15MIN 10MIN 5MIN 2MIN 1MIN 30SECS 15SECS 10SECS 5SECS 2SECS 1SECS	Must be a string.
min_events	integer	Minimum valid integer value is 2.
qualifying_pct	integer	Must be in the range of 1 and 100.
add_extension_as	Prefix Suffix	
name_extension	string	

distinctnode properties

The Distinct node removes duplicate records, either by passing the first distinct record to the data stream or by discarding the first record and passing any duplicates to the data stream instead.

Example

```
node = stream.create("distinct", "My node")
node.setPropertyValue("mode", "Include")
node.setPropertyValue("fields", ["Age" "Sex"])
node.setPropertyValue("keys_pre_sorted", True)
```

Table 1. distinctnode properties

distinctnode properties	Data type	Property description
mode	Include Discard	You can include the first distinct record in the data stream, or discard the first distinct record and pass any duplicate records to the data stream instead.
grouping_fields	list	Lists fields used to determine whether records are identical. Note: This property is deprecated from IBM® SPSS® Modeler 16 onwards.
composite_value	Structured slot	See example below.
composite_values	Structured slot	See example below.
inc_record_count	flag	Creates an extra field that specifies how many input records were aggregated to form each aggregate record.
count_field	string	Specifies the name of the record count field.
sort_keys	Structured slot.	Note: This property is deprecated from IBM SPSS Modeler 16 onwards.
default_ascending	flag	
low_distinct_key_count	flag	Specifies that you have only a small number of records and/or a small number of unique values of the key field(s).
keys_pre_sorted	flag	Specifies that all records with the same key values are grouped together in the input.
disable_sql_generation	flag	

Example for composite_value property

The composite_value property has the following general form:

```
node.setKeyedPropertyValue("composite_value", FIELD, FİLLOPTION)
```

FİLLOPTION has the form [FillType, Option1, Option2, ...].

Examples:

```
node.setKeyedPropertyValue("composite_value", "Age", ["First"])
node.setKeyedPropertyValue("composite_value", "Age", ["last"])
node.setKeyedPropertyValue("composite_value", "Age", ["Total"])
node.setKeyedPropertyValue("composite_value", "Age", ["Average"])
node.setKeyedPropertyValue("composite_value", "Age", ["Min"])
node.setKeyedPropertyValue("composite_value", "Age", ["Max"])
node.setKeyedPropertyValue("composite_value", "Date", ["Earliest"])
node.setKeyedPropertyValue("composite_value", "Date", ["Latest"])
node.setKeyedPropertyValue("composite_value", "Code", ["FirstAlpha"])
node.setKeyedPropertyValue("composite_value", "Code", ["LastAlpha"])
```

The custom options require more than one argument, these are added as a list, for example:

```
node.setKeyedPropertyValue("composite_value", "Name", ["MostFrequent", "FirstRecord"])
node.setKeyedPropertyValue("composite_value", "Date", ["LeastFrequent", "LastRecord"])
node.setKeyedPropertyValue("composite_value", "Pending", ["IncludesValue", "T", "F"])
node.setKeyedPropertyValue("composite_value", "Marital", ["FirstMatch", "Married", "Divorced", "Separated"])
node.setKeyedPropertyValue("composite_value", "Code", ["Concatenate"])
node.setKeyedPropertyValue("composite_value", "Code", ["Concatenate", "Space"])
node.setKeyedPropertyValue("composite_value", "Code", ["Concatenate", "Comma"])
node.setKeyedPropertyValue("composite_value", "Code", ["Concatenate", "UnderScore"])
```

Example for composite_values property

The composite_values property has the following general form:

```
node.setPropertyValue("composite_values", [
    [FIELD1, [FILLOPTION1]],
    [FIELD2, [FILLOPTION2]],
    .
    .
])
```

Example:

```
node.setPropertyValue("composite_values", [
    ["Age", ["First"]],
    ["Name", ["MostFrequent", "First"]],
    ["Pending", ["IncludesValue", "T"]],
    ["Marital", ["FirstMatch", "Married", "Divorced", "Separated"]],
    ["Code", ["Concatenate", "Comma"]]
])
```

extensionprocessnode properties

With the Extension Transform node, you can take data from a stream and apply transformations to the data using R scripting or Python for Spark scripting.

Python for Spark example

```
#### script example for Python for Spark
import modeler.api
stream = modeler.script.stream()
node = stream.create("extension_process", "extension_process")
node.setPropertyValue("syntax_type", "Python")

process_script = """
import spss.pyspark.runtime
from pyspark.sql.types import *

ctx = spss.pyspark.runtime.getContext()

if ctx.isComputeDataModelOnly():
    _schema = StructType([StructField("Age", LongType(), nullable=True), \
        StructField("Sex", StringType(), nullable=True), \
        StructField("BP", StringType(), nullable=True), \
        StructField("Na", DoubleType(), nullable=True), \
        StructField("K", DoubleType(), nullable=True), \
        StructField("Drug", StringType(), nullable=True)])
    ctx.setSparkOutputSchema(_schema)
else:
```

```

df = ctxt.getSparkInputData()
print df.dtypes[:]
_newDF = df.select("Age", "Sex", "BP", "Na", "K", "Drug")
print _newDF.dtypes[:]
ctxt.setSparkOutputData(_newDF)
"""

node.setPropertyValue("python_syntax", process_script)

```

R example

```

#### script example for R
node.setPropertyValue("syntax_type", "R")
node.setPropertyValue("r_syntax", """day<-as.Date(modelerData$dob, format="%Y-%m-%d")
next_day<-day + 1
modelerData<-cbind(modelerData,next_day)
var1<-c(fieldName="Next day",fieldLabel="",fieldStorage="date",fieldMeasure="",fieldFormat="",
fieldRole="")
modelerDataModel<-data.frame(modelerDataModel,var1)""")

```

Table 1. extensionprocessnode properties

extensionprocessnode properties	Data type	Property description
syntax_type	<i>R Python</i>	Specify which script runs – R or Python (R is the default).
r_syntax	<i>string</i>	The R scripting syntax to run.
python_syntax	<i>string</i>	The Python scripting syntax to run.
use_batch_size	<i>flag</i>	Enable use of batch processing.
batch_size	<i>integer</i>	Specify the number of data records to include in each batch.
convert_flags	<i>StringsAndDoubles LogicalValues</i>	Option to convert flag fields.
convert_missing	<i>flag</i>	Option to convert missing values to the R NA value.
convert_datetime	<i>flag</i>	Option to convert variables with date or datetime formats to R date/time formats.
convert_datetime_class	<i>POSIXct POSIXlt</i>	Options to specify to what format variables with date or datetime formats are converted.

mergenode properties

The Merge node takes multiple input records and creates a single output record containing some or all of the input fields. It is useful for merging data from different sources, such as internal customer data and purchased demographic data.

Example

```

node = stream.create("merge", "My node")
# assume customerdata and salesdata are configured database import nodes
stream.link(customerdata, node)
stream.link(salesdata, node)
node.setPropertyValue("method", "Keys")
node.setPropertyValue("key_fields", ["id"])
node.setPropertyValue("common_keys", True)
node.setPropertyValue("join", "PartialOuter")
node.setKeyedPropertyValue("outer_join_tag", "2", True)
node.setKeyedPropertyValue("outer_join_tag", "4", True)
node.setPropertyValue("single_large_input", True)
node.setPropertyValue("single_large_input_tag", "2")
node.setPropertyValue("use_existing_sort_keys", True)
node.setPropertyValue("existing_sort_keys", [{"id": "Ascending"}])

```

Table 1. mergenode properties

mergenode properties	Data type	Property description
method	<i>Order Keys Condition Rankedcondition</i>	Specify whether records are merged in the order they are listed in the data files, if one or more key fields will be used to merge records with the same value in the key fields, if records will be merged if a specified condition is satisfied, or if each row pairing in the primary and all secondary data sets are to be merged; using the ranking expression to sort any multiple matches into order from low to high.
condition	<i>string</i>	If method is set to Condition , specifies the condition for including or discarding records.
key_fields	<i>list</i>	
common_keys	<i>flag</i>	

mergenode properties	Data type	Property description
join	Inner FullOuter PartialOuter Anti	
outer_join_tag.n	flag	In this property, <i>n</i> is the tag name as displayed in the Select Dataset dialog box. Note that multiple tag names may be specified, as any number of datasets could contribute incomplete records.
single_large_input	flag	Specifies whether optimization for having one input relatively large compared to the other inputs will be used.
single_large_input_tag	string	Specifies the tag name as displayed in the Select Large Dataset dialog box. Note that the usage of this property differs slightly from the outer_join_tag property (flag versus string) because only one input dataset can be specified.
use_existing_sort_keys	flag	Specifies whether the inputs are already sorted by one or more key fields.
existing_sort_keys	[['string', 'Ascending'] \['string', 'Descending']]	Specifies the fields that are already sorted and the direction in which they are sorted.
primary_data_set	string	If method is Rankedcondition , select the primary data set in the merge. This can be considered as the left side of an outer join merge.
rename_duplicate_fields	Boolean	If method is Rankedcondition , and this is set to Y , if the resulting merged data set contains multiple fields with the same name from different data sources the respective tags from the data sources are added at the start of the field column headers.
merge_condition	string	
ranking_expression	string	
Num_matches	integer	The number of matches to be returned, based on the merge_condition and ranking_expression . Minimum 1, maximum 100.

rfmaggrenode properties

	The Recency, Frequency, Monetary (RFM) Aggregate node enables you to take customers' historical transactional data, strip away any unused data, and combine all of their remaining transaction data into a single row that lists when they last dealt with you, how many transactions they have made, and the total monetary value of those transactions.
---	---

Example

```
node = stream.create("rfmaggrenode", "My node")
node.setPropertyValue("relative_to", "Fixed")
node.setPropertyValue("reference_date", "2007-10-12")
node.setPropertyValue("id_field", "CardID")
node.setPropertyValue("date_field", "Date")
node.setPropertyValue("value_field", "Amount")
node.setPropertyValue("only_recent_transactions", True)
node.setPropertyValue("transaction_date_after", "2000-10-01")
```

Table 1. rfmaggrenode properties

rfmaggrenode properties	Data type	Property description
relative_to	Fixed Today	Specify the date from which the recency of transactions will be calculated.
reference_date	date	Only available if Fixed is chosen in relative_to .
contiguous	flag	If your data are presorted so that all records with the same ID appear together in the data stream, selecting this option speeds up processing.
id_field	field	Specify the field to be used to identify the customer and their transactions.
date_field	field	Specify the date field to be used to calculate recency against.
value_field	field	Specify the field to be used to calculate the monetary value.
extension	string	Specify a prefix or suffix for duplicate aggregated fields.
add_as	Suffix Prefix	Specify if the extension should be added as a suffix or a prefix.
discard_low_value_records	flag	Enable use of the discard_records_below setting.

rfmaggregate node properties	Data type	Property description
discard_records_below	<i>number</i>	Specify a minimum value below which any transaction details are not used when calculating the RFM totals. The units of value relate to the value field selected.
only_recent_transactions	<i>flag</i>	Enable use of either the specify_transaction_date or transaction_within_last settings.
specify_transaction_date	<i>flag</i>	
transaction_date_after	<i>date</i>	Only available if specify_transaction_date is selected. Specify the transaction date after which records will be included in your analysis.
transaction_within_last	<i>number</i>	Only available if transaction_within_last is selected. Specify the number and type of periods (days, weeks, months, or years) back from the Calculate Recency relative to date after which records will be included in your analysis.
transaction_scale	Days Weeks Months Years	Only available if transaction_within_last is selected. Specify the number and type of periods (days, weeks, months, or years) back from the Calculate Recency relative to date after which records will be included in your analysis.
save_r2	<i>flag</i>	Displays the date of the second most recent transaction for each customer.
save_r3	<i>flag</i>	Only available if save_r2 is selected. Displays the date of the third most recent transaction for each customer.

samplenode properties

The Sample node selects a subset of records. A variety of sample types are supported, including stratified, clustered, and nonrandom (structured) samples. Sampling can be useful to improve performance, and to select groups of related records or transactions for analysis.

Example

```
/* Create two Sample nodes to extract
   different samples from the same data */

node = stream.create("sample", "My node")
node.setPropertyValue("method", "Simple")
node.setPropertyValue("mode", "Include")
node.setPropertyValue("sample_type", "First")
node.setPropertyValue("first_n", 500)

node = stream.create("sample", "My node")
node.setPropertyValue("method", "Complex")
node.setPropertyValue("stratify_by", ["Sex", "Cholesterol"])
node.setPropertyValue("sample_units", "Proportions")
node.setPropertyValue("sample_size_proportions", "Custom")
node.setPropertyValue("sizes_proportions", [{"M": "High", "Default"}, {"M": "Normal", "Default"}, {"F": "High", 0.3}, {"F": "Normal", 0.3}])
```

Table 1. samplenode properties

samplenode properties	Data type	Property description
method	Simple Complex	
mode	Include Discard	Include or discard records that meet the specified condition.
sample_type	First OneInN RandomPct	Specifies the sampling method.
first_n	<i>integer</i>	Records up to the specified cutoff point will be included or discarded.
one_in_n	<i>number</i>	Include or discard every <i>n</i> th record.
rand_pct	<i>number</i>	Specify the percentage of records to include or discard.
use_max_size	<i>flag</i>	Enable use of the maximum_size setting.
maximum_size	<i>integer</i>	Specify the largest sample to be included or discarded from the data stream. This option is redundant and therefore disabled when First and Include are specified.
set_random_seed	<i>flag</i>	Enables use of the random seed setting.
random_seed	<i>integer</i>	Specify the value used as a random seed.
complex_sample_type	Random Systematic	
sample_units	Proportions Counts	
sample_size_proportions	Fixed Custom Variable	

samplenode properties	Data type	Property description
sample_size_counts	Fixed Custom Variable	
fixed_proportions	number	
fixed_counts	integer	
variable_proportions	field	
variable_counts	field	
use_min_stratum_size	flag	
minimum_stratum_size	integer	This option only applies when a Complex sample is taken with Sample units=Proportions .
use_max_stratum_size	flag	
maximum_stratum_size	integer	This option only applies when a Complex sample is taken with Sample units=Proportions .
clusters	field	
stratify_by	[field1 ... fieldN]	
specify_input_weight	flag	
input_weight	field	
new_output_weight	string	
sizes_proportions	[[string string value] [string string value]...]	If sample_units=proportions and sample_size_proportions=Custom , specifies a value for each possible combination of values of stratification fields.
default_proportion	number	
sizes_counts	[[string string value] [string string value]...]	Specifies a value for each possible combination of values of stratification fields. Usage is similar to sizes_proportions but specifying an integer rather than a proportion.
default_count	number	

selectnode properties

The Select node selects or discards a subset of records from the data stream based on a specific condition. For example, you might select the records that pertain to a particular sales region.

Example

```
node = stream.create("select", "My node")
node.setPropertyValue("mode", "Include")
node.setPropertyValue("condition", "Age < 18")
```

Table 1. selectnode properties

selectnode properties	Data type	Property description
mode	Include Discard	Specifies whether to include or discard selected records.
condition	string	Condition for including or discarding records.

sortnode properties

The Sort node sorts records into ascending or descending order based on the values of one or more fields.

Example

```
node = stream.create("sort", "My node")
node.setPropertyValue("keys", [[{"Age": "Ascending"}, {"Sex": "Descending"}]])
node.setPropertyValue("defaultAscending", False)
node.setPropertyValue("useExistingKeys", True)
node.setPropertyValue("existingKeys", [{"Age": "Ascending"}])
```

Table 1. sortnode properties

sortnode properties	Data type	Property description
keys	<i>list</i>	Specifies the fields you want to sort against. If no direction is specified, the default is used.
default_ascending	<i>flag</i>	Specifies the default sort order.
use_existing_keys	<i>flag</i>	Specifies whether sorting is optimized by using the previous sort order for fields that are already sorted.
existing_keys		Specifies the fields that are already sorted and the direction in which they are sorted. Uses the same format as the keys property.

spacetimeboxes properties

Space-Time-Boxes (STB) are an extension of Geohashed spatial locations. More specifically, an STB is an alphanumeric string that represents a regularly shaped region of space and time.

Table 1. spacetimeboxes properties

spacetimeboxes properties	Data type	Property description
mode	<i>IndividualRecords</i> <i>Hangouts</i>	
latitude_field	<i>field</i>	
longitude_field	<i>field</i>	
timestamp_field	<i>field</i>	
densities	<i>[density, density, density...]</i>	<p>Each density is a string. For example: STB_GH8_1DAY Note there are limits to which densities are valid.</p> <p>For the geohash, values from GH1-GH15 can be used.</p> <p>For the temporal part, the following values can be used:</p> <pre> EVER 1YEAR 1MONTH 1DAY 12HOURS 8HOURS 6HOURS 4HOURS 3HOURS 2HOURS 1HOUR 30MINS 15MINS 10MINS 5MINS 2 MINS 1 MIN 30SECS 15SECS 10SECS 5 SECS 2 SECS 1SEC </pre>
field_name_extension	<i>string</i>	
add_extension_as	<i>Prefix</i> <i>Suffix</i>	
hangout_density	<i>density</i>	Single density (see above)
id_field	<i>field</i>	

spacetimeboxes properties	Data type	Property description
qualifying_duration	1DAY 12HOURS 8HOURS 6HOURS 4HOURS 2HOURS 1HOUR 30MIN 15MIN 10MIN 5MIN 2MIN 1MIN 30SECS 15SECS 10SECS 5SECS 2SECS 1SECS	This must be a string.
min_events	integer	Minimum value is 2
qualifying_pct	integer	Must be in range 1-100

streamingtimeseries Properties

The Streaming Time Series node builds and scores time series models in one step.
Note: This Streaming Time Series node replaces the original Streaming TS node that was deprecated in version 18 of SPSS® Modeler.

Table 1. streamingtimeseries properties

streamingtimeseries Properties	Values	Property description
targets	field	The Streaming Time Series node forecasts one or more targets, optionally using one or more input fields as predictors. Frequency and weight fields are not used. See the topic Common modeling node properties for more information.
candidate_inputs	[field1 ... fieldN]	Input or predictor fields used by the model.
use_period	flag	
date_time_field	field	
input_interval	None Unknown Year Quarter Month Week Day Hour Hour_nonperiod Minute Minute_nonperiod Second Second_nonperiod

anonymizenode properties

The Anonymize node transforms the way field names and values are represented downstream, thus disguising the original data. This can be useful if you want to allow other users to build models using sensitive data, such as customer names or other details.

Example

```
stream = modeler.script.stream()
varfilenode = stream.createAt("variablefile", "File", 96, 96)
varfilenode.setPropertyValue("full_filename", "$CLEO/DEMOS/DRUG1n")
node = stream.createAt("anonymize", "My node", 192, 96)
# Anonymize node requires the input fields while setting the values
stream.link(varfilenode, node)
node.setKeyedPropertyValue("enable_anonymize", "Age", True)
node.setKeyedPropertyValue("transformation", "Age", "Random")
node.setKeyedPropertyValue("set_random_seed", "Age", True)
node.setKeyedPropertyValue("random_seed", "Age", 123)
node.setKeyedPropertyValue("enable_anonymize", "Drug", True)
node.setKeyedPropertyValue("use_prefix", "Drug", True)
node.setKeyedPropertyValue("prefix", "Drug", "myprefix")
```

Table 1. anonymizenode properties

anonymizene properties	Data type	Property description
<code>enable_anonymize</code>	<code>flag</code>	When set to <code>True</code> , activates anonymization of field values (equivalent to selecting Yes for that field in the Anonymize Values column).
<code>use_prefix</code>	<code>flag</code>	When set to <code>True</code> , a custom prefix will be used if one has been specified. Applies to fields that will be anonymized by the Hash method and is equivalent to choosing the Custom radio button in the Replace Values dialog box for that field.
<code>prefix</code>	<code>string</code>	Equivalent to typing a prefix into the text box in the Replace Values dialog box. The default prefix is the default value if nothing else has been specified.
<code>transformation</code>	<code>Random Fixed</code>	Determines whether the transformation parameters for a field anonymized by the Transform method will be random or fixed.
<code>set_random_seed</code>	<code>flag</code>	When <code>set_random_seed</code> is set to <code>True</code> , the specified seed value will be used (if <code>transformation</code> is also set to <code>Random</code>).
<code>random_seed</code>	<code>integer</code>	When <code>set_random_seed</code> is set to <code>True</code> , this is the seed for the random number.
<code>scale</code>	<code>number</code>	When <code>transformation</code> is set to <code>Fixed</code> , this value is used for "scale by." The maximum scale value is normally 10 but may be reduced to avoid overflow.
<code>translate</code>	<code>number</code>	When <code>transformation</code> is set to <code>Fixed</code> , this value is used for "translate." The maximum translate value is normally 1000 but may be reduced to avoid overflow.

autodataprepnode properties

The Automated Data Preparation (ADP) node can analyze your data and identify fixes, screen out fields that are problematic or not likely to be useful, derive new attributes when appropriate, and improve performance through intelligent screening and sampling techniques. You can use the node in fully automated fashion, allowing the node to choose and apply fixes, or you can preview the changes before they are made and accept, reject, or amend them as desired.

Example

```
node = stream.create("autodataprep", "My node")
node.setPropertyValue("objective", "Balanced")
```

```

node.setPropertyValue("excluded_fields", "Filter")
node.setPropertyValue("prepare_dates_and_times", True)
node.setPropertyValue("compute_time_until_date", True)
node.setPropertyValue("reference_date", "Today")
node.setPropertyValue("units_for_date_durations", "Automatic")

```

Table 1. autodataprepnode properties

autodataprepnode properties	Data type	Property description
objective	Balanced Speed Accuracy Custom	
custom_fields	flag	If true, allows you to specify target, input, and other fields for the current node. If false, the current settings from an upstream Type node are used.

astimeintervalsnode properties

Use the Time Intervals node to specify intervals and derive a new time field for estimating or forecasting. A full range of time intervals is supported, from seconds to years.

Table 1. astimeintervalsnode properties

astimeintervals node properties	Data type	Property description
time_field	field	Can accept only a single continuous field. That field is used by the node as the aggregation key for converting the interval. If an integer field is used here it is considered to be a time index.
dimensions	[field1 field2 ... fieldn]	These fields are used to create individual time series based on the field values.
fields_to_aggregate	[field1 field2 ... fieldn]	These fields are aggregated as part of changing the period of the time field. Any fields not included in this picker are filtered out of the data leaving the node.

binningnode properties

The Binning node automatically creates new nominal (set) fields based on the values of one or more existing continuous (numeric range) fields. For example, you can transform a continuous income field into a new categorical field containing groups of income as deviations from the mean. Once you have created bins for the new field, you can generate a Derive node based on the cut points.

Example

```
node = stream.create("binning", "My node")
node.setPropertyValue("fields", ["Na", "K"])
node.setPropertyValue("method", "Rank")
node.setPropertyValue("fixed_width_name_extension", "_binned")
node.setPropertyValue("fixed_width_add_as", "Suffix")
node.setPropertyValue("fixed_bin_method", "Count")
node.setPropertyValue("fixed_bin_count", 10)
node.setPropertyValue("fixed_bin_width", 3.5)
node.setPropertyValue("tile10", True)
```

Table 1. binningnode properties

binningnode properties	Data type	Property description
fields	[field1 field2 ... fieldn]	Continuous (numeric range) fields pending transformation. You can bin multiple fields simultaneously.
method	FixedWidth EqualCount Rank SDev Optimal	Method used for determining cut points for new field bins (categories).
rcalculate_bins	Always IfNecessary	Specifies whether the bins are recalculated and the data placed in the relevant bin every time the node is executed, or that data is added only to existing bins and any new bins that have been added.

binningnode properties	Data type	Property description
<code>fixed_width_name_extension</code>	<code>string</code>	The default extension is <code>_BIN</code> .
<code>fixed_width_add_as</code>	<code>Suffix Prefix</code>	Specifies whether the extension is added to the end (suffix) or to the start (prefix). The default extension is <code>income_BIN</code> .
<code>fixed_bin_method</code>	<code>Width Count</code>	
<code>fixed_bin_count</code>	<code>integer</code>	Specifies an integer used to determine the number of fixed-width bins (categories) for the new field(s).
<code>fixed_bin_width</code>	<code>real</code>	Value (integer or real) for calculating width of the bin.
<code>equal_count_name_extension</code>	<code>string</code>	The default extension is <code>_TILE</code> .
<code>equal_count_add_as</code>	<code>Suffix Prefix</code>	Specifies an extension, either suffix or prefix, used for the field name generated by using standard p-tiles. The default extension is <code>_TILE plus N</code> , where <code>N</code> is the tile number.
<code>tile4</code>	<code>flag</code>	Generates four quantile bins, each containing 25% of cases.
<code>tile5</code>	<code>flag</code>	Generates five quintile bins.
<code>tile10</code>	<code>flag</code>	Generates 10 decile bins.
<code>tile20</code>	<code>flag</code>	Generates 20 vingtile bins.
<code>tile100</code>	<code>flag</code>	Generates 100 percentile bins.
<code>use_custom_tile</code>	<code>flag</code>	
<code>custom_tile_name_extension</code>	<code>string</code>	The default extension is <code>_TILEN</code> .
<code>custom_tile_add_as</code>	<code>Suffix Prefix</code>	
<code>custom_tile</code>	<code>integer</code>	
<code>equal_count_method</code>	<code>RecordCount ValueSum</code>	The <code>RecordCount</code> method seeks to assign an equal number of records to each bin, while <code>ValueSum</code> assigns records so that the sum of the values in each bin is equal.
<code>tied_values_method</code>	<code>Next Current Random</code>	Specifies which bin tied value data is to be put in.
<code>rank_order</code>	<code>Ascending Descending</code>	This property includes <code>Ascending</code> (lowest value is marked 1) or <code>Descending</code> (highest value is marked 1).
<code>rank_add_as</code>	<code>Suffix Prefix</code>	This option applies to rank, fractional rank, and percentage rank.
<code>rank</code>	<code>flag</code>	
<code>rank_name_extension</code>	<code>string</code>	The default extension is <code>_RANK</code> .
<code>rank_fractional</code>	<code>flag</code>	Ranks cases where the value of the new field equals rank divided by the sum of the weights of the nonmissing cases. Fractional ranks fall in the range of 0–1.
<code>rank_fractional_name_extension</code>	<code>string</code>	The default extension is <code>_F_RANK</code> .
<code>rank_pct</code>	<code>flag</code>	Each rank is divided by the number of records with valid values and multiplied by 100. Percentage fractional ranks fall in the range of 1–100.
<code>rank_pct_name_extension</code>	<code>string</code>	The default extension is <code>_P_RANK</code> .
<code>sdev_name_extension</code>	<code>string</code>	
<code>sdev_add_as</code>	<code>Suffix Prefix</code>	
<code>sdev_count</code>	<code>One Two Three</code>	
<code>optimal_name_extension</code>	<code>string</code>	The default extension is <code>_OPTIMAL</code> .
<code>optimal_add_as</code>	<code>Suffix Prefix</code>	
<code>optimal_supervisor_field</code>	<code>field</code>	Field chosen as the supervisory field to which the fields selected for binning are related.
<code>optimal_merge_bins</code>	<code>flag</code>	Specifies that any bins with small case counts will be added to a larger, neighboring bin.
<code>optimal_small_bin_threshold</code>	<code>integer</code>	
<code>optimal_pre_bin</code>	<code>flag</code>	Indicates that prebinning of dataset is to take place.
<code>optimal_max_bins</code>	<code>integer</code>	Specifies an upper limit to avoid creating an inordinately large number of bins.
<code>optimal_lower_end_point</code>	<code>Inclusive Exclusive</code>	
<code>optimal_first_bin</code>	<code>Unbounded Bounded</code>	

binningnode properties	Data type	Property description
optimal_last_bin	Unbounded Bounded	

derivenode properties

The Derive node modifies data values or creates new fields from one or more existing fields. It creates fields of type formula, flag, nominal, state, count, and conditional.

Example 1

```
# Create and configure a Flag Derive field node
node = stream.create("derive", "My node")
node.setPropertyValue("new_name", "DrugX_Flag")
node.setPropertyValue("result_type", "Flag")
node.setPropertyValue("flag_true", "1")
node.setPropertyValue("flag_false", "0")
node.setPropertyValue("flag_expr", "'Drug' == \"drugX\"")

# Create and configure a Conditional Derive field node
node = stream.create("derive", "My node")
node.setPropertyValue("result_type", "Conditional")
node.setPropertyValue("cond_if_cond", "@OFFSET(\"Age\", 1) = \"Age\"")
node.setPropertyValue("cond_then_expr", "(@OFFSET(\"Age\", 1) = \"Age\") >< @INDEX")
node.setPropertyValue("cond_else_expr", "\"Age\"")
```

Example 2

This script assumes that there are two numeric columns called **XPos** and **YPos** that represent the X and Y coordinates of a point (for example, where an event took place). The script creates a Derive node that computes a geospatial column from the X and Y coordinates representing that point in a specific coordinate system:

```
stream = modeler.script.stream()
# Other stream configuration code
node = stream.createAt("derive", "Location", 192, 96)
node.setPropertyValue("new_name", "Location")
node.setPropertyValue("formula_expr", "[['XPos', 'YPos']]")
node.setPropertyValue("formula_type", "Geospatial")
# Now we have set the general measurement type, define the
# specifics of the geospatial object
node.setPropertyValue("geo_type", "Point")
node.setPropertyValue("has_coordinate_system", True)
node.setPropertyValue("coordinate_system", "ETRS_1989_EPSG_Arctic_zone_5-47")
```

Table 1. derivenode properties

derivenode properties	Data type	Property description
new_name	<i>string</i>	Name of new field.
mode	Single Multiple	Specifies single or multiple fields.
fields	<i>list</i>	Used in Multiple mode only to select multiple fields.
name_extension	<i>string</i>	Specifies the extension for the new field name(s).
add_as	Suffix Prefix	Adds the extension as a prefix (at the beginning) or as a suffix (at the end) of the field name.
result_type	Formula Flag Set State Count Conditional	The six types of new fields that you can create.
formula_expr	<i>string</i>	Expression for calculating a new field value in a Derive node.
flag_expr	<i>string</i>	
flag_true	<i>string</i>	
flag_false	<i>string</i>	
set_default	<i>string</i>	
set_value_cond	<i>string</i>	Structured to supply the condition associated with a given value.
state_on_val	<i>string</i>	Specifies the value for the new field when the On condition is met.
state_off_val	<i>string</i>	Specifies the value for the new field when the Off condition is met.

derivenode properties	Data type	Property description
state_on_expression	string	
state_off_expression	string	
state_initial	On Off	Assigns each record of the new field an initial value of on or off . This value can change as each condition is met.
count_initial_val	string	
count_inc_condition	string	
count_inc_expression	string	
count_reset_condition	string	
cond_if_cond	string	
cond_then_expr	string	
cond_else_expr	string	
formula_measure_type	Range / MeasureType.RANGE Discrete / MeasureType.DISCRETE Flag / MeasureType.FLAG Set / MeasureType.SET OrderedSet / MeasureType.ORDERED_SET Typeless / MeasureType.TYPELESS Collection / MeasureType.COLLECTION Geospatial / MeasureType.GEOSPATIAL	This property can be used to define the measurement associated with the derived field. The setter function can be passed either a string or one of the MeasureType values. The getter will always return on the MeasureType values.
collection_measure	Range / MeasureType.RANGE Flag / MeasureType.FLAG Set / MeasureType.SET OrderedSet / MeasureType.ORDERED_SET Typeless / MeasureType.TYPELESS	For collection fields (lists with a depth of 0), this property defines the measurement type associated with the underlying values.
geo_type	PointMultiPoint LineString MultiLineString Polygon MultiPolygon	For geospatial fields, this property defines the type of geospatial object represented by this field. This should be consistent with the list depth of the values
has_coordinate_system	boolean	For geospatial fields, this property defines whether this field has a coordinate system
coordinate_system	string	For geospatial fields, this property defines the coordinate system for this field

ensemblenode properties

The Ensemble node combines two or more model nuggets to obtain more accurate predictions than can be gained from any one model.

Example

```
# Create and configure an Ensemble node
# Use this node with the models in demos\streams\pm_binaryclassifier.str
node = stream.create("ensemble", "My node")
node.setPropertyValue("ensemble_target_field", "response")
node.setPropertyValue("filter_individual_model_output", False)
node.setPropertyValue("flag_ensemble_method", "ConfidenceWeightedVoting")
node.setPropertyValue("flag_voting_tie_selection", "HighestConfidence")
```

Table 1. ensemblenode properties

ensemblenode properties	Data type	Property description
<code>ensemble_target_field</code>	<code>field</code>	Specifies the target field for all models used in the ensemble.
<code>filter_individual_model_output</code>	<code>flag</code>	Specifies whether scoring results from individual models should be suppressed.
<code>flag_ensemble_method</code>	<code>Voting ConfidenceWeightedVoting RawPropensityWeightedVoting AdjustedPropensityWeightedVoting HighestConfidence AverageRawPropensity AverageAdjustedPropensity</code>	Specifies the method used to determine the ensemble score. This setting applies only if the selected target is a flag field.
<code>set_ensemble_method</code>	<code>Voting ConfidenceWeightedVoting HighestConfidence</code>	Specifies the method used to determine the ensemble score. This setting applies only if the selected target is a nominal field.
<code>flag_voting_tie_selection</code>	<code>Random HighestConfidence RawPropensity AdjustedPropensity</code>	If a voting method is selected, specifies how ties are resolved. This setting applies only if the selected target is a flag field.
<code>set_voting_tie_selection</code>	<code>Random HighestConfidence</code>	If a voting method is selected, specifies how ties are resolved. This setting applies only if the selected target is a nominal field.
<code>calculate_standard_error</code>	<code>flag</code>	If the target field is continuous, a standard error calculation is run by default to calculate the difference between the measured or estimated values and the true values; and to show how close those estimates matched.

fillernode properties

The Filler node replaces field values and changes storage. You can choose to replace values based on a CLEM condition, such as `@BLANK(@FIELD)`. Alternatively, you can choose to replace all blanks or null values with a specific value. A Filler node is often used together with a Type node to replace missing values.

Example

```
node = stream.create("filler", "My node")
node.setPropertyValue("fields", ["Age"])
node.setPropertyValue("replace_mode", "Always")
node.setPropertyValue("condition", "(\"Age\> 60) and (\"Sex\<= \"M\")")
node.setPropertyValue("replace_with", "\"old man\"")
```

Table 1. fillernode properties

fillernode properties	Data type	Property description
<code>fields</code>	<code>list</code>	Fields from the dataset whose values will be examined and replaced.
<code>replace_mode</code>	<code>Always Conditional Blank Null BlankAndNull</code>	You can replace all values, blank values, or null values, or replace based on a specified condition.
<code>condition</code>	<code>string</code>	
<code>replace_with</code>	<code>string</code>	

filternode properties

The Filter node filters (discards) fields, renames fields, and maps fields from one source node to another.

Example:

```
node = stream.create("filter", "My node")
node.setPropertyValue("default_include", True)
node.setKeyedPropertyValue("new_name", "Drug", "Chemical")
node.setKeyedPropertyValue("include", "Drug", False)
```

Using the `default_include` property. Note that setting the value of the `default_include` property does not automatically include or exclude all fields; it simply determines the default for the current selection. This is functionally equivalent to clicking the Include fields by default button in the Filter node dialog box. For example, suppose you run the following script:

```
node = modeler.script.stream().create("filter", "Filter")
node.setPropertyValue("default_include", False)
# Include these two fields in the list
```

```

for f in ["Age", "Sex"]:
    node.setKeyedPropertyValue("include", f, True)

```

This will cause the node to pass the fields **Age** and **Sex** and discard all others. After running the previous script, now suppose you add the following lines to the script to name two more fields:

```

node.setPropertyValue("default_include", False)
# Include these two fields in the list
for f in ["BP", "Na"]:
    node.setKeyedPropertyValue("include", f, True)

```

This will add two more fields to the filter so that a total of four fields are passed (**Age**, **Sex**, **BP**, **Na**). In other words, resetting the value of **default_include** to **False** doesn't automatically reset all fields.

Alternatively, if you now change **default_include** to **True**, either using a script or in the Filter node dialog box, this would flip the behavior so the four fields listed above would be discarded rather than included. When in doubt, experimenting with the controls in the Filter node dialog box may be helpful in understanding this interaction.

Table 1. **filternode** properties

filternode properties	Data type	Property description
default_incl ude	<i>flag</i>	Keyed property to specify whether the default behavior is to pass or filter fields: Note that setting this property does not automatically include or exclude all fields; it simply determines whether selected fields are included or excluded by default. See example below for additional comments.
include	<i>flag</i>	Keyed property for field inclusion and removal.
new_name	<i>string</i>	

historynode properties

The History node creates new fields containing data from fields in previous records. History nodes are most often used for sequential data, such as time series data. Before using a History node, you may want to sort the data using a Sort node.

Example

```

node = stream.create("history", "My node")
node.setPropertyValue("fields", ["Drug"])
node.setPropertyValue("offset", 1)
node.setPropertyValue("span", 3)
node.setPropertyValue("unavailable", "Discard")
node.setPropertyValue("fill_with", "undef")

```

Table 1. **historynode** properties

historynode properties	Data type	Property description
fields	<i>list</i>	Fields for which you want a history.
offset	<i>number</i>	Specifies the latest record (prior to the current record) from which you want to extract historical field values.
span	<i>number</i>	Specifies the number of prior records from which you want to extract values.
unavailable	Discard Leave Fill	For handling records that have no history values, usually referring to the first several records (at the top of the dataset) for which there are no previous records to use as a history.
fill_with	String Number	Specifies a value or string to be used for records where no history value is available.

partitionnode properties

The Partition node generates a partition field, which splits the data into separate subsets for the training, testing, and validation stages of model building.

Example

```

node = stream.create("partition", "My node")
node.setPropertyValue("create_validation", True)
node.setPropertyValue("training_size", 33)
node.setPropertyValue("testing_size", 33)
node.setPropertyValue("validation_size", 33)
node.setPropertyValue("set_random_seed", True)

```

```

node.setPropertyValue("random_seed", 123)
node.setPropertyValue("value_mode", "System")

```

Table 1. partitionnode properties

partitionnode properties	Data type	Property description
<code>new_name</code>	<code>string</code>	Name of the partition field generated by the node.
<code>create_validation</code>	<code>flag</code>	Specifies whether a validation partition should be created.
<code>training_size</code>	<code>integer</code>	Percentage of records (0–100) to be allocated to the training partition.
<code>testing_size</code>	<code>integer</code>	Percentage of records (0–100) to be allocated to the testing partition.
<code>validation_size</code>	<code>integer</code>	Percentage of records (0–100) to be allocated to the validation partition. Ignored if a validation partition is not created.
<code>training_label</code>	<code>string</code>	Label for the training partition.
<code>testing_label</code>	<code>string</code>	Label for the testing partition.
<code>validation_label</code>	<code>string</code>	Label for the validation partition. Ignored if a validation partition is not created.
<code>value_mode</code>	<code>System</code> <code>SystemAndLabel</code> <code>Label</code>	Specifies the values used to represent each partition in the data. For example, the training sample can be represented by the system integer <code>1</code> , the label <code>Training</code> , or a combination of the two, <code>1_Training</code> .
<code>set_random_seed</code>	<code>Boolean</code>	Specifies whether a user-specified random seed should be used.
<code>random_seed</code>	<code>integer</code>	A user-specified random seed value. For this value to be used, <code>set_random_seed</code> must be set to <code>True</code> .
<code>enable_sql_generation</code>	<code>Boolean</code>	Specifies whether to use SQL pushback to assign records to partitions.
<code>unique_field</code>		Specifies the input field used to ensure that records are assigned to partitions in a random but repeatable way. For this value to be used, <code>enable_sql_generation</code> must be set to <code>True</code> .

reclassifynode properties

The Reclassify node transforms one set of categorical values to another. Reclassification is useful for collapsing categories or regrouping data for analysis.

Example

```

node = stream.create("reclassify", "My node")
node.setPropertyValue("mode", "Multiple")
node.setPropertyValue("replace_field", True)
node.setPropertyValue("field", "Drug")
node.setPropertyValue("new_name", "Chemical")
node.setPropertyValue("fields", ["Drug", "BP"])
node.setPropertyValue("name_extension", "reclassified")
node.setPropertyValue("add_as", "Prefix")
node.setKeyedPropertyValue("reclassify", "drugA", True)
node.setPropertyValue("use_default", True)
node.setPropertyValue("default", "BrandX")
node.setPropertyValue("pick_list", ["BrandX", "Placebo", "Generic"])

```

Table 1. reclassifynode properties

reclassifynode properties	Data type	Property description
<code>mode</code>	<code>Single</code> <code>Multiple</code>	<code>Single</code> reclassifies the categories for one field. <code>Multiple</code> activates options enabling the transformation of more than one field at a time.
<code>replace_field</code>	<code>flag</code>	
<code>field</code>	<code>string</code>	Used only in Single mode.
<code>new_name</code>	<code>string</code>	Used only in Single mode.
<code>fields</code>	<code>[field1 field2 ... fieldn]</code>	Used only in Multiple mode.
<code>name_extension</code>	<code>string</code>	Used only in Multiple mode.
<code>add_as</code>	<code>Suffix</code> <code>Prefix</code>	Used only in Multiple mode.
<code>reclassify</code>	<code>string</code>	Structured property for field values.
<code>use_default</code>	<code>flag</code>	Use the default value.
<code>default</code>	<code>string</code>	Specify a default value.

reclassifynode properties	Data type	Property description
pick_list	[string string ... string]	Allows a user to import a list of known new values to populate the drop-down list in the table.

reordernode properties

	The Field Reorder node defines the natural order used to display fields downstream. This order affects the display of fields in a variety of places, such as tables, lists, and the Field Chooser. This operation is useful when working with wide datasets to make fields of interest more visible.
---	--

Example

```
node = stream.create("reorder", "My node")
node.setPropertyValue("mode", "Custom")
node.setPropertyValue("sort_by", "Storage")
node.setPropertyValue("ascending", False)
node.setPropertyValue("start_fields", ["Age", "Cholesterol"])
node.setPropertyValue("end_fields", ["Drug"])
```

Table 1. reordernode properties

reordernode properties	Data type	Property description
mode	Custom Auto	You can sort values automatically or specify a custom order.
sort_by	Name Type Storage	
ascending	flag	
start_fields	[field1 field2 ... fieldn]	New fields are inserted after these fields.
end_fields	[field1 field2 ... fieldn]	New fields are inserted before these fields.

reprojectnode properties

	Within SPSS® Modeler, items such as the Expression Builder spatial functions, the Spatio-Temporal Prediction (STP) Node, and the Map Visualization Node use the projected coordinate system. Use the Reproject node to change the coordinate system of any data that you import that uses a geographic coordinate system.
---	---

Table 1. reprojectnode properties

reprojectnode properties	Data type	Property description
reproject_fileds	[field1 field2 ... fieldn]	List all the fields that are to be reprojected.
reproject_type	Streamdefault Specify	Choose how to reproject the fields.
coordinate_system	string	The name of the coordinate system to be applied to the fields. Example: set reprojectnode.coordinate_system = "WGS_1984_World_Mercator"

restructurenode properties

	The Restructure node converts a nominal or flag field into a group of fields that can be populated with the values of yet another field. For example, given a field named <i>payment type</i> , with values of <i>credit</i> , <i>cash</i> , and <i>debit</i> , three new fields would be created (<i>credit</i> , <i>cash</i> , <i>debit</i>), each of which might contain the value of the actual payment made.
---	---

Example

```
node = stream.create("restructure", "My node")
node.setKeyedPropertyValue("fields_from", "Drug", ["drugA", "drugX"])
node.setPropertyValue("include_field_name", True)
node.setPropertyValue("value_mode", "OtherFields")
node.setPropertyValue("value_fields", ["Age", "BP"])
```

Table 1. restructurenode properties

restructurenode properties	Data type	Property description
-----------------------------------	------------------	-----------------------------

restructurenode properties	Data type	Property description
fields_from	[category category category] all	
include_field_name	flag	Indicates whether to use the field name in the restructured field name.
value_mode	OtherFields Flags	Indicates the mode for specifying the values for the restructured fields. With OtherFields, you must specify which fields to use (see below). With Flags, the values are numeric flags.
value_fields	list	Required if value_mode is OtherFields. Specifies which fields to use as value fields.

rfmanalysisnode properties

The Recency, Frequency, Monetary (RFM) Analysis node enables you to determine quantitatively which customers are likely to be the best ones by examining how recently they last purchased from you (recency), how often they purchased (frequency), and how much they spent over all transactions (monetary).

Example

```
node = stream.create("rfmanalysis", "My node")
node.setPropertyValue("recency", "Recency")
node.setPropertyValue("frequency", "Frequency")
node.setPropertyValue("monetary", "Monetary")
node.setPropertyValue("tied_values_method", "Next")
node.setPropertyValue("recalculate_bins", "IfNecessary")
node.setPropertyValue("recency_thresholds", [1, 500, 800, 1500, 2000, 2500])
```

Table 1. rfmanalysisnode properties

rfmanalysisnode properties	Data type	Property description
recency	field	Specify the recency field. This may be a date, timestamp, or simple number.
frequency	field	Specify the frequency field.
monetary	field	Specify the monetary field.
recency_bins	integer	Specify the number of recency bins to be generated.
recency_weight	number	Specify the weighting to be applied to recency data. The default is 100.
frequency_bins	integer	Specify the number of frequency bins to be generated.
frequency_weight	number	Specify the weighting to be applied to frequency data. The default is 10.
monetary_bins	integer	Specify the number of monetary bins to be generated.
monetary_weight	number	Specify the weighting to be applied to monetary data. The default is 1.
tied_values_method	Next Current	Specify which bin tied value data is to be put in.
recalculate_bins	Always IfNecessary	
add_outliers	flag	Available only if recalculate_bins is set to IfNecessary. If set, records that lie below the lower bin will be added to the lower bin, and records above the highest bin will be added to the highest bin.
binned_field	Recency Frequency Monetary	
recency_thresholds	value value	Available only if recalculate_bins is set to Always. Specify the upper and lower thresholds for the recency bins. The upper threshold of one bin is used as the lower threshold of the next—for example, [10 30 60] would define two bins, the first bin with upper and lower thresholds of 10 and 30, with the second bin thresholds of 30 and 60.
frequency_thresholds	value value	Available only if recalculate_bins is set to Always.
monetary_thresholds	value value	Available only if recalculate_bins is set to Always.

settoflagnode properties

The Set to Flag node derives multiple flag fields based on the categorical values defined for one or more nominal fields.

Example

```
node = stream.create("settoflag", "My node")
node.setKeyedPropertyValue("fields_from", "Drug", ["drugA", "drugX"])
node.setPropertyValue("true_value", "1")
node.setPropertyValue("false_value", "0")
node.setPropertyValue("use_extension", True)
node.setPropertyValue("extension", "Drug_Flag")
node.setPropertyValue("add_as", "Suffix")
node.setPropertyValue("aggregate", True)
node.setPropertyValue("keys", ["Cholesterol"])
```

Table 1. settoflagnode properties

settoflagnode properties	Data type	Property description
fields_from	[category category category] all	
true_value	string	Specifies the true value used by the node when setting a flag. The default is T.
false_value	string	Specifies the false value used by the node when setting a flag. The default is F.
use_extension	flag	Use an extension as a suffix or prefix to the new flag field.
extension	string	
add_as	Suffix Prefix	Specifies whether the extension is added as a suffix or prefix.
aggregate	flag	Groups records together based on key fields. All flag fields in a group are enabled if any record is set to true.
keys	list	Key fields.

statisticstransformnode properties

The Statistics Transform node runs a selection of IBM® SPSS® Statistics syntax commands against data sources in IBM SPSS Modeler. This node requires a licensed copy of IBM SPSS Statistics.

The properties for this node are described under [statisticstransformnode.properties](#).

timeintervalsnode properties (deprecated)

Note: This node was deprecated in version 18 of SPSS® Modeler and replaced by the new Time Series node. The Time Intervals node specifies intervals and creates labels (if needed) for modeling time series data. If values are not evenly spaced, the node can pad or aggregate values as needed to generate a uniform interval between records.

Example

```
node = stream.create("timeintervals", "My node")
node.setPropertyValue("interval_type", "SecondsPerDay")
node.setPropertyValue("days_per_week", 4)
node.setPropertyValue("week_begins_on", "Tuesday")
node.setPropertyValue("hours_per_day", 10)
node.setPropertyValue("day_begins_hour", 7)
node.setPropertyValue("day_begins_minute", 5)
node.setPropertyValue("day_begins_second", 17)
node.setPropertyValue("mode", "Label")
node.setPropertyValue("year_start", 2005)
node.setPropertyValue("month_start", "January")
node.setPropertyValue("day_start", 4)
node.setKeyedPropertyValue("pad", "AGE", "MeanOfRecentPoints")
node.setPropertyValue("agg_mode", "Specify")
node.setPropertyValue("agg_set_default", "Last")
```

Table 1. timeintervalsnode properties

timeinterval snode properties	Data type	Property description

timeinterval snode properties	Data type	Property description
interval_type	None Periods CyclicPeriods Years Quarters Months Days DaysPerWeek DaysNonPeriodic HoursPerDay HoursNonPeriodic MinutesPerDay MinutesNonPeriodic SecondsPerDay SecondsNonPeriodic	
mode	Label Create	Specifies whether you want to label records consecutively or build the series based on a specified date, timestamp, or time field.
field	field	When building the series from the data, specifies the field that indicates the date or time for each record.
period_start	integer	Specifies the starting interval for periods or cyclic periods
cycle_start	integer	Starting cycle for cyclic periods.
year_start	integer	For interval types where applicable, year in which the first interval falls.
quarter_start	integer	For interval types where applicable, quarter in which the first interval falls.
month_start	January February March April May June July August September October November December	
day_start	integer	
hour_start	integer	
minute_start	integer	
second_start	integer	
periods_per_cycle	integer	For cyclic periods, number within each cycle.
fiscal_year_begins	January February March April May June July August September October November December	For quarterly intervals, specifies the month when the fiscal year begins.
week_begins_on	Sunday Monday Tuesday Wednesday Thursday Friday Saturday Sunday	For periodic intervals (days per week, hours per day, minutes per day, and seconds per day), specifies the day on which the week begins.
day_begins_hour	integer	For periodic intervals (hours per day, minutes per day, seconds per day), specifies the hour when the day begins. Can be used in combination with <code>day_begins_minute</code> and <code>day_begins_second</code> to specify an exact time such as 8:05:01. See usage example below.
day_begins_minute	integer	For periodic intervals (hours per day, minutes per day, seconds per day), specifies the minute when the day begins (for example, the 5 in 8:05).
day_begins_second	integer	For periodic intervals (hours per day, minutes per day, seconds per day), specifies the second when the day begins (for example, the 17 in 8:05:17).
days_per_week	integer	For periodic intervals (days per week, hours per day, minutes per day, and seconds per day), specifies the number of days per week.
hours_per_day	integer	For periodic intervals (hours per day, minutes per day, and seconds per day), specifies the number of hours in the day.
interval_increment	1 2 3 4 5 6 10 15 20 30	For minutes per day and seconds per day, specifies the number of minutes or seconds to increment for each record.
field_name_extension	string

transposenode properties

The Transpose node swaps the data in rows and columns so that records become fields and fields become records.

Example

```
node = stream.create("transpose", "My node")
node.setPropertyValue("transposed_names", "Read")
node.setPropertyValue("read_from_field", "TimeLabel")
node.setPropertyValue("max_num_fields", "1000")
node.setPropertyValue("id_field_name", "ID")
```

Table 1. transposenode properties

transposenode properties	Data type	Property description
transpose_method	enum	Specifies the transpose method: Normal (<code>normal</code>), CASE to VAR (<code>casetovar</code>), or VAR to CASE (<code>vartocase</code>).
transposed_names	Prefix Read	Property for the Normal transpose method. New field names can be generated automatically based on a specified prefix, or they can be read from an existing field in the data.
prefix	string	Property for the Normal transpose method.
num_new_fields	integer	Property for the Normal transpose method. When using a prefix, specifies the maximum number of new fields to create.
read_from_field	field	Property for the Normal transpose method. Field from which names are read. This must be an instantiated field or an error will occur when the node is executed.
max_num_fields	integer	Property for the Normal transpose method. When reading names from a field, specifies an upper limit to avoid creating an inordinately large number of fields.
transpose_type	Numeric String Custom	Property for the Normal transpose method. By default, only continuous (numeric range) fields are transposed, but you can choose a custom subset of numeric fields or transpose all string fields instead.
transpose_fields	list	Property for the Normal transpose method. Specifies the fields to transpose when the <code>Custom</code> option is used.
id_field_name	field	Property for the Normal transpose method.
transpose_caseto var_idfields	field	Property for the CASE to VAR (<code>casetovar</code>) transpose method. Accepts multiple fields to be used as index fields. <code>field1 ... fieldN</code>
transpose_caseto var_columnfields	field	Property for the CASE to VAR (<code>casetovar</code>) transpose method. Accepts multiple fields to be used as column fields. <code>field1 ... fieldN</code>
transpose_caseto var_valuefields	field	Property for the CASE to VAR (<code>casetovar</code>) transpose method. Accepts multiple fields to be used as value fields. <code>field1 ... fieldN</code>
transpose_vartoc ase_idfields	field	Property for the VAR to CASE (<code>vartocase</code>) transpose method. Accepts multiple fields to be used as ID variable fields. <code>field1 ... fieldN</code>
transpose_vartoc ase_valfields	field	Property for the VAR to CASE (<code>vartocase</code>) transpose method. Accepts multiple fields to be used as value variable fields. <code>field1 ... fieldN</code>

typenode properties

The Type node specifies field metadata and properties. For example, you can specify a measurement level (continuous, nominal, ordinal, or flag) for each field, set options for handling missing values and system nulls, set the role of a field for

modeling purposes, specify field and value labels, and specify values for a field.

Example

```
node = stream.createAt("type", "My node", 50, 50)
node.setKeyedPropertyValue("check", "Cholesterol", "Coerce")
node.setKeyedPropertyValue("direction", "Drug", "Input")
node.setKeyedPropertyValue("type", "K", "Range")
node.setKeyedPropertyValue("values", "Drug", ["drugA", "drugB", "drugC", "drugD", "drugX",
    "drugY", "drugZ"])
node.setKeyedPropertyValue("null_missing", "BP", False)
node.setKeyedPropertyValue("whitespace_missing", "BP", False)
node.setKeyedPropertyValue("description", "BP", "Blood Pressure")
node.setKeyedPropertyValue("value_labels", "BP", [{"HIGH": "High Blood Pressure"}, {"NORMAL": "normal blood pressure"}])
```

Note that in some cases you may need to fully instantiate the Type node in order for other nodes to work correctly, such as the **fields from** property of the Set to Flag node. You can simply connect a Table node and execute it to instantiate the fields:

```
tablenode = stream.createAt("table", "Table node", 150, 50)
stream.link(node, tablenode)
tablenode.run(None)
stream.delete(tablenode)
```

Table 1. typenode properties

typenode properties	Data type	Property description
direction	Input Target Both None Partition Split Frequency RecordID	Keyed property for field roles. Note: The values In and Out are now deprecated. Support for them may be withdrawn in a future release.
type	Range Flag Set Typeless Discrete OrderedSet Default	Measurement level of the field (previously called the "type" of field). Setting type to Default will clear any values parameter setting, and if value_mode has the value Specify , it will be reset to Read . If value_mode is set to Pass or Read , setting type will not affect value_mode . Note: The data types used internally differ from those visible in the type node. The correspondence is as follows: Range -> Continuous Set -> Nominal OrderedSet -> Ordinal Discrete- > Categorical
storage	Unknown String Integer Real Time Date Timestamp	Read-only keyed property for field storage type.
check	None Nullify Coerce Discard Warn Abort	Keyed property for field type and range checking.
values	[value value]	For continuous fields, the first value is the minimum, and the last value is the maximum. For nominal fields, specify all values. For flag fields, the first value represents <i>false</i> , and the last value represents <i>true</i> . Setting this property automatically sets the value_mode property to Specify .
value_mode	Read Pass Read+ Current Specify	Determines how values are set. Note that you cannot set this property to Specify directly; to use specific values, set the values property.
extend_values	flag	Applies when value_mode is set to Read . Set to T to add newly read values to any existing values for the field. Set to F to discard existing values in favor of the newly read values.
enable_missing	flag	When set to T , activates tracking of missing values for the field.
missing_values	[value value ...]	Specifies data values that denote missing data.
range_missing	flag	Specifies whether a missing-value (blank) range is defined for a field.
missing_lower	string	When range_missing is true, specifies the lower bound of the missing-value range.
missing_upper	string	When range_missing is true, specifies the upper bound of the missing-value range.
null_missing	flag	When set to T , nulls (undefined values that are displayed as \$null\$ in the software) are considered missing values.
whitespace_missing	flag	When set to T , values containing only white space (spaces, tabs, and new lines) are considered missing values.
description	string	Specifies the description for a field.
value_labels	[[Value LabelString] / Value LabelString] ...]	Used to specify labels for value pairs.

typenode properties	Data type	Property description
<code>display_places</code>	<code>integer</code>	Sets the number of decimal places for the field when displayed (applies only to fields with <code>REAL</code> storage). A value of <code>-1</code> will use the stream default.
<code>export_places</code>	<code>integer</code>	Sets the number of decimal places for the field when exported (applies only to fields with <code>REAL</code> storage). A value of <code>-1</code> will use the stream default.
<code>decimal_separator</code>	<code>DEFAULT PERIOD COMMA</code>	Sets the decimal separator for the field (applies only to fields with <code>REAL</code> storage).
<code>date_format</code>	"DDMMYY" "MMDDYY" "YYMMDD" "YYYYMMDD" "YYYYDDD" DAY MONTH "DD-MM-YY" "DD-MM-YYYY" "MM-DD-YY" "MM-DD-YYYY" "DD-MON-YY" "DD-MON-YYYY" "YYYY-MM-DD" "DD.MM.YY" "DD.MM.YYYY" "MM.DD.YYYY" "DD.MON.YY" "DD.MON.YYYY" "DD/MM/YY" "DD/MM/YYYY" "MM/DD/YY" "MM/DD/YYYY" "DD/MON/YY" "DD/MON/YYYY" MON YYYY q Q YYYY ww WK YYYY	Sets the date format for the field (applies only to fields with <code>DATE</code> or <code>TIMESTAMP</code> storage).
<code>time_format</code>	"HHMMSS" "HHMM" "MMSS" "HH : MM : SS" "HH : MM" "MM : SS" "(H) H : (M) M : (S) S" "(H) H : (M) M" "(M) M : (S) S" "HH.MM.SS" "HH.MM" "MM.SS" "(H) H . (M) M . (S) S" "(H) H . (M) M" "(M) M . (S) S"	Sets the time format for the field (applies only to fields with <code>TIME</code> or <code>TIMESTAMP</code> storage).
<code>number_format</code>	<code>DEFAULT STANDARD</code> <code>SCIENTIFIC CURRENCY</code>	Sets the number display format for the field.
<code>standard_places</code>	<code>integer</code>	Sets the number of decimal places for the field when displayed in standard format. A value of <code>-1</code> will use the stream default. Note that the existing <code>display_places</code> slot will also change this but is now deprecated.
<code>scientific_places</code>	<code>integer</code>	Sets the number of decimal places for the field when displayed in scientific format. A value of <code>-1</code> will use the stream default.
<code>currency_places</code>	<code>integer</code>	Sets the number of decimal places for the field when displayed in currency format. A value of <code>-1</code> will use the stream default.
<code>grouping_symbol</code>	<code>DEFAULT NONE LOCALE</code> <code>PERIOD COMMA SPACE</code>	Sets the grouping symbol for the field.
<code>column_width</code>	<code>integer</code>	Sets the column width for the field. A value of <code>-1</code> will set column width to <code>Auto</code> .
<code>justify</code>	<code>AUTO CENTER LEFT</code> <code>RIGHT</code>	Sets the column justification for the field.

typenode properties	Data type	Property description
<code>measure_type</code>	<code>Range / MeasureType.RANGE Discrete / MeasureType.DISCRETE Flag / MeasureType.FLAG Set / MeasureType.SET OrderedSet / MeasureType.ORDERED_SET Typeless / MeasureType.TYPELESS S Collection / MeasureType.COLLECTION Geospatial / MeasureType.GEOSPATIAL</code>	This keyed property is similar to <code>type</code> in that it can be used to define the measurement associated with the field. What is different is that in Python scripting, the setter function can also be passed one of the <code>MeasureType</code> values while the getter will always return on the <code>MeasureType</code> values.
<code>collection_measure</code>	<code>Range / MeasureType.RANGE Flag / MeasureType.FLAG Set / MeasureType.SET OrderedSet / MeasureType.ORDERED_SET Typeless / MeasureType.TYPELESS</code>	For collection fields (lists with a depth of 0), this keyed property defines the measurement type associated with the underlying values.
<code>geo_type</code>	<code>Point MultiPoint LineString MultiLineString Polygon MultiPolygon</code>	For geospatial fields, this keyed property defines the type of geospatial object represented by this field. This should be consistent with the list depth of the values.
<code>has_coordinate_system</code>	<code>boolean</code>	For geospatial fields, this property defines whether this field has a coordinate system
<code>coordinate_system</code>	<code>string</code>	For geospatial fields, this keyed property defines the coordinate system for this field.
<code>custom_storage_type</code>	<code>Unknown / MeasureType.UNKNOWN String / MeasureType.STRING Integer / MeasureType.INTEGER Real / MeasureType.REAL Time / MeasureType.TIME Date / MeasureType.DATE Timestamp / MeasureType.TIMESTAMP List / MeasureType.LIST</code>	This keyed property is similar to <code>custom_storage</code> in that it can be used to define the override storage for the field. What is different is that in Python scripting, the setter function can also be passed one of the <code>StorageType</code> values while the getter will always return on the <code>StorageType</code> values.
<code>custom_list_storage_type</code>	<code>String / MeasureType.STRING Integer / MeasureType.INTEGER Real / MeasureType.REAL Time / MeasureType.TIME Date / MeasureType.DATE Timestamp / MeasureType.TIMESTAMP</code>	For list fields, this keyed property specifies the storage type of the underlying values.
<code>custom_list_depth</code>	<code>integer</code>	For list fields, this keyed property specifies the depth of the field
<code>max_list_length</code>	<code>integer</code>	Only available for data with a measurement level of either <i>Geospatial</i> or <i>Collection</i> . Set the maximum length of the list by specifying the number of elements the list can contain.
<code>max_string_length</code>	<code>integer</code>	Only available for <i>typeless</i> data and used when you are generating SQL to create a table. Enter the value of the largest string in your data; this generates a column in the table that is big enough to contain the string.

Graph Node Properties

Graph node common properties

This section describes the properties available for graph nodes, including common properties and properties that are specific to each node type.

Table 1. Common graph node properties

Common graph node properties	Data type	Property description
<code>title</code>	<code>string</code>	Specifies the title. Example: "This is a title."
<code>caption</code>	<code>string</code>	Specifies the caption. Example: "This is a caption."
<code>output_mode</code>	<code>Screen File</code>	Specifies whether output from the graph node is displayed or written to a file.
<code>output_format</code>	<code>BMP JPEG PNG HTML output (.cou)</code>	Specifies the type of output. The exact type of output allowed for each node varies.
<code>full_filename</code>	<code>string</code>	Specifies the target path and filename for output generated from the graph node.
<code>use_graph_size</code>	<code>flag</code>	Controls whether the graph is sized explicitly, using the width and height properties below. Affects only graphs that are output to screen. Not available for the Distribution node.
<code>graph_width</code>	<code>number</code>	When <code>use_graph_size</code> is <code>True</code> , sets the graph width in pixels.
<code>graph_height</code>	<code>number</code>	When <code>use_graph_size</code> is <code>True</code> , sets the graph height in pixels.

Turning off optional fields

Optional fields, such as an overlay field for plots, can be turned off by setting the property value to " " (empty string), as shown in the following example:

```
plotnode.setPropertyValue("color_field", "")
```

Specifying colors

The colors for titles, captions, backgrounds, and labels can be specified by using the hexadecimal strings starting with the hash (#) symbol. For example, to set the graph background to sky blue, you would use the following statement:

```
mygraphnode.setPropertyValue("graph_background", "#87CEEB")
```

Here, the first two digits, 87, specify the red content; the middle two digits, CE, specify the green content; and the last two digits, EB, specify the blue content. Each digit can take a value in the range 0–9 or A–F. Together, these values can specify a red-green-blue, or RGB, color.

Note: When specifying colors in RGB, you can use the Field Chooser in the user interface to determine the correct color code. Simply hover over the color to activate a ToolTip with the desired information.

collectionnode Properties

The Collection node shows the distribution of values for one numeric field relative to the values of another. (It creates graphs that are similar to histograms.) It is useful for illustrating a variable or field whose values change over time. Using 3-D

graphing, you can also include a symbolic axis displaying distributions by category.

Example

```
node = stream.create("collection", "My node")
# "Plot" tab
node.setPropertyValue("three_D", True)
node.setPropertyValue("collect_field", "Drug")
node.setPropertyValue("over_field", "Age")
node.setPropertyValue("by_field", "BP")
node.setPropertyValue("operation", "Sum")
# "Overlay" section
node.setPropertyValue("color_field", "Drug")
node.setPropertyValue("panel_field", "Sex")
node.setPropertyValue("animation_field", "")
# "Options" tab
node.setPropertyValue("range_mode", "Automatic")
node.setPropertyValue("range_min", 1)
node.setPropertyValue("range_max", 100)
node.setPropertyValue("bins", "ByNumber")
node.setPropertyValue("num_bins", 10)
node.setPropertyValue("bin_width", 5)
```

Table 1. collectionnode properties

collectionnode properties	Data type	Property description

- [distributionnode Properties](#)

distributionnode Properties

The Distribution node shows the occurrence of symbolic (categorical) values, such as mortgage type or gender. Typically, you might use the Distribution node to show imbalances in the data, which you could then rectify using a Balance node before creating a model.

Example

```
node = stream.create("distribution", "My node")
# "Plot" tab
node.setPropertyValue("plot", "Flags")
node.setPropertyValue("x_field", "Age")
```

```

node.setPropertyValue("color_field", "Drug")
node.setPropertyValue("normalize", True)
node.setPropertyValue("sort_mode", "ByOccurrence")
node.setPropertyValue("use_proportional_scale", True)

```

use_proportional_scale	flag	

Related information

- [collectionnode Properties](#)

evaluationnode Properties

The Evaluation node helps to evaluate and compare predictive models. The evaluation chart shows how well models predict particular outcomes. It sorts records based on the predicted value and confidence of the prediction. It splits the records into groups of equal size (**quantiles**) and then plots the value of the business criterion for each quantile from highest to lowest. Multiple models are shown as separate lines in the plot.

Example

```

node = stream.create("evaluation", "My node")
# "Plot" tab
node.setPropertyValue("chart_type", "Gains")
node.setPropertyValue("cumulative", False)
node.setPropertyValue("field_detection_method", "Name")
node.setPropertyValue("inc_baseline", True)
node.setPropertyValue("n_tile", "Deciles")
node.setPropertyValue("style", "Point")
node.setPropertyValue("point_type", "Dot")
node.setPropertyValue("use_fixed_cost", True)
node.setPropertyValue("cost_value", 5.0)
node.setPropertyValue("cost_field", "Na")
node.setPropertyValue("use_fixed_revenue", True)
node.setPropertyValue("revenue_value", 30.0)
node.setPropertyValue("revenue_field", "Age")
node.setPropertyValue("use_fixed_weight", True)
node.setPropertyValue("weight_value", 2.0)
node.setPropertyValue("weight_field", "K")

```

graphboardnode Properties

The Graphboard node offers many different types of graphs in one single node. Using this node, you can choose the data fields you want to explore and then select a graph from those available for the selected data. The node automatically filters out any graph types that would not work with the field choices.

Note: If you set a property that is not valid for the graph type (for example, specifying **y_field** for a histogram), that property is ignored.

Note: In the UI, on the Detailed tab of many different graph types, there is a Summary field; this field is not currently supported by scripting.

Example

```
node = stream.create("graphboard", "My node")
node.setPropertyValue("graph_type", "Line")
node.setPropertyValue("x_field", "K")
node.setPropertyValue("y_field", "Na")
```

histogramnode Properties

	The Histogram node shows the occurrence of values for numeric fields. It is often used to explore the data before manipulations and model building. Similar to the Distribution node, the Histogram node frequently reveals imbalances in the data.
---	---

Example

```
node = stream.create("histogram", "My node")
# "Plot" tab
node.setPropertyValue("field", "Drug")
```

```

node.setPropertyValue("color_field", "Drug")
node.setPropertyValue("panel_field", "Sex")
node.setPropertyValue("animation_field", "")
# "Options" tab
node.setPropertyValue("range_mode", "Automatic")
node.setPropertyValue("range_min", 1.0)
node.setPropertyValue("range_max", 100.0)
node.setPropertyValue("num_bins", 10)
node.setPropertyValue("bin_width", 10)
node.setPropertyValue("normalize", True)
node.setPropertyValue("separate_bands", False)

```

mapvisualization properties

The Map Visualization node can accept multiple input connections and display geospatial data on a map as a series of layers. Each layer is a single geospatial field; for example, the base layer might be a map of a country, then above that you might have one layer for roads, one layer for rivers, and one layer for towns.

Table 1. mapvisualization properties

mapvisualization properties	Data type	Property description
tag	string	Sets the name of the tag for the input. The default tag is a number based on the order that inputs were connected to the node (the first connection tag is 1, the second connection tag is 2, etc.).

mapvisualizati on properties	Data type	Property description
layer_field	<i>field</i>	Selects which geo-field from the data set is displayed as a layer on the map. The default selection is based on the following sort order: <ul style="list-style-type: none"> • First - Point • Linestring • Polygon • Multipoint • MultiLinestring • Last - MultiPolygon If there are two fields with the same measurement type, the first field alphabetically (by name) will be selected by default.
color_type	<i>boolean</i>	Specifies whether a standard color is applied to all features of the geo-field, or an overlay field which colors the features based on values from another field in the data set. Possible values are standard or overlay . The default is standard .
color	<i>string</i>	If standard is selected for color_type , the drop-down contains the same color palette as the chart category color order on the user options Display tab. Default is chart category color 1.
color_field	<i>field</i>	If overlay is selected for color_type , the drop-down contains all fields from the same data set as the geo-field selected as the layer.
symbol_type	<i>boolean</i>	Specifies whether a standard symbol is applied to all records of the geo-field, or an overlay symbol which changes the symbol icon for the points based on values from another field in the data set. Possible values are standard or overlay . The default is standard .
symbol	<i>string</i>	If standard is selected for symbol_type , the drop-down contains a selection of symbols that can be used to display points on the map.
symbol_field	<i>field</i>	If overlay is selected for symbol_type , the drop-down contains all of the nominal, ordinal, or categorical fields from the same data set as the geo-field selected as the layer.
size_type	<i>boolean</i>	Specifies whether a standard size is applied to all records of the geo-field, or an overlay size which changes the size of symbol icon or the line thickness based on values from another field in the data set. Possible values are standard or overlay . The default is standard .
size	<i>string</i>	If standard is selected for size_type , for point or multipoint , the drop-down contains a selection of sizes for the symbol selected. For linestring or multilinestring , the drop-down contains a selection of line thicknesses.
size_field	<i>field</i>	If overlay is selected for size_type , the drop-down contains all of the fields from the same data set as the geo-field selected as the layer.
transp_type	<i>boolean</i>	Specifies whether a standard transparency is applied to all records of the geo-field, or an overlay transparency which changes the level of transparency for the symbol, line, or polygon based on values from another field in the data set. Possible values are standard or overlay . The default is standard .
transp	<i>integer</i>	If standard is selected for transp_type , the drop-down contains a selection of transparency levels starting at 0% (opaque) and increasing to 100% (transparent) in 10% increments. Sets the transparency of points, lines, or polygons on the map. If overlay is selected for size_type , the drop-down contains all of the fields from the same data set as the geo-field selected as the layer. For points , multipoints , linestrings , and multilinestrings , polygons and multipolygons (that are the bottom layer), the default is 0%. For polygons and multipolygons that are not the bottom layer, the default is 50% (to avoid obscuring layers beneath these polygons).
transp_field	<i>field</i>	If overlay is selected for transp_type , the drop-down contains all of the fields from the same data set as the geo-field selected as the layer.
data_label_fie ld	<i>field</i>	Specifies the field to use as data labels on the map. For example, if the layer this setting is applied to is a polygon layer, then the data label might be the name field – containing the name of each polygon. So selecting the name field here would result in those names being displayed on the map.
use_hex_binnin g	<i>boolean</i>	Enables hex binning and enables all of the aggregation drop-downs. This setting is turned off by default.

mapvisualizati on properties	Data type	Property description
color_aggregat ion and transp_aggrega tion	string	<p>If you select an overlay field for a points layer using hex binning, then all the values for that field must be aggregated for all points within the hexagon. Therefore, you must specify an aggregation function for any overlay fields you want to apply to the map.</p> <p>The available aggregation functions are:</p> <p>Continuous (Real or Integer storage):</p> <ul style="list-style-type: none"> • Sum • Mean • Min • Max • Median • 1st Quartile • 3rd Quartile <p>Continuous (Time, Date, or Timestamp storage):</p> <ul style="list-style-type: none"> • Mean • Min • Max <p>Nominal/Categorical:</p> <ul style="list-style-type: none"> • Mode • Min • Max <p>Flag:</p> <ul style="list-style-type: none"> • True if any true • False if any false
custom_storage	string	Sets the overall storage type of the field. Default is List . If List is specified, the following custom_value_storage and list_depth controls are disabled.
custom_value_s torage	string	Sets the storage types of the elements in the list instead of to the field as a whole. The default is Real .
list_depth	integer	<p>Sets the depth of the list field. Ther required depth depends on the type of geofield, following these criteria:</p> <ul style="list-style-type: none"> • Point - 0 • LineString - 1 • Polygon - 2 • Multipoint - 1 • MultiLineString - 2 • Multipolygon - 3 <p>You must know the type of geospatial field you are converting back to a list and the required depth for that kind of field. If set incorrectly, the field cannot be used.</p> <p>The default value is 0, minimum is 0, and maximum is 10.</p>

multiplotnode Properties

The Multiplot node creates a plot that displays multiple Y fields over a single X field. The Y fields are plotted as colored lines; each is equivalent to a Plot node with Style set to Line and X Mode set to Sort. Multiplots are useful when you want to explore the fluctuation of several variables over time.

Example

```
node = stream.create("multiplot", "My node")
# "Plot" tab
node.setPropertyValue("x_field", "Age")
node.setPropertyValue("y_fields", ["Drug", "BP"])
node.setPropertyValue("panel_field", "Sex")
# "Overlay" section
node.setPropertyValue("animation_field", "")
node.setPropertyValue("tooltip", "test")
node.setPropertyValue("normalize", True)
```

```

node.setPropertyValue("use_overlay_expr", False)
node.setPropertyValue("overlay_expression", "test")
node.setPropertyValue("records_limit", 500)
node.setPropertyValue("if_over_limit", "PlotSample")

```

plotnode Properties

The Plot node shows the relationship between numeric fields. You can create a plot by using points (a scatterplot) or lines.

Example

```

node = stream.create("plot", "My node")
# "Plot" tab
node.setPropertyValue("three_D", True)
node.setPropertyValue("x_field", "BP")
node.setPropertyValue("y_field", "Cholesterol")
node.setPropertyValue("z_field", "Drug")
# "Overlay" section
node.setPropertyValue("color_field", "Drug")
node.setPropertyValue("size_field", "Age")
node.setPropertyValue("shape_field", "")
node.setPropertyValue("panel_field", "Sex")
node.setPropertyValue("animation_field", "BP")
node.setPropertyValue("transp_field", "")
node.setPropertyValue("style", "Point")
# "Output" tab
node.setPropertyValue("output_mode", "File")
node.setPropertyValue("output_format", "JPEG")
node.setPropertyValue("full_filename", "C:/temp/graph_output/plot_output.jpeg")

```

Table 1. plotnode properties

plotnode properties	Data type	Property description
x_field	field	Specifies a custom label for the x axis. Available only for labels.
y_field	field	Specifies a custom label for the y axis. Available only for labels.

plotnode properties	Data type	Property description
<code>three_D</code>	<code>flag</code>	Specifies a custom label for the <i>y</i> axis. Available only for labels in 3-D graphs.
<code>z_field</code>	<code>field</code>	
<code>color_field</code>	<code>field</code>	Overlay field.
<code>size_field</code>	<code>field</code>	
<code>shape_field</code>	<code>field</code>	
<code>panel_field</code>	<code>field</code>	Specifies a nominal or flag field for use in making a separate chart for each category. Charts are paneled together in one output window.
<code>animation_field</code>	<code>field</code>	Specifies a nominal or flag field for illustrating data value categories by creating a series of charts displayed in sequence using animation.
<code>transp_field</code>	<code>field</code>	Specifies a field for illustrating data value categories by using a different level of transparency for each category. Not available for line plots.
<code>overlay_type</code>	<code>None Smoother Function</code>	Specifies whether an overlay function or LOESS smoother is displayed.
<code>overlay_expression</code>	<code>string</code>	Specifies the expression used when <code>overlay_type</code> is set to <code>Function</code> .
<code>style</code>	<code>Point Line</code>	
<code>point_type</code>	<code>Rectangle</code> <code>Dot</code> <code>Triangle</code> <code>Hexagon</code> <code>Plus</code> <code>Pentagon</code> <code>Star</code> <code>BowTie</code> <code>HorizontalDash</code> <code>VerticalDash</code> <code>IronCross</code> <code>Factory</code> <code>House</code> <code>Cathedral</code> <code>OnionDome</code> <code>ConcaveTriangle</code> <code>OblateGlobe</code> <code>CatEye</code> <code>FourSidedPillow</code> <code>RoundRectangle</code> <code>Fan</code>	
<code>x_mode</code>	<code>Sort Overlay As Read</code>	
<code>x_range_mode</code>	<code>Automatic</code> <code>UserDefined</code>	
<code>x_range_min</code>	<code>number</code>	
<code>x_range_max</code>	<code>number</code>	
<code>y_range_mode</code>	<code>Automatic</code> <code>UserDefined</code>	
<code>y_range_min</code>	<code>number</code>	
<code>y_range_max</code>	<code>number</code>	
<code>z_range_mode</code>	<code>Automatic</code> <code>UserDefined</code>	
<code>z_range_min</code>	<code>number</code>	
<code>z_range_max</code>	<code>number</code>	
<code>jitter</code>	<code>flag</code>	
<code>records_limit</code>	<code>number</code>	
<code>if_over_limit</code>	<code>PlotBins</code> <code>PlotSample PlotAll</code>	
<code>x_label_auto</code>	<code>flag</code>	
<code>x_label</code>	<code>string</code>	
<code>y_label_auto</code>	<code>flag</code>	
<code>y_label</code>	<code>string</code>	
<code>z_label_auto</code>	<code>flag</code>	
<code>z_label</code>	<code>string</code>	
<code>use_grid</code>	<code>flag</code>	
<code>graph_background</code>	<code>color</code>	Standard graph colors are described at the beginning of this section.
<code>page_background</code>	<code>color</code>	Standard graph colors are described at the beginning of this section.

plotnode properties	Data type	Property description
use_overlay_expr	flag	Deprecated in favor of <code>overlay_type</code> .

timeplotnode Properties

	The Time Plot node displays one or more sets of time series data. Typically, you would first use a Time Intervals node to create a <code>TimeLabel</code> field, which would be used to label the x axis.
---	---

Example

```
node = stream.create("timeplot", "My node")
node.setPropertyValue("y_fields", ["sales", "men", "women"])
node.setPropertyValue("panel", True)
node.setPropertyValue("normalize", True)
node.setPropertyValue("line", True)
node.setPropertyValue("smoother", True)
node.setPropertyValue("use_records_limit", True)
node.setPropertyValue("records_limit", 2000)
# Appearance settings
node.setPropertyValue("symbol_size", 2.0)
```

Table 1. timeplotnode properties

timeplotnode properties	Data type	Property description
plot_series	Series Models	
use_custom_x_field	flag	
x_field	field	
y_fields	list	
panel	flag	
normalize	flag	
line	flag	
points	flag	
point_type	Rectangle Dot Triangle Hexagon Plus Pentagon Star BowTie HorizontalDash VerticalDash IronCross Factory House Cathedral OnionDome ConcaveTriangle OblateGlobe CatEye FourSidedPillow RoundRectangle Fan	
smoother	flag	You can add smoothers to the plot only if you set <code>panel</code> to <code>True</code> .
use_records_limit	flag	
records_limit	integer	
symbol_size	number	Specifies a symbol size.
panel_layout	Horizontal Vertical

eplotnode Properties

	The E-Plot (Beta) node shows the relationship between numeric fields. It is similar to the Plot node, but its options differ and its output uses a new graphing interface specific to this node. Use the beta-level node to play around with new graphing features.
---	---

Table 1. eplotnode properties

eplotnode properties	Data type	Property description
x_field	<i>string</i>	Specify the field to display on the horizontal X axis.
y_field	<i>string</i>	Specify the field to display on the vertical Y axis.
color_field	<i>string</i>	Specify the field to use for the color map overlay in the output, if desired.
size_field	<i>string</i>	Specify the field to use for the size map overlay in the output, if desired.
shape_field	<i>string</i>	Specify the field to use for the shape map overlay in the output, if desired.
interested_fields	<i>string</i>	Specify the fields you'd like to include in the output.
records_limit	<i>integer</i>	Specify a number for the maximum number of records to plot in the output. 2000 is the default.
if_over_limit	<i>Boolean</i>	Specify whether to use the Sample option or the Use all data option if the records_limit is surpassed. Sample is the default, and it randomly samples the data until it hits the records_limit . If you specify Use all data to ignore the records_limit and plot all data points, note that this may dramatically decrease performance.

tsnenode Properties

	t-Distributed Stochastic Neighbor Embedding (t-SNE) is a tool for visualizing high-dimensional data. It converts affinities of data points to probabilities. This t-SNE node in SPSS® Modeler is implemented in Python and requires the scikit-learn® Python library.
---	--

Table 1. tsnenode properties

tsnenode properties	Data type	Property description
mode_type	<i>string</i>	Specify simple or expert mode.
n_components	<i>string</i>	Dimension of the embedded space (2D or 3D). Specify 2 or 3 . Default is 2 .
method	<i>string</i>	Specify barnes_hut or exact . Default is barnes_hut .
init	<i>string</i>	Initialization of embedding. Specify random or pca . Default is random .
target_field Renamed to target starting with version 18.2.1.1	<i>string</i>	Target field name. It will be a colormap on the output graph. The graph will use one color if no target field is specified.
perplexity	<i>float</i>	The perplexity is related to the number of nearest neighbors used in other manifold learning algorithms. Larger datasets usually require a larger perplexity. Consider selecting a value between 5 and 50. Default is 30 .
early_exaggeration	<i>float</i>	Controls how tight the natural clusters in the original space are in the embedded space, and how much space will be between them. Default is 12.0 .
learning_rate	<i>float</i>	Default is 200 .
n_iter	<i>integer</i>	Maximum number of iterations for the optimization. Set to at least 250 . Default is 1000 .
angle	<i>float</i>	The angular size of the distant node as measured from a point. Specify a value in the range of 0-1. Default is 0.5 .
enable_random_seed	<i>Boolean</i>	Set to true to enable the random_seed parameter. Default is false .
random_seed	<i>integer</i>	The random number seed to use. Default is None .
n_iter_without_progress	<i>integer</i>	Maximum iterations without progress. Default is 300 .

tsnenode properties	Data type	Property description
<code>min_grad_norm</code>	<code>string</code>	If the gradient norm is below this threshold, the optimization will be stopped. Default is <code>1.0E-7</code> . Possible values are: <ul style="list-style-type: none">• <code>1.0E-1</code>• <code>1.0E-2</code>• <code>1.0E-3</code>• <code>1.0E-4</code>• <code>1.0E-5</code>• <code>1.0E-6</code>• <code>1.0E-7</code>• <code>1.0E-8</code>
<code>isGridSearch</code>	<code>Boolean</code>	Set to <code>true</code> to perform t-SNE with several different perplexities. Default is <code>false</code> .
<code>output_Rename</code>	<code>Boolean</code>	Specify <code>true</code> if you want to provide a custom name, or <code>false</code> to name the output automatically. Default is <code>false</code> .
<code>output_to</code>	<code>string</code>	Specify <code>Screen</code> or <code>Output</code> . Default is <code>Screen</code> .
<code>full_filename</code>	<code>string</code>	Specify the output file name.
<code>output_file_type</code>	<code>string</code>	Output file format. Specify <code>HTML</code> or <code>Output object</code> . Default is <code>HTML</code> .

webnode Properties

The Web node illustrates the strength of the relationship between values of two or more symbolic (categorical) fields. The graph uses lines of various widths to indicate connection strength. You might use a Web node, for example, to explore the relationship between the purchase of a set of items at an e-commerce site.

Example

```
node = stream.create("web", "My node")
# "Plot" tab
node.setPropertyValue("use_directed_web", True)
node.setPropertyValue("to_field", "Drug")
node.setPropertyValue("fields", ["BP", "Cholesterol", "Sex", "Drug"])
node.setPropertyValue("from_fields", ["BP", "Cholesterol", "Sex"])
node.setPropertyValue("true_flags_only", False)
node.setPropertyValue("line_values", "Absolute")
node.setPropertyValue("strong_links_heavier", True)
# "Options" tab
node.setPropertyValue("max_num_links", 300)
node.setPropertyValue("links_above", 10)
node.setPropertyValue("num_links", "ShowAll")
node.setPropertyValue("discard_links_min", True)
node.setPropertyValue("links_min_records", 5)
node.setPropertyValue("discard_links_max", True)
node.setPropertyValue("weak_below", 10)
node.setPropertyValue("strong_above", 19)
node.setPropertyValue("link_size_continuous", True)
node.setPropertyValue("web_display", "Circular")
```

Table 1. webnode properties

webnode properties	Data type	Property description
<code>use_directed_web</code>	<code>flag</code>	
<code>fields</code>	<code>list</code>	
<code>to_field</code>	<code>field</code>	
<code>from_fields</code>	<code>list</code>	
<code>true_flags_only</code>	<code>flag</code>	
<code>line_values</code>	<code>Absolute OverallPct PctLarger PctSmaller</code>	
<code>strong_links_heavier</code>	<code>flag</code>	
<code>num_links</code>	<code>ShowMaximum ShowLinksAbove ShowAll</code>	
<code>max_num_links</code>	<code>number</code>	
<code>links_above</code>	<code>number</code>

Common modeling node properties

The following properties are common to some or all modeling nodes. Any exceptions are noted in the documentation for individual modeling nodes as appropriate.

Table 1. Common modeling node properties

Property	Values	Property description
<code>custom_fields</code>	<code>flag</code>	If true, allows you to specify target, input, and other fields for the current node. If false, the current settings from an upstream Type node are used.
<code>target or targets</code>	<code>field</code> or <code>[field1 ... fieldN]</code>	Specifies a single target field or multiple target fields depending on the model type.
<code>inputs</code>	<code>[field1 ... fieldN]</code>	Input or predictor fields used by the model.
<code>partition</code>	<code>field</code>	
<code>use_partitioned_data</code>	<code>flag</code>	If a partition field is defined, this option ensures that only data from the training partition is used to build the model.
<code>use_split_data</code>	<code>flag</code>	
<code>splits</code>	<code>[field1 ... fieldN]</code>	Specifies the field or fields to use for split modeling. Effective only if <code>use_split_data</code> is set to <code>True</code> .
<code>use_frequency</code>	<code>flag</code>	Weight and frequency fields are used by specific models as noted for each model type.
<code>frequency_field</code>	<code>field</code>	
<code>use_weight</code>	<code>flag</code>	
<code>weight_field</code>	<code>field</code>	
<code>use_model_name</code>	<code>flag</code>	
<code>model_name</code>	<code>string</code>	Custom name for new model.
<code>mode</code>	<code>Simple</code> <code>Expert</code>	

anomalydetectionnode properties

The Anomaly Detection node identifies unusual cases, or outliers, that do not conform to patterns of “normal” data. With this node, it is possible to identify outliers even if they do not fit any previously known patterns and even if you are not exactly sure what you are looking for.

Example

```
node = stream.create("anomalydetection", "My node")
node.setPropertyValue("anomaly_method", "PerRecords")
node.setPropertyValue("percent_records", 95)
node.setPropertyValue("mode", "Expert")
node.setPropertyValue("peer_group_num_auto", True)
node.setPropertyValue("min_num_peer_groups", 3)
node.setPropertyValue("max_num_peer_groups", 10)
```

Table 1. anomalydetectionnode properties

anomalydetectionnode Properties	Values	Property description
<code>inputs</code>	<code>[field1 ... fieldN]</code>	Anomaly Detection models screen records based on the specified input fields. They do not use a target field. Weight and frequency fields are also not used. See the topic Common modeling node properties for more information.
<code>mode</code>	<code>Expert</code> <code>Simple</code>	
<code>anomaly_method</code>	<code>IndexLevel</code> <code>PerRecords</code> <code>NumRecords</code>	Specifies the method used to determine the cutoff value for flagging records as anomalous.
<code>index_level</code>	<code>number</code>	Specifies the minimum cutoff value for flagging anomalies.
<code>percent_records</code>	<code>number</code>	Sets the threshold for flagging records based on the percentage of records in the training data.
<code>num_records</code>	<code>number</code>	Sets the threshold for flagging records based on the number of records in the training data.
<code>num_fields</code>	<code>integer</code>	The number of fields to report for each anomalous record.

anomalydetect ionnode Properties	Values	Property description
impute_missing_values	<i>flag</i>	
adjustment_coeff	<i>number</i>	Value used to balance the relative weight given to continuous and categorical fields in calculating the distance.
peer_group_num_auto	<i>flag</i>	Automatically calculates the number of peer groups.
min_num_peer_groups	<i>integer</i>	Specifies the minimum number of peer groups used when peer_group_num_auto is set to True .
max_num_per_groups	<i>integer</i>	Specifies the maximum number of peer groups.
num_peer_groups	<i>integer</i>	Specifies the number of peer groups used when peer_group_num_auto is set to False .
noise_level	<i>number</i>	Determines how outliers are treated during clustering. Specify a value between 0 and 0.5.
noise_ratio	<i>number</i>	Specifies the portion of memory allocated for the component that should be used for noise buffering. Specify a value between 0 and 0.5.

apriorinode properties

The Apriori node extracts a set of rules from the data, pulling out the rules with the highest information content. Apriori offers five different methods of selecting rules and uses a sophisticated indexing scheme to process large data sets efficiently. For large problems, Apriori is generally faster to train; it has no arbitrary limit on the number of rules that can be retained, and it can handle rules with up to 32 preconditions. Apriori requires that input and output fields all be categorical but delivers better performance because it is optimized for this type of data.

Example

```
node = stream.create("apriori", "My node")
# "Fields" tab
node.setPropertyValue("custom_fields", True)
node.setPropertyValue("partition", "Test")
# For non-transactional
node.setPropertyValue("use_transactional_data", False)
node.setPropertyValue("consequents", ["Age"])
node.setPropertyValue("antecedents", ["BP", "Cholesterol", "Drug"])
# For transactional
node.setPropertyValue("use_transactional_data", True)
node.setPropertyValue("id_field", "Age")
node.setPropertyValue("contiguous", True)
node.setPropertyValue("content_field", "Drug")
# "Model" tab
node.setPropertyValue("use_model_name", False)
node.setPropertyValue("model_name", "Apriori_bp_choles_drug")
node.setPropertyValue("min_supp", 7.0)
node.setPropertyValue("min_conf", 30.0)
node.setPropertyValue("max_antecedents", 7)
node.setPropertyValue("true_flags", False)
node.setPropertyValue("optimize", "Memory")
# "Expert" tab
node.setPropertyValue("mode", "Expert")
node.setPropertyValue("evaluation", "ConfidenceRatio")
node.setPropertyValue("lower_bound", 7)
```

Table 1. apriorinode properties

apriorinode Properties	Values	Property description
consequents	<i>field</i>	Apriori models use Consequents and Antecedents in place of the standard target and input fields. Weight and frequency fields are not used. See the topic Common modeling node properties for more information.
antecedents	<i>[field1 ... fieldN]</i>	
min_supp	<i>number</i>	
min_conf	<i>number</i>	
max_antecedents	<i>number</i>	
true_flags	<i>flag</i>	
optimize	<i>Speed Memory</i>	

apriorinode Properties	Values	Property description
use_transactional_data	<i>flag</i>	When the value is true , the score for each transaction ID is independent from other transaction IDs. When the data to be scored is too large to obtain acceptable performance, we recommend separating the data.
contiguous	<i>flag</i>	
id_field	<i>string</i>	
content_field	<i>string</i>	
mode	Simple Expert	
evaluation	RuleConfidence DifferenceToPrior ConfidenceRatio InformationDifference NormalizedChiSquare	
lower_bound	<i>number</i>	
optimize	Speed Memory	Use to specify whether model building should be optimized for speed or for memory.

associationrulesnode properties

The Association Rules Node is similar to the Apriori Node; however, unlike Apriori, the Association Rules Node can process list data. In addition, the Association Rules Node can be used with IBM® SPSS® Analytic Server to process big data and take advantage of faster parallel processing.

Table 1. associationrulesnode properties

associationrulesnode properties	Data type	Property description
predictions	<i>field</i>	Fields in this list can only appear as a predictor of a rule
conditions	<i>[field1...fieldN]</i>	Fields in this list can only appear as a condition of a rule
max_rule_conditions	<i>integer</i>	The maximum number of conditions that can be included in a single rule. Minimum 1, maximum 9.
max_rule_predictions	<i>integer</i>	The maximum number of predictions that can be included in a single rule. Minimum 1, maximum 5.
max_num_rules	<i>integer</i>	The maximum number of rules that can be considered as part of rule building. Minimum 1, maximum 10,000.
rule_criterion_top_n	Confidence Rulesupport Lift Conditionsupport Deployability	The rule criterion that determines the value by which the top "N" rules in the model are chosen.
true_flags	<i>Boolean</i>	Setting as Y determines that only the true values for flag fields are considered during rule building.
rule_criterion	<i>Boolean</i>	Setting as Y determines that the rule criterion values are used for excluding rules during model building.
min_confidence	<i>number</i>	0.1 to 100 - the percentage value for the minimum required confidence level for a rule produced by the model. If the model produces a rule with a confidence level less than the value specified here the rule is discarded.
min_rule_support	<i>number</i>	0.1 to 100 - the percentage value for the minimum required rule support for a rule produced by the model. If the model produces a rule with a rule support level less than the specified value the rule is discarded.
min_condition_support	<i>number</i>	0.1 to 100 - the percentage value for the minimum required condition support for a rule produced by the model. If the model produces a rule with a condition support level less than the specified value the rule is discarded.
min_lift	<i>integer</i>	1 to 10 - represents the minimum required lift for a rule produced by the model. If the model produces a rule with a lift level less than the specified value the rule is discarded.
exclude_rules	<i>Boolean</i>	Used to select a list of related fields from which you do not want the model to create rules. Example: set :gsarsnode.exclude_rules = [[[field1,field2, field3]],[[field4, field5]]] - where each list of fields separated by [] is a row in the table.
num_bins	<i>integer</i>	Set the number of automatic bins that continuous fields are binned to. Minimum 2, maximum 10.
max_list_length	<i>integer</i>	Applies to any list fields for which the maximum length is not known. Elements in the list up until the number specified here are included in the model build; any further elements are discarded. Minimum 1, maximum 100.

associationrulesnode properties	Data type	Property description
output_confidence	Boolean	
output_rule_support	Boolean	
output_lift	Boolean	
output_condition_support	Boolean	
output_deployability	Boolean	
rules_to_display	upto all	The maximum number of rules to display in the output tables.
display_upto	integer	If upto is set in rules_to_display, set the number of rules to display in the output tables. Minimum 1.
field_transformations	Boolean	
records_summary	Boolean	
rule_statistics	Boolean	
most_frequent_values	Boolean	
most_frequent_fields	Boolean	
word_cloud	Boolean	
word_cloud_sort	Confidence Rulesupport Lift Conditionsupport Deployability	
word_cloud_display	integer	Minimum 1, maximum 20
max_predictions	integer	The maximum number of rules that can be applied to each input to the score.
criterion	Confidence Rulesupport Lift Conditionsupport Deployability	Select the measure used to determine the strength of rules.
allow_repeats	Boolean	Determine whether rules with the same prediction are included in the score.
check_input	NoPredictions Predictions NoCheck	

autoclassifiernode properties

The Auto Classifier node creates and compares a number of different models for binary outcomes (yes or no, churn or do not churn, and so on), allowing you to choose the best approach for a given analysis. A number of modeling algorithms are supported, making it possible to select the methods you want to use, the specific options for each, and the criteria for comparing the results. The node generates a set of models based on the specified options and ranks the best candidates according to the criteria you specify.

Example

```
node = stream.create("autoclassifier", "My node")
node.setPropertyValue("ranking_measure", "Accuracy")
node.setPropertyValue("ranking_dataset", "Training")
node.setPropertyValue("enable_accuracy_limit", True)
node.setPropertyValue("accuracy_limit", 0.9)
node.setPropertyValue("calculate_variable_importance", True)
node.setPropertyValue("use_costs", True)
node.setPropertyValue("svm", False)
```

Table 1. autoclassifiernode properties

autoclassifiernode Properties	Values	Property description
target	field	For flag targets, the Auto Classifier node requires a single target and one or more input fields. Weight and frequency fields can also be specified. See the topic Common modeling node properties for more information.

autoclassifiernode Properties	Values	Property description
ranking_measure	Accuracy Area_under_curve Profit Lift Num variables	
ranking_dataset	Training Test	
number_of_models	integer	Number of models to include in the model nugget. Specify an integer between 1 and 100.
calculate_variable_importance	flag	
enable_accuracy_limit	flag	
accuracy_limit	integer	Integer between 0 and 100.
enable_area_under_curve_limit	flag	
area_under_curve_limit	number	Real number between 0.0 and 1.0.
enable_profit_limit	flag	
profit_limit	number	Integer greater than 0.
enable_lift_limit	flag	
lift_limit	number	Real number greater than 1.0.
enable_number_of_variables_limit	flag	
number_of_variables_limit	number	Integer greater than 0.
use_fixed_cost	flag	
fixed_cost	number	Real number greater than 0.0.
variable_cost	field	
use_fixed_revenue	flag	
fixed_revenue	number	Real number greater than 0.0.
variable_revenue	field	
use_fixed_weight	flag	
fixed_weight	number	Real number greater than 0.0
variable_weight	field	
lift_percentile	number	Integer between 0 and 100.
enable_model_build_time_limit	flag	
model_build_time_limit	number	Integer set to the number of minutes to limit the time taken to build each individual model.
enable_stop_after_time_limit	flag	
stop_after_time_limit	number	Real number set to the number of hours to limit the overall elapsed time for an auto classifier run.
enable_stop_after_valid_model_produced	flag	
use_costs	flag	
<algorithm>	flag	Enables or disables the use of a specific algorithm.
<algorithm>. <property>	string	Sets a property value for a specific algorithm. See the topic Setting Algorithm Properties for more information.

- [Setting Algorithm Properties](#)

Setting Algorithm Properties

For the Auto Classifier, Auto Numeric, and Auto Cluster nodes, properties for specific algorithms used by the node can be set using the general form:

```
autonode.setKeyedPropertyValue(<algorithm>, <property>, <value>)
```

For example:

```
node.setKeyedPropertyValue("neuralnetwork", "method", "MultilayerPerceptron")
```

Algorithm names for the Auto Classifier node are `cart`, `chaid`, `quest`, `c50`, `logreg`, `decisionlist`, `bayesnet`, `discriminant`, `svm` and `knn`.

Algorithm names for the Auto Numeric node are `cart`, `chaid`, `neuralnetwork`, `genlin`, `svm`, `regression`, `linear` and `knn`.

Algorithm names for the Auto Cluster node are `twostep`, `k-means`, and `kohonen`.

Property names are standard as documented for each algorithm node.

Algorithm properties that contain periods or other punctuation must be wrapped in single quotes, for example:

```
node.setKeyedPropertyValue("logreg", "tolerance", "1.0E-5")
```

Multiple values can also be assigned for property, for example:

```
node.setKeyedPropertyValue("decisionlist", "search_direction", ["Up", "Down"])
```

To enable or disable the use of a specific algorithm:

```
node.setPropertyValue("chaid", True)
```

Note: In cases where certain algorithm options are not available in the Auto Classifier node, or when only a single value can be specified rather than a range of values, the same limits apply with scripting as when accessing the node in the standard manner.

autoclusternode properties

The Auto Cluster node estimates and compares clustering models, which identify groups of records that have similar characteristics. The node works in the same manner as other automated modeling nodes, allowing you to experiment with multiple combinations of options in a single modeling pass. Models can be compared using basic measures with which to attempt to filter and rank the usefulness of the cluster models, and provide a measure based on the importance of particular fields.

Example

```
node = stream.create("autocluster", "My node")
node.setPropertyValue("ranking_measure", "Silhouette")
node.setPropertyValue("ranking_dataset", "Training")
node.setPropertyValue("enable_silhouette_limit", True)
node.setPropertyValue("silhouette_limit", 5)
```

Table 1. autoclusternode properties

autoclusternode Properties	Values	Property description
<code>evaluation</code>	<code>field</code>	Note: Auto Cluster node only. Identifies the field for which an importance value will be calculated. Alternatively, can be used to identify how well the cluster differentiates the value of this field and, therefore; how well the model will predict this field.
<code>ranking_measure</code>	<code>Silhouette</code> <code>Num_clusters</code> <code>Size_smallest_cluster</code> <code>Size_largest_cluster</code> <code>Smallest_to_largest_Importance</code>	
<code>ranking_dataset</code>	<code>Training</code> <code>Test</code>	
<code>summary_limit</code>	<code>integer</code>	Number of models to list in the report. Specify an integer between 1 and 100.
<code>enable_silhouette_limit</code>	<code>flag</code>	
<code>silhouette_limit</code>	<code>integer</code>	Integer between 0 and 100.
<code>enable_numberless_limit</code>	<code>flag</code>	

autoclusternode Properties	Values	Property description
number_less_limit	number	Real number between 0.0 and 1.0.
enable_number_greater_limit	flag	
number_greater_limit	number	Integer greater than 0.
enable_smallest_cluster_limit	flag	
smallest_cluster_units	Percentage Counts	
smallest_cluster_limit_percentage	number	
smallest_cluster_limit_count	integer	Integer greater than 0.
enable_largest_cluster_limit	flag	
largest_cluster_units	Percentage Counts	
largest_cluster_limit_percentage	number	
largest_cluster_limit_count	integer	
enable_smallest_largest_limit	flag	
smallest_largest_limit	number	
enable_importance_limit	flag

importance_limit_greater_than	number	Integer between 0 and 100.
importance_limit_less_than	number	Integer between 0 and 100.
<algorithm>	flag	Enables or disables the use of a specific algorithm.
<algorithm>. <property>	string	Sets a property value for a specific algorithm. See the topic Setting Algorithm Properties for more information.

autonumericnode properties

The Auto Numeric node estimates and compares models for continuous numeric range outcomes using a number of different methods. The node works in the same manner as the Auto Classifier node, allowing you to choose the algorithms to use and to experiment with multiple combinations of options in a single modeling pass. Supported algorithms include neural networks, C&R Tree, CHAID, linear regression, generalized linear regression, and support vector machines (SVM). Models can be compared based on correlation, relative error, or number of variables used.

Example

```
node = stream.create("autonumeric", "My node")
node.setPropertyValue("ranking_measure", "Correlation")
node.setPropertyValue("ranking_dataset", "Training")
node.setPropertyValue("enable_correlation_limit", True)
node.setPropertyValue("correlation_limit", 0.8)
node.setPropertyValue("calculate_variable_importance", True)
node.setPropertyValue("neuralnetwork", True)
node.setPropertyValue("chaid", False)
```

stop_after_time_limit	<i>integer</i>	
stop_if_valid_model	<i>flag</i>	
<algorithm>	<i>flag</i>	Enables or disables the use of a specific algorithm.
<algorithm>. <property>	<i>string</i>	Sets a property value for a specific algorithm. See the topic Setting Algorithm Properties for more information.

bayesnetnode properties

The Bayesian Network node enables you to build a probability model by combining observed and recorded evidence with real-world knowledge to establish the likelihood of occurrences. The node focuses on Tree Augmented Naïve Bayes (TAN) and Markov Blanket networks that are primarily used for classification.

Example

```
node = stream.create("bayesnet", "My node")
node.setPropertyValue("continue_training_existing_model", True)
node.setPropertyValue("structure_type", "MarkovBlanket")
node.setPropertyValue("use_feature_selection", True)
# Expert tab
node.setPropertyValue("mode", "Expert")
node.setPropertyValue("all_probabilities", True)
node.setPropertyValue("independence", "Pearson")
```

Table 1. bayesnetnode properties

bayesnetnode Properties	Values	Property description
inputs	<i>[field1 ... fieldN]</i>	Bayesian network models use a single target field, and one or more input fields. Continuous fields are automatically binned. See the topic Common modeling node properties for more information.
continue_training_existing_model	<i>flag</i>	
structure_type	TAN MarkovBlanket	Select the structure to be used when building the Bayesian network.
use_feature_selection	<i>flag</i>	
parameter_learning_method	Likelihood Bayes	Specifies the method used to estimate the conditional probability tables between nodes where the values of the parents are known.
mode	Expert Simple	
missing_values	<i>flag</i>	
all_probabilities	<i>flag</i>	
independence	Likelihood Pearson	Specifies the method used to determine whether paired observations on two variables are independent of each other.
significance_level	<i>number</i>	Specifies the cutoff value for determining independence.
maximal_conditioning_set	<i>number</i>	Sets the maximal number of conditioning variables to be used for independence testing.
inputs_always_selected	<i>[field1 ... fieldN]</i>	Specifies which fields from the dataset are always to be used when building the Bayesian network. Note: The target field is always selected.
maximum_number_inputs	<i>number</i>	Specifies the maximum number of input fields to be used in building the Bayesian network.
calculate_variable_importance	<i>flag</i>	
calculate_raw_propensities	<i>flag</i>	
calculate_adjusted_propensities	<i>flag</i>	
adjusted_propensity_partition	Test Validation	

c50node properties

The C5.0 node builds either a decision tree or a rule set. The model works by splitting the sample based on the field that provides the maximum information gain at each level. The target field must be categorical. Multiple splits into more than two subgroups are allowed.

Example

```
node = stream.create("c50", "My node")
# "Model" tab
node.setPropertyValue("use_model_name", False)
node.setPropertyValue("model_name", "C5_Drug")
node.setPropertyValue("use_partitioned_data", True)
node.setPropertyValue("output_type", "DecisionTree")
node.setPropertyValue("use_xval", True)
node.setPropertyValue("xval_num_folds", 3)
node.setPropertyValue("mode", "Expert")
node.setPropertyValue("favor", "Generality")
node.setPropertyValue("min_child_records", 3)
# "Costs" tab
node.setPropertyValue("use_costs", True)
node.setPropertyValue("costs", [{"drugA": "drugX", 2}])
```

Table 1. c50node properties

c50node Properties	Values	Property description
target	<i>field</i>	C50 models use a single target field and one or more input fields. A weight field can also be specified. See the topic Common modeling node properties for more information.
output_type	DecisionTree RuleSet	
group_symbolics	<i>flag</i>	
use_boost	<i>flag</i>	
boost_num_trials	<i>number</i>	

c50node Properties	Values	Property description
use_xval	flag	
xval_num_folds	number	
mode	Simple Expert	
favor	Accuracy Generality	Favor accuracy or generality.
expected_noise	number	
min_child_records	number	
pruning_severity	number	
use_costs	flag	
costs	structured	This is a structured property. See the example for usage.
use_winning	flag	
use_global_pruning	flag	On (True) by default.
calculate_variable_importance	flag	
calculate_raw_propensities	flag	
calculate_adjusted_propensities	flag	
adjusted_propensity_partition	Test Validation	

carmanode properties

The CARMA model extracts a set of rules from the data without requiring you to specify input or target fields. In contrast to Apriori the CARMA node offers build settings for rule support (support for both antecedent and consequent) rather than just antecedent support. This means that the rules generated can be used for a wider variety of applications—for example, to find a list of products or services (antecedents) whose consequent is the item that you want to promote this holiday season.

Example

```
node = stream.create("carma", "My node")
# "Fields" tab
node.setPropertyValue("custom_fields", True)
node.setPropertyValue("use_transactional_data", True)
node.setPropertyValue("inputs", ["BP", "Cholesterol", "Drug"])
node.setPropertyValue("partition", "Test")
# "Model" tab
node.setPropertyValue("use_model_name", False)
node.setPropertyValue("model_name", "age_bp_drug")
node.setPropertyValue("use_partitioned_data", False)
node.setPropertyValue("min_supp", 10.0)
node.setPropertyValue("min_conf", 30.0)
node.setPropertyValue("max_size", 5)
# Expert Options
node.setPropertyValue("mode", "Expert")
node.setPropertyValue("use_pruning", True)
node.setPropertyValue("pruning_value", 300)
node.setPropertyValue("vary_support", True)
node.setPropertyValue("estimated_transactions", 30)
node.setPropertyValue("rules_without_antecedents", True)
```

Table 1. carmanode properties

carmanode Properties	Values	Property description
inputs	[field1 ... fieldn]	CARMA models use a list of input fields, but no target. Weight and frequency fields are not used. See the topic Common modeling node properties for more information.
id_field	field	Field used as the ID field for model building.
contiguous	flag	Used to specify whether IDs in the ID field are contiguous.
use_transactional_data	flag	
content_field	field	
min_supp	number(percent)	Relates to rule support rather than antecedent support. The default is 20%.
min_conf	number(percent)	The default is 20%.
max_size	number	The default is 10.
mode	Simple Expert	The default is Simple.

cartnode Properties	Values	Property description
<code>exclude_multiple</code>	<code>flag</code>	Excludes rules with multiple consequents. The default is <code>False</code> .
<code>use_pruning</code>	<code>flag</code>	The default is <code>False</code> .
<code>pruning_value</code>	<code>number</code>	The default is 500.
<code>vary_support</code>	<code>flag</code>	
<code>estimated_transactions</code>	<code>integer</code>	
<code>rules_without_ancestors</code>	<code>flag</code>	

cartnode properties

	The Classification and Regression (C&R) Tree node generates a decision tree that allows you to predict or classify future observations. The method uses recursive partitioning to split the training records into segments by minimizing the impurity at each step, where a node in the tree is considered “pure” if 100% of cases in the node fall into a specific category of the target field. Target and input fields can be numeric ranges or categorical (nominal, ordinal, or flags); all splits are binary (only two subgroups).
---	--

Example

```
node = stream.createAt("cart", "My node", 200, 100)
# "Fields" tab
node.setPropertyValue("custom_fields", True)
node.setPropertyValue("target", "Drug")
node.setPropertyValue("inputs", ["Age", "BP", "Cholesterol"])
# "Build Options" tab, "Objective" panel
node.setPropertyValue("model_output_type", "InteractiveBuilder")
node.setPropertyValue("use_tree_directives", True)
node.setPropertyValue("tree_directives", """Grow Node Index 0 Children 1 2
Grow Node Index 2 Children 3 4""")
# "Build Options" tab, "Basics" panel
node.setPropertyValue("prune_tree", False)
node.setPropertyValue("use_std_err_rule", True)
node.setPropertyValue("std_err_multiplier", 3.0)
node.setPropertyValue("max_surrogates", 7)
# "Build Options" tab, "Stopping Rules" panel
node.setPropertyValue("use_percentage", True)
node.setPropertyValue("min_parent_records_pc", 5)
node.setPropertyValue("min_child_records_pc", 3)
# "Build Options" tab, "Advanced" panel
node.setPropertyValue("min_impurity", 0.0003)
node.setPropertyValue("impurity_measure", "Twoing")
# "Model Options" tab
node.setPropertyValue("use_model_name", True)
node.setPropertyValue("model_name", "Cart_Drug")
```

Table 1. cartnode properties

cartnode Properties	Values	Property description
<code>target</code>	<code>field</code>	C&R Tree models require a single target and one or more input fields. A frequency field can also be specified. See the topic Common modeling node properties for more information.
<code>continue_training_existing_model</code>	<code>flag</code>	
<code>objective</code>	<code>StandardBoosting</code> <code>Bagging psm</code>	<code>psm</code> is used for very large datasets, and requires a Server connection.
<code>model_output_type</code>	<code>Single</code> <code>InteractiveBuilder</code>	
<code>use_tree_directives</code>	<code>flag</code>	
<code>tree_directives</code>	<code>string</code>	Specify directives for growing the tree. Directives can be wrapped in triple quotes to avoid escaping newlines or quotes. Note that directives may be highly sensitive to minor changes in data or modeling options and may not generalize to other datasets. See the example for usage.
<code>use_max_depth</code>	<code>Default</code> <code>Custom</code>	
<code>max_depth</code>	<code>integer</code>	Maximum tree depth, from 0 to 1000. Used only if <code>use_max_depth = Custom</code> .

cartnode Properties	Values	Property description
<code>prune_tree</code>	<code>flag</code>	Prune tree to avoid overfitting.
<code>use_std_err</code>	<code>flag</code>	Use maximum difference in risk (in Standard Errors).
<code>std_err_mult_iplier</code>	<code>number</code>	Maximum difference.
<code>max_surrogates</code>	<code>number</code>	Maximum surrogates.
<code>use_percentage</code>	<code>flag</code>	
<code>min_parent_records_pc</code>	<code>number</code>	
<code>min_child_records_pc</code>	<code>number</code>	
<code>min_parent_records_abs</code>	<code>number</code>	
<code>min_child_records_abs</code>	<code>number</code>	
<code>use_costs</code>	<code>flag</code>	
<code>costs</code>	<code>structured</code>	Structured property.
<code>priors</code>	<code>Data Equal</code> <code>Custom</code>	
<code>custom_priors</code>	<code>structured</code>	Structured property.
<code>adjust_priors</code>	<code>flag</code>	
<code>trails</code>	<code>number</code>	Number of component models for boosting or bagging.
<code>set_ensemble_method</code>	<code>Voting</code> <code>HighestProbability</code> <code>HighestMeanProbability</code>	Default combining rule for categorical targets.
<code>range_ensemble_method</code>	<code>Mean</code> <code>Median</code>	Default combining rule for continuous targets.
<code>large_boost</code>	<code>flag</code>	Apply boosting to very large data sets.
<code>min_impurity</code>	<code>number</code>	
<code>impurity_measure</code>	<code>Gini</code> <code>Twoing</code> <code>Ordered</code>	
<code>train_pct</code>	<code>number</code>	Overfit prevention set.
<code>set_random_seed</code>	<code>flag</code>	Replicate results option.
<code>seed</code>	<code>number</code>	
<code>calculate_variable_importance</code>	<code>flag</code>	
<code>calculate_raw_propensities</code>	<code>flag</code>	
<code>calculate_adjusted_propensities</code>	<code>flag</code>	
<code>adjusted_propensity_partition</code>	<code>Test Validation</code>	

chaidnode properties

	The CHAID node generates decision trees using chi-square statistics to identify optimal splits. Unlike the C&R Tree and QUEST nodes, CHAID can generate nonbinary trees, meaning that some splits have more than two branches. Target and input fields can be numeric range (continuous) or categorical. Exhaustive CHAID is a modification of CHAID that does a more thorough job of examining all possible splits but takes longer to compute.
---	--

Example

```

filenode = stream.createAt("variablefile", "My node", 100, 100)
filenode.setPropertyValue("full_filename", "$CLEO_DEMOS/DRUG1n")
node = stream.createAt("chaid", "My node", 200, 100)
stream.link(filenode, node)

node.setPropertyValue("custom_fields", True)

```

```

node.setPropertyValue("target", "Drug")
node.setPropertyValue("inputs", ["Age", "Na", "K", "Cholesterol", "BP"])
node.setPropertyValue("use_model_name", True)
node.setPropertyValue("model_name", "CHAID")
node.setPropertyValue("method", "Chaid")
node.setPropertyValue("model_output_type", "InteractiveBuilder")
node.setPropertyValue("use_tree_directives", True)
node.setPropertyValue("tree_directives", "Test")
node.setPropertyValue("split_alpha", 0.03)
node.setPropertyValue("merge_alpha", 0.04)
node.setPropertyValue("chi_square", "Pearson")
node.setPropertyValue("use_percentage", False)
node.setPropertyValue("min_parent_records_abs", 40)
node.setPropertyValue("min_child_records_abs", 30)
node.setPropertyValue("epsilon", 0.003)
node.setPropertyValue("max_iterations", 75)
node.setPropertyValue("split_merged_categories", True)
node.setPropertyValue("bonferroni_adjustment", True)

```

coxregnode properties

	The Cox regression node enables you to build a survival model for time-to-event data in the presence of censored records. The model produces a survival function that predicts the probability that the event of interest has occurred at a given time (t) for given values of the input variables.
---	---

Example

```
node = stream.create("coxreg", "My node")
node.setPropertyValue("survival_time", "tenure")
node.setPropertyValue("method", "BackwardsStepwise")
# Expert tab
node.setPropertyValue("mode", "Expert")
node.setPropertyValue("removal_criterion", "Conditional")
node.setPropertyValue("survival", True)
```

Table 1. coxregnode properties

coxregnode Properties	Values	Property description

coxregnode Properties	Values	Property description
separate_line	<i>field</i>	
value	<i>number or string</i>	If no value is specified for a field, the default option "Mean" will be used for that field.

decisionlistnode properties

	The Decision List node identifies subgroups, or segments, that show a higher or lower likelihood of a given binary outcome relative to the overall population. For example, you might look for customers who are unlikely to churn or are most likely to respond favorably to a campaign. You can incorporate your business knowledge into the model by adding your own custom segments and previewing alternative models side by side to compare the results. Decision List models consist of a list of rules in which each rule has a condition and an outcome. Rules are applied in order, and the first rule that matches determines the outcome.
---	---

Example

```
node = stream.create("decisionlist", "My node")
node.setPropertyValue("search_direction", "Down")
node.setPropertyValue("target_value", 1)
node.setPropertyValue("max_rules", 4)
node.setPropertyValue("min_group_size_pct", 15)
```

Table 1. decisionlistnode properties

decisionlistnode Properties	Values	Property description
target	<i>field</i>	Decision List models use a single target and one or more input fields. A frequency field can also be specified. See the topic Common modeling node properties for more information.
model_output_type	<i>Model InteractiveBuilder</i>	
search_direction	<i>Up Down</i>	Relates to finding segments; where Up is the equivalent of High Probability, and Down is the equivalent of Low Probability..
target_value	<i>string</i>	If not specified, will assume true value for flags.
max_rules	<i>integer</i>	The maximum number of segments excluding the remainder.
min_group_size	<i>integer</i>	Minimum segment size.
min_group_size_pct	<i>number</i>	Minimum segment size as a percentage.
confidence_level	<i>number</i>	Minimum threshold that an input field has to improve the likelihood of response (give lift), to make it worth adding to a segment definition.
max_segments_per_rule	<i>integer</i>	
mode	<i>Simple Expert</i>	
bin_method	<i>EqualWidth EqualCount</i>	
bin_count	<i>number</i>	
max_models_per_cycle	<i>integer</i>	Search width for lists.
max_rules_per_cycle	<i>integer</i>	Search width for segment rules.
segment_growth	<i>number</i>	
include_missing	<i>flag</i>	
final_results_only	<i>flag</i>	
reuse_fields	<i>flag</i>	Allows attributes (input fields which appear in rules) to be re-used.
max_alternatives	<i>integer</i>	
calculate_raw_propensities	<i>flag</i>	
calculate_adjusted_propensities	<i>flag</i>	
adjusted_propensity_partition	<i>Test Validation</i>	

discriminantnode properties

	Discriminant analysis makes more stringent assumptions than logistic regression but can be a valuable alternative or supplement to a logistic regression analysis when those assumptions are met.
---	---

Example

```
node = stream.create("discriminant", "My node")
node.setPropertyValue("target", "custcat")
node.setPropertyValue("use_partitioned_data", False)
node.setPropertyValue("method", "Stepwise")
```

extensionmodelnode Properties	Values	Property description
<code>syntax_type</code>	<code>R Python</code>	Specify which script runs – R or Python (R is the default).
<code>r_build_syntax</code>	<code>string</code>	The R scripting syntax for model building.
<code>r_score_syntax</code>	<code>string</code>	The R scripting syntax for model scoring.
<code>python_build_syntax</code>	<code>string</code>	The Python scripting syntax for model building.
<code>python_score_syntax</code>	<code>string</code>	The Python scripting syntax for model scoring.
<code>convert_flags</code>	<code>StringsAndDouble s LogicalValues</code>	Option to convert flag fields.
<code>convert_missing</code>	<code>flag</code>	Option to convert missing values to R NA value.
<code>convert_datetime</code>	<code>flag</code>	Option to convert variables with date or datetime formats to R date/time formats.
<code>convert_datetime_class</code>	<code>POSIXct POSIXlt</code>	Options to specify to what format variables with date or datetime formats are converted.
<code>output_html</code>	<code>flag</code>	Option to display graphs on a tab in the R model nugget.

extensionmodelnode Properties	Values	Property description
output_text	<i>flag</i>	Option to write R console text output to a tab in the R model nugget.

factornode properties

	The PCA/Factor node provides powerful data-reduction techniques to reduce the complexity of your data. Principal components analysis (PCA) finds linear combinations of the input fields that do the best job of capturing the variance in the entire set of fields, where the components are orthogonal (perpendicular) to each other. Factor analysis attempts to identify underlying factors that explain the pattern of correlations within a set of observed fields. For both approaches, the goal is to find a small number of derived fields that effectively summarizes the information in the original set of fields.
---	--

Example

```
node = stream.create("factor", "My node")
# "Fields" tab
node.setPropertyValue("custom_fields", True)
node.setPropertyValue("inputs", ["BP", "Na", "K"])
node.setPropertyValue("partition", "Test")
# "Model" tab
node.setPropertyValue("use_model_name", True)
node.setPropertyValue("model_name", "Factor_Age")
node.setPropertyValue("use_partitioned_data", False)

kappa	number	If you select Promax as your rotation data type, you can specify a value for kappa . If you do not specify a value, the default value for kappa is used.
sort_values	flag	
hide_values	flag	
hide_below	number	

featureselectionnode properties

The Feature Selection node screens input fields for removal based on a set of criteria (such as the percentage of missing values); it then ranks the importance of remaining inputs relative to a specified target. For example, given a data set with hundreds of potential inputs, which are most likely to be useful in modeling patient outcomes?

Example

```
node = stream.create("featureselection", "My node")
node.setPropertyValue("screen_single_category", True)
node.setPropertyValue("max_single_category", 95)
node.setPropertyValue("screen_missing_values", True)
node.setPropertyValue("max_missing_values", 80)
node.setPropertyValue("criteria", "Likelihood")
node.setPropertyValue("unimportant_below", 0.8)
node.setPropertyValue("important_above", 0.9)
node.setPropertyValue("important_label", "Check Me Out!")
node.setPropertyValue("selection_mode", "TopN")
node.setPropertyValue("top_n", 15)
```

For a more detailed example that creates and applies a Feature Selection model, see [in](#).

Table 1. featureselectionnode properties

featureselectionnode Properties	Values	Property description
<code>target</code>	<code>field</code>	Feature Selection models rank predictors relative to the specified target. Weight and frequency fields are not used. See the topic Common modeling node properties for more information.
<code>screen_single_category</code>	<code>flag</code>	If <code>True</code> , screens fields that have too many records falling into the same category relative to the total number of records.
<code>max_single_category</code>	<code>number</code>	Specifies the threshold used when <code>screen_single_category</code> is <code>True</code> .
<code>screen_missing_values</code>	<code>flag</code>	If <code>True</code> , screens fields with too many missing values, expressed as a percentage of the total number of records.
<code>max_missing_values</code>	<code>number</code>	
<code>screen_num_categories</code>	<code>flag</code>	If <code>True</code> , screens fields with too many categories relative to the total number of records.
<code>max_num_categories</code>	<code>number</code>	
<code>screen_std_dev</code>	<code>flag</code>	If <code>True</code> , screens fields with a standard deviation of less than or equal to the specified minimum.
<code>min_std_dev</code>	<code>number</code>	
<code>screen_coeff_of_var</code>	<code>flag</code>	If <code>True</code> , screens fields with a coefficient of variance less than or equal to the specified minimum.
<code>min_coeff_of_var</code>	<code>number</code>	
<code>criteria</code>	<code>Pearson Likelihood</code> <code>Cramers V Lambda</code>	When ranking categorical predictors against a categorical target, specifies the measure on which the importance value is based.
<code>unimportant_below</code>	<code>number</code>	Specifies the threshold p values used to rank variables as important, marginal, or unimportant. Accepts values from 0.0 to 1.0.
<code>important_above</code>	<code>number</code>	Accepts values from 0.0 to 1.0.
<code>unimportant_label</code>	<code>string</code>	Specifies the label for the unimportant ranking.
<code>marginal_label</code>	<code>string</code>	
<code>important_label</code>	<code>string</code>	
<code>selection_mode</code>	<code>ImportanceLevel</code> <code>ImportanceValue</code> <code>TopN</code>	
<code>select_important</code>	<code>flag</code>	When <code>selection_mode</code> is set to <code>ImportanceLevel</code> , specifies whether to select important fields.
<code>select_marginal</code>	<code>flag</code>	When <code>selection_mode</code> is set to <code>ImportanceLevel</code> , specifies whether to select marginal fields.
<code>select_unimportant</code>	<code>flag</code>	When <code>selection_mode</code> is set to <code>ImportanceLevel</code> , specifies whether to select unimportant fields.
<code>importance_value</code>	<code>number</code>	When <code>selection_mode</code> is set to <code>ImportanceValue</code> , specifies the cutoff value to use. Accepts values from 0 to 100.

featureselecti onnode Properties	Values	Property description
top_n	<i>integer</i>	When selection_mode is set to TopN , specifies the cutoff value to use. Accepts values from 0 to 1000.

genlinnode properties

	The Generalized Linear model expands the general linear model so that the dependent variable is linearly related to the factors and covariates through a specified link function. Moreover, the model allows for the dependent variable to have a non-normal distribution. It covers the functionality of a wide number of statistical models, including linear regression, logistic regression, loglinear models for count data, and interval-censored survival models.
---	--

Example

```
node = stream.create("genlin", "My node")
node.setPropertyValue("model_type", "MainAndAllTwoWayEffects")
node.setPropertyValue("offset_type", "Variable")
node.setPropertyValue("offset_field", "Claimant")
```

Table 1. genlinnode properties

glmmnode properties

	A generalized linear mixed model (GLMM) extends the linear model so that the target can have a non-normal distribution, is linearly related to the factors and covariates via a specified link function, and so that the observations can be correlated. Generalized linear mixed models cover a wide variety of models, from simple linear regression to complex multilevel models for non-normal longitudinal data.
---	---

Table 1. glmmnode properties

glmmnode Properties	Values	Property description
residual_sub ject_spec	structured	The combination of values of the specified categorical fields that uniquely define subjects within the data set
repeated_me asures	structured	Fields used to identify repeated observations.
residual_gro up_spec	[field1 ... fieldN]	Fields that define independent sets of repeated effects covariance parameters.
residual_cov ariance_type	Diagonal AR1 ARMA11 COMPOUND_SYMME TRY IDENTITY TOEPLITZ UNSTRUCTURED VARIANCE_COMPONENTS	Specifies covariance structure for residuals.
custom_targe t	flag	Indicates whether to use target defined in upstream node (false) or custom target specified by target_field (true).
target_field	field	Field to use as target if custom_target is true .
use_trials	flag	Indicates whether additional field or value specifying number of trials is to be used when target response is a number of events occurring in a set of trials. Default is false .
use_field_or _value	FieldValue	Indicates whether field (default) or value is used to specify number of trials.
trials_field	field	Field to use to specify number of trials.
trials_value	integer	Value to use to specify number of trials. If specified, minimum value is 1.
use_custom_t arget_referen ce	flag	Indicates whether custom reference category is to be used for a categorical target. Default is false .
target_refer ence_value	string	Reference category to use if use_custom_target_reference is true .
dist_link_co mbination	Nominal Logit Gamma Log Binomial Logit Poisson Log Binomial Probit Negbin Log Binomial LogC Custom	Common models for distribution of values for target. Choose Custom to specify a distribution from the list provided by target_distribution .
target_distr ibution	Normal Binomial Multinomial Gamma Inverse NegativeBinomial Poisson	Distribution of values for target when dist_link_combination is Custom .
link_funcatio n_type	Identity LogC Log CLOGLOG Logit NLOGLOG PROBIT POWER CAUCHIT	Link function to relate target values to predictors. If target_distribution is Binomial you can use any of the listed link functions. If target_distribution is Multinomial you can use CLOGLOG , CAUCHIT , LOGIT , NLOGLOG , or PROBIT . If target_distribution is anything other than Binomial or Multinomial you can use IDENTITY , LOG , or POWER .
link_funcatio n_param	number	Link function parameter value to use. Only applicable if normal_link_function or link_function_type is POWER .

glmmnode Properties	Values	Property description
<code>use_predefined_inputs</code>	<code>flag</code>	Indicates whether fixed effect fields are to be those defined upstream as input fields (<code>true</code>) or those from <code>fixed_effects_list</code> (<code>false</code>). Default is <code>false</code> .
<code>fixed_effects_list</code>	<code>structured</code>	If <code>use_predefined_inputs</code> is <code>false</code> , specifies the input fields to use as fixed effect fields.
<code>use_intercept</code>	<code>flag</code>	If <code>true</code> (default), includes the intercept in the model.
<code>random_effecs_list</code>	<code>structured</code>	List of fields to specify as random effects.
<code>regression_weight_field</code>	<code>field</code>	Field to use as analysis weight field.
<code>use_offset</code>	<code>None offset_value offset_field</code>	Indicates how offset is specified. Value <code>None</code> means no offset is used.
<code>offset_value</code>	<code>number</code>	Value to use for offset if <code>use_offset</code> is set to <code>offset_value</code> .
<code>offset_field</code>	<code>field</code>	Field to use for offset value if <code>use_offset</code> is set to <code>offset_field</code> .
<code>target_categorical_order</code>	<code>Ascending Descending Data</code>	Sorting order for categorical targets. Value <code>Data</code> specifies using the sort order found in the data. Default is <code>Ascending</code> .
<code>inputs_categorical_order</code>	<code>Ascending Descending Data</code>	Sorting order for categorical predictors. Value <code>Data</code> specifies using the sort order found in the data. Default is <code>Ascending</code> .
<code>max_iterations</code>	<code>integer</code>	Maximum number of iterations the algorithm will perform. A non-negative integer; default is 100.
<code>confidence_level</code>	<code>integer</code>	Confidence level used to compute interval estimates of the model coefficients. A non-negative integer; maximum is 100, default is 95.
<code>degrees_of_freedom_method</code>	<code>Fixed Varied</code>	Specifies how degrees of freedom are computed for significance test.
<code>test_fixed_effects_coefficients</code>	<code>Model Robust</code>	Method for computing the parameter estimates covariance matrix.
<code>use_p_converge</code>	<code>flag</code>	Option for parameter convergence.
<code>p_converge</code>	<code>number</code>	Blank, or any positive value.
<code>p_converge_type</code>	<code>Absolute Relative</code>	
<code>use_l_converge</code>	<code>flag</code>	Option for log-likelihood convergence.
<code>l_converge</code>	<code>number</code>	Blank, or any positive value.
<code>l_converge_type</code>	<code>Absolute Relative</code>	
<code>use_h_converge</code>	<code>flag</code>	Option for Hessian convergence.
<code>h_converge</code>	<code>number</code>	Blank, or any positive value.
<code>h_converge_type</code>	<code>Absolute Relative</code>	
<code>max_fisher_steps</code>	<code>integer</code>	
<code>singularity_tolerance</code>	<code>number</code>	
<code>use_model_name</code>	<code>flag</code>	Indicates whether to specify a custom name for the model (<code>true</code>) or to use the system-generated name (<code>false</code>). Default is <code>false</code> .
<code>model_name</code>	<code>string</code>	If <code>use_model_name</code> is <code>true</code> , specifies the model name to use.
<code>confidence</code>	<code>onProbability onIncrease</code>	Basis for computing scoring confidence value: highest predicted probability, or difference between highest and second highest predicted probabilities.
<code>score_categorical_probabilities</code>	<code>flag</code>	If <code>true</code> , produces predicted probabilities for categorical targets. Default is <code>false</code> .
<code>max_categories</code>	<code>integer</code>	If <code>score_categorical_probabilities</code> is <code>true</code> , specifies maximum number of categories to save.
<code>score_propensity</code>	<code>flag</code>	If <code>true</code> , produces propensity scores for flag target fields that indicate likelihood of "true" outcome for field.
<code>emeans</code>	<code>structure</code>	For each categorical field from the fixed effects list, specifies whether to produce estimated marginal means.
<code>covariance_list</code>	<code>structure</code>	For each continuous field from the fixed effects list, specifies whether to use the mean or a custom value when computing estimated marginal means.

glmmnode Properties	Values	Property description
mean_scale	Original Transformed	Specifies whether to compute estimated marginal means based on the original scale of the target (default) or on the link function transformation.
comparison_adjustment_method	LSD SEQBONFERRONI SEQSIDAK	Adjustment method to use when performing hypothesis tests with multiple contrasts.

gle properties

A GLE extends the linear model so that the target can have a non-normal distribution, is linearly related to the factors and covariates via a specified link function, and so that the observations can be correlated. Generalized linear mixed models cover a wide variety of models, from simple linear regression to complex multilevel models for non-normal longitudinal data.

Table 1. gle properties

gle Properties	Values	Property description
custom_target	flag	Indicates whether to use target defined in upstream node (<code>false</code>) or custom target specified by <code>target_field</code> (<code>true</code>).
target_field	field	Field to use as target if <code>custom_target</code> is <code>true</code> .
use_trials	flag	Indicates whether additional field or value specifying number of trials is to be used when target response is a number of events occurring in a set of trials. Default is <code>false</code> .
use_trials_field_or_value	FieldValue	Indicates whether field (default) or value is used to specify number of trials.
trials_field	field	Field to use to specify number of trials.
trials_value	integer	Value to use to specify number of trials. If specified, minimum value is 1.
use_custom_target_reference	flag	Indicates whether custom reference category is to be used for a categorical target. Default is <code>false</code> .
target_reference_value	string	Reference category to use if <code>use_custom_target_reference</code> is <code>true</code> .
dist_link_combination	NormalIdentity GammaLog PoissonLog NegbinLog TweedieIdentity NominalLogit BinomialLogit BinomialProbit BinomialLogC CUSTOM	Common models for distribution of values for target. link_function_param	number	Tweedie parameter value to use. Only applicable if <code>normal_link_function</code> or <code>link_function_type</code> is <code>POWER</code> .
tweedie_param	number	Link function parameter value to use. Only applicable if <code>dist_link_combination</code> is set to <code>TweedieIdentity</code> , or <code>link_function_type</code> is <code>TWEEDIE</code> .
use_predefined_inputs	flag	Indicates whether model effect fields are to be those defined upstream as input fields (<code>true</code>) or those from <code>fixed_effects_list</code> (<code>false</code>).
model_effect_list	structured	If <code>use_predefined_inputs</code> is <code>false</code> , specifies the input fields to use as model effect fields.
use_intercept	flag	If <code>true</code> (default), includes the intercept in the model.
regression_weight_field	field	Field to use as analysis weight field.
use_offset	None Value Variable	Indicates how offset is specified. Value <code>None</code> means no offset is used.
offset_value	number	Value to use for offset if <code>use_offset</code> is set to <code>offset_value</code> .
offset_field	field	Field to use for offset value if <code>use_offset</code> is set to <code>offset_field</code> .

gle Properties	Values	Property description
target_categ ory_order	Ascending Descending	Sorting order for categorical targets. Default is Ascending .
inputs_categ ory_order	Ascending Descending	Sorting order for categorical predictors. Default is Ascending .
max_iterations	integer	Maximum number of iterations the algorithm will perform. A non-negative integer; default is 100.
confidence_level	number	Confidence level used to compute interval estimates of the model coefficients. A non-negative integer; maximum is 100, default is 95.
test_fixed_effects_coefficients	Model Robust	Method for computing the parameter estimates covariance matrix.
detect_outliers	flag	When true the algorithm finds influential outliers for all distributions except multinomial distribution.
conduct_trend_analysis	flag	When true the algorithm conducts trend analysis for the scatter plot.
estimation_method	FISHER_SCORING NEWTON_RAPHSON HYBRID	Specify the maximum likelihood estimation algorithm.
max_fisher_iterations	integer	If using the FISHER_SCORING estimation_method , the maximum number of iterations. Minimum 0, maximum 20.
scale_parameter_method	MLE FIXED DEVIANCE PEARSON_CHISQUARE	Specify the method to be used for the estimation of the scale parameter.
scale_value	number	Only available if scale_parameter_method is set to Fixed .
negative_binomial_method	MLE FIXED	Specify the method to be for the estimation of the negative binomial ancillary parameter.
negative_binomial_value	number	Only available if negative_binomial_method is set to Fixed .
non_neg_least_squares	flag	Whether to perform non-negative least squares. Default is false .
use_p_converge	flag	Option for parameter convergence.
p_converge	number	Blank, or any positive value.
p_converge_type	flag	True = Absolute, False = Relative
use_l_converge	flag	Option for log-likelihood convergence.
l_converge	number	Blank, or any positive value.
l_converge_type	flag	True = Absolute, False = Relative
use_h_converge	flag	Option for Hessian convergence.
h_converge	number	Blank, or any positive value.
h_converge_type	flag	True = Absolute, False = Relative
max_iterations	integer	Maximum number of iterations the algorithm will perform. A non-negative integer; default is 100.
sing_tolerance	integer	
use_model_selection	flag	Enables the parameter threshold and model selection method controls..
method	LASSO ELASTIC_NET FORWARD_STEPWISE RIDGE	Determines the model selection method, or if using Ridge the regularization method, used.
detect_two_way_interactions	flag	When True the model will automatically detect two-way interactions between input fields. This control should only be enabled if the model is main effects only (that is, where the user has not created any higher order effects) and if the method selected is Forward Stepwise, Lasso, or Elastic Net.
automatic_penalty_params	flag	Only available if model selection method is Lasso or Elastic Net. Use this function to enter penalty parameters associated with either the Lasso or Elastic Net variable selection methods. If True , default values are used. If False , the penalty parameters are enabled custom values can be entered.
lasso_penalty_param	number	Only available if model selection method is Lasso or Elastic Net and automatic_penalty_params is False . Specify the penalty parameter value for Lasso.

gle Properties	Values	Property description
<code>elastic_net_penalty_params1</code>	<code>number</code>	Only available if model selection <code>method</code> is Lasso or Elastic Net and <code>automatic_penalty_params</code> is <code>False</code> . Specify the penalty parameter value for Elastic Net parameter 1.
<code>elastic_net_penalty_params2</code>	<code>number</code>	Only available if model selection <code>method</code> is Lasso or Elastic Net and <code>automatic_penalty_params</code> is <code>False</code> . Specify the penalty parameter value for Elastic Net parameter 2.
<code>probability_entry</code>	<code>number</code>	Only available if the <code>method</code> selected is Forward Stepwise. Specify the significance level of the f statistic criterion for effect inclusion.
<code>probability_removal</code>	<code>number</code>	Only available if the <code>method</code> selected is Forward Stepwise. Specify the significance level of the f statistic criterion for effect removal.
<code>use_max_effects</code>	<code>flag</code>	Only available if the <code>method</code> selected is Forward Stepwise. Enables the <code>max_effects</code> control. When <code>False</code> the default number of effects included should equal the total number of effects supplied to the model, minus the intercept.
<code>max_effects</code>	<code>integer</code>	Specify the maximum number of effects when using the forward stepwise building method.
<code>use_max_steps</code>	<code>flag</code>	Enables the <code>max_steps</code> control. When <code>False</code> the default number of steps should equal three times the number of effects supplied to the model, excluding the intercept.
<code>max_steps</code>	<code>integer</code>	Specify the maximum number of steps to be taken when using the Forward Stepwise building <code>method</code> .
<code>use_model_name</code>	<code>flag</code>	Indicates whether to specify a custom name for the model (<code>true</code>) or to use the system-generated name (<code>false</code>). Default is <code>false</code> .
<code>model_name</code>	<code>string</code>	If <code>use_model_name</code> is <code>true</code> , specifies the model name to use.
<code>usePI</code>	<code>flag</code>	If <code>true</code> , predictor importance is calculated..

kmeansnode properties

The K-Means node clusters the data set into distinct groups (or clusters). The method defines a fixed number of clusters, iteratively assigns records to clusters, and adjusts the cluster centers until further refinement can no longer improve the model. Instead of trying to predict an outcome, k-means uses a process known as unsupervised learning to uncover patterns in the set of input fields.

Example

```
node = stream.create("kmeans", "My node")
# "Fields" tab
node.setPropertyValue("custom_fields", True)
node.setPropertyValue("inputs", ["Cholesterol", "BP", "Drug", "Na", "K", "Age"])
# "Model" tab
node.setPropertyValue("use_model_name", True)
node.setPropertyValue("model_name", "Kmeans_allinputs")
node.setPropertyValue("num_clusters", 9)
node.setPropertyValue("gen_distance", True)
node.setPropertyValue("cluster_label", "Number")
node.setPropertyValue("label_prefix", "Kmeans_")
node.setPropertyValue("optimize", "Speed")
# "Expert" tab
node.setPropertyValue("mode", "Expert")
node.setPropertyValue("stop_on", "Custom")
node.setPropertyValue("max_iterations", 10)
node.setPropertyValue("tolerance", 3.0)
node.setPropertyValue("encoding_value", 0.3)
```

Table 1. kmeansnode properties

kmeansnode Properties	Values	Property description
<code>inputs</code>	<code>[field1 ... fieldN]</code>	K-means models perform cluster analysis on a set of input fields but do not use a target field. Weight and frequency fields are not used. See the topic Common modeling node properties for more information.
<code>num_clusters</code>	<code>number</code>	
<code>gen_distance</code>	<code>flag</code>	
<code>cluster_label</code>	<code>String</code> <code>Number</code>	
<code>label_prefix</code>	<code>string</code>	
<code>mode</code>	<code>Simple</code> <code>Expert</code>	

kmeansnode Properties	Values	Property description
stop_on	Default Custom	
max_iterations	number	
tolerance	number	
encoding_value	number	
optimize	Speed Memory	Use to specify whether model building should be optimized for speed or for memory.

kmeansasnode properties

K-Means is one of the most commonly used clustering algorithms. It clusters data points into a predefined number of clusters. The K-Means-AS node in SPSS® Modeler is implemented in Spark. For details about K-Means algorithms, see <https://spark.apache.org/docs/2.2.0/ml-clustering.html>. Note that the K-Means-AS node performs one-hot encoding automatically for categorical variables.

Table 1. kmeansasnode properties

kmeansasnode Properties	Values	Property description
roleUse	string	Specify predefined to use predefined roles, or custom to use custom field assignments. Default is predefined .
autoModel	Boolean	Specify true to use the default name (\$S-prediction) for the new generated scoring field, or false to use a custom name. Default is true .
features	field	List of the field names for input when the roleUse property is set to custom .
name	string	The name of the new generated scoring field when the autoModel property is set to false .
clustersNum	integer	The number of clusters to create. Default is 5.
initMode	string	The initialization algorithm. Possible values are k-means or random . Default is k-means .
initSteps	integer	The number of initialization steps when initMode is set to k-means . Default is 2.
advancedSettings	Boolean	Specify true to make the following four properties available. Default is false .
maxIteration	integer	Maximum number of iterations for clustering. Default is 20.
tolerance	string	The tolerance to stop the iterations. Possible settings are 1.0E-1 , 1.0E-2 , ..., 1.0E-6 . Default is 1.0E-4 .
setSeed	Boolean	Specify true to use a custom random seed. Default is false .
randomSeed	integer	The custom random seed when the setSeed property is true .

knnnode properties

The *k*-Nearest Neighbor (KNN) node associates a new case with the category or value of the *k* objects nearest to it in the predictor space, where *k* is an integer. Similar cases are near each other and dissimilar cases are distant from each other.

Example

```
node = stream.create("knn", "My node")
# Objectives tab
node.setPropertyValue("objective", "Custom")
# Settings tab - Neighbors panel
node.setPropertyValue("automatic_k_selection", False)
node.setPropertyValue("fixed_k", 2)
node.setPropertyValue("weight_by_importance", True)
# Settings tab - Analyze panel
node.setPropertyValue("save_distances", True)
```

Table 1. knnnnode properties

knnnode Properties	Values	Property description
analysis	PredictTarget IdentifyNeighbors	
objective	Balance Speed Accuracy Custom	
normalize_ranges	flag	
use_case_labels	flag	Check box to enable next option.
case_labels_field	field	

knnnode Properties	Values	Property description
identify_focal_cases	flag	Check box to enable next option.
focal_cases_field	field	
automatic_k_selection	flag	
fixed_k	integer	Enabled only if automatic_k_selection is False.
minimum_k	integer	Enabled only if automatic_k_selection is True.
maximum_k	integer	
distance_computation	Euclidean CityBlock	
weight_by_importance	flag	
range_predictions	Mean Median	
perform_feature_selection	flag	
forced_entry_inputs	[field1 ... fieldN]	
stop_on_error_ratio	flag	
number_to_select	integer	
minimum_change	number	
validation_fold_assign_by_field	flag	
number_of_folds	integer	Enabled only if validation_fold_assign_by_field is False
set_random_seed	flag	
random_seed	number	
folds_field	field	Enabled only if validation_fold_assign_by_field is True
all_probabilities	flag	
save_distances	flag	
calculate_raw_propensities	flag	
calculate_adjusted_propensities	flag	
adjusted_propensity_partition	Test Validation	

kohonennode properties

The Kohonen node generates a type of neural network that can be used to cluster the data set into distinct groups. When the network is fully trained, records that are similar should be close together on the output map, while records that are different will be far apart. You can look at the number of observations captured by each unit in the model nugget to identify the strong units. This may give you a sense of the appropriate number of clusters.

Example

```
node = stream.create("kohonen", "My node")
# "Model" tab
node.setPropertyValue("use_model_name", False)
node.setPropertyValue("model_name", "Symbolic Cluster")
node.setPropertyValue("stop_on", "Time")
node.setPropertyValue("time", 1)
node.setPropertyValue("set_random_seed", True)
node.setPropertyValue("random_seed", 12345)
node.setPropertyValue("optimize", "Speed")
# "Expert" tab
node.setPropertyValue("mode", "Expert")
node.setPropertyValue("width", 3)
node.setPropertyValue("length", 3)
node.setPropertyValue("decay_style", "Exponential")
node.setPropertyValue("phasel_neighborhood", 3)
node.setPropertyValue("phasel_eta", 0.5)
node.setPropertyValue("phasel_cycles", 10)
node.setPropertyValue("phase2_neighborhood", 1)
node.setPropertyValue("phase2_eta", 0.2)
node.setPropertyValue("phase2_cycles", 75)
```

Table 1. kohonennode properties

kohonennode Properties	Values	Property description
inputs	[field1 ... fieldN]	Kohonen models use a list of input fields, but no target. Frequency and weight fields are not used. See the topic Common modeling node properties for more information.
continue	flag

phase2_cycles	number	

linarnode properties

Linear regression models predict a continuous target based on linear relationships between the target and one or more predictors.

Example

```
node = stream.create("linear", "My node")
# Build Options tab - Objectives panel
node.setPropertyValue("objective", "Standard")
# Build Options tab - Model Selection panel
node.setPropertyValue("model_selection", "BestSubsets")
node.setPropertyValue("criteria_best_subsets", "ASE")
# Build Options tab - Ensembles panel
node.setPropertyValue("combining_rule_categorical", "HighestMeanProbability")
```

Table 1. linarnode properties

linarnode Properties	Values	Property description
target	field	Specifies a single target field.
inputs	[field1 ... fieldN]	Predictor fields used by the model.

linearasnode properties

Linear regression models predict a continuous target based on linear relationships between the target and one or more predictors.

Table 1. linearasnode properties

linearasnode Properties	Values	Property description
target	field	Specifies a single target field.
inputs	[field1 ... fieldN]	Predictor fields used by the model.
weight_field	field	Analysis field used by the model.
custom_fields	flag	The default value is TRUE .
intercept	flag	The default value is TRUE .
detect_2way_interaction	flag	Whether or not to consider two way interaction. The default value is TRUE .
cin	number	The interval of confidence used to compute estimates of the model coefficients. Specify a value greater than 0 and less than 100. The default value is 95 .
factor_order	ascending descending	The sort order for categorical predictors. The default value is ascending .
var_select_method	ForwardStepwise BestSubsets none	The model selection method to use. The default value is ForwardStepwise .
criteria_for_forward_stepwise	AICC Fstatistics AdjustedRSquare ASE	The statistic used to determine whether an effect should be added to or removed from the model. The default value is AdjustedRSquare .
pin	number	The effect that has the smallest p-value less than this specified pin threshold is added to the model. The default value is 0 . 05 .
pout	number	Any effects in the model with a p-value greater than this specified pout threshold are removed. The default value is 0 . 10 .
use_custom_max_effects	flag	Whether to use max number of effects in the final model. The default value is FALSE .
max_effects	number	Maximum number of effects to use in the final model. The default value is 1 .
use_custom_max_steps	flag	Whether to use the maximum number of steps. The default value is FALSE .
max_steps	number	The maximum number of steps before the stepwise algorithm stops. The default value is 1 .
criteria_for_best_subsets	AICC AdjustedRSquare ASE	The mode of criteria to use. The default value is AdjustedRSquare .

logregnode properties

Logistic regression is a statistical technique for classifying records based on values of input fields. It is analogous to linear regression but takes a categorical target field instead of a numeric range.

Multinomial Example

```
node = stream.create("logreg", "My node")
# "Fields" tab
node.setPropertyValue("custom_fields", True)
node.setPropertyValue("target", "Drug")
node.setPropertyValue("inputs", ["BP", "Cholesterol", "Age"])
node.setPropertyValue("partition", "Test")
# "Model" tab
node.setPropertyValue("use_model_name", True)
node.setPropertyValue("model_name", "Log_reg Drug")
node.setPropertyValue("use_partitioned_data", True)
```

```

node.setPropertyValue("method", "Stepwise")
node.setPropertyValue("logistic_procedure", "Multinomial")
node.setPropertyValue("multinomial_base_category", "BP")

lsvmnode properties

The Linear Support Vector Machine (LSVM) node enables you to classify data into one of two groups without overfitting. LSVM is linear and works well with wide data sets, such as those with a very large number of records.

Table 1. lsvmnode properties

lsvmnode Properties	Values	Property description
intercept	<i>flag</i>	Includes the intercept in the model. Default value is True .
target_order	<i>Ascending</i> <i>Descending</i>	Specifies the sorting order for the categorical target. Ignored for continuous targets. Default is Ascending .

lsvmnode Properties	Values	Property description
precision	<i>number</i>	Used only if measurement level of target field is Continuous . Specifies the parameter related to the sensitiveness of the loss for regression. Minimum is 0 and there is no maximum. Default value is 0 . 1 .
exclude_missing_values	<i>flag</i>	When True , a record is excluded if any single value is missing. The default value is False .
penalty_function	L1 L2	Specifies the type of penalty function used. The default value is L2 .
lambda	<i>number</i>	Penalty (regularization) parameter.
calculate_variable_importance	<i>flag</i>	For models that produce an appropriate measure of importance, this option displays a chart that indicates the relative importance of each predictor in estimating the model. Note that variable importance may take longer to calculate for some models, particularly when working with large datasets, and is off by default for some models as a result. Variable importance is not available for decision list models.

neuralnetnode properties

Important: A newer version of the Neural Net modeling node, with enhanced features, is available in this release and is described in the next section (*neuralnetwork*). Although you can still build and score a model with the previous version, we recommend updating your scripts to use the new version. Details of the previous version are retained here for reference.

Example

```
node = stream.create("neuralnet", "My node")
# "Fields" tab
node.setPropertyValue("custom_fields", True)
node.setPropertyValue("targets", ["Drug"])
node.setPropertyValue("inputs", ["Age", "Na", "K", "Cholesterol", "BP"])
# "Model" tab
node.setPropertyValue("use_partitioned_data", True)
node.setPropertyValue("method", "Dynamic")
node.setPropertyValue("train_pct", 30)
node.setPropertyValue("set_random_seed", True)
node.setPropertyValue("random_seed", 12345)
node.setPropertyValue("stop_on", "Time")
node.setPropertyValue("accuracy", 95)
node.setPropertyValue("cycles", 200)
node.setPropertyValue("time", 3)
node.setPropertyValue("optimize", "Speed")
# "Multiple Method Expert Options" section
node.setPropertyValue("m_topologies", "5 30 5; 2 20 3, 1 10 1")
node.setPropertyValue("m_non_pyramids", False)
node.setPropertyValue("m_persistence", 100)
```

Table 1. neuralnetnode properties

<code>calculate_adjusted_propensities</code>	<code>flag</code>	
<code>adjusted propensity_partition</code>	<code>Test Validation</code>	

neuralnetworknode properties

	The Neural Net node uses a simplified model of the way the human brain processes information. It works by simulating a large number of interconnected simple processing units that resemble abstract versions of neurons. Neural networks are powerful general function estimators and require minimal statistical or mathematical knowledge to train or apply.
---	---

Example

```
node = stream.create("neuralnetwork", "My node")
# Build Options tab - Objectives panel
```

```

node.setPropertyValue("objective", "Standard")
# Build Options tab - Ensembles panel
node.setPropertyValue("combining_rule_categorical", "HighestMeanProbability")

```

Table 1. neuralnetworknode properties

neuralnetworknode Properties	Values	Property description

questnode properties

The QUEST node provides a binary classification method for building decision trees, designed to reduce the processing time required for large C&R Tree analyses while also reducing the tendency found in classification tree methods to favor inputs that allow more splits. Input fields can be numeric ranges (continuous), but the target field must be categorical. All splits are binary.

Example

```

node = stream.create("quest", "My node")
node.setPropertyValue("custom_fields", True)
node.setPropertyValue("target", "Drug")
node.setPropertyValue("inputs", ["Age", "Na", "K", "Cholesterol", "BP"])
node.setPropertyValue("model_output_type", "InteractiveBuilder")

```

```

node.setPropertyValue("use_tree_directives", True)
node.setPropertyValue("max_surrogates", 5)
node.setPropertyValue("split_alpha", 0.03)
node.setPropertyValue("use_percentage", False)
node.setPropertyValue("min_parent_records_abs", 40)
node.setPropertyValue("min_child_records_abs", 30)
node.setPropertyValue("prune_tree", True)
node.setPropertyValue("use_std_err", True)
node.setPropertyValue("std_err_multiplier", 3)

```

Table 1. questnode properties

questnode Properties	Values	Property description
target	<i>field</i>	QUEST models require a single target and one or more input fields. A frequency field can also be specified. See the topic Common modeling node properties for more information.
continue_training_existing_model	<i>flag</i>	
objective	Standard Boosting Bagging psm	psm is used for very large datasets, and requires a Server connection.
model_output_type	Single InteractiveBuilder	
use_tree_directives	<i>flag</i>	
tree_directives	<i>string</i>	
use_max_depth	Default Custom	
max_depth	<i>integer</i>	Maximum tree depth, from 0 to 1000. Used only if use_max_depth = Custom .
prune_tree	<i>flag</i>	Prune tree to avoid overfitting.
use_std_err	<i>flag</i>	Use maximum difference in risk (in Standard Errors).
std_err_multiplier	<i>number</i>	Maximum difference.
max_surrogates	<i>number</i>	Maximum surrogates.
use_percentage	<i>flag</i>	
min_parent_records_pc	<i>number</i>	
min_child_records_pc	<i>number</i>	
min_parent_records_abs	<i>number</i>	
min_child_records_abs	<i>number</i>	
use_costs	<i>flag</i>

randomtrees properties

The Random Trees node is similar to the existing C&RT node; however, the Random Trees node is designed to process big data to create a single tree and displays the resulting model in the output viewer that was added in SPSS® Modeler version 17. The Random Trees tree node generates a decision tree that you use to predict or classify future observations. The method uses recursive partitioning to split the training records into segments by minimizing the impurity at each step, where a node in the tree is considered *pure* if 100% of cases in the node fall into a specific category of the target field. Target and input fields can be numeric ranges or categorical (nominal, ordinal, or flags); all splits are binary (only two subgroups).

Table 1. randomtrees properties

Properties	Values	Property description
target	<i>field</i>	In the Random Trees node, models require a single target and one or more input fields. A frequency field can also be specified. See the topic Common modeling node properties for more information.
number_of_models	<i>integer</i>	Determines the number of models to build as part of the ensemble modeling.
use_number_of_predictors	<i>flag</i>	Determines whether number_of_predictors is used.
number_of_predictors	<i>integer</i>	Specifies the number of predictors to be used when building split models.
use_stop_rule_for_accuracy	<i>flag</i>	Determines whether model building stops when accuracy cannot be improved.
sample_size	<i>number</i>	Reduce this value to improve performance when processing very large datasets.
handle_imbalanced_data	<i>flag</i>	If the target of the model is a particular flag outcome, and the ratio of the desired outcome to a non-desired outcome is very small, then the data is imbalanced and the bootstrap sampling that is conducted by the model may affect the model's accuracy. Enable imbalanced data handling so that the model will capture a larger proportion of the desired outcome and generate a stronger model.
use_weighted_sampling	<i>flag</i>	When <i>False</i> , variables for each node are randomly selected with the same probability. When <i>True</i> , variables are weighted and selected accordingly.
max_node_number	<i>integer</i>	Maximum number of nodes allowed in individual trees. If the number would be exceeded on the next split, tree growth halts.
max_depth	<i>integer</i>	Maximum tree depth before growth halts.
min_child_node_size	<i>integer</i>	Determines the minimum number of records allowed in a child node after the parent node is split. If a child node would contain fewer records than specified here the parent node will not be split
use_costs	<i>flag</i>	
costs	<i>structured</i>	Structured property. The format is a list of 3 values: the actual value, the predicted value, and the cost if that prediction is wrong. For example: tree.setPropertyValue("costs", [{"drugA": "drugB", 3.0}, {"drugX": "drugY", 4.0}])
default_cost_increase	<i>none linear square custom</i>	Note: only enabled for ordinal targets. Set default values in the costs matrix.
max_pct_missing	<i>integer</i>	If the percentage of missing values in any input is greater than the value specified here, the input is excluded. Minimum 0, maximum 100.
exclude_single_cat_pct	<i>integer</i>	If one category value represents a higher percentage of the records than specified here, the entire field is excluded from model building. Minimum 1, maximum 99.
max_category_number	<i>integer</i>	If the number of categories in a field exceeds this value, the field is excluded from model building. Minimum 2.
min_field_variation	<i>number</i>	If the coefficient of variation of a continuous field is smaller than this value, the field is excluded from model building.
num_bins	<i>integer</i>	Only used if the data is made up of continuous inputs. Set the number of equal frequency bins to be used for the inputs; options are: 2, 4, 5, 10, 20, 25, 50, or 100.
topN	<i>integer</i>	Specifies the number of rules to report. Default value is 50, with a minimum of 1 and a maximum of 1000.

regressionnode properties

Linear regression is a common statistical technique for summarizing data and making predictions by fitting a straight line or surface that minimizes the discrepancies between predicted and actual output values.

Note: The Regression node is due to be replaced by the Linear node in a future release. We recommend using Linear models for linear regression from now on.

Example

```

node = stream.create("regression", "My node")
# "Fields" tab
node.setPropertyValue("custom_fields", True)
node.setPropertyValue("target", "Age")
node.setPropertyValue("inputs", ["Na", "K"])
node.setPropertyValue("partition", "Test")
node.setPropertyValue("use_weight", True)
node.setPropertyValue("weight_field", "Drug")
# "Model" tab
node.setPropertyValue("use_model_name", True)
node.setPropertyValue("model_name", "Regression Age")
node.setPropertyValue("use_partitioned_data", True)
node.setPropertyValue("method", "Stepwise")
node.setPropertyValue("include_constant", False)
# "Expert" tab
node.setPropertyValue("mode", "Expert")
node.setPropertyValue("complete_records", False)
node.setPropertyValue("tolerance", "1.0E-3")
# "Stepping..." section
node.setPropertyValue("stepping_method", "Probability")
node.setPropertyValue("probability_entry", 0.77)
node.setPropertyValue("probability_removal", 0.88)
node.setPropertyValue("F_value_entry", 7.0)
node.setPropertyValue("F_value_removal", 8.0)
# "Output..." section

sequencenode properties

The Sequence node discovers association rules in sequential or time-oriented data. A sequence is a list of item sets that tends to occur in a predictable order. For example, a customer who purchases a razor and aftershave lotion may purchase shaving cream the next time he shops. The Sequence node is based on the CARMA association rules algorithm, which uses an efficient two-pass method for finding sequences.

Example

```
node = stream.create("sequence", "My node")
# "Fields" tab
node.setPropertyValue("id_field", "Age")
node.setPropertyValue("contiguous", True)
node.setPropertyValue("use_time_field", True)
node.setPropertyValue("time_field", "Date1")
node.setPropertyValue("content_fields", ["Drug", "BP"])
node.setPropertyValue("partition", "Test")
# "Model" tab
node.setPropertyValue("use_model_name", True)
node.setPropertyValue("model_name", "Sequence_test")

slrmnode properties

	The Self-Learning Response Model (SLRM) node enables you to build a model in which a single new case, or small number of new cases, can be used to reestimate the model without having to retrain the model using all data.
---	---

Example

```
node = stream.create("slrm", "My node")
node.setPropertyValue("target", "Offer")
node.setPropertyValue("target_response", "Response")
node.setPropertyValue("inputs", ["Cust_ID", "Age", "Ave_Bal"])
```

Table 1. slrmnode properties

slrmnode Properties	Values	Property description
target	field	The target field must be a nominal or flag field. A frequency field can also be specified. See the topic Common modeling node properties for more information.
target_response	field	Type must be flag.
continue_training_existing_model	flag	
target_field_values	flag	Use all: Use all values from source. Specify: Select values required.
target_field_values_specify	[field1 ... fieldN]	
include_model_assessment	flag	
model_assessment_random_seed	number	Must be a real number.
model_assessment_sample_size	number	Must be a real number.
model_assessment_iterations	number	Number of iterations.
display_model_evaluation	flag	
max_predictions	number	
randomization	number	
scoring_random_seed	number	
sort	Ascending Descending	Specifies whether the offers with the highest or lowest scores will be displayed first.
model_reliability	flag	
calculate_variable_importance	flag	

statisticsmodelnode properties

	The Statistics Model node enables you to analyze and work with your data by running IBM® SPSS® Statistics procedures that produce PMML. This node requires a licensed copy of IBM SPSS Statistics.
---	--

The properties for this node are described under [statisticsmodelnode properties](#).

stpnnode properties

The Spatio-Temporal Prediction (STP) node uses data that contains location data, input fields for prediction (predictors), a time field, and a target field. Each location has numerous rows in the data that represent the values of each predictor at each time of measurement. After the data is analyzed, it can be used to predict target values at any location within the shape data that is used in the analysis.

Table 1. stpnnode properties

stpnnode properties	Data type	Property description
Fields tab		
target	field	This is the target field.
location	field	The location field for the model. Only geospatial fields are allowed.
location_label	field	The categorical field to be used in the output to label the locations chosen in location
time_field	field	The time field for the model. Only fields with continuous measurement are allowed, and the storage type must be time, date, timestamp, or integer.
inputs	[field1 ... fieldN]	A list of input fields.
Time Intervals tab		
interval_type_timestamp	Years Quarters Months Weeks Days Hours Minutes Seconds	
interval_type_date	Years Quarters Months Weeks Days	
interval_type_time	Hours Minutes Seconds	Limits the number of days per week that are taken into account when creating the time index that STP uses for calculation
interval_type_integer	Periods (Time index fields only, Integer storage)	The interval to which the data set will be converted. The selection available is dependent on the storage type of the field that is chosen as the time_field for the model.
period_start	integer	
start_month	January February March April May June July August September October November December	The month the model will start to index from (for example, if set to March but the first record in the data set is January , the model will skip the first two records and start indexing at March).
week_begins_on	Sunday Monday Tuesday Wednesday Thursday Friday Saturday	The starting point for the time index created by STP from the data
days_per_week	integer	Minimum 1, maximum 7, in increments of 1
hours_per_day	integer	The number of hours the model accounts for in a day. If this is set to 10 , the model will start indexing at the day_begins_at time and continue indexing for 10 hours, then skip to the next value matching the day_begins_at value, etc.
day_begins_at	00:00 01:00 02:00 03:00 ... 23:00	Sets the hour value that the model starts indexing from.
interval_increment	1 2 3 4 5 6 10 12 15 20 30	This increment setting is for minutes or seconds. This determines where the model creates indexes from the data. So with an increment of 30 and interval type seconds , the model will create an index from the data every 30 seconds.
data_matches_interval	Boolean	If set to N , the conversion of the data to the regular interval_type occurs before the model is built. If your data is already in the correct format, and the interval_type and any associated settings match your data, set this to Y to prevent the conversion or aggregation of your data. Setting this to Y disables all of the Aggregation controls.
agg_range_default	Sum Mean Min Max Median 1stQuartile 3rdQuartile	This determines the default aggregation method used for continuous fields. Any continuous fields which are not specifically included in the custom aggregation will be aggregated using the method specified here.
custom_agg	[[field, aggregation method], [..]] Demo: [['x5', 'FirstQuartile'], ['x4', 'Sum']]	Structured property: Script parameter: custom_agg For example: set :stpnnode.custom_agg = [[[field1 function] [field2 function]]] Where function is the aggregation function to be used with that field.
Basics tab		

stpmnode properties	Data type	Property description
<code>include_intercept</code>	<code>flag</code>	
<code>max_autoregressive_lag</code>	<code>integer</code>	Minimum 1, maximum 5, in increments of 1. This is the number of previous records required for a prediction. So if set to 5, for example, then the previous 5 records are used to create a new forecast. The number of records specified here from the build data are incorporated into the model and, therefore, the user does not need to provide the data again when scoring the model.
<code>estimation_method</code>	<code>Parametric Nonparametric</code>	The method for modeling the spatial covariance matrix
<code>parametric_model</code>	<code>Gaussian Exponential PoweredExponential</code>	Order parameter for <code>Parametric</code> spatial covariance model
<code>exponential_power</code>	<code>number</code>	Power level for <code>PoweredExponential</code> model. Minimum 1, maximum 2.
Advanced tab		
<code>max_missing_values</code>	<code>integer</code>	The maximum percentage of records with missing values allowed in the model.
<code>significance</code>	<code>number</code>	The significance level for hypotheses testing in the model build. Specifies the significance value for all the tests in STP model estimation, including two Goodness of Fit tests, effect F-tests, and coefficient t-tests.
Output tab		
<code>model_specifications</code>	<code>flag</code>	
<code>temporal_summary</code>	<code>flag</code>	
<code>location_summary</code>	<code>flag</code>	Determines whether the Location Summary table is included in the model output.
<code>model_quality</code>	<code>flag</code>	
<code>test_mean_structure</code>	<code>flag</code>	
<code>mean_structural_coefficients</code>	<code>flag</code>	
<code>autoregressive_coefficients</code>	<code>flag</code>	
<code>test_decay_rate</code>	<code>flag</code>	
<code>parametric_spatial_covariance</code>	<code>flag</code>	
<code>correlations_heat_map</code>	<code>flag</code>	
<code>correlations_map</code>	<code>flag</code>	
<code>location_clusters</code>	<code>flag</code>	
<code>similarity_threshold</code>	<code>number</code>	The threshold at which output clusters are considered similar enough to be merged into a single cluster.
<code>max_number_clusters</code>	<code>integer</code>	The upper limit for the number of clusters which can be included in the model output.
Model Options tab		
<code>use_model_name</code>	<code>flag</code>	
<code>model_name</code>	<code>string</code>	
<code>uncertainty_factor</code>	<code>number</code>	Minimum 0, maximum 100. Determines the increase in uncertainty (error) applied to predictions in the future. It is the upper and lower bound for the predictions.

svmnode properties

	The Support Vector Machine (SVM) node enables you to classify data into one of two groups without overfitting. SVM works well with wide data sets, such as those with a very large number of input fields.
---	--

Example

```

node = stream.create("svm", "My node")
# Expert tab
node.setPropertyValue("mode", "Expert")
node.setPropertyValue("all_probabilities", True)
node.setPropertyValue("kernel", "Polynomial")
node.setPropertyValue("gamma", 1.5)

```

Table 1. svmnode properties

svmnode Properties	Values	Property description
all_probabilities	flag	
stopping_criteria	1.0E-11 1.0E-2 1.0E-3 (default) 1.0E-4 1.0E-5 1.0E-6	Determines when to stop the optimization algorithm.
regularization	number	Also known as the C parameter.
precision	number	Used only if measurement level of target field is Continuous .
kernel	RBF(default) Polynomial Sigmoid Linear	Type of kernel function used for the transformation.
rbf_gamma	number	Used only if kernel is RBF.
gamma	number	Used only if kernel is Polynomial or Sigmoid.
bias	number	
degree	number	Used only if kernel is Polynomial.
calculate_variable_importance	flag	
calculate_raw_propensities	flag	
calculate_adjusted_propensities	flag	
adjusted_propensity_partition	Test Validation	

tcmnode Properties

Temporal causal modeling attempts to discover key causal relationships in time series data. In temporal causal modeling, you specify a set of target series and a set of candidate inputs to those targets. The procedure then builds an autoregressive time series model for each target and includes only those inputs that have the most significant causal relationship with the target.

ts properties

	The Time Series node estimates exponential smoothing, univariate Autoregressive Integrated Moving Average (ARIMA), and multivariate ARIMA (or transfer function) models for time series data and produces forecasts of future performance. This Time Series node is similar to the previous Time Series node that was deprecated in SPSS® Modeler version 18. However, this newer Time Series node is designed to harness the power of IBM® SPSS Analytic Server to process big data, and display the resulting model in the output viewer that was added in SPSS Modeler version 17.

arima_outlier_local_trend	flag	
arima_outlier_additive_patch	flag	
max_lags	integer	
cal_PI	flag	

ts Properties	Values	Property description
<code>conf_limit_pc</code>	<code>real</code>	
<code>events</code>	<code>fields</code>	
<code>continue</code>	<code>flag</code>	
<code>scoring_mode_l_only</code>	<code>flag</code>	Use for models with very large numbers (tens of thousands) of time series.
<code>forecastperiods</code>	<code>integer</code>	
<code>extend_records_into_future</code>	<code>flag</code>	
<code>extend_metric_values</code>	<code>fields</code>	Allows you to provide future values for predictors.
<code>conf_limits</code>	<code>flag</code>	
<code>noise_res</code>	<code>flag</code>	
<code>max_models_output</code>	<code>integer</code>	Controls how many models are shown in output. Default is 10. Models are not shown in output if the total number of models built exceeds this value. Models are still available for scoring.

treeas properties

	The Tree-AS node is similar to the existing CHAID node; however, the Tree-AS node is designed to process big data to create a single tree and displays the resulting model in the output viewer that was added in SPSS® Modeler version 17. The node generates a decision tree by using chi-square statistics (CHAID) to identify optimal splits. This use of CHAID can generate nonbinary trees, meaning that some splits have more than two branches. Target and input fields can be numeric range (continuous) or categorical. Exhaustive CHAID is a modification of CHAID that does a more thorough job of examining all possible splits but takes longer to compute.
---	---

Table 1. treeas properties

treeas Properties	Values	Property description
<code>target</code>	<code>field</code>	In the Tree-AS node, CHAID models require a single target and one or more input fields. A frequency field can also be specified. See the topic Common modeling node properties for more information.
<code>method</code>	<code>chaid</code> <code>exhaustive_chaid</code>	
<code>max_depth</code>	<code>integer</code>	Maximum tree depth, from 0 to 20. The default value is 5.
<code>num_bins</code>	<code>integer</code>	Only used if the data is made up of continuous inputs. Set the number of equal frequency bins to be used for the inputs; options are: 2, 4, 5, 10, 20, 25, 50, or 100.
<code>record_threshold</code>	<code>integer</code>	The number of records at which the model will switch from using p-values to Effect sizes while building the tree. The default is 1,000,000; increase or decrease this in increments of 10,000.
<code>split_alpha</code>	<code>number</code>	Significance level for splitting. The value must be between 0.01 and 0.99.
<code>merge_alpha</code>	<code>number</code>	Significance level for merging. The value must be between 0.01 and 0.99.
<code>bonferroni_adjustment</code>	<code>flag</code>	Adjust significance values using Bonferroni method.
<code>effect_size_threshold_continuous</code>	<code>number</code>	Set the Effect size threshold when splitting nodes and merging categories when using a continuous target. The value must be between 0.01 and 0.99.
<code>effect_size_threshold_categorical</code>	<code>number</code>	Set the Effect size threshold when splitting nodes and merging categories when using a categorical target. The value must be between 0.01 and 0.99.
<code>split_merged_categories</code>	<code>flag</code>	Allow resplitting of merged categories.
<code>grouping_significance_level</code>	<code>number</code>	Used to determine how groups of nodes are formed or how unusual nodes are identified.
<code>chi_square</code>	<code>pearson</code> <code>likelihood_ratio</code>	Method used to calculate the chi-square statistic: Pearson or Likelihood Ratio
<code>minimum_records_use</code>	<code>use_percentage</code> <code>use_absolute</code>	
<code>min_parent_records_pc</code>	<code>number</code>	Default value is 2. Minimum 1, maximum 100, in increments of 1. Parent branch value must be higher than child branch.
<code>min_child_records_pc</code>	<code>number</code>	Default value is 1. Minimum 1, maximum 100, in increments of 1.

treesas Properties	Values	Property description
min_parent_records_abs	number	Default value is 100. Minimum 1, maximum 100, in increments of 1. Parent branch value must be higher than child branch.
min_child_records_abs	number	Default value is 50. Minimum 1, maximum 100, in increments of 1.
epsilon	number	Minimum change in expected cell frequencies..
max_iterations	number	Maximum iterations for convergence.
use_costs	flag	
costs	structured	Structured property. The format is a list of 3 values: the actual value, the predicted value, and the cost if that prediction is wrong. For example: tree.setPropertyValue("costs", [{"drugA": "drugB", "value": 3.0}, {"drugX": "drugY", "value": 4.0}])
default_cost_increase	none linear square custom	Note: only enabled for ordinal targets. Set default values in the costs matrix.
calculate_conf	flag	
display_rule_id	flag	Adds a field in the scoring output that indicates the ID for the terminal node to which each record is assigned.

twostepnode Properties

The TwoStep node uses a two-step clustering method. The first step makes a single pass through the data to compress the raw input data into a manageable set of subclusters. The second step uses a hierarchical clustering method to progressively merge the subclusters into larger and larger clusters. TwoStep has the advantage of automatically estimating the optimal number of clusters for the training data. It can handle mixed field types and large data sets efficiently.

Example

```
node = stream.create("twostep", "My node")
node.setPropertyValue("custom_fields", True)
node.setPropertyValue("inputs", ["Age", "K", "Na", "BP"])
node.setPropertyValue("partition", "Test")
node.setPropertyValue("use_model_name", False)
node.setPropertyValue("model_name", "TwoStep_Drug")
node.setPropertyValue("use_partitioned_data", True)
node.setPropertyValue("exclude_outliers", True)
node.setPropertyValue("cluster_label", "String")
node.setPropertyValue("label_prefix", "TwoStep_")
node.setPropertyValue("cluster_num_auto", False)
node.setPropertyValue("max_num_clusters", 9)
node.setPropertyValue("min_num_clusters", 3)
node.setPropertyValue("num_clusters", 7)
```

Table 1. twostepnode properties

clustering_criterion	AIC BIC	

twostepAS Properties

	TwoStep Cluster is an exploratory tool that is designed to reveal natural groupings (or clusters) within a data set that would otherwise not be apparent. The algorithm that is employed by this procedure has several desirable features that differentiate it from traditional clustering techniques, such as handling of categorical and continuous variables, automatic selection of number of clusters, and scalability.

applyanomalydetectionnode Properties

Anomaly Detection modeling nodes can be used to generate an Anomaly Detection model nugget. The scripting name of this model nugget is `applyanomalydetectionnode`. For more information on scripting the modeling node itself, [anomalydetectionnode properties](#)

Table 1. `applyanomalydetectionnode` properties

<code>applyanomalydetectionnode Properties</code>	Values	Property description
<code>anomaly_score_method</code>	<code>FlagAndScore</code> <code>FlagOnly</code> <code>ScoreOnly</code>	Determines which outputs are created for scoring.
<code>num_fields</code>	<code>integer</code>	Fields to report.
<code>discard_records</code>	<code>flag</code>	Indicates whether records are discarded from the output or not.
<code>discard_anomalous_records</code>	<code>flag</code>	Indicator of whether to discard the anomalous or <i>non</i> -anomalous records. The default is <code>off</code> , meaning that <i>non</i> -anomalous records are discarded. Otherwise, if <code>on</code> , anomalous records will be discarded. This property is enabled only if the <code>discard_records</code> property is enabled.

applyautoclassifiernode Properties

Auto Classifier modeling nodes can be used to generate an Auto Classifier model nugget. The scripting name of this model nugget is `applyautoclassifiernode`. For more information on scripting the modeling node itself, [autoclassifiernode.properties](#)

Table 1. applyautoclassifiernode properties

applyautoclassifiernode Properties	Values	Property description
<code>flag_ensemble_method</code>	<code>Voting</code> <code>Evaluation</code> <code>WeightedVoting</code> <code>Confidence</code> <code>WeightedVoting</code> <code>RawPropensity</code> <code>WeightedVoting</code> <code>HighestConfidence</code> <code>AverageRawPropensity</code>	Specifies the method used to determine the ensemble score. This setting applies only if the selected target is a flag field.
<code>flag_evaluation_selection</code>	<code>Accuracy</code> <code>AUC_ROC</code>	This option is for flag target only, to decide which evaluation measure is chosen for evaluation-weighted voting.
<code>filter_individual_model_output</code>	<code>flag</code>	Specifies whether scoring results from individual models should be suppressed.
<code>is_ensemble_update</code>	<code>flag</code>	Enables continuous auto machine learning mode, which adds new component models into an existing auto model set instead of replacing the existing auto model, and re-evaluates measures of existing component models using newly available data.
<code>is_auto_ensemble_weights_reevaluation</code>	<code>flag</code>	Enables automatic model weights reevaluation.
<code>use_accumulated_factor</code>	<code>flag</code>	Accumulated factor is used to compute accumulated measures.
<code>accumulated_factor</code>	<code>number (double)</code>	Max value is <code>0 . 99</code> , and min value is <code>0 . 85</code> .
<code>use_accumulated_reducing</code>	<code>flag</code>	Performs model reducing based on accumulated limit during model refresh.
<code>accumulated_reducing_limit</code>	<code>number (double)</code>	Max value is <code>0 . 7</code> , and min value is <code>0 . 1</code> .
<code>use_accumulated_weighted_evaluation</code>	<code>flag</code>	Accumulated evaluation measure is used for voting when the evaluation-weighted voting method is selected for the ensemble method.
<code>flag_voting_tie_selection</code>	<code>Random</code> <code>HighestConfidence</code> <code>RawPropensity</code>	If a voting method is selected, specifies how ties are resolved. This setting applies only if the selected target is a flag field.
<code>set_ensemble_method</code>	<code>Voting</code> <code>Evaluation</code> <code>WeightedVoting</code> <code>Confidence</code> <code>WeightedVoting</code> <code>HighestConfidence</code>	Specifies the method used to determine the ensemble score. This setting applies only if the selected target is a set field.

applyautoclusternode Properties	Values	Property description
<code>set_voting_type_selection</code>	<code>Random</code> <code>HighestConfidence</code>	If a voting method is selected, specifies how ties are resolved. This setting applies only if the selected target is a nominal field.

applyglmmnode Properties

GLMM modeling nodes can be used to generate a GLMM model nugget. The scripting name of this model nugget is *applyglmmnode*. For more information on scripting the modeling node itself, [glmmnode properties](#).

Table 1. applyglmmnode properties

applyglmmnode Properties	Values	Property description
confidence	onProbability onIncrease	Basis for computing scoring confidence value: highest predicted probability, or difference between highest and second highest predicted probabilities.
score_categorical_probabilities	flag	If set to True , produces the predicted probabilities for categorical targets. A field is created for each category. Default is False .
max_categories	integer	Maximum number of categories for which to predict probabilities. Used only if score_category_probabilities is True .
score_propensity	flag	If set to True , produces raw propensity scores (likelihood of "True" outcome) for models with flag targets. If partitions are in effect, also produces adjusted propensity scores based on the testing partition. Default is False .
enable_sql_generation	udf native	Used to set SQL generation options during stream execution. The options are to pushback to the database and score using a SPSS® Modeler Server scoring adapter (if connected to a database with a scoring adapter installed), or to score within SPSS Modeler. The default value is udf .

applyneuralnetnode Properties

Neural Net modeling nodes can be used to generate a Neural Net model nugget. The scripting name of this model nugget is *applyneuralnetnode*. For more information on scripting the modeling node itself, [neuralnetnode properties](#).

Caution: A newer version of the Neural Net nugget, with enhanced features, is available in this release and is described in the next section (*applyneuralnetwork*). Although the previous version is still available, we recommend updating your scripts to use the new version. Details of the previous version are retained here for reference, but support for it will be removed in a future release.

Table 1. applyneuralnetnode properties

applyneuralnetnode Properties	Values	Property description
calculate_conf	flag	Available when SQL generation is enabled; this property includes confidence calculations in the generated tree.
enable_sql_generation	flag	
nn_score_method	Difference SoftMax	
calculate_raw_propensities	flag	
calculate_adjusted_propensities	flag

XGBoost Linear nodes can be used to generate an XGBoost Linear model nugget. The scripting name of this model nugget is `applyxgboostlinearnode`. No other properties exist for this model nugget. For more information on scripting the modeling node itself, see [xgboostlinearnode Properties](#).

hdbscannugget properties

The HDBSCAN node can be used to generate an HDBSCAN model nugget. The scripting name of this model nugget is `hdbscannugget`. No other properties exist for this model nugget. For more information on scripting the modeling node itself, see [hdbscannode properties](#).

kdeapply properties

The KDE Modeling node can be used to generate a KDE model nugget. The scripting name of this model nugget is `kdeapply`. For information on scripting the modeling node itself, see [kdemodel properties](#).

Table 1. kdeapply properties

kdeapply properties	Data type	Property description
<code>outLogDensity</code> Renamed to <code>out_log_density</code> starting with version 18.2.1.1	<code>boolean</code>	Specify <code>True</code> or <code>False</code> to include or exclude the log density value in the output. Default is <code>False</code> .

Database modeling node properties

IBM® SPSS® Modeler supports integration with data mining and modeling tools available from database vendors, including Microsoft SQL Server Analysis Services, Oracle Data Mining, and IBM Netezza® Analytics. You can build and score models using native database algorithms, all from within the IBM SPSS Modeler application. Database models can also be created and manipulated through scripting using the properties described in this section.

For example, the following script excerpt illustrates the creation of a Microsoft Decision Trees model by using the IBM SPSS Modeler scripting interface:

```
stream = modeler.script.stream()
msbuilder = stream.createAt("mstreenode", "MSBuilder", 200, 200)

msbuilder.setPropertyValue("analysis_server_name", 'localhost')
msbuilder.setPropertyValue("analysis_database_name", 'TESTDB')
msbuilder.setPropertyValue("mode", 'Expert')
msbuilder.setPropertyValue("datasource", 'LocalServer')
msbuilder.setPropertyValue("target", 'Drug')
msbuilder.setPropertyValue("inputs", ['Age', 'Sex'])
msbuilder.setPropertyValue("unique_field", 'IDX')
msbuilder.setPropertyValue("custom_fields", True)
msbuilder.setPropertyValue("model_name", 'MSDRUG')

typenode = stream.findByType("type", None)
stream.link(typenode, msbuilder)
results = []
msbuilder.run(results)
msapplier = stream.createModelApplierAt(results[0], "Drug", 200, 300)
tablenode = stream.createAt("table", "Results", 300, 300)
stream.linkBetween(msapplier, typenode, tablenode)
msapplier.setPropertyValue("sql_generate", True)
tablenode.run([])
```

Node Properties for Microsoft Modeling

- [Microsoft Modeling Node Properties](#)
- [Microsoft Model Nugget Properties](#)

Microsoft Modeling Node Properties

Common Properties

The following properties are common to the Microsoft database modeling nodes.

Table 1. Common Microsoft node properties

Common Microsoft Node Properties	Values	Property Description
<code>analysis_database_name</code>	<code>string</code>	Name of the Analysis Services database.
<code>analysis_server_name</code>	<code>string</code>	Name of the Analysis Services host.
<code>use_transactional_data</code>	<code>flag</code>	Specifies whether input data is in tabular or transactional format.
<code>inputs</code>	<code>list</code>	Input fields for tabular data.
<code>target</code>	<code>field</code>	Predicted field (not applicable to MS Clustering or Sequence Clustering nodes).
<code>unique_field</code>	<code>field</code>	Key field.
<code>msas_parameters</code>	<code>structured</code>	Algorithm parameters. See the topic Algorithm Parameters for more information.

Common Microsoft Node Properties	Values	Property Description
with_drillthrough	flag	With Drillthrough option.

MS Decision Tree

There are no specific properties defined for nodes of type `mstreenode`. See the common Microsoft properties at the start of this section.

MS Clustering

There are no specific properties defined for nodes of type `msclusternode`. See the common Microsoft properties at the start of this section.

MS Association Rules

The following specific properties are available for nodes of type `msassocnode`:

Table 2. `msassocnode` properties

msassocnode Properties	Values	Property Description
<code>id_field</code>	<code>field</code>	Identifies each transaction in the data.
<code>trans_inputs</code>	<code>list</code>	Input fields for transactional data.
<code>transactional_target</code>	<code>field</code>	Predicted field (transactional data).

MS Naive Bayes

There are no specific properties defined for nodes of type `msbayesnode`. See the common Microsoft properties at the start of this section.

MS Linear Regression

There are no specific properties defined for nodes of type `msregressionnode`. See the common Microsoft properties at the start of this section.

MS Neural Network

There are no specific properties defined for nodes of type `msneuralnetworknode`. See the common Microsoft properties at the start of this section.

MS Logistic Regression

There are no specific properties defined for nodes of type `mslogisticnode`. See the common Microsoft properties at the start of this section.

MS Time Series

There are no specific properties defined for nodes of type `mstimeseriesnode`. See the common Microsoft properties at the start of this section.

MS Sequence Clustering

The following specific properties are available for nodes of type `mssequenceclusternode`:

Table 3. `mssequenceclusternode` properties

mssequenceclusternode Properties	Values	Property Description
<code>id_field</code>	<code>field</code>	Identifies each transaction in the data.
<code>input_fields</code>	<code>list</code>	Input fields for transactional data.
<code>sequence_field</code>	<code>field</code>	Sequence identifier.
<code>target_field</code>	<code>field</code>	Predicted field (tabular data).

- [Algorithm Parameters](#)

Algorithm Parameters

Each Microsoft database model type has specific parameters that can be set using the `msas_parameters` property--for example:

```

stream = modeler.script.stream()
msregressionnode = stream.findByType("msregression", None)
msregressionnode.setPropertyValue("msas_parameters", [[ "MAXIMUM_INPUT_ATTRIBUTES", 255], ["MAXIMUM_OUTPUT_ATTRIBUTES", 255]])

```

These parameters are derived from SQL Server. To see the relevant parameters for each node:

1. Place a database source node on the canvas.
2. Open the database source node.
3. Select a valid source from the Data source drop-down list.
4. Select a valid table from the Table name list.
5. Click OK to close the database source node.
6. Attach the Microsoft database modeling node whose properties you want to list.
7. Open the database modeling node.
8. Select the Expert tab.

The available **msas_parameters** properties for this node are displayed.

Microsoft Model Nugget Properties

The following properties are for the model nuggets created using the Microsoft database modeling nodes.

MS Decision Tree

Table 1. MS Decision Tree properties

applymsstreenode Properties	Values	Description
analysis_database_name	<i>string</i>	This node can be scored directly in a stream. This property is used to identify the name of the Analysis Services database.
analysis_server_name	<i>string</i>	Name of the Analysis server host.
datasource	<i>string</i>	Name of the SQL Server ODBC data source name (DSN).
sql_generate	<i>flag udf</i>	Enables SQL generation.

MS Linear Regression

Table 2. MS Linear Regression properties

applymsregressionnode Properties	Values	Description
analysis_database_name	<i>string</i>	This node can be scored directly in a stream. This property is used to identify the name of the Analysis Services database.
analysis_server_name	<i>string</i>	Name of the Analysis server host.

MS Neural Network

Table 3. MS Neural Network properties

applymsneuralnetworknode Properties	Values	Description
analysis_database_name	<i>string</i>	This node can be scored directly in a stream. This property is used to identify the name of the Analysis Services database.
analysis_server_name	<i>string</i>	Name of the Analysis server host.

MS Logistic Regression

Table 4. MS Logistic Regression properties

applymslogisticnode Properties	Values	Description
analysis_database_name	<i>string</i>	This node can be scored directly in a stream. This property is used to identify the name of the Analysis Services database.
analysis_server_name	<i>string</i>	Name of the Analysis server host.

MS Time Series

Table 5. MS Time Series properties

Properties	Values	Description
<code>analysis_database_name</code>	<code>string</code>	This node can be scored directly in a stream. This property is used to identify the name of the Analysis Services database.
<code>analysis_server_name</code>	<code>string</code>	Name of the Analysis server host.
<code>start_from</code>	<code>new_prediction</code> <code>historical_prediction</code>	Specifies whether to make future predictions or historical predictions.
<code>new_step</code>	<code>number</code>	Defines starting time period for future predictions.
<code>historical_step</code>	<code>number</code>	Defines starting time period for historical predictions.
<code>end_step</code>	<code>number</code>	Defines ending time period for predictions.

MS Sequence Clustering

Table 6. MS Sequence Clustering properties

Properties	Values	Description
<code>analysis_database_name</code>	<code>string</code>	This node can be scored directly in a stream. This property is used to identify the name of the Analysis Services database.
<code>analysis_server_name</code>	<code>string</code>	Name of the Analysis server host.

Node Properties for Oracle Modeling

- [Oracle Modeling Node Properties](#)
- [Oracle Model Nugget Properties](#)

Oracle Modeling Node Properties

The following properties are common to Oracle database modeling nodes.

Table 1. Common Oracle node properties

Common Oracle Node Properties	Values	Property Description
<code>target</code>	<code>field</code>	
<code>inputs</code>	<code>List of fields</code>	
<code>partition</code>	<code>field</code>	Field used to partition the data into separate samples for the training, testing, and validation stages of model building.
<code>datasource</code>		
<code>username</code>		
<code>password</code>		
<code>epassword</code>		
<code>use_model_name</code>	<code>flag</code>	
<code>model_name</code>	<code>string</code>	Custom name for new model.
<code>use_partitioned_data</code>	<code>flag</code>	If a partition field is defined, this option ensures that only data from the training partition is used to build the model.
<code>unique_field</code>	<code>field</code>	
<code>auto_data_prep</code>	<code>flag</code>	Enables or disables the Oracle automatic data preparation feature (11g databases only).
<code>costs</code>	<code>structured</code>	Structured property in the form: <code>[[drugA drugB 1.5] [drugA drugC 2.1]]</code> , where the arguments in <code>[]</code> are actual predicted costs.
<code>mode</code>	<code>Simple</code> <code>Expert</code>	Causes certain properties to be ignored if set to <code>Simple</code> , as noted in the individual node properties.
<code>use_prediction_probability</code>	<code>flag</code>	

Common Oracle Node Properties	Values	Property Description
<code>prediction_probability</code>	<code>string</code>	
<code>use_prediction_set</code>	<code>flag</code>	

Oracle Naive Bayes

The following properties are available for nodes of type `oranbnode`.

Table 2. oranbnode properties

oranbnode Properties	Values	Property Description
<code>singleton_threshold</code>	<code>number</code>	0.0–1.0.*
<code>pairwise_threshold</code>	<code>number</code>	0.0–1.0.*
<code>priors</code>	<code>Data Equal Custom</code>	
<code>custom_priors</code>	<code>structured</code>	Structured property in the form: <code>set :oranbnode.custom_priors = [[drugA 1][drugB 2][drugC 3][drugX 4][drugY 5]]</code>

* Property ignored if `mode` is set to `Simple`.

Oracle Adaptive Bayes

The following properties are available for nodes of type `oraabnnnode`.

Table 3. oraabnnnode properties

oraabnnnode Properties	Values	Property Description
<code>model_type</code>	<code>SingleFeature</code> <code>MultiFeature NaiveBayes</code>	
<code>use_execution_time_limit</code>	<code>flag</code>	*
<code>execution_time_limit</code>	<code>integer</code>	Value must be greater than 0.*
<code>max_naive_bayes_predictors</code>	<code>integer</code>	Value must be greater than 0.*
<code>max_predictors</code>	<code>integer</code>	Value must be greater than 0.*
<code>priors</code>	<code>Data Equal Custom</code>	
<code>custom_priors</code>	<code>structured</code>	Structured property in the form: <code>set :oraabnnnode.custom_priors = [[drugA 1][drugB 2][drugC 3][drugX 4][drugY 5]]</code>

* Property ignored if `mode` is set to `Simple`.

Oracle Support Vector Machines

The following properties are available for nodes of type `orasvmnode`.

Table 4. orasvmnode properties

orasvmnode Properties	Values	Property Description
<code>active_learning</code>	<code>Enable Disable</code>	
<code>kernel_function</code>	<code>Linear Gaussian System</code>	
<code>normalization_method</code>	<code>zscore minmax none</code>	
<code>kernel_cache_size</code>	<code>integer</code>	Gaussian kernel only. Value must be greater than 0.*
<code>convergence_tolerance</code>	<code>number</code>	Value must be greater than 0.*
<code>use_standard_deviation</code>	<code>flag</code>	Gaussian kernel only.*
<code>standard_deviation</code>	<code>number</code>	Value must be greater than 0.*
<code>use_epsilon</code>	<code>flag</code>	Regression models only.*
<code>epsilon</code>	<code>number</code>	Value must be greater than 0.*

orasvmnode Properties	Values	Property Description
use_complexity_factor	flag	*
complexity_fact or	number	*
use_outlier_rate	flag	One-Class variant only.*
outlier_rate	number	One-Class variant only. 0.0–1.0.*
weights	Data Equal Custom	
custom_weights	structured	Structured property in the form: <code>set :orasvmnode.custom_weights = [[drugA 1][drugB 2][drugC 3][drugX 4][drugY 5]]</code>

* Property ignored if mode is set to Simple.

Oracle Generalized Linear Models

The following properties are available for nodes of type oraglmnode.

Table 5. oraglmnode properties

oraglmnode Properties	Values	Property Description
normalization_method	zscore minmax none	
missing_value_handling	ReplaceWithMean UseCompleteRecords	
use_row_weights	flag	*
row_weights_field	field	*
save_row_diagnostics	flag	*
row_diagnostics_table	string	*
coefficient_confidence	number	*
use_reference_category	flag	*
reference_category	string	*
ridge_regression	Auto Off On	*
parameter_value	number	*
vif_for_ridge	flag	*

* Property ignored if mode is set to Simple.

Oracle Decision Tree

The following properties are available for nodes of type oradecisiontreenode.

Table 6. oradecisiontreenode properties

oradecisiontreenode Properties	Values	Property Description
use_costs	flag	
impurity_metric	Entropy Gini	
term_max_depth	integer	2–20.*
term_minpct_node	number	0.0–10.0.*
term_minpct_split	number	0.0–20.0.*
term_minrec_node	integer	Value must be greater than 0.*
term_minrec_split	integer	Value must be greater than 0.*
display_rule_ids	flag	*

* Property ignored if mode is set to Simple.

Oracle O-Cluster

The following properties are available for nodes of type oraoclusternode.

Table 7. oraoclusternode properties

oraoclusternode Properties	Values	Property Description
max_num_clusters	integer	Value must be greater than 0.
max_buffer	integer	Value must be greater than 0.*
sensitivity	number	0.0–1.0.*

* Property ignored if mode is set to Simple.

Oracle KMeans

The following properties are available for nodes of type `orakmeansnode`.

Table 8. orakmeansnode properties

orakmeansnode Properties	Values	Property Description
<code>num_clusters</code>	<code>integer</code>	Value must be greater than 0.
<code>normalization_method</code>	<code>zscore minmax none</code>	
<code>distance_function</code>	<code>Euclidean Cosine</code>	
<code>iterations</code>	<code>integer</code>	0–20.*
<code>conv_tolerance</code>	<code>number</code>	0.0–0.5.*
<code>split_criterion</code>	<code>Variance Size</code>	Default is Variance.*
<code>num_bins</code>	<code>integer</code>	Value must be greater than 0.*
<code>block_growth</code>	<code>integer</code>	1–5.*
<code>min_pct_attr_support</code>	<code>number</code>	0.0–1.0.*

* Property ignored if `mode` is set to `Simple`.

Oracle NMF

The following properties are available for nodes of type `oranmfnode`.

Table 9. oranmfnode properties

oranmfnode Properties	Values	Property Description
<code>normalization_method</code>	<code>minmax none</code>	
<code>use_num_features</code>	<code>flag</code>	*
<code>num_features</code>	<code>integer</code>	0–1. Default value is estimated from the data by the algorithm.*
<code>random_seed</code>	<code>number</code>	*
<code>num_iterations</code>	<code>integer</code>	0–500.*
<code>conv_tolerance</code>	<code>number</code>	0.0–0.5.*
<code>display_all_features</code>	<code>flag</code>	*

* Property ignored if `mode` is set to `Simple`.

Oracle Apriori

The following properties are available for nodes of type `oraapriorinode`.

Table 10. oraapriorinode properties

oraapriorinode Properties	Values	Property Description
<code>content_field</code>	<code>field</code>	
<code>id_field</code>	<code>field</code>	
<code>max_rule_length</code>	<code>integer</code>	2–20.
<code>min_confidence</code>	<code>number</code>	0.0–1.0.
<code>min_support</code>	<code>number</code>	0.0–1.0.
<code>use_transactional_data</code>	<code>flag</code>	

Oracle Minimum Description Length (MDL)

There are no specific properties defined for nodes of type `oramdlnode`. See the common Oracle properties at the start of this section.

Oracle Attribute Importance (AI)

The following properties are available for nodes of type `oraainode`.

Table 11. oraainode properties

oraainode Properties	Values	Property Description
<code>custom_fields</code>	<code>flag</code>	If true, allows you to specify target, input, and other fields for the current node. If false, the current settings from an upstream Type node are used.
<code>selection_mode</code>	<code>ImportanceLevel</code> <code>ImportanceValue</code> <code>TopN</code>	

oraainode Properties	Values	Property Description
select_important	flag	When selection_mode is set to ImportanceLevel , specifies whether to select important fields.
important_label	string	Specifies the label for the "important" ranking.
select_marginal	flag	When selection_mode is set to ImportanceLevel , specifies whether to select marginal fields.
marginal_label	string	Specifies the label for the "marginal" ranking.
important_above	number	0.0–1.0.
select_unimportant	flag	When selection_mode is set to ImportanceLevel , specifies whether to select unimportant fields.
unimportant_label	string	Specifies the label for the "unimportant" ranking.
unimportant_below	number	0.0–1.0.
importance_value	number	When selection_mode is set to ImportanceValue , specifies the cutoff value to use. Accepts values from 0 to 100.
top_n	number	When selection_mode is set to TopN , specifies the cutoff value to use. Accepts values from 0 to 1000.

Oracle Model Nugget Properties

The following properties are for the model nuggets created using the Oracle models.

Oracle Naive Bayes

There are no specific properties defined for nodes of type `applyorabnnode`.

Oracle Adaptive Bayes

There are no specific properties defined for nodes of type `applyoraabnnode`.

Oracle Support Vector Machines

There are no specific properties defined for nodes of type `applyorasvmnode`.

Oracle Decision Tree

The following properties are available for nodes of type `applyoradecisiontreenode`.

Table 1. `applyoradecisiontreenode` properties

applyoradecisiontreenode Properties	Values	Property Description
use_costs	flag	
display_rule_ids	flag	

Oracle O-Cluster

There are no specific properties defined for nodes of type `applyoraoclusternode`.

Oracle KMeans

There are no specific properties defined for nodes of type `applyorakmeansnode`.

Oracle NMF

The following property is available for nodes of type `applyoranmfnode`:

Table 2. `applyoranmfnode` properties

applyoranmfnode Properties	Values	Property Description
display_all_features	flag	

Oracle Apriori

This model nugget cannot be applied in scripting.

Oracle MDL

This model nugget cannot be applied in scripting.

Node Properties for IBM® Netezza® Analytics Modeling

- [Netezza Modeling Node Properties](#)
- [Netezza Model Nugget Properties](#)

Netezza Modeling Node Properties

The following properties are common to IBM Netezza database modeling nodes.

Table 1. Common Netezza node properties

Common Netezza Node Properties	Values	Property Description
custom_fields	flag	If true, allows you to specify target, input, and other fields for the current node. If false, the current settings from an upstream Type node are used.
inputs	[field1 ... fieldN]	Input or predictor fields used by the model.
target	field	Target field (continuous or categorical).
record_id	field	Field to be used as unique record identifier.
use_upstream_connection	flag	If true (default), the connection details specified in an upstream node. Not used if move_data_to_connection is specified.
move_data_connection	flag	If true, moves the data to the database specified by connection. Not used if use_upstream_connection is specified.
connection	structured	The connection string for the Netezza database where the model is stored. Structured property in the form: ['odbc' '<dsn>' '<username>' '<psw>' '<catname>' '<conn_attribs>' [true false]] where: <dsn> is the data source name <username> and <psw> are the username and password for the database <catname> is the catalog name <conn_attribs> are the connection attributes true false indicates whether the password is needed.
table_name	string	Name of database table where model is to be stored.
use_model_name	flag	If true, uses the name specified by model_name as the name of the model, otherwise model name is created by the system.
model_name	string	Custom name for new model.
include_input_fields	flag	If true, passes all input fields downstream, otherwise passes only record_id and fields generated by model.

Netezza Decision Tree

The following properties are available for nodes of type `netezzadectreenode`.

Table 2. netezzadectreenode properties

netezzadectreenode Properties	Values	Property Description
impurity_measure	Entropy Gini	The measurement of impurity, used to evaluate the best place to split the tree.
max_tree_depth	integer	Maximum number of levels to which tree can grow. Default is 62 (the maximum possible).
min_improvement_splits	number	Minimum improvement in impurity for split to occur. Default is 0.01.

netezzadectr eenode Properties	Values	Property Description
min_instances_split	<i>integer</i>	Minimum number of unsplit records remaining before split can occur. Default is 2 (the minimum possible).
weights	<i>structured</i>	Relative weightings for classes. Structured property in the form: <code>set :netezza_dectree.weights = [[drugA 0.3] [drugB 0.6]]</code> Default is weight of 1 for all classes.
pruning_measure	Acc wAcc	Default is Acc (accuracy). Alternative wAcc (weighted accuracy) takes class weights into account while applying pruning.
prune_tree_options	allTrainingData partitionTrainingData useOtherTable	Default is to use allTrainingData to estimate model accuracy. Use partitionTrainingData to specify a percentage of training data to use, or useOtherTable to use a training data set from a specified database table.
perc_training_data	<i>number</i>	If prune_tree_options is set to partitionTrainingData , specifies percentage of data to use for training.
prune_seed	<i>integer</i>	Random seed to be used for replicating analysis results when prune_tree_options is set to partitionTrainingData ; default is 1.
pruning_table	<i>string</i>	Table name of a separate pruning dataset for estimating model accuracy.
compute_probabilities	<i>flag</i>	If true, produces a confidence level (probability) field as well as the prediction field.

Netezza K-Means

The following properties are available for nodes of type **netezzakmeansnode**.

Table 3. netezzakmeansnode properties

netezzakmeansnode Properties	Values	Property Description
distance_measure	Euclidean Manhattan Canberra maximum	Method to be used for measuring distance between data points.
num_clusters	<i>integer</i>	Number of clusters to be created; default is 3.
max_iterations	<i>integer</i>	Number of algorithm iterations after which to stop model training; default is 5.
rand_seed	<i>integer</i>	Random seed to be used for replicating analysis results; default is 12345.

Netezza Bayes Net

The following properties are available for nodes of type **netezzabayesnode**.

Table 4. netezzabayesnode properties

netezzabayesnode Properties	Values	Property Description
base_index	<i>integer</i>	Numeric identifier assigned to first input field for internal management; default is 777.
sample_size	<i>integer</i>	Size of sample to take if number of attributes is very large; default is 10,000.
display_additional_information	<i>flag</i>	If true, displays additional progress information in a message dialog box.
type_of_prediction	best neighbors nn-neighbors	Type of prediction algorithm to use: best (most correlated neighbor), neighbors (weighted prediction of neighbors), or nn-neighbors (non null-neighbors).

Netezza Naive Bayes

The following properties are available for nodes of type **netezzanaivebayesnode**.

Table 5. netezzanaivebayesnode properties

netezzanaivebayesnode Properties	Values	Property Description
compute_probabilities	<i>flag</i>	If true, produces a confidence level (probability) field as well as the prediction field.
use_m_estimation	<i>flag</i>	If true, uses m-estimation technique for avoiding zero probabilities during estimation.

Netezza KNN

The following properties are available for nodes of type `netezzaknnnode`.

Table 6. netezzaknnnode properties

<code>netezzaknnnode</code> Properties	Values	Property Description
<code>weights</code>	<code>structured</code>	Structured property used to assign weights to individual classes. Example: <code>set :netezzaknnnode.weights = [[drugA 0.3] [drugB 0.6]]</code>
<code>distance_measure</code>	<code>Euclidean Manhattan</code> <code>Canberra Maximum</code>	Method to be used for measuring the distance between data points.
<code>num_nearest_neighbors</code>	<code>integer</code>	Number of nearest neighbors for a particular case; default is 3.
<code>standardize_measurements</code>	<code>flag</code>	If true, standardizes measurements for continuous input fields before calculating distance values.
<code>use_coresets</code>	<code>flag</code>	If true, uses core set sampling to speed up calculation for large data sets.

Netezza Divisive Clustering

The following properties are available for nodes of type `netezzadivclusternode`.

Table 7. netezzadivclusternode properties

<code>netezzadivclusternode</code> Properties	Values	Property Description
<code>distance_measure</code>	<code>Euclidean Manhattan</code> <code>Canberra Maximum</code>	Method to be used for measuring the distance between data points.
<code>max_iterations</code>	<code>integer</code>	Maximum number of algorithm iterations to perform before model training stops; default is 5.
<code>max_tree_depth</code>	<code>integer</code>	Maximum number of levels to which data set can be subdivided; default is 3.
<code>rand_seed</code>	<code>integer</code>	Random seed, used to replicate analyses; default is 12345.
<code>min_instances_split</code>	<code>integer</code>	Minimum number of records that can be split, default is 5.
<code>level</code>	<code>integer</code>	Hierarchy level to which records are to be scored; default is -1.

Netezza PCA

The following properties are available for nodes of type `netezzapcanode`.

Table 8. netezzapcanode properties

<code>netezzapcanode</code> Properties	Values	Property Description
<code>center_data</code>	<code>flag</code>	If true (default), performs data centering (also known as "mean subtraction") before the analysis.
<code>perform_data_scaling</code>	<code>flag</code>	If true, performs data scaling before the analysis. Doing so can make the analysis less arbitrary when different variables are measured in different units.
<code>force_eigensolve</code>	<code>flag</code>	If true, uses less accurate but faster method of finding principal components.
<code>pc_number</code>	<code>integer</code>	Number of principal components to which data set is to be reduced; default is 1.

Netezza Regression Tree

The following properties are available for nodes of type `netezzaregtreenode`.

Table 9. netezzaregtreenode properties

<code>netezzaregtreenode</code> Properties	Values	Property Description
<code>max_tree_depth</code>	<code>integer</code>	Maximum number of levels to which the tree can grow below the root node; default is 10.
<code>split_evaluation_measure</code>	<code>Variance</code>	Class impurity measure, used to evaluate the best place to split the tree; default (and currently only option) is <code>Variance</code> .
<code>min_improvement_splits</code>	<code>number</code>	Minimum amount to reduce impurity before new split is created in tree.
<code>min_instances_split</code>	<code>integer</code>	Minimum number of records that can be split.

netezzaregtr eenode Properties	Values	Property Description
pruning_measure	mse r2 pearson spearman	Method to be used for pruning.
prune_tree_options	allTrainingData partitionTrainingData useOtherTable	Default is to use <code>allTrainingData</code> to estimate model accuracy. Use <code>partitionTrainingData</code> to specify a percentage of training data to use, or <code>useOtherTable</code> to use a training data set from a specified database table.
perc_training_data	number	If <code>prune_tree_options</code> is set to <code>PercTrainingData</code> , specifies percentage of data to use for training.
prune_seed	integer	Random seed to be used for replicating analysis results when <code>prune_tree_options</code> is set to <code>PercTrainingData</code> ; default is 1.
pruning_table	string	Table name of a separate pruning dataset for estimating model accuracy.
compute_probabilities	flag	If true, specifies that variances of assigned classes should be included in output.

Netezza Linear Regression

The following properties are available for nodes of type `netezzalineregressionnode`.

Table 10. netezzalineregressionnode properties

netezzalineregressionnode Properties	Values	Property Description
use_svd	flag	If true, uses Singular Value Decomposition matrix instead of original matrix, for increased speed and numerical accuracy.
include_intercept	flag	If true (default), increases overall accuracy of solution.
calculate_model_diagnoses	flag	If true, calculates diagnostics on the model.

Netezza Time Series

The following properties are available for nodes of type `netezzatimeseriesnode`.

Table 11. netezzatimeseriesnode properties

netezzatimeseriesnode Properties	Values	Property Description
time_points	field	Input field containing the date or time values for the time series.
time_series_ids	field	Input field containing time series IDs; used if input contains more than one time series.
model_table	field	Name of database table where Netezza time series model will be stored.
description_table	field	Name of input table that contains time series names and descriptions.
seasonal_adjustment_table	field	Name of output table where seasonally adjusted values computed by exponential smoothing or seasonal trend decomposition algorithms will be stored.
algorithm_name	SpectralAnalysis or spectral ExponentialSmoothing or esmoothing ARIMA SeasonalTrendDecomposition or std	Algorithm to be used for time series modeling.
trend_name	N A D A M D M	Trend type for exponential smoothing: N - none A - additive D - damped additive M - multiplicative D - damped multiplicative
seasonality_type	N A M	Seasonality type for exponential smoothing: N - none A - additive M - multiplicative
interpolation_method	linear cubic spline exponential spline	Interpolation method to be used.
timerange_setting	SD SP	Setting for time range to use: SD - system-determined (uses full range of time series data) SP - user-specified via <code>earliest_time</code> and <code>latest_time</code>
earliest_time	integer date time timestamp	Start and end values, if <code>timerange_setting</code> is <code>SP</code> . Format should follow <code>time_points</code> value. For example, if the <code>time_points</code> field contains a date, this should also be a date. Example: <code>set NZ_DT1.timerange_setting = 'SP' .set NZ_DT1.earliest_time = '1921-01-01' .set NZ_DT1.latest_time = '2121-01-01'</code>
latest_time		

netezzatimeseriesnode	Values	Property Description
arima_setting	SD SP	Setting for the ARIMA algorithm (used only if algorithm_name is set to ARIMA): SD - system-determined SP - user-specified If arima_setting = SP , use the following parameters to set the seasonal and non-seasonal values. Example (non-seasonal only): <code>set NZ_DT1.algorithm_name = 'arima' set NZ_DT1.arima_setting = 'SP' set NZ_DT1.p_symbol = 'lesseq' set NZ_DT1.p = '4' set NZ_DT1.d_symbol = 'lesseq' set NZ_DT1.d = '2' set NZ_DT1.q_symbol = 'lesseq' set NZ_DT1.q = '4'</code>
p_symbol d_symbol q_symbol sp_symbol sd_symbol sq_symbol	less eq lesseq	ARIMA - operator for parameters p , d , q , sp , sd , and sq : less - less than eq - equals lesseq - less than or equal to
p	<i>integer</i>	ARIMA - non-seasonal degrees of autocorrelation.
q	<i>integer</i>	ARIMA - non-seasonal derivation value.
d	<i>integer</i>	ARIMA - non-seasonal number of moving average orders in the model.
sp	<i>integer</i>	ARIMA - seasonal degrees of autocorrelation.
sq	<i>integer</i>	ARIMA - seasonal derivation value.
sd	<i>integer</i>	ARIMA - seasonal number of moving average orders in the model.
advanced_setting	SD SP	Determines how advanced settings are to be handled: SD - system-determined SP - user-specified via period , units_period and forecast_setting . Example: <code>set NZ_DT1.advanced_setting = 'SP' set NZ_DT1.period = 5 set NZ_DT1.units_period = 'd'</code>
period	<i>integer</i>	Length of seasonal cycle, specified in conjunction with units_period . Not applicable for spectral analysis.
units_period	ms s min h d wk q y	Units in which period is expressed: ms - milliseconds s - seconds min - minutes h - hours d - days wk - weeks q - quarters y - years For example, for a weekly time series use 1 for period and wk for units_period .
forecast_setting	forecasthorizon forecasttimes	Specifies how forecasts are to be made.
forecast_horizon	<i>integer date time timestamp</i>	If forecast_setting = forecasthorizon , specifies end point value for forecasting. Format should follow time_points value. For example, if the time_points field contains a date, this should also be a date.
forecast_times	<i>integer date time timestamp</i>	If forecast_setting = forecasttimes , specifies values to use for making forecasts. Format should follow time_points value. For example, if the time_points field contains a date, this should also be a date.
include_history	<i>flag</i>	Indicates if historical values are to be included in output.
include_interpolated_values	<i>flag</i>	Indicates if interpolated values are to be included in output. Not applicable if include_history is false .

Netezza Generalized Linear

The following properties are available for nodes of type **netezzaglmnode**.

Table 12. netezzaglmnode properties

netezzaglmnode Properties	Values	Property Description
dist_family	bernoulli gaussian poisson negativebinomial wald gamma	Distribution type; default is bernoulli .
dist_params	<i>number</i>	Distribution parameter value to use. Only applicable if distribution is Negativebinomial .
trials	<i>integer</i>	Only applicable if distribution is Binomial . When target response is a number of events occurring in a set of trials, target field contains number of events, and trials field contains number of trials.
model_table	<i>field</i>	Name of database table where Netezza generalized linear model will be stored.
maxit	<i>integer</i>	Maximum number of iterations the algorithm should perform; default is 20.
eps	<i>number</i>	Maximum error value (in scientific notation) at which algorithm should stop finding best fit model. Default is -3, meaning 1E-3, or 0.001.

netezzaglmnode Properties	Values	Property Description
tol	<i>number</i>	Value (in scientific notation) below which errors are treated as having a value of zero. Default is -7, meaning that error values below 1E-7 (or 0.0000001) are counted as insignificant.
link_func	<code>identity inverse invnegative invsquare sqrt power oddspower log clog loglog cloglog logit probit gaussit cauchit canbinom cangeom cannegbinom</code>	Link function to use; default is <code>logit</code> .
link_params	<i>number</i>	Link function parameter value to use. Only applicable if <code>link_function</code> is <code>power</code> or <code>oddspower</code> .
interaction	<code>[[[colnames1],[levels1]], [[colnames2],[levels2]], ...,[[colnamesN],[levelsN]],]</code>	Specifies interactions between fields. <code>colnames</code> is a list of input fields, and <code>level</code> is always 0 for each field. Example: <code>[[["K", "BP", "Sex", "K"], [0, 0, 0, 0]], [[("Age", "Na"), [0, 0]]]</code>
intercept	<i>flag</i>	If <code>true</code> , includes the intercept in the model.

Netezza Model Nugget Properties

The following properties are common to Netezza database model nuggets.

Table 1. Common Netezza model nugget properties

Common Netezza Model Nugget Properties	Values	Property Description
connection	<i>string</i>	The connection string for the Netezza database where the model is stored.
table_name	<i>string</i>	Name of database table where model is stored.

Other model nugget properties are the same as those for the corresponding modeling node.

The script names of the model nuggets are as follows.

Table 2. Script names of Netezza model nuggets

Model Nugget	Script Name
Decision Tree	<code>applynetezzadectreenode</code>
K-Means	<code>applynetezzakmeansnode</code>
Bayes Net	<code>applynetezzabayesnode</code>
Naive Bayes	<code>applynetezzanaivebayesnode</code>
KNN	<code>applynetezzaknnnode</code>
Divisive Clustering	<code>applynetezzadivclusternode</code>
PCA	<code>applynetezzapcanode</code>
Regression Tree	<code>applynetezzaregtreenode</code>
Linear Regression	<code>applynetezzalineregressionnode</code>
Time Series	<code>applynetezzatimeseriesnode</code>
Generalized Linear	<code>applynetezzaglmnode</code>

Output node properties

Output node properties differ slightly from those of other node types. Rather than referring to a particular node option, output node properties store a reference to the output object. This is useful in taking a value from a table and then setting it as a stream parameter.

The following topics describe the scripting properties available for output nodes.

- [analysisnode properties](#)
- [dataauditnode properties](#)
- [extensionoutputnode properties](#)
- [kdeexport properties](#)
- [matrixnode properties](#)
- [meansnode properties](#)
- [reportnode properties](#)
- [setglobalsnode properties](#)
- [simevalnode properties](#)
- [simfitnode properties](#)

- [statisticsnode properties](#)
- [statisticoutputnode Properties](#)
- [tablenode properties](#)
- [transformnode properties](#)

analysisnode properties

The Analysis node evaluates predictive models' ability to generate accurate predictions. Analysis nodes perform various comparisons between predicted values and actual values for one or more model nuggets. They can also compare predictive models to each other.

Example

```
node = stream.create("analysis", "My node")
# "Analysis" tab
node.setPropertyValue("coincidence", True)
node.setPropertyValue("performance", True)
node.setPropertyValue("confidence", True)
node.setPropertyValue("threshold", 75)
node.setPropertyValue("improve_accuracy", 3)
node.setPropertyValue("inc_user_measure", True)
# "Define User Measure..."
node.setPropertyValue("user_if", "@TARGET = @PREDICTED")
node.setPropertyValue("user_then", "101")
node.setPropertyValue("user_else", "1")
node.setPropertyValue("user_compute", ["Mean", "Sum"])
node.setPropertyValue("by_fields", ["Drug"])
# "Output" tab
node.setPropertyValue("output_format", "HTML")
node.setPropertyValue("full_filename", "C:/output/analysis_out.html")
```

Table 1. analysisnode properties

analysisnode properties	Data type	Property description
<code>output_mode</code>	<code>Screen File</code>	Used to specify target location for output generated from the output node.
<code>use_output_name</code>	<code>flag</code>	Specifies whether a custom output name is used.
<code>output_name</code>	<code>string</code>	If <code>use_output_name</code> is true, specifies the name to use.
<code>output_format</code>	<code>Text (.txt) HTML (.html)</code> <code>Output (.cou)</code>	Used to specify the type of output.
<code>by_fields</code>	<code>list</code>	
<code>full_filename</code>	<code>string</code>	If disk, data, or HTML output, the name of the output file.
<code>coincidence</code>	<code>flag</code>	
<code>performance</code>	<code>flag</code>	
<code>evaluation_binary</code>	<code>flag</code>	
<code>confidence</code>	<code>flag</code>	
<code>threshold</code>	<code>number</code>	
<code>improve_accuracy</code>	<code>number</code>	
<code>field_detection_meth</code>	<code>Metadata Name</code>	Determines how predicted fields are matched to the original target field. Specify <code>Metadata</code> or <code>Name</code> .
<code>inc_user_measure</code>	<code>flag</code>	
<code>user_if</code>	<code>expr</code>	
<code>user_then</code>	<code>expr</code>	
<code>user_else</code>	<code>expr</code>	
<code>user_compute</code>	<code>[Mean Sum Min Max SDev]</code>	

dataauditnode properties

The Data Audit node provides a comprehensive first look at the data, including summary statistics, histograms and distribution for each field, as well as information on outliers, missing values, and extremes. Results are displayed in an easy-to-read matrix that can be sorted and used to generate full-size graphs and data preparation nodes.

Example

```
filenode = stream.createAt("variablefile", "File", 100, 100)
filenode.setPropertyValue("full_filename", "$CLEO_DEMOS/DRUG1n")
```

```

node = stream.createAt("dataaudit", "My node", 196, 100)
stream.link(filenode, node)
node.setPropertyValue("custom_fields", True)
node.setPropertyValue("fields", ["Age", "Na", "K"])
node.setPropertyValue("display_graphs", True)
node.setPropertyValue("basic_stats", True)
node.setPropertyValue("advanced_stats", True)
node.setPropertyValue("median_stats", False)
node.setPropertyValue("calculate", ["Count", "Breakdown"])
node.setPropertyValue("outlier_detection_method", "std")
node.setPropertyValue("outlier_detection_std_outlier", 1.0)
node.setPropertyValue("outlier_detection_std_extreme", 3.0)
node.setPropertyValue("output_mode", "Screen")

```

Table 1. dataauditnode properties

dataauditnode properties	Data type	Property description
custom_fields	flag	
fields	[field1 ... fieldN]	
overlay	field	
display_graphs	flag	Used to turn the display of graphs in the output matrix on or off.
basic_stats	flag	
advanced_stats	flag	
median_stats	flag	
calculate	Count Breakdown	Used to calculate missing values. Select either, both, or neither calculation method.
outlier_detection_method	std iqr	Used to specify the detection method for outliers and extreme values.
outlier_detection_std_outlier	number	If outlier_detection_method is std , specifies the number to use to define outliers.
outlier_detection_std_extreme	number	If outlier_detection_method is std , specifies the number to use to define extreme values.
outlier_detection_iqr_outlier	number	If outlier_detection_method is iqr , specifies the number to use to define outliers.
outlier_detection_iqr_extreme	number	If outlier_detection_method is iqr , specifies the number to use to define extreme values.
use_output_name	flag	Specifies whether a custom output name is used.
output_name	string	If use_output_name is true, specifies the name to use.
output_mode	Screen File	Used to specify target location for output generated from the output node.
output_format	Formatted (.tab) Delimited (.csv) HTML (.html) Output (.cou)	Used to specify the type of output.
paginate_output	flag	When the output_format is HTML , causes the output to be separated into pages.
lines_per_page	number	When used with paginate_output , specifies the lines per page of output.
full_filename	string	

extensionoutputnode properties

The Extension Output node enables you to analyze data and the results of model scoring using your own custom R or Python for Spark script. The output of the analysis can be text or graphical. The output is added to the Output tab of the manager pane; alternatively, the output can be redirected to a file.

Python for Spark example

```

##### script example for Python for Spark
import modeler.api
stream = modeler.script.stream()
node = stream.create("extension_output", "extension_output")
node.setPropertyValue("syntax_type", "Python")

python_script = """
import json

```

```

import spss.pyspark.runtime

ctx = spss.pyspark.runtime.getContext()
df = ctx.getSparkInputData()
schema = df.dtypes[:]
print df
"""

node.setPropertyValue("python_syntax", python_script)

```

R example

```

##### script example for R
node.setPropertyValue("syntax_type", "R")
node.setPropertyValue("r_syntax", "print(modelerData$Age)")

```

Table 1. extensionoutputnode properties

extensionoutputnode properties	Data type	Property description
syntax_type	<i>R Python</i>	Specify which script runs – R or Python (R is the default).
r_syntax	<i>string</i>	R scripting syntax for model scoring.
python_syntax	<i>string</i>	Python scripting syntax for model scoring.
convert_flags	<i>StringsAndDouble s LogicalValues</i>	Option to convert flag fields.
convert_missing	<i>flag</i>	Option to convert missing values to the R NA value.
convert_datetime	<i>flag</i>	Option to convert variables with date or datetime formats to R date/time formats.
convert_datetime_class	<i>POSIXct POSIXlt</i>	Options to specify to what format variables with date or datetime formats are converted.
output_to	<i>Screen File</i>	Specify the output type (Screen or File).
output_type	<i>Graph Text</i>	Specify whether to produce graphical or text output.
full_filename	<i>string</i>	File name to use for the generated output.
graph_file_type	<i>HTML COU</i>	File type for the output file (.html or .cou).
text_file_type	<i>HTML TEXT COU</i>	Specify the file type for text output (.html, .txt, or .cou).

kdeexport properties

Kernel Density Estimation (KDE)© uses the Ball Tree or KD Tree algorithms for efficient queries, and combines concepts from unsupervised learning, feature engineering, and data modeling. Neighbor-based approaches such as KDE are some of the most popular and useful density estimation techniques. The KDE Modeling and KDE Simulation nodes in SPSS® Modeler expose the core features and commonly used parameters of the KDE library. The nodes are implemented in Python.

Table 1. kdeexport properties

kdeexport properties	Data type	Property description
bandwidth	<i>double</i>	Default is 1.
kernel	<i>string</i>	The kernel to use: gaussian or tophat . Default is gaussian .
algorithm	<i>string</i>	The tree algorithm to use: kd_tree , ball_tree , or auto . Default is auto .
metric	<i>string</i>	The metric to use when calculating distance. For the kd_tree algorithm, choose from: Euclidean , Chebyshev , Cityblock , Minkowski , Manhattan , Infinity , P , L2 , or L1 . For the ball_tree algorithm, choose from: Euclidian , Braycurtis , Chebyshev , Canberra , Cityblock , Dice , Hamming , Infinity , Jaccard , L1 , L2 , Minkowski , Matching , Manhattan , P , Rogersanimoto , Russellrao , Sokalmichener , Sokalsneath , or Kulsinski . Default is Euclidean .
atol	<i>float</i>	The desired absolute tolerance of the result. A larger tolerance will generally lead to faster execution. Default is 0 . 0.
rtol	<i>float</i>	The desired relative tolerance of the result. A larger tolerance will generally lead to faster execution. Default is 1E-8.
breadthFirst	<i>boolean</i>	Set to True to use a breadth-first approach. Set to False to use a depth-first approach. Default is True .
LeafSize	<i>integer</i>	The leaf size of the underlying tree. Default is 40. Changing this value may significantly impact the performance.
pValue	<i>double</i>	Specify the P Value to use if you're using Minkowski for the metric. Default is 1 . 5.

matrixnode properties

The Matrix node creates a table that shows relationships between fields. It is most commonly used to show the relationship between two symbolic fields, but it can also show relationships between flag fields or numeric fields.

Example

```
node = stream.create("matrix", "My node")
# "Settings" tab
node.setPropertyValue("fields", "Numerics")
node.setPropertyValue("row", "K")
node.setPropertyValue("column", "Na")
node.setPropertyValue("cell_contents", "Function")
node.setPropertyValue("function_field", "Age")
node.setPropertyValue("function", "Sum")
# "Appearance" tab
node.setPropertyValue("sort_mode", "Ascending")
node.setPropertyValue("highlight_top", 1)
node.setPropertyValue("highlight_bottom", 5)
node.setPropertyValue("display", ["Counts", "Expected", "Residuals"])
node.setPropertyValue("include_totals", True)
# "Output" tab
node.setPropertyValue("full_filename", "C:/output/matrix_output.html")
node.setPropertyValue("output_format", "HTML")
node.setPropertyValue("paginate_output", True)
node.setPropertyValue("lines_per_page", 50)
```

Table 1. matrixnode properties

matrixnode properties	Data type	Property description
fields	Selected Flags Numerics	
row	field	
column	field	
include_missing_values	flag	Specifies whether user-missing (blank) and system missing (null) values are included in the row and column output.
cell_contents	CrossTabs Function	
function_file	string	
function	Sum Mean Min Max SDev	
sort_mode	Unsorted Ascending Descending	
highlight_top	number	If non-zero, then true.
highlight_bottom	number	If non-zero, then true.
display	[Counts Expected Residuals RowPct ColumnPct TotalPct]	
include_totals	flag	
use_output_name	flag	Specifies whether a custom output name is used.
output_name	string	If <code>use_output_name</code> is true, specifies the name to use.
output_mode	Screen File	Used to specify target location for output generated from the output node.
output_format	Formatted (.tab) Delimited (.csv) HTML (.html) Output (.cou)	Used to specify the type of output. Both the <code>Formatted</code> and <code>Delimited</code> formats can take the modifier <code>transposed</code> , which transposes the rows and columns in the table.
paginate_output	flag	When the <code>output_format</code> is <code>HTML</code> , causes the output to be separated into pages.
lines_per_page	number	When used with <code>paginate_output</code> , specifies the lines per page of output.
full_filename	string	

meansnode properties

The Means node compares the means between independent groups or between pairs of related fields to test whether a significant difference exists. For example, you could compare mean revenues before and after running a promotion or

compare revenues from customers who did not receive the promotion with those who did.

Example

```
node = stream.create("means", "My node")
node.setPropertyValue("means_mode", "BetweenFields")
node.setPropertyValue("paired_fields", [["OPEN_BAL", "CURR_BAL"]])
node.setPropertyValue("label_correlations", True)
node.setPropertyValue("output_view", "Advanced")
node.setPropertyValue("output_mode", "File")
node.setPropertyValue("output_format", "HTML")
node.setPropertyValue("full_filename", "C:/output/means_output.html")
```

Table 1. meansnode properties

meansnode properties	Data type	Property description
means_mode	BetweenGroups BetweenFields	Specifies the type of means statistic to be executed on the data.
test_fields	[field1 ... fieldn]	Specifies the test field when means_mode is set to BetweenGroups .
grouping_field	field	Specifies the grouping field.
paired_fields	[[field1 field2] [field3 field4] ...]	Specifies the field pairs to use when means_mode is set to BetweenFields .
label_correlations	flag	Specifies whether correlation labels are shown in output. This setting applies only when means_mode is set to BetweenFields .
correlation_mode	Probability Absolute	Specifies whether to label correlations by probability or absolute value.
weak_label	string	
medium_label	string	
strong_label	string	
weak_below_probability	number	When correlation_mode is set to Probability , specifies the cutoff value for weak correlations. This must be a value between 0 and 1—for example, 0.90.
strong_above_probability	number	Cutoff value for strong correlations.
weak_below_absolute	number	When correlation_mode is set to Absolute , specifies the cutoff value for weak correlations. This must be a value between 0 and 1—for example, 0.90.
strong_above_absolute	number	Cutoff value for strong correlations.
unimportant_label	string	
marginal_label	string	
important_label	string	
unimportant_below	number	Cutoff value for low field importance. This must be a value between 0 and 1—for example, 0.90.
important_above	number	
use_output_name	flag	Specifies whether a custom output name is used.
output_name	string	Name to use.
output_mode	Screen File	Specifies the target location for output generated from the output node.
output_format	Formatted (.tab) Delimited (.csv) HTML (.html) Output (.cou)	Specifies the type of output.
full_filename	string	
output_view	Simple Advanced	Specifies whether the simple or advanced view is displayed in the output.

reportnode properties

The Report node creates formatted reports containing fixed text as well as data and other expressions derived from the data. You specify the format of the report using text templates to define the fixed text and data output constructions. You can provide custom text formatting by using HTML tags in the template and by setting options on the Output tab. You can include data values and other conditional output by using CLEM expressions in the template.

Example

```

node = stream.create("report", "My node")
node.setPropertyValue("output format", "HTML")
node.setPropertyValue("full_filename", "C:/report_output.html")
node.setPropertyValue("lines_per_page", 50)
node.setPropertyValue("title", "Report node created by a script")
node.setPropertyValue("highlights", False)

```

Table 1. reportnode properties

reportnode properties	Data type	Property description
output_mode	Screen File	Used to specify target location for output generated from the output node.
output_format	HTML (.html) Text (.txt) Output (.cou)	Used to specify the type of file output.
format	Auto Custom	Used to choose whether output is automatically formatted or formatted using HTML included in the template. To use HTML formatting in the template, specify Custom.
use_output_name	flag	Specifies whether a custom output name is used.
output_name	string	If use_output_name is true, specifies the name to use.
text	string	
full_filename	string	
highlights	flag	
title	string	
lines_per_page	number	

setglobalsnode properties

The Set Globals node scans the data and computes summary values that can be used in CLEM expressions. For example, you can use this node to compute statistics for a field called *age* and then use the overall mean of *age* in CLEM expressions by inserting the function @GLOBAL_MEAN(*age*).

Example

```

node = stream.create("setglobals", "My node")
node.setKeyedPropertyValue("globals", "Na", ["Max", "Sum", "Mean"])
node.setKeyedPropertyValue("globals", "K", ["Max", "Sum", "Mean"])
node.setKeyedPropertyValue("globals", "Age", ["Max", "Sum", "Mean", "SDev"])
node.setPropertyValue("clear_first", False)
node.setPropertyValue("show_preview", True)

```

Table 1. setglobalsnode properties

setglobalsnode properties	Data type	Property description
globals	[Sum Mean Min Max SDev]	Structured property where fields to be set must be referenced with the following syntax: node.setKeyedPropertyValue("globals", "Age", ["Max", "Sum", "Mean", "SDev"])
clear_first	flag	
show_preview	flag	

simevalnode properties

The Simulation Evaluation node evaluates a specified predicted target field, and presents distribution and correlation information about the target field.

Table 1. simevalnode properties

simevalnode properties	Data type	Property description
target	field	
iteration	field	

simevalnode properties	Data type	Property description
<code>presorted_by_iteration</code>	<code>boolean</code>	
<code>max_iterations</code>	<code>number</code>	
<code>tornado_fields</code>	<code>[field1...fieldN]</code>	
<code>plot_pdf</code>	<code>boolean</code>	
<code>plot_cdf</code>	<code>boolean</code>	
<code>show_ref_mean</code>	<code>boolean</code>	
<code>show_ref_median</code>	<code>boolean</code>	
<code>show_ref_sigma</code>	<code>boolean</code>	
<code>num_ref_sigma</code>	<code>number</code>	
<code>show_ref_pct</code>	<code>boolean</code>	
<code>ref_pct_bottom</code>	<code>number</code>	
<code>ref_pct_top</code>	<code>number</code>	
<code>show_ref_custom</code>	<code>boolean</code>	
<code>ref_custom_values</code>	<code>[number1...numberN]</code>	
<code>category_values</code>	<code>Category Probabilities Both</code>	
<code>category_groups</code>	<code>Categories Iterations</code>	
<code>create_pct_table</code>	<code>boolean</code>	
<code>pct_table</code>	<code>Quartiles Intervals Custom</code>	
<code>pct_intervals_num</code>	<code>number</code>	
<code>pct_custom_values</code>	<code>[number1...numberN]</code>	

simfitnode properties

The Simulation Fitting node examines the statistical distribution of the data in each field and generates (or updates) a Simulation Generate node, with the best fitting distribution assigned to each field. The Simulation Generate node can then be used to generate simulated data.

Table 1. simfitnode properties

simfitnode properties	Data type	Property description
<code>build</code>	<code>Node XMLEXport Both</code>	
<code>use_source_node_name</code>	<code>boolean</code>	
<code>source_node_name</code>	<code>string</code>	The custom name of the source node that is either being generated or updated.
<code>use_cases</code>	<code>All LimitFirstN</code>	
<code>use_case_limit</code>	<code>integer</code>	
<code>fit_criterion</code>	<code>AndersonDarling KolmogorovSmirnov</code>	
<code>num_bins</code>	<code>integer</code>	
<code>parameter_xml_filename</code>	<code>string</code>	
<code>generate_parameter_import</code>	<code>boolean</code>	

statisticsnode properties

The Statistics node provides basic summary information about numeric fields. It calculates summary statistics for individual fields and correlations between fields.

Example

```
node = stream.create("statistics", "My node")
# "Settings" tab
node.setPropertyValue("examine", ["Age", "BP", "Drug"])
node.setPropertyValue("statistics", ["mean", "sum", "sdev"])
node.setPropertyValue("correlate", ["BP", "Drug"])
```

```

# "Correlation Labels..." section
node.setPropertyValue("label_correlations", True)
node.setPropertyValue("weak_below_absolute", 0.25)
node.setPropertyValue("weak_label", "lower quartile")
node.setPropertyValue("strong_above_absolute", 0.75)
node.setPropertyValue("medium_label", "middle quartiles")
node.setPropertyValue("strong_label", "upper quartile")
# "Output" tab
node.setPropertyValue("full_filename", "c:/output/statistics_output.html")
node.setPropertyValue("output_format", "HTML")

```

Table 1. statisticsnode properties

statisticsnode properties	Data type	Property description
use_output_name	flag	Specifies whether a custom output name is used.
output_name	string	If use_output_name is true, specifies the name to use.
output_mode	Screen File	Used to specify target location for output generated from the output node.
output_format	Text (.txt) HTML (.html) Output (.cou)	Used to specify the type of output.
full_filename	string	
examine	list	
correlate	list	
statistics	[count mean sum min max range variance sdev semean median mode]	
correlation_mode	Probability Absolute	Specifies whether to label correlations by probability or absolute value.
label_correlations	flag	
weak_label	string	
medium_label	string	
strong_label	string	
weak_below_probability	number	When correlation_mode is set to Probability , specifies the cutoff value for weak correlations. This must be a value between 0 and 1—for example, 0.90.
strong_above_probability	number	Cutoff value for strong correlations.
weak_below_absolute	number	When correlation_mode is set to Absolute , specifies the cutoff value for weak correlations. This must be a value between 0 and 1—for example, 0.90.
strong_above_absolute	number	Cutoff value for strong correlations.

statisticsoutputnode Properties

The Statistics Output node allows you to call an IBM® SPSS® Statistics procedure to analyze your IBM SPSS Modeler data. A wide variety of IBM SPSS Statistics analytical procedures is available. This node requires a licensed copy of IBM SPSS Statistics.

The properties for this node are described under [statisticsoutputnode Properties](#).

tablenode properties

The Table node displays the data in table format, which can also be written to a file. This is useful anytime that you need to inspect your data values or export them in an easily readable form.

Example

```

node = stream.create("table", "My node")
node.setPropertyValue("highlight_expr", "Age > 30")
node.setPropertyValue("output_format", "HTML")
node.setPropertyValue("transpose_data", True)
node.setPropertyValue("full_filename", "C:/output/table_output.htm")
node.setPropertyValue("paginate_output", True)
node.setPropertyValue("lines_per_page", 50)

```

Table 1. tablenode properties

tablenode properties	Data type	Property description
<code>full_filename</code>	<code>string</code>	If disk, data, or HTML output, the name of the output file.
<code>use_output_name</code>	<code>flag</code>	Specifies whether a custom output name is used.
<code>output_name</code>	<code>string</code>	If <code>use_output_name</code> is true, specifies the name to use.
<code>output_mode</code>	<code>Screen File</code>	Used to specify target location for output generated from the output node.
<code>output_format</code>	<code>Formatted (.tab) Delimited (.csv) HTML (.html) Output (.cou)</code>	Used to specify the type of output.
<code>transpose_data</code>	<code>flag</code>	Transposes the data before export so that rows represent fields and columns represent records.
<code>paginate_output</code>	<code>flag</code>	When the <code>output_format</code> is <code>HTML</code> , causes the output to be separated into pages.
<code>lines_per_page</code>	<code>number</code>	When used with <code>paginate_output</code> , specifies the lines per page of output.
<code>highlight_expr</code>	<code>string</code>	
<code>output</code>	<code>string</code>	A read-only property that holds a reference to the last table built by the node.
<code>value_labels</code>	<code>[[Value LabelString] [Value LabelString] ...]</code>	Used to specify labels for value pairs.
<code>display_places</code>	<code>integer</code>	Sets the number of decimal places for the field when displayed (applies only to fields with REAL storage). A value of -1 will use the stream default.
<code>export_places</code>	<code>integer</code>	Sets the number of decimal places for the field when exported (applies only to fields with REAL storage). A value of -1 will use the stream default.
<code>decimal_separator</code>	<code>DEFAULT PERIOD COMMA</code>	Sets the decimal separator for the field (applies only to fields with REAL storage).
<code>date_format</code>	<pre>"DDMMYY" "MMDDYY" "YYMMDD" "YYYYMMDD" "YYYYDDD" DAY MONTH "DD-MM-YY" "DD-MM-YYYY" "MM-DD-YY" "MM-DD-YYYY" "DD-MON-YY" "DD-MON-YYYY" "YYYY-MM-DD" "DD.MM.YY" "DD.MM.YYYY" "MM.DD.YYYY" "DD.MON.XX" "DD.MON.YYYY" "DD/MM/YY" "DD/MM/YYYY" "MM/DD/YY" "MM/DD/YYYY" "DD/MON/YY" "DD/MON/YYYY" MON YYYY Q YYYY WW WK YYYY</pre>	Sets the date format for the field (applies only to fields with <code>DATE</code> or <code>TIMESTAMP</code> storage).
<code>time_format</code>	<pre>"HHMMSS" "HHMM" "MMSS" "HH:MM:SS" "HH:MM" "MM:SS" " (H) H: (M) M: (S) S" "(H) H: (M) M" "(M) M: (S) S" "HH.MM.SS" "HH.MM" "MM.SS" "(H) H. (M) M. (S) S" "(H) H. (M) M" "(M) M. (S) S"</pre>	Sets the time format for the field (applies only to fields with <code>TIME</code> or <code>TIMESTAMP</code> storage).
<code>column_width</code>	<code>integer</code>	Sets the column width for the field. A value of -1 will set column width to <code>Auto</code> .
<code>justify</code>	<code>AUTO CENTER LEFT RIGHT</code>	Sets the column justification for the field.

transformnode properties

The Transform node allows you to select and visually preview the results of transformations before applying them to selected

fields.

Example

```
node = stream.create("transform", "My node")
node.setPropertyValue("fields", ["AGE", "INCOME"])
node.setPropertyValue("formula", "Select")
node.setPropertyValue("formula_log_n", True)
node.setPropertyValue("formula_log_n_offset", 1)
```

Table 1. transformnode properties

transformnode properties	Data type	Property description
fields	[field1... fieldn]	The fields to be used in the transformation.
formula	All Select	Indicates whether all or selected transformations should be calculated.
formula_inverse	flag	Indicates if the inverse transformation should be used.
formula_inverse_offset	number	Indicates a data offset to be used for the formula. Set as 0 by default, unless specified by user.
formula_log_n	flag	Indicates if the \log_n transformation should be used.
formula_log_n_offset	number	
formula_log_10	flag	Indicates if the \log_{10} transformation should be used.
formula_log_10_offset	number	
formula_exponential	flag	Indicates if the exponential transformation (e^x) should be used.
formula_square_root	flag	Indicates if the square root transformation should be used.
use_output_name	flag	Specifies whether a custom output name is used.
output_name	string	If use_output_name is true, specifies the name to use.
output_mode	Screen File	Used to specify target location for output generated from the output node.
output_format	HTML (.html) Output (.cou)	Used to specify the type of output.
paginate_output	flag	When the output_format is HTML, causes the output to be separated into pages.
lines_per_page	number	When used with paginate_output , specifies the lines per page of output.
full_filename	string	Indicates the file name to be used for the file output.

Export Node Properties

- [Common Export Node Properties](#)
- [asexport Properties](#)

- [statisticsexportnode Properties](#)
- [tm1odataexport Node Properties](#)
- [tm1export Node Properties \(deprecated\)](#)
- [xmlexportnode Properties](#)

Common Export Node Properties

The following properties are common to all export nodes.

Table 1. Common export node properties

Property	Values	Property description
publish_path	string	Enter the rootname name to be used for the published image and parameter files.

Property	Values	Property description
<code>publish_metadata</code>	<code>flag</code>	Specifies if a metadata file is produced that describes the inputs and outputs of the image and their data models.
<code>publish_use_parameters</code>	<code>flag</code>	Specifies if stream parameters are included in the *.par file.
<code>publish_parameters</code>	<code>string list</code>	Specify the parameters to be included.
<code>execute_mode</code>	<code>export_data publish</code>	Specifies whether the node executes without publishing the stream, or if the stream is automatically published when the node is executed.

aselexport Properties

The Analytic Server export enables you to run a stream on Hadoop Distributed File System (HDFS).

Example

```
node.setPropertyValue("use_default_as", False)
node.setPropertyValue("connection",
["false","9.119.141.141","9080","analyticserver","ibm","admin","admin","false","","","",""])

```

Table 1. asexport properties

aselexport properties	Data type	Property description
<code>data_source</code>	<code>string</code>	The name of the data source.
<code>export_mode</code>	<code>string</code>	Specifies whether to append exported data to the existing data source, or to overwrite the existing data source.
<code>use_default_as</code>	<code>boolean</code>	If set to <code>True</code> , uses the default Analytic Server connection configured in the server options.cfg file. If set to <code>False</code> , uses the connection of this node.
<code>connection</code>	<code>["string", "string", "string", "string", "string", "string", "string", "string", "string", "string", "string", "string"]</code>	A list property containing the Analytic Server connection details. The format is: <code>["is_secure_connect", "server_url", "server_port", "context_root", "consumer", "user_name", "password", "use-kerberos-auth", "kerberos-krb5-config-file-path", "kerberos-jaas-config-file-path", "kerberos-krb5-service-principal-name", "enable-kerberos-debug"]</code> Where: <code>is_secure_connect</code> : indicates whether secure connection is used, and is either <code>true</code> or <code>false</code> . <code>use-kerberos-auth</code> : indicates whether kerberos authentication is used, and is either <code>true</code> or <code>false</code> . <code>enable-kerberos-debug</code> : indicates whether the debug mode of kerberos authentication is used, and is either <code>true</code> or <code>false</code> .

cognosexportnode Properties

The IBM Cognos Export node exports data in a format that can be read by Cognos databases.

For this node, you must define a Cognos connection and an ODBC connection.

Cognos connection

The properties for the Cognos connection are as follows.

Table 1. cognosexportnode properties

cognosexport node properties	Data type	Property description

cognosexport node properties	Data type	Property description
cognos_connection	["string","flag","string","string"]	A list property containing the connection details for the Cognos server. The format is: ["Cognos_server_URL", "login_mode", "namespace", "username", "password"] where: Cognos_server_URL is the URL of the Cognos server containing the source. login_mode indicates whether anonymous login is used, and is either true or false; if set to true, the following fields should be set to "". namespace specifies the security authentication provider used to log on to the server. username and password are those used to log on to the Cognos server. Instead of login_mode, the following modes are also available: <ul style="list-style-type: none"> anonymousMode. For example: ['Cognos_server_url', 'anonymousMode', 'namespace', 'username', 'password'] credentialMode. For example: ['Cognos_server_url', 'credentialMode', 'namespace', 'username', 'password']
		<ul style="list-style-type: none"> storedCredentialMode. For example: ['Cognos_server_url', 'storedCredentialMode', 'stored_credential_name'] Where stored_credential_name is the name of a Cognos credential in the repository.
cognos_package_name	string	The path and name of the Cognos package to which you are exporting data, for example: /Public Folders/MyPackage
cognos_datasource	string	
cognos_export_mode	Publish ExportFile	
cognos_filename	string	

ODBC connection

The properties for the ODBC connection are identical to those listed for **databaseexportnode** in the next section, with the exception that the **datasource** property is not valid.

databaseexportnode properties

	The Database export node writes data to an ODBC-compliant relational data source. In order to write to an ODBC data source, the data source must exist and you must have write permission for it.
---	---

Example

```
'''
Assumes a datasource named "MyDatasource" has been configured
'''

stream = modeler.script.stream()
db_exportnode = stream.createAt("databaseexport", "DB Export", 200, 200)
applynn = stream.findByName("applyneuralnetwork", None)
stream.link(applynn, db_exportnode)

# Export tab
db_exportnode.setPropertyValue("username", "user")
db_exportnode.setPropertyValue("datasource", "MyDatasource")
db_exportnode.setPropertyValue("password", "password")
db_exportnode.setPropertyValue("table_name", "predictions")
db_exportnode.setPropertyValue("write_mode", "Create")
db_exportnode.setPropertyValue("generate_import", True)
db_exportnode.setPropertyValue("drop_existing_table", True)
db_exportnode.setPropertyValue("delete_existing_rows", True)
db_exportnode.setPropertyValue("default_string_size", 32)

# Schema dialog
db_exportnode.setKeyedPropertyValue("type", "region", "VARCHAR(10)")
db_exportnode.setKeyedPropertyValue("export_db_primarykey", "id", True)
db_exportnode.setPropertyValue("use_custom_create_table_command", True)
db_exportnode.setPropertyValue("custom_create_table_command", "My SQL Code")

# Indexes dialog
db_exportnode.setPropertyValue("use_custom_create_index_command", True)
db_exportnode.setPropertyValue("custom_create_index_command", "CREATE BITMAP INDEX <index-name>
```

```

ON <table-name> <(index-columns)>"')
db_exportnode.setKeyedPropertyValue("indexes", "MYINDEX", ["fields", ["id", "region"]])

```

Table 1. databaseexportnode properties

databaseexportnode properties	Data type	Property description
datasource	<i>string</i>	
username	<i>string</i>	
password	<i>string</i>	
epassword	<i>string</i>	This slot is read-only during execution. To generate an encoded password, use the Password Tool available from the Tools menu. See the topic Generating an encoded password for more information.
table_name	<i>string</i>	
write_mode	<i>Create</i> <i>Append Merge</i>	
map	<i>string</i>	Maps a stream field name to a database column name (valid only if write_mode is Merge). For a merge, all fields must be mapped in order to be exported. Field names that do not exist in the database are added as new columns.
key_fields	<i>list</i>	Specifies the stream field that is used for key; map property shows what this corresponds to in the database.
join	<i>Database Add</i>	
drop_existing_table	<i>flag</i>	
delete_existing_rows	<i>flag</i>	
default_string_size	<i>integer</i>	
type		Structured property used to set the schema type.
generate_import	<i>flag</i>	
use_custom_create_table_command	<i>flag</i>	Use the <i>custom_create_table</i> slot to modify the standard CREATE TABLE SQL command.
custom_create_table_command	<i>string</i>	Specifies a string command to use in place of the standard CREATE TABLE SQL command.
use_batch	<i>flag</i>	The following properties are advanced options for database bulk-loading. A True value for Use_batch turns off row-by-row commits to the database.
batch_size	<i>number</i>	Specifies the number of records to send to the database before committing to memory.
bulk_loading	<i>Off</i> <i>ODBC</i> <i>External</i>	Specifies the type of bulk-loading. Additional options for ODBC and External are listed below.
not_logged	<i>flag</i>	
odbc_binding	<i>Row Column</i>	Specify row-wise or column-wise binding for bulk-loading via ODBC.
loader_delimit_mode	<i>Tab Space</i> <i>Other</i>	For bulk-loading via an external program, specify type of delimiter. Select Other in conjunction with the loader_other_delimiter property to specify delimiters, such as the comma (,).
loader_other_delimiter	<i>string</i>	
specify_data_file	<i>flag</i>	A True flag activates the data_file property below, where you can specify the filename and path to write to when bulk-loading to the database.
data_file	<i>string</i>	
specify_loader_program	<i>flag</i>	A True flag activates the loader_program property below, where you can specify the name and location of an external loader script or program.
loader_program	<i>string</i>	
gen_logfile	<i>flag</i>	A True flag activates the logfile_name below, where you can specify the name of a file on the server to generate an error log.
logfile_name	<i>string</i>	
check_table_size	<i>flag</i>	A True flag allows table checking to ensure that the increase in database table size corresponds to the number of rows exported from IBM® SPSS® Modeler.
loader_options	<i>string</i>	Specify additional arguments, such as -comment and -specialdir , to the loader program.
export_db_primarykey	<i>flag</i>	Specifies whether a given field is a primary key.
use_custom_create_index_command	<i>flag</i>	If true , enables custom SQL for all indexes.
custom_create_index_command	<i>string</i>	Specifies the SQL command used to create indexes when custom SQL is enabled. (This value can be overridden for specific indexes as indicated below.)
indexes.INDEXNAME.fields		Creates the specified index if necessary and lists field names to be included in that index.
INDEXNAME "use_custom_create_index_command"	<i>flag</i>	Used to enable or disable custom SQL for a specific index. See examples after the following table.

databaseexportnode properties	Data type	Property description
<code>INDEXNAME "custom_create_index_command"</code>	<code>string</code>	Specifies the custom SQL used for the specified index. See examples after the following table.
<code>indexes.INDEXNAME.rmove</code>	<code>flag</code>	If <code>True</code> , removes the specified index from the set of indexes.
<code>table_space</code>	<code>string</code>	Specifies the table space that will be created.
<code>use_partition</code>	<code>flag</code>	Specifies that the distribute hash field will be used.
<code>partition_field</code>	<code>string</code>	Specifies the contents of the distribute hash field.

Note: For some databases, you can specify that database tables are created for export with compression (for example, the equivalent of `CREATE TABLE MYTABLE (...) COMPRESS YES` in SQL). The properties `use_compression` and `compression_mode` are provided to support this feature, as follows.

Table 2. databaseexportnode properties using compression features

databaseexportnode properties	Data type	Property description
<code>use_compression</code>	<code>Boolean</code>	If set to <code>True</code> , creates tables for export with compression.
<code>compression_mode</code>	<code>Row Page</code> <code>Default Direct_Load_Operations</code> <code>All_Operations Basic OLTP Query_High</code> <code>Query_Low Archive_High Archive_Low</code>	Sets the level of compression for SQL Server databases. Sets the level of compression for Oracle databases. Note that the values <code>OLTP</code> , <code>Query_High</code> , <code>Query_Low</code> , <code>Archive_High</code> , and <code>Archive_Low</code> require a minimum of Oracle 11gR2.

Example showing how to change the `CREATE INDEX` command for a specific index:

```
db_exportnode.setKeyedPropertyValue("indexes", "MYINDEX", ["use_custom_create_index_command", True]) db_exportnode.setKeyedPropertyValue("indexes", "MYINDEX", ["custom_create_index_command", "CREATE BITMAP INDEX <index-name> ON <table-name> <(index-columns)>"])
```

Alternatively, this can be done via a hash table:

```
db_exportnode.setKeyedPropertyValue("indexes", "MYINDEX", {"fields": ["id", "region"], "use_custom_create_index_command": True, "custom_create_index_command": "CREATE INDEX <index-name> ON <table-name> <(index-columns)>"})
```

datacollectionexportnode Properties

	The Data Collection export node outputs data in the format used by Data Collection market research software. A Data Collection Data Library must be installed to use this node.
---	---

Example

```
stream = modeler.script.stream()
datacollectionexportnode = stream.createAt("datacollectionexport", "Data Collection", 200, 200)
datacollectionexportnode.setPropertyValue("metadata_file", "c:\\\\museums.mdd")
datacollectionexportnode.setPropertyValue("merge_metadata", "Overwrite")
datacollectionexportnode.setPropertyValue("casedata_file", "c:\\\\museumdata.sav")
datacollectionexportnode.setPropertyValue("generate_import", True)
datacollectionexportnode.setPropertyValue("enable_system_variables", True)
```

Table 1. datacollectionexportnode properties

datacollectionexportnode properties	Data type	Property description
<code>metadata_file</code>	<code>string</code>	The name of the metadata file to export.
<code>merge_metadata</code>	<code>Overwrite</code> <code>MergeCurrent</code>	
<code>enable_system_variables</code>	<code>flag</code>	Specifies whether the exported <code>.mdd</code> file should include Data Collection system variables.
<code>casedata_file</code>	<code>string</code>	The name of the <code>.sav</code> file to which case data is exported.
<code>generate_import</code>	<code>flag</code>

excelexportnode Properties

The Excel export node outputs data in the Microsoft Excel .xlsx file format. Optionally, you can choose to launch Excel automatically and open the exported file when the node is executed.

Example

```
stream = modeler.script.stream()
excelexportnode = stream.createAt("excelexport", "Excel", 200, 200)
excelexportnode.setPropertyValue("full_filename", "C:/output/myexport.xlsx")
excelexportnode.setPropertyValue("excel_file_type", "Excel2007")
excelexportnode.setPropertyValue("inc_field_names", True)
excelexportnode.setPropertyValue("inc_labels_as_cell_notes", False)
excelexportnode.setPropertyValue("launch_application", True)
excelexportnode.setPropertyValue("generate_import", True)
```

Table 1. excelexportnode properties

excelexportnode properties	Data type	Property description
full_filename	string	
excel_file_type	Excel2007	
export_mode	Create Append	
inc_field_names	flag	Specifies whether field names should be included in the first row of the worksheet.
start_cell	string	Specifies starting cell for export.
worksheet_name	string	Name of the worksheet to be written.
launch_application	flag	Specifies whether Excel should be invoked on the resulting file. Note that the path for launching Excel must be specified in the Helper Applications dialog box (Tools menu, Helper Applications).
generate_import	flag	Specifies whether an Excel Import node should be generated that will read the exported data file.

extensionexportnode properties

With the Extension Export node, you can run R or Python for Spark scripts to export data.

Python for Spark example

```
#### script example for Python for Spark
import modeler.api
stream = modeler.script.stream()
node = stream.create("extension_export", "extension_export")
node.setPropertyValue("syntax_type", "Python")
```

```

python_script = """import spss.pyspark.runtime
from pyspark.sql import SQLContext
from pyspark.sql.types import *

ctx = spss.pyspark.runtime.getContext()
df = ctx.getSparkInputData()
print df.dtypes[:]
_newDF = df.select("Age", "Drug")
print _newDF.dtypes[:]

df.select("Age", "Drug").write.save("c:/data/ageAndDrug.json", format="json")
"""

node.setPropertyValue("python_syntax", python_script)

```

R example

```

#### script example for R
node.setPropertyValue("syntax_type", "R")
node.setPropertyValue("r_syntax", """write.csv(modelerData, "C:/export.csv")""")

```

Table 1. extensionexportnode properties

extensionexportnode properties	Data type	Property description
syntax_type	<i>R Python</i>	Specify which script runs – R or Python (R is the default).
r_syntax	<i>string</i>	The R scripting syntax to run.
python_syntax	<i>string</i>	The Python scripting syntax to run.
convert_flags	<i>StringsAndDouble s LogicalValues</i>	Option to convert flag fields.
convert_missing	<i>flag</i>	Option to convert missing values to the R NA value.
convert_datetime	<i>flag</i>	Option to convert variables with date or datetime formats to R date/time formats.
convert_datetime_class	<i>POSIXct POSIXlt</i>	Options to specify to what format variables with date or datetime formats are converted.

jsonexportnode Properties

The JSON export node outputs data in JSON format. See [JSON Export node](#) for more information.

Table 1. jsonexportnode properties

jsonexportnode properties	Data type	Property description
full_filename	<i>string</i>	The complete filename, including path.
string_format	<i>records values</i>	Specify the format of the JSON string. Default is records .
generate_import	<i>flag</i>	Specifies whether a JSON Import node should be generated that will read the exported data file. Default is False .

outputfilenode Properties

The Flat File export node outputs data to a delimited text file. It is useful for exporting data that can be read by other analysis or spreadsheet software.

Example

```

stream = modeler.script.stream()
outputfile = stream.createAt("outputfile", "File Output", 200, 200)
outputfile.setPropertyValue("full_filename", "c:/output/flatfile_output.txt")
outputfile.setPropertyValue("write_mode", "Append")
outputfile.setPropertyValue("inc field names", False)
outputfile.setPropertyValue("use_newline_after_records", False)
outputfile.setPropertyValue("delimit_mode", "Tab")
outputfile.setPropertyValue("other_delimiter", ",")
outputfile.setPropertyValue("quote_mode", "Double")
outputfile.setPropertyValue("other_quote", "*")

```

```

outputfile.setPropertyValue("decimal_symbol", "Period")
outputfile.setPropertyValue("generate_import", True)

```

Table 1. outputfilenode properties

outputfilenode properties	Data type	Property description
full_filename	string	Name of output file.
write_mode	Overwrite Append	
inc_field_names	flag	
use_newline_after_records	flag	
delimit_mode	Comma Tab Space Other	
other_delimiter	char	
quote_mode	None Single Double Other	
other_quote	flag	
generate_import	flag	
encoding	StreamDefault SystemDefault "UTF-8"

sasexportnode Properties

The SAS export node outputs data in SAS format, to be read into SAS or a SAS-compatible software package. Three SAS file formats are available: SAS for Windows/OS2, SAS for UNIX, or SAS Version 7/8.

Example

```

stream = modeler.script.stream()
sasexportnode = stream.createAt("sasexport", "SAS Export", 200, 200)
sasexportnode.setPropertyValue("full_filename", "c:/output/SAS_output.sas7bdat")
sasexportnode.setPropertyValue("format", "SAS8")
sasexportnode.setPropertyValue("export_names", "NamesAndLabels")
sasexportnode.setPropertyValue("generate_import", True)

```

Table 1. sasexportnode properties

sasexportnode properties	Data type	Property description
format	Windows UNIX SAS7 SAS8	Variant property label fields.
full_filename	string	
export_names	NamesAndLabels NamesAsLabels	Used to map field names from IBM® SPSS® Modeler upon export to IBM SPSS Statistics or SAS variable names.
generate_import	flag

staticsexportnode Properties

The Statistics Export node outputs data in IBM® SPSS® Statistics .sav or .zsav format. The .sav or .zsav files can be read by IBM SPSS Statistics Base and other products. This is also the format used for cache files in IBM SPSS Modeler.

The properties for this node are described under [statisticsexportnode Properties](#).

tm1odataexport Node Properties

The IBM Cognos TM1 Export node exports data in a format that can be read by Cognos TM1 databases.

Table 1. tm1odataexport node properties

tm1odataexpo rt node properties	Data type	Property description
<code>credential_t ype</code>	<code>inputCredential or storedCredentia l</code>	Used to indicate the credential type.
<code>input_creden tial</code>	<code>list</code>	When the <code>credential_type</code> is <code>inputCredential</code> ; specify the domain, user name and password.
<code>stored_crede ntial_name</code>	<code>string</code>	When the <code>credential_type</code> is <code>storedCredential</code> ; specify the name of credential on the C&DS server.
<code>selected_cub e</code>	<code>field</code>	The name of the cube to which you are exporting data. For example: <code>TM1_export.setPropertyValue("selected_cube", "plan_BudgetPlan")</code>

tm1odataexpo rt node properties	Data type	Property description
spss_field_t o_tm1_eleme nt_mapping	<i>list</i>	<p>The tm1 element to be mapped to must be part of the column dimension for selected cube view. The format is: [[[Field_1, Dimension_1, False], [Element_1, Dimension_2, True], ...], [[Field_2, ExistMeasureElement, False], [Field_3, NewMeasureElement, True], ...]]</p> <p>There are 2 lists to describe the mapping information. Mapping a leaf element to a dimension corresponds to example 2 below:</p> <p>Example 1: The first list: ([[Field_1, Dimension_1, False], [Element_1, Dimension_2, True], ...]) is used for the TM1 Dimension map information.</p> <p>Each 3 value list indicates dimension mapping information. The third Boolean value is used to indicate if it selects an element of a dimension. For example: "[Field_1, Dimension_1, False]" means that Field_1 is mapped to Dimension_1; "[Element_1, Dimension_2, True]" means that Element_1 is selected for Dimension_2.</p> <p>Example 2: The second list: ([[Field_2, ExistMeasureElement, False], [Field_3, NewMeasureElement, True], ...]) is used for the TM1 Measure Dimension Element map information.</p> <p>Each 3 value list indicates measure element mapping information. The third Boolean value is used to indicate the need to create a new element. "[Field_2, ExistMeasureElement, False]" means that Field_2 is mapped to the ExistMeasureElement; "[Field_3, NewMeasureElement, True]" means the NewMeasureElement needs to be the measure dimension chosen in selected_measure and that Field_3 is mapped to it.</p>
selected_me asure	<i>string</i>	<p>Specify the measure dimension.</p> <p>Example: <code>setPropertyValue("selected_measure", "Measures")</code></p>
connection_t ype	<i>AdminServer TM1Server</i>	Indicates the connection type. Default is AdminServer.
admin_host	<i>string</i>	The URL for the host name of the REST API. Required if the connection_type is AdminServer.
server_name	<i>string</i>	The name of the TM1 server selected from the admin_host. Required if the connection_type is AdminServer.
server_url	<i>string</i>	The URL for the TM1 Server REST API. Required if the connection_type is TM1Server.

tm1export Node Properties (deprecated)

The IBM Cognos TM1 Export node exports data in a format that can be read by Cognos TM1 databases.

Note: This node was deprecated in Modeler 18.0. The replacement node script name is *tm1odataexport*.

Table 1. tm1export node properties

tm1export node properties	Data type	Property description
pm_host	<i>string</i>	<p>Note: Only for version 16.0 and 17.0</p> <p>The host name. For example: <code>TM1_export.setPropertyValue("pm_host", "http://9.191.86.82:9510/pmhub/pm")</code></p>
tm1_connecti on	<i>["field","field", ... , "field"]</i>	<p>Note: Only for version 16.0 and 17.0</p> <p>A list property containing the connection details for the TM1 server. The format is: ["TM1_Server_Name", "tm1_username", "tm1_password"] For example: <code>TM1_export.setPropertyValue("tm1_connection", ["Planning Sample", "admin" "apple"])</code></p>
selected_cub e	<i>field</i>	<p>The name of the cube to which you are exporting data. For example:</p> <p><code>TM1_export.setPropertyValue("selected_cube", "plan_BudgetPlan")</code></p>

tm1export node properties	Data type	Property description
spssfield_tm1element_mapping	<i>list</i>	The tm1 element to be mapped to must be part of the column dimension for selected cube view. The format is: [[[Field_1, Dimension_1, False], [Element_1, Dimension_2, True], ...], [[Field_2, ExistMeasureElement, False], [Field_3, NewMeasureElement, True], ...]] There are 2 lists to describe the mapping information. Mapping a leaf element to a dimension corresponds to example 2 below: Example 1: The first list: ([[Field_1, Dimension_1, False], [Element_1, Dimension_2, True], ...]) is used for the TM1 Dimension map information. Each 3 value list indicates dimension mapping information. The third Boolean value is used to indicate if it selects an element of a dimension. For example: "[Field_1, Dimension_1, False]" means that Field_1 is mapped to Dimension_1; "[Element_1, Dimension_2, True]" means that Element_1 is selected for Dimension_2. Example 2: The second list: ([[Field_2, ExistMeasureElement, False], [Field_3, NewMeasureElement, True], ...]) is used for the TM1 Measure Dimension Element map information. Each 3 value list indicates measure element mapping information. The third Boolean value is used to indicate the need to create a new element. "[Field_2, ExistMeasureElement, False]" means that Field_2 is mapped to the ExistMeasureElement; "[Field_3, NewMeasureElement, True]" means the NewMeasureElement needs to be the measure dimension chosen in selected_measure and that Field_3 is mapped to it.
selected_measure	<i>string</i>	Specify the measure dimension. Example: setPropertyValue("selected_measure", "Measures")

xmlexportnode Properties

	The XML export node outputs data to a file in XML format. You can optionally create an XML source node to read the exported data back into the stream.
---	--

Example

```
stream = modeler.script.stream()
xmlexportnode = stream.createAt("xmlexport", "XML Export", 200, 200)
xmlexportnode.setPropertyValue("full_filename", "c:/export/data.xml")
xmlexportnode.setPropertyValue("map", ["/catalog/book/genre", "genre"], ["/catalog/book/title", "title"])
```

Table 1. xmlexportnode properties

xmlexportnode properties	Data type	Property description
full_filename	<i>string</i>	(required) Full path and file name of XML export file.
