use_xml_schema	<i>flag</i>	Specifies whether to use an XML schema (XSD or DTD file) to control the structure of the exported data.
full_schema_filename	<i>string</i>	Full path and file name of XSD or DTD file to use. Required if use_xml_schema is set to true.
generate_import	<i>flag</i>	Generates an XML source node that will read the exported data file back into the stream.
records	<i>string</i>	XPath expression denoting the record boundary.
map	<i>string</i>	Maps field name to XML structure.

statisticsimportnode Properties

The Statistics File node reads data from the .sav or .zsav file format used by IBM® SPSS® Statistics, as well as cache files saved in IBM SPSS Modeler, which also use the same format.

Example

```
stream = modeler.script.stream()
statisticsimportnode = stream.createAt("statisticsimport", "SAV Import", 200, 200)
statisticsimportnode.setPropertyValue("full_filename", "C:/data/drug1n.sav")
statisticsimportnode.setPropertyValue("import_names", True)
statisticsimportnode.setPropertyValue("import_data", True)
```

Table 1. statisticsimportnode properties

statisticsimportnode properties	Data type	Property description
full_filename	string	The complete filename, including path.
password	string	The password. The password parameter must be set before the file_encrypted parameter.
file_encrypted	flag	Whether or not the file is password protected.
import_names	NamesAndLabels LabelsAsNames	Method for handling variable names and labels.
import_data	DataAndLabels LabelsAsData	Method for handling values and labels.
use_field_format_for_storange	Boolean	Specifies whether to use IBM SPSS Statistics field format information when importing.

statisticstransformnode properties

The Statistics Transform node runs a selection of IBM® SPSS® Statistics syntax commands against data sources in IBM SPSS Modeler. This node requires a licensed copy of IBM SPSS Statistics.

Example

```

stream = modeler.script.stream()
statisticstransformnode = stream.createAt("statisticstransform", "Transform", 200, 200)
statisticstransformnode.setPropertyValue("syntax", "COMPUTE NewVar = Na + K.")
statisticstransformnode.setKeyedPropertyValue("new_name", "NewVar", "Mixed Drugs")
statisticstransformnode.setPropertyValue("check_before_saving", True)

```

Table 1. statisticstransformnode properties

statisticstransformnode properties	Data type	Property description
syntax	<i>string</i>	
check_before_saving	<i>flag</i>	Validates the entered syntax before saving the entries. Displays an error message if the syntax is invalid.
default_include	<i>flag</i>	See the topic filternode properties for more information.
include	<i>flag</i>	See the topic filternode properties for more information.
new_name	<i>string</i>	See the topic filternode properties for more information.

statisticsmodelnode properties

	The Statistics Model node enables you to analyze and work with your data by running IBM® SPSS® Statistics procedures that produce PMML. This node requires a licensed copy of IBM SPSS Statistics.
---	--

Example

```

stream = modeler.script.stream()
statisticsmodelnode = stream.createAt("statisticsmodel", "Model", 200, 200)
statisticsmodelnode.setPropertyValue("syntax", "COMPUTE NewVar = Na + K.")
statisticsmodelnode.setKeyedPropertyValue("new_name", "NewVar", "Mixed Drugs")

```

statisticsmodelnode properties	Data type	Property description
syntax	<i>string</i>	
default_include	<i>flag</i>	See the topic filternode properties for more information.
include	<i>flag</i>	See the topic filternode properties for more information.
new_name	<i>string</i>	See the topic filternode properties for more information.

statisticsoutputnode Properties

	The Statistics Output node allows you to call an IBM® SPSS® Statistics procedure to analyze your IBM SPSS Modeler data. A wide variety of IBM SPSS Statistics analytical procedures is available. This node requires a licensed copy of IBM SPSS Statistics.
---	--

Example

```

stream = modeler.script.stream()
statisticsoutputnode = stream.createAt("statisticsoutput", "Output", 200, 200)
statisticsoutputnode.setPropertyValue("syntax", "SORT CASES BY Age(A) Sex(A) BP(A) Cholesterol(A) ")
statisticsoutputnode.setPropertyValue("use_output_name", False)
statisticsoutputnode.setPropertyValue("output_mode", "File")
statisticsoutputnode.setPropertyValue("full_filename", "Cases by Age, Sex and Medical History")
statisticsoutputnode.setPropertyValue("file_type", "HTML")

```

Table 1. statisticsoutputnode properties

statisticsoutputnode properties	Data type	Property description
mode	Dialog Syntax	Selects "IBM SPSS Statistics dialog" option or Syntax Editor
syntax	<i>string</i>	
use_output_name	<i>flag</i>	
output_name	<i>string</i>	
output_mode	Screen File	
full_filename	<i>string</i>	
file_type	HTML SPV SPW

statisticsexportnode Properties

The Statistics Export node outputs data in IBM® SPSS® Statistics .sav or .zsav format. The .sav or .zsav files can be read by IBM SPSS Statistics Base and other products. This is also the format used for cache files in IBM SPSS Modeler.

Example

```
stream = modeler.script.stream()
statisticsexportnode = stream.createAt("statisticsexport", "Export", 200, 200)
statisticsexportnode.setPropertyValue("full_filename", "c:/output/SPSS_Statistics_out.sav")
statisticsexportnode.setPropertyValue("field_names", "Names")
statisticsexportnode.setPropertyValue("launch_application", True)
statisticsexportnode.setPropertyValue("generate_import", True)
```

Table 1. statisticsexportnode properties

statisticsexportnode properties	Data type	Property description
full_filename	string	
file_type	sav zsav	Save file in sav or zsav format. For example: <code>statisticsexportnode.setPropertyValue("file_type", "sav")</code>
encrypt_file	flag	Whether or not the file is password protected.
password	string	The password.
launch_application	flag	
export_names	NamesAndLabels NamesAsLabels	Used to map field names from IBM SPSS Modeler upon export to IBM SPSS Statistics or SAS variable names.
generate_import	flag

gmm properties

A Gaussian Mixture© model is a probabilistic model that assumes all the data points are generated from a mixture of a finite number of Gaussian distributions with unknown parameters. One can think of mixture models as generalizing k-means clustering to incorporate information about the covariance structure of the data as well as the centers of the latent Gaussians. The Gaussian Mixture node in SPSS® Modeler exposes the core features and commonly used parameters of the Gaussian Mixture library. The node is implemented in Python.

Table 1. gmm properties

gmm properties	Data type	Property description
<code>use_partition</code>	<code>boolean</code>	Set to <code>True</code> or <code>False</code> to specify whether to use partitioned data. Default is <code>False</code> .
<code>covariance_type</code>	<code>string</code>	Specify <code>Full</code> , <code>Tied</code> , <code>Diag</code> , or <code>Spherical</code> to set the covariance type.
<code>number_component</code>	<code>integer</code>	Specify an integer for the number of mixture components. Minimum value is 1. Default value is 2.
<code>component_label</code>	<code>boolean</code>	Specify <code>True</code> to set the cluster label to a string or <code>False</code> to set the cluster label to a number. Default is <code>False</code> .
<code>label_prefix</code>	<code>string</code>	If using a string cluster label, you can specify a prefix.
<code>enable_random_seed</code>	<code>boolean</code>	Specify <code>True</code> if you want to use a random seed. Default is <code>False</code> .
<code>random_seed</code>	<code>integer</code>	If using a random seed, specify an integer to be used for generating random samples.
<code>tol</code>	<code>Double</code>	Specify the convergence threshold. Default is <code>0.000_1</code> .
<code>max_iter</code>	<code>integer</code>	Specify the maximum number of iterations to perform. Default is 100.
<code>init_params</code>	<code>string</code>	Set the initialization parameter to use. Options are <code>Kmeans</code> or <code>Random</code> .
<code>warm_start</code>	<code>boolean</code>	Specify <code>True</code> to use the solution of the last fitting as the initialization for the next call of fit. Default is <code>False</code> .

hdbscannode properties

Hierarchical Density-Based Spatial Clustering (HDBSCAN)© uses unsupervised learning to find clusters, or dense regions, of a data set. The HDBSCAN node in SPSS® Modeler exposes the core features and commonly used parameters of the HDBSCAN library. The node is implemented in Python, and you can use it to cluster your dataset into distinct groups when you don't know what those groups are at first.

Table 1. hdbscannode properties

hdbscannode properties	Data type	Property description
<code>inputs</code>	<code>field</code>	Input fields for clustering.
<code>useHPO</code>	<code>boolean</code>	Specify <code>true</code> or <code>false</code> to enable or disable Hyper-Parameter Optimization (HPO) based on Rbfopt, which automatically discovers the optimal combination of parameters so that the model will achieve the expected or lower error rate on the samples. Default is <code>false</code> .
<code>min_cluster_size</code>	<code>integer</code>	The minimum size of clusters. Specify an integer. Default is 5.

hdbscannode properties	Data type	Property description
<code>min_samples</code>	<code>integer</code>	The number of samples in a neighborhood for a point to be considered a core point. Specify an integer. If set to 0, the <code>min_cluster_size</code> is used. Default is 0.
<code>algorithm</code>	<code>string</code>	Specify which algorithm to use: <code>best</code> , <code>generic</code> , <code>prims_kdtree</code> , <code>prims_balltree</code> , <code>boruvka_kdtree</code> , or <code>boruvka_balltree</code> . Default is <code>best</code> .
<code>metric</code>	<code>string</code>	Specify which metric to use when calculating distance between instances in a feature array: <code>euclidean</code> , <code>cityblock</code> , <code>L1</code> , <code>L2</code> , <code>manhattan</code> , <code>braycurtis</code> , <code>canberra</code> , <code>chebyshev</code> , <code>correlation</code> , <code>minkowski</code> , or <code>squareeuclidean</code> . Default is <code>euclidean</code> .
<code>useStringLabel</code>	<code>boolean</code>	Specify <code>true</code> to use a string cluster label, or <code>false</code> to use a number cluster label. Default is <code>false</code> .
<code>stringLabelPrefix</code>	<code>string</code>	If the <code>useStringLabel</code> parameter is set to <code>true</code> , specify a value for the string label prefix. Default prefix is <code>cluster</code> .
<code>approx_min_span_tree</code>	<code>boolean</code>	Specify <code>true</code> to accept an approximate minimum spanning tree, or <code>false</code> if you are willing to sacrifice speed for correctness. Default is <code>true</code> .
<code>cluster_selection_method</code>	<code>string</code>	Specify the method to use for selecting clusters from the condensed tree: <code>eom</code> or <code>leaf</code> . Default is <code>eom</code> (Excess of Mass algorithm).
<code>allow_single_cluster</code>	<code>boolean</code>	Specify <code>true</code> if you want to allow single cluster results. Default is <code>false</code> .
<code>p_value</code>	<code>double</code>	Specify the <code>p_value</code> to use if you're using <code>minkowski</code> for the metric. Default is 1.5.
<code>leaf_size</code>	<code>integer</code>	If using a space tree algorithm (<code>boruvka_kdtree</code> , or <code>boruvka_balltree</code>), specify the number of points in a leaf node of the tree. Default is 40.
<code>outputValidity</code>	<code>boolean</code>	Specify <code>true</code> or <code>false</code> to control whether the Validity Index chart is included in the model output.
<code>outputCondensed</code>	<code>boolean</code>	Specify <code>true</code> or <code>false</code> to control whether the Condensed Tree chart is included in the model output.
<code>outputSingleLinkage</code>	<code>boolean</code>	Specify <code>true</code> or <code>false</code> to control whether the Single Linkage Tree chart is included in the model output.
<code>outputMinSpan</code>	<code>boolean</code>	Specify <code>true</code> or <code>false</code> to control whether the Min Span Tree chart is included in the model output.
<code>is_split</code>		Added in version 18.2.1.1.

kdemodel properties

Kernel Density Estimation (KDE)© uses the Ball Tree or KD Tree algorithms for efficient queries, and combines concepts from unsupervised learning, feature engineering, and data modeling. Neighbor-based approaches such as KDE are some of the most popular and useful density estimation techniques. The KDE Modeling and KDE Simulation nodes in SPSS® Modeler expose the core features and commonly used parameters of the KDE library. The nodes are implemented in Python.

Table 1. kdemodel properties

kdemodel properties	Data type	Property description
<code>bandwidth</code>	<code>double</code>	Default is 1.
<code>kernel</code>	<code>string</code>	The kernel to use: <code>gaussian</code> , <code>tophat</code> , <code>epanechnikov</code> , <code>exponential</code> , <code>linear</code> , or <code>cosine</code> . Default is <code>gaussian</code> .
<code>algorithm</code>	<code>string</code>	The tree algorithm to use: <code>kd_tree</code> , <code>ball_tree</code> , or <code>auto</code> . Default is <code>auto</code> .
<code>metric</code>	<code>string</code>	The metric to use when calculating distance. For the <code>kd_tree</code> algorithm, choose from: <code>Euclidean</code> , <code>Chebyshev</code> , <code>Cityblock</code> , <code>Minkowski</code> , <code>Manhattan</code> , <code>Infinity</code> , <code>P</code> , <code>L2</code> , or <code>L1</code> . For the <code>ball_tree</code> algorithm, choose from: <code>Euclidian</code> , <code>Braycurtis</code> , <code>Chebyshev</code> , <code>Canberra</code> , <code>Cityblock</code> , <code>Dice</code> , <code>Hamming</code> , <code>Infinity</code> , <code>Jaccard</code> , <code>L1</code> , <code>L2</code> , <code>Minkowski</code> , <code>Matching</code> , <code>Manhattan</code> , <code>P</code> , <code>Rogersanimoto</code> , <code>Russellrao</code> , <code>Sokalmichener</code> , <code>Sokalsneath</code> , or <code>Kulsinski</code> . Default is <code>Euclidean</code> .
<code>atol</code>	<code>float</code>	The desired absolute tolerance of the result. A larger tolerance will generally lead to faster execution. Default is 0.0.
<code>rtol</code>	<code>float</code>	The desired relative tolerance of the result. A larger tolerance will generally lead to faster execution. Default is <code>1E-8</code> .
<code>breadthFirst</code> renamed to <code>breadth_first</code> starting with version 18.2.1.1	<code>boolean</code>	Set to <code>True</code> to use a breadth-first approach. Set to <code>False</code> to use a depth-first approach. Default is <code>True</code> .
<code>LeafSize</code> renamed to <code>leaf_size</code> starting with version 18.2.1.1	<code>integer</code>	The leaf size of the underlying tree. Default is 40. Changing this value may significantly impact the performance.

kdemodel properties	Data type	Property description
pValue	double	Specify the P Value to use if you're using Minkowski for the metric. Default is 1.5 .
custom_name		
default_node_name		
use_HPO		

kdeexport properties

	Kernel Density Estimation (KDE)© uses the Ball Tree or KD Tree algorithms for efficient queries, and combines concepts from unsupervised learning, feature engineering, and data modeling. Neighbor-based approaches such as KDE are some of the most popular and useful density estimation techniques. The KDE Modeling and KDE Simulation nodes in SPSS® Modeler expose the core features and commonly used parameters of the KDE library. The nodes are implemented in Python.
---	---

Table 1. kdeexport properties

kdeexport properties	Data type	Property description
bandwidth	double	Default is 1 .
kernel	string	The kernel to use: gaussian or tophat . Default is gaussian .
algorithm	string	The tree algorithm to use: kd_tree , ball_tree , or auto . Default is auto .
metric	string	The metric to use when calculating distance. For the kd_tree algorithm, choose from: Euclidean , Chebyshev , Cityblock , Minkowski , Manhattan , Infinity , P , L2 , or L1 . For the ball_tree algorithm, choose from: Euclidian , Braycurtis , Chebyshev , Canberra , Cityblock , Dice , Hamming , Infinity , Jaccard , L1 , L2 , Minkowski , Matching , Manhattan , P , Rogersanimoto , Russellrao , Sokalmichener , Sokalsneath , or Kulsinski . Default is Euclidean .
atol	float	The desired absolute tolerance of the result. A larger tolerance will generally lead to faster execution. Default is 0.0 .
rtol	float	The desired relative tolerance of the result. A larger tolerance will generally lead to faster execution. Default is 1E-8 .
breadthFirst	boolean	Set to True to use a breadth-first approach. Set to False to use a depth-first approach. Default is True .
LeafSize	integer	The leaf size of the underlying tree. Default is 40 . Changing this value may significantly impact the performance.
pValue	double	Specify the P Value to use if you're using Minkowski for the metric. Default is 1.5 .

gmm properties

	A Gaussian Mixture© model is a probabilistic model that assumes all the data points are generated from a mixture of a finite number of Gaussian distributions with unknown parameters. One can think of mixture models as generalizing k-means clustering to incorporate information about the covariance structure of the data as well as the centers of the latent Gaussians. The Gaussian Mixture node in SPSS® Modeler exposes the core features and commonly used parameters of the Gaussian Mixture library. The node is implemented in Python.
---	---

Table 1. gmm properties

gmm properties	Data type	Property description
use_partition	boolean	Set to True or False to specify whether to use partitioned data. Default is False .
covariance_type	string	Specify Full , Tied , Diag , or Spherical to set the covariance type.
number_component	integer	Specify an integer for the number of mixture components. Minimum value is 1 . Default value is 2 .
component_label	boolean	Specify True to set the cluster label to a string or False to set the cluster label to a number. Default is False .
label_prefix	string	If using a string cluster label, you can specify a prefix.
enable_random_seed	boolean	Specify True if you want to use a random seed. Default is False .
random_seed	integer	If using a random seed, specify an integer to be used for generating random samples.
tol	Double	Specify the convergence threshold. Default is 0.0001 .
max_iter	integer	Specify the maximum number of iterations to perform. Default is 100 .
init_params	string	Set the initialization parameter to use. Options are Kmeans or Random .
warm_start	boolean	Specify True to use the solution of the last fitting as the initialization for the next call of fit. Default is False .

ocsvmnode properties

The One-Class SVM node uses an unsupervised learning algorithm. The node can be used for novelty detection. It will detect the soft boundary of a given set of samples, to then classify new points as belonging to that set or not. This One-Class SVM modeling node in SPSS® Modeler is implemented in Python and requires the scikit-learn© Python library.

Table 1. ocsvmnode properties

ocsvmnode properties	Data type	Property description
role_use Renamed to custom_fields starting with version 18.2.1.1	string	Specify predefined to use predefined roles or custom to use custom field assignments. Default is predefined.
splits	field	List of the field names for split.
use_partition	Boolean	Specify true or false . Default is true . If set to true , only training data will be used when building the model.
mode_type	string	The mode. Possible values are simple or expert . All parameters on the Expert tab will be disabled if simple is specified.
stopping_criteria	string	A string of scientific notation. Possible values are 1.0E-1 , 1.0E-2 , 1.0E-3 , 1.0E-4 , 1.0E-5 , or 1.0E-6 . Default is 1.0E-3 .
precision	float	The regression precision (<i>nu</i>). Bound on the fraction of training errors and support vectors. Specify a number greater than 0 and less than or equal to 1.0. Default is 0.1.
kernel	string	The kernel type to use in the algorithm. Possible values are linear , poly , rbf , sigmoid , or precomputed . Default is rbf .
enable_gamma	Boolean	Enables the gamma parameter. Specify true or false . Default is true .
gamma	float	This parameter is only enabled for the kernels rbf , poly , and sigmoid . If the enable_gamma parameter is set to false , this parameter will be set to auto . If set to true , the default is 0.1.
coef0	float	Independent term in the kernel function. This parameter is only enabled for the poly kernel and the sigmoid kernel. Default value is 0.0.
degree	integer	Degree of the polynomial kernel function. This parameter is only enabled for the poly kernel. Specify any integer. Default is 3.
shrinking	Boolean	Specifies whether to use the shrinking heuristic option. Specify true or false . Default is false .
enable_cache_size	Boolean	Enables the cache_size parameter. Specify true or false . Default is false .
cache_size	float	The size of the kernel cache in MB. Default is 200.
pc_type	string	The type of the parallel coordinates graphic. Possible options are independent or general .
lines_amount	integer	Maximum number of lines to include on the graphic. Specify an integer between 1 and 1000.
lines_fields_custom	Boolean	Enables the lines_fields parameter, which allows you to specify custom fields to show in the graph output. If set to false , all fields will be shown. If set to true , only the fields specified with the lines_fields parameter will be shown. For performance reasons, a maximum of 20 fields will be displayed.
lines_fields	field	List of the field names to include on the graphic as vertical axes.
enable_graphic	Boolean	Specify true or false . Enables graphic output (disable this option if you want to save time and reduce stream file size).
enable_hpo	Boolean	Specify true or false to enable or disable the HPO options. If set to true , Rbfopt will be applied to find out the "best" One-Class SVM model automatically, which reaches the target objective value defined by the user with the following target_objval parameter.
target_objval	float	The objective function value (error rate of the model on the samples) we want to reach (for example, the value of the unknown optimum). Set this parameter to the appropriate value if the optimum is unknown (for example, 0.01).
max_iterations	integer	Maximum number of iterations for trying the model. Default is 1000.
max_evaluations	integer	Maximum number of function evaluations for trying the model, where the focus is accuracy over speed. Default is 300.

rfnode properties

The Random Forest node uses an advanced implementation of a bagging algorithm with a tree model as the base model. This Random Forest modeling node in SPSS® Modeler is implemented in Python and requires the scikit-learn© Python library.

Table 1. rfnode properties

rfnode properties	Data type	Property description
<code>role_use</code>	<code>string</code>	Specify <code>predefined</code> to use predefined roles or <code>custom</code> to use custom field assignments. Default is <code>predefined</code> .
<code>inputs</code>	<code>field</code>	List of the field names for input.
<code>splits</code>	<code>field</code>	List of the field names for split.
<code>n_estimators</code>	<code>integer</code>	Number of trees to build. Default is <code>10</code> .
<code>specify_max_depth</code>	<code>Boolean</code>	Specify custom max depth. If <code>false</code> , nodes are expanded until all leaves are pure or until all leaves contain less than <code>min_samples_split</code> samples. Default is <code>false</code> .
<code>max_depth</code>	<code>integer</code>	The maximum depth of the tree. Default is <code>10</code> .
<code>min_samples_leaf</code>	<code>integer</code>	Minimum leaf node size. Default is <code>1</code> .
<code>max_features</code>	<code>string</code>	<p>The number of features to consider when looking for the best split:</p> <ul style="list-style-type: none"> If <code>auto</code>, then <code>max_features=sqrt(n_features)</code> for classifier and <code>max_features=sqrt(n_features)</code> for regression. If <code>sqrt</code>, then <code>max_features=sqrt(n_features)</code>. If <code>log2</code>, then <code>max_features=log2 (n_features)</code>. <p>Default is <code>auto</code>.</p>
<code>bootstrap</code>	<code>Boolean</code>	Use bootstrap samples when building trees. Default is <code>true</code> .
<code>oob_score</code>	<code>Boolean</code>	Use out-of-bag samples to estimate the generalization accuracy. Default value is <code>false</code> .
<code>extreme</code>	<code>Boolean</code>	Use extremely randomized trees. Default is <code>false</code> .
<code>use_random_seed</code>	<code>Boolean</code>	Specify this to get replicated results. Default is <code>false</code> .
<code>random_seed</code>	<code>integer</code>	The random number seed to use when build trees. Specify any integer.
<code>cache_size</code>	<code>float</code>	The size of the kernel cache in MB. Default is <code>200</code> .
<code>enable_random_seed</code>	<code>Boolean</code>	Enables the <code>random_seed</code> parameter. Specify true or false. Default is <code>false</code> .
<code>enable_hpo</code>	<code>Boolean</code>	Specify <code>true</code> or <code>false</code> to enable or disable the HPO options. If set to <code>true</code> , Rbfopt will be applied to determine the "best" Random Forest model automatically, which reaches the target objective value defined by the user with the following <code>target_objval</code> parameter.
<code>target_objval</code>	<code>float</code>	The objective function value (error rate of the model on the samples) you want to reach (for example, the value of the unknown optimum). Set this parameter to the appropriate value if the optimum is unknown (for example, <code>0.01</code>).
<code>max_iterations</code>	<code>integer</code>	Maximum number of iterations for trying the model. Default is <code>1000</code> .
<code>max_evaluations</code>	<code>integer</code>	Maximum number of function evaluations for trying the model, where the focus is accuracy over speed. Default is <code>300</code> .

smotenode Properties

The Synthetic Minority Over-sampling Technique (SMOTE) node provides an over-sampling algorithm to deal with imbalanced data sets. It provides an advanced method for balancing data. The SMOTE process node in SPSS® Modeler is implemented in Python and requires the imbalanced-learn© Python library.

Table 1. smotenode properties

smotenode properties	Data type	Property description
<code>target_field</code> Renamed to <code>target</code> starting with version 18.2.1.1	<code>field</code>	The target field.
<code>sample_ratio</code>	<code>string</code>	Enables a custom ratio value. The two options are Auto (<code>sample_ratio_auto</code>) or Set ratio (<code>sample_ratio_manual</code>).
<code>sample_ratio_value</code>	<code>float</code>	The ratio is the number of samples in the minority class over the number of samples in the majority class. It must be larger than <code>0</code> and less than or equal to <code>1</code> . Default is <code>auto</code> .
<code>enable_random_seed</code>	<code>Boolean</code>	If set to <code>true</code> , the <code>random_seed</code> property will be enabled.
<code>random_seed</code>	<code>integer</code>	The seed used by the random number generator.
<code>k_neighbours</code>	<code>integer</code>	The number of nearest neighbours to be used for constructing synthetic samples. Default is <code>5</code> .
<code>m_neighbours</code>	<code>integer</code>	The number of nearest neighbours to be used for determining if a minority sample is in danger. This option is only enabled with the SMOTE algorithm types <code>borderline1</code> and <code>borderline2</code> . Default is <code>10</code> .

smotenode properties	Data type	Property description
algorithm_kind Renamed to algorithm starting with version 18.2.1.1	<i>string</i>	The type of SMOTE algorithm: <code>regular</code> , <code>borderline1</code> , or <code>borderline2</code> .
usepartition Renamed to use_partition starting with version 18.2.1.1	<i>Boolean</i>	If set to <code>true</code> , only training data will be used for model building. Default is <code>true</code> .

tsnenode Properties

t-Distributed Stochastic Neighbor Embedding (t-SNE) is a tool for visualizing high-dimensional data. It converts affinities of data points to probabilities. This t-SNE node in SPSS® Modeler is implemented in Python and requires the `scikit-learn`® Python library.

Table 1. tsnenode properties

tsnenode properties	Data type	Property description
mode_type	<i>string</i>	Specify <code>simple</code> or <code>expert</code> mode.
n_components	<i>string</i>	Dimension of the embedded space (2D or 3D). Specify <code>2</code> or <code>3</code> . Default is <code>2</code> .
method	<i>string</i>	Specify <code>barnes_hut</code> or <code>exact</code> . Default is <code>barnes_hut</code> .
init	<i>string</i>	Initialization of embedding. Specify <code>random</code> or <code>pca</code> . Default is <code>random</code> .
target_field Renamed to target starting with version 18.2.1.1	<i>string</i>	Target field name. It will be a colormap on the output graph. The graph will use one color if no target field is specified.
perplexity	<i>float</i>	The perplexity is related to the number of nearest neighbors used in other manifold learning algorithms. Larger datasets usually require a larger perplexity. Consider selecting a value between 5 and 50. Default is 30.
early_exaggeration	<i>float</i>	Controls how tight the natural clusters in the original space are in the embedded space, and how much space will be between them. Default is 12.0.
learning_rate	<i>float</i>	Default is 200.
n_iter	<i>integer</i>	Maximum number of iterations for the optimization. Set to at least 250. Default is 1000.
angle	<i>float</i>	The angular size of the distant node as measured from a point. Specify a value in the range of 0-1. Default is 0.5.
enable_random_seed	<i>Boolean</i>	Set to <code>true</code> to enable the <code>random_seed</code> parameter. Default is <code>false</code> .
random_seed	<i>integer</i>	The random number seed to use. Default is <code>None</code> .
n_iter_without_progress	<i>integer</i>	Maximum iterations without progress. Default is 300.
min_grad_norm	<i>string</i>	If the gradient norm is below this threshold, the optimization will be stopped. Default is <code>1.0E-7</code> . Possible values are: <ul style="list-style-type: none"> • <code>1.0E-1</code> • <code>1.0E-2</code> • <code>1.0E-3</code> • <code>1.0E-4</code> • <code>1.0E-5</code> • <code>1.0E-6</code> • <code>1.0E-7</code> • <code>1.0E-8</code>
isGridSearch	<i>Boolean</i>	Set to <code>true</code> to perform t-SNE with several different perplexities. Default is <code>false</code> .
output_Rename	<i>Boolean</i>	Specify <code>true</code> if you want to provide a custom name, or <code>false</code> to name the output automatically. Default is <code>false</code> .
output_to	<i>string</i>	Specify <code>Screen</code> or <code>Output</code> . Default is <code>Screen</code> .
full_filename	<i>string</i>	Specify the output file name.
output_file_type	<i>string</i>	Output file format. Specify <code>HTML</code> or <code>Output object</code> . Default is <code>HTML</code> .

xgboostlinearnode Properties

XGBoost Linear® is an advanced implementation of a gradient boosting algorithm with a linear model as the base model. Boosting algorithms iteratively learn weak classifiers and then add them to a final strong classifier. The XGBoost Linear node in SPSS® Modeler is implemented in Python.

Table 1. xgboostlinearnode properties

xgboostlinearnode properties	Data type	Property description
TargetField Renamed to target starting with version 18.2.1.1	<i>field</i>	
InputFields Renamed to inputs starting with version 18.2.1.1	<i>field</i>	
alpha	<i>Double</i>	The alpha linear booster parameter. Specify any number 0 or greater. Default is 0.
lambda	<i>Double</i>	The lambda linear booster parameter. Specify any number 0 or greater. Default is 1.
lambdaBias	<i>Double</i>	The lambda bias linear booster parameter. Specify any number. Default is 0.
numBoostRound Renamed to num_boost_round starting with version 18.2.1.1	<i>integer</i>	The num boost round value for model building. Specify a value between 1 and 1000. Default is 10.
objectiveType	<i>string</i>	The objective type for the learning task. Possible values are reg:linear , reg:logistic , reg:gamma , reg:tweedie , count:poisson , rank:pairwise , binary:logistic , or multi . Note that for flag targets, only binary:logistic or multi can be used. If multi is used, the score result will show the multi:softmax and multi:softprob XGBoost objective types.
random_seed	<i>integer</i>	The random number seed. Any number between 0 and 9999999. Default is 0.
useHPO	<i>Boolean</i>	Specify true or false to enable or disable the HPO options. If set to true , Rbfopt will be applied to find out the "best" One-Class SVM model automatically, which reaches the target objective value defined by the user with the target_objval parameter.

xgboosttreenode Properties

XGBoost Tree® is an advanced implementation of a gradient boosting algorithm with a tree model as the base model. Boosting algorithms iteratively learn weak classifiers and then add them to a final strong classifier. XGBoost Tree is very flexible and provides many parameters that can be overwhelming to most users, so the XGBoost Tree node in SPSS® Modeler exposes the core features and commonly used parameters. The node is implemented in Python.

Table 1. xgboosttreenode properties

xgboosttreenode properties	Data type	Property description
TargetField Renamed to target starting with version 18.2.1.1	<i>field</i>	The target fields.
InputFields Renamed to inputs starting with version 18.2.1.1	<i>field</i>	The input fields.
treeMethod Renamed to tree_method starting with version 18.2.1.1	<i>string</i>	The tree method for model building. Possible values are auto , exact , or approx . Default is auto .
numBoostRound Renamed to num_boost_round starting with version 18.2.1.1	<i>integer</i>	The num boost round value for model building. Specify a value between 1 and 1000. Default is 10.
maxDepth Renamed to max_depth starting with version 18.2.1.1	<i>integer</i>	The max depth for tree growth. Specify a value of 1 or higher. Default is 6.
minChildWeight Renamed to min_child_weight starting with version 18.2.1.1	<i>Double</i>	The min child weight for tree growth. Specify a value of 0 or higher. Default is 1.
maxDeltaStep Renamed to max_delta_step starting with version 18.2.1.1	<i>Double</i>	The max delta step for tree growth. Specify a value of 0 or higher. Default is 0.

xgboosttreenode properties	Data type	Property description
objectiveType Renamed to objective_type starting with version 18.2.1.1	<i>string</i>	The objective type for the learning task. Possible values are reg: linear , reg: logistic , reg: gamma , reg: tweedie , count: poisson , rank: pairwise , binary: logistic , or multi . Note that for flag targets, only binary: logistic or multi can be used. If multi is used, the score result will show the multi: softmax and multi: softprob XGBoost objective types.
earlyStopping Renamed to early_stopping starting with version 18.2.1.1	<i>Boolean</i>	Whether to use the early stopping function. Default is False .
earlyStoppingRounds Renamed to early_stopping_rounds starting with version 18.2.1.1	<i>integer</i>	Validation error needs to decrease at least every early stopping round(s) to continue training. Default is 10 .
evaluationDataRatio Renamed to evaluation_data_ratio starting with version 18.2.1.1	<i>Double</i>	Ration of input data used for validation errors. Default is 0 . 3 .
random_seed	<i>integer</i>	The random number seed. Any number between 0 and 9999999 . Default is 0 .
sampleSize Renamed to sample_size starting with version 18.2.1.1	<i>Double</i>	The sub sample for control overfitting. Specify a value between 0 . 1 and 1 . 0 . Default is 0 . 1 .
eta	<i>Double</i>	The eta for control overfitting. Specify a value between 0 and 1 . Default is 0 . 3 .
gamma	<i>Double</i>	The gamma for control overfitting. Specify any number 0 or greater. Default is 6 .
colsSampleRatio Renamed to col_sample_ratio starting with version 18.2.1.1	<i>Double</i>	The colsample by tree for control overfitting. Specify a value between 0 . 01 and 1 . Default is 1 .
colsSampleLevel Renamed to col_sample_level starting with version 18.2.1.1	<i>Double</i>	The colsample by level for control overfitting. Specify a value between 0 . 01 and 1 . Default is 1 .
lambda	<i>Double</i>	The lambda for control overfitting. Specify any number 0 or greater. Default is 1 .
alpha	<i>Double</i>	The alpha for control overfitting. Specify any number 0 or greater. Default is 0 .
scalePosWeight Renamed to scale_pos_weight starting with version 18.2.1.1	<i>Double</i>	The scale pos weight for handling imbalanced datasets. Default is 1 .
use_HPO Added for version 18.2.1.1		

Spark Node Properties

- [isotonicasnode Properties](#)
- [kmeansasnodel properties](#)
- [multilayerperceptronnode Properties](#)
- [xgboostasnodel Properties](#)

isotonicasnode Properties

Isotonic Regression belongs to the family of regression algorithms. The Isotonic-AS node in SPSS® Modeler is implemented in Spark. For details about Isotonic Regression algorithms, see <https://spark.apache.org/docs/2.2.0/mllib-isotonic-regression.html>.

Table 1. isotonicasnode properties

isotonicasnode properties	Data type	Property description
----------------------------------	------------------	-----------------------------

isotonicasnode properties	Data type	Property description
label	string	This property is a dependent variable for which isotonic regression is calculated.
features	string	This property is an independent variable.
weightCol	string	The weight represents a number of measures. Default is 1.
isotonic	Boolean	This property indicates whether the type is isotonic or antitonic .
featureIndex	integer	This property is for the index of the feature if featuresCol is a vector column. Default is 0.

kmeansasnode properties

K-Means is one of the most commonly used clustering algorithms. It clusters data points into a predefined number of clusters. The K-Means-AS node in SPSS® Modeler is implemented in Spark. For details about K-Means algorithms, see <https://spark.apache.org/docs/2.2.0/ml-clustering.html>. Note that the K-Means-AS node performs one-hot encoding automatically for categorical variables.

Table 1. kmeansasnode properties

kmeansasnode Properties	Values	Property description
roleUse	string	Specify predefined to use predefined roles, or custom to use custom field assignments. Default is predefined .
autoModel	Boolean	Specify true to use the default name (\$S-prediction) for the new generated scoring field, or false to use a custom name. Default is true .
features	field	List of the field names for input when the roleUse property is set to custom .
name	string	The name of the new generated scoring field when the autoModel property is set to false .
clustersNum	integer	The number of clusters to create. Default is 5.
initMode	string	The initialization algorithm. Possible values are k-means or random . Default is k-means .
initSteps	integer	The number of initialization steps when initMode is set to k-means . Default is 2.
advancedSettings	Boolean	Specify true to make the following four properties available. Default is false .
maxIteration	integer	Maximum number of iterations for clustering. Default is 20.
tolerance	string	The tolerance to stop the iterations. Possible settings are 1.0E-1, 1.0E-2, ..., 1.0E-6 . Default is 1.0E-4 .
setSeed	Boolean	Specify true to use a custom random seed. Default is false .
randomSeed	integer	The custom random seed when the setSeed property is true .

multilayerperceptronnode Properties

Multilayer perceptron is a classifier based on the feedforward artificial neural network and consists of multiple layers. Each layer is fully connected to the next layer in the network. The MultiLayerPerceptron-AS node in SPSS® Modeler is implemented in Spark. For details about the multilayer perceptron classifier (MLPC), see <https://spark.apache.org/docs/latest/ml-classification-regression.html#multilayer-perceptron-classifier>.

Table 1. multilayerperceptronnode properties

multilayerperceptronnode properties	Data type	Property description
features	field	One or more fields to use as inputs for the prediction.
label	field	The field to use as the target for the prediction.
layers[0]	integer	The number of perceptron layers to include. Default is 1.
layers[1...<latest-1>]	integer	The number of hidden layers. Default is 1.
layers[<latest>]	integer	The number of output layers. Default is 1.
seed	integer	The custom random seed.
maxiter	integer	The maximum number of iterations to perform. Default is 10.

xgboostasnode Properties

XGBoost is an advanced implementation of a gradient boosting algorithm. Boosting algorithms iteratively learn weak classifiers and then add them to a final strong classifier. XGBoost is very flexible and provides many parameters that can be overwhelming to most users, so the XGBoost-AS node in SPSS® Modeler exposes the core features and commonly used parameters. The XGBoost-AS node is implemented in Spark.

Table 1. xgboostasnode properties

xgboostasnode properties	Data type	Property description
target_field	<i>field</i>	List of the field names for target.
input_fields	<i>field</i>	List of the field names for inputs.
nWorkers	<i>integer</i>	The number of workers used to train the XGBoost model. Default is 1.
numThreadPerTask	<i>integer</i>	The number of threads used per worker. Default is 1.
useExternalMemory	<i>Boolean</i>	Whether to use external memory as cache. Default is false.
boosterType	<i>string</i>	The booster type to use. Available options are gbtree , gblinear , or dart . Default is gbtree .
numBoostRound	<i>integer</i>	The number of rounds for boosting. Specify a value of 0 or higher. Default is 10.
scalePosWeight	<i>Double</i>	Control the balance of positive and negative weights. Default is 1.
randomseed	<i>integer</i>	The seed used by the random number generator. Default is 0.
objectiveType	<i>string</i>	The learning objective. Possible values are reg:linear , reg:logistic , reg:gamma , reg:tweedie , rank:pairwise , binary:logistic , or multi . Note that for flag targets, only binary:logistic or multi can be used. If multi is used, the score result will show the multi:softmax and multi:softprob XGBoost objective types. Default is reg:linear .
evalMetric	<i>string</i>	Evaluation metrics for validation data. A default metric will be assigned according to the objective. Possible values are rmse , mae , logloss , error , merror , mlogloss , auc , ndcg , map , or gamma-deviance . Default is rmse .
lambda	<i>Double</i>	L2 regularization term on weights. Increasing this value will make the model more conservative. Specify any number 0 or greater. Default is 1.
alpha	<i>Double</i>	L1 regularization term on weights. Increasing this value will make the model more conservative. Specify any number 0 or greater. Default is 0.
lambdaBias	<i>Double</i>	L2 regularization term on bias. If the gblinear booster type is used, this lambda bias linear booster parameter is available. Specify any number 0 or greater. Default is 0.
treeMethod	<i>string</i>	If the gbtree or dart booster type is used, this tree method parameter for tree growth (and the other tree parameters that follow) is available. It specifies the XGBoost tree construction algorithm to use. Available options are auto , exact , or approx . Default is auto .
maxDepth	<i>integer</i>	The maximum depth for trees. Specify a value of 2 or higher. Default is 6.
minChildWeight	<i>Double</i>	The minimum sum of instance weight (hessian) needed in a child. Specify a value of 0 or higher. Default is 1.
maxDeltaStep	<i>Double</i>	The maximum delta step to allow for each tree's weight estimation. Specify a value of 0 or higher. Default is 0.
sampleSize	<i>Double</i>	The sub sample for is the ratio of the training instance. Specify a value between 0.1 and 1.0. Default is 1.0.
eta	<i>Double</i>	The step size shrinkage used during the update step to prevent overfitting. Specify a value between 0 and 1. Default is 0.3.
gamma	<i>Double</i>	The minimum loss reduction required to make a further partition on a leaf node of the tree. Specify any number 0 or greater. Default is 6.
colSampleRatio	<i>Double</i>	The sub sample ratio of columns when constructing each tree. Specify a value between 0.01 and 1. Default is 1.
colSampleLevel	<i>Double</i>	The sub sample ratio of columns for each split, in each level. Specify a value between 0.01 and 1. Default is 1.
normalizeType	<i>string</i>	If the dart booster type is used, this dart parameter and the following three dart parameters are available. This parameter sets the normalization algorithm. Specify tree or forest . Default is tree .
sampleType	<i>string</i>	The sampling algorithm type. Specify uniform or weighted . Default is uniform .
rateDrop	<i>Double</i>	The dropout rate dart booster parameter. Specify a value between 0.0 and 1.0. Default is 0.0.
skipDrop	<i>Double</i>	The dart booster parameter for the probability of skip dropout. Specify a value between 0.0 and 1.0. Default is 0.0.

SuperNode properties

Properties that are specific to SuperNodes are described in the following tables. Note that common node properties also apply to SuperNodes.

Table 1. Terminal supernode properties

Property name	Property type/List of values	Property description
execute_method	Script Normal	

Property name	Property type/List of values	Property description
script	string	

SuperNode Parameters

You can use scripts to create or set SuperNode parameters using the general format:

```
mySuperNode.setParameterValue("minvalue", 30)
```

You can retrieve the parameter value with:

```
value mySuperNode.getParameterValue("minvalue")
```

Finding Existing SuperNodes

You can find SuperNodes in streams using the `findByType()` function:

```
source_supernode = modeler.script.stream().findByType("source_super", None)
process_supernode = modeler.script.stream().findByType("process_super", None)
terminal_supernode = modeler.script.stream().findByType("terminal_super", None)
```

Setting Properties for Encapsulated Nodes

You can set properties for specific nodes encapsulated within a SuperNode by accessing the child diagram within the SuperNode. For example, suppose you have a source SuperNode with an encapsulated Variable File node to read in the data. You can pass the name of the file to read (specified using the `full_filename` property) by accessing the child diagram and finding the relevant node as follows:

```
childDiagram = source_supernode.getChildDiagram()
varfilename = childDiagram.findByType("variablefile", None)
varfilename.setPropertyValue("full_filename", "c:/mydata.txt")
```

Creating SuperNodes

If you want to create a SuperNode and its content from scratch, you can do that in a similar way by creating the SuperNode, accessing the child diagram, and creating the nodes you want. You must also ensure that the nodes within the SuperNode diagram are also linked to the input- and/or output connector nodes. For example, if you want to create a process SuperNode:

```
process_supernode = modeler.script.stream().createAt("process_super", "My SuperNode", 200, 200)
childDiagram = process_supernode.getChildDiagram()
filternode = childDiagram.createAt("filter", "My Filter", 100, 100)
childDiagram.linkFromInputConnector(filternode)
childDiagram.linkToOutputConnector(filternode)
```

General Classes

This provides general classes used by other parts of the API.

- [enum Objects](#)
- [ModelerException Objects](#)
- [VersionInfo Objects](#)

Related information

- [enum Objects](#)
- [ModelerException Objects](#)
- [VersionInfo Objects](#)

enum Objects

This class provides the basis for all enumerated classes in the Modeler API. Note that enum names are not case-sensitive.

```
e.equals(object) : boolean
```

`object` (`Object`): the other object.

Returns `True` if the supplied object is equal to this object.

`e.getName() : string`

Returns the name of the enumeration. Same as `toString()`.

`e.hashCode() : int`

Returns the hash code for this object.

`e.isUnknown() : boolean`

Returns `True` if this enumeration value represents an unknown or undefined object or `False` otherwise. An enumeration may contain at most one value that represents an unknown or undefined value.

`e.toString() : string`

Returns the name of the enumeration. Same as `getName()`.

Related information

- [General Classes](#)

ModelerException Objects

A generic Predictive Server exception.

Related information

- [General Classes](#)

VersionInfo Objects

Default Modeler API version information. The version information is made up of the major version, minor version and patch version. A change in the major version number indicates significant extensions to the functionality; a change in the minor version number indicates small extensions or refinements to the functionality; a change in the patch version number indicates a bug-fix release and that the documented functionality has not changed.

Constants:

`MAJOR_VERSION (int) :`
`MINOR_VERSION (int) :`
`RELEASE_VERSION (int) :`

`getBuildDate() : Date`

Returns the build date and time. If the build time is not available then `None` is returned.

`getBuildVersion() : string`

Returns the build version of this library. If the build version is not available then the empty string is returned.

`getCopyright() : string`

Returns the copyright message.

`getMajorVersion() : int`

Returns the major version number.

`getMinorVersion() : int`

Returns the minor version number.

`getName() : string`

Returns the name of the library.

`getPatchVersion() : int`

Returns the patch version number.

ColumnStatsContentModel Objects

Subclass of [ContentModel](#).

An interface that provides a mechanism for accessing column/univariate statistics from nodes which can produce them.

```
c.getAvailableColumns() : List
```

Returns the names of the columns that can be queried.

```
c.getAvailableStatistics() : List
```

Returns the statistics which have been computed. Note that not all columns may have values for all available statistics.

```
c.getStatistic(column, statistic) : Number
```

column (string) : the column

statistic (StatisticType) : the statistic

Returns the value of the statistic for the specified.

Related information

- [Content Management](#)
-

ContentModel Objects

An interface that provides a mechanism for accessing the content of a [ContentContainer](#) in a structured way.

```
c.getContainerName() : string
```

Returns the name of the container that this content model is associated with.

```
c.reset()
```

Flushes any internal storage associated with this content model.

Related information

- [Content Management](#)

JSONContentModel Objects

Subclass of **ContentModel**.

An interface that provides a mechanism for accessing the JSON content of a **ContentContainer**. Content is accessed using lists of strings or integers. Strings are used to access named children in the JSON object while integers are used to access specific values in JSON arrays.

```
j.getChildValuesAt(path, artifact) : Map
```

path (**List**) : the path to the required object

artifact (**JSONArtifact**) : the starting artifact or **None**

Returns the child values of the specified path if the path leads to a JSON object or **None** otherwise. The keys in the table are strings while the associated value may be a literal string, integer, real or boolean, or a JSON artifact (either a JSON object or a JSON array).

Exceptions:

Exception : if there is an error parsing the JSON or when accessing specific content.

```
j.getChildrenAt(path, artifact) : List
```

path (**List**) : the path to the required object

artifact (**JSONArtifact**) : the starting artifact or **None**

Returns the list of objects at the specified path if the path leads to a JSON array or **None** otherwise. The returned values may be a literal string, integer, real or boolean, or a JSON artifact (either a JSON object or a JSON array).

Exceptions:

Exception : if there is an error parsing the JSON or when accessing specific content.

```
j.getJSONAsString() : string
```

Returns the JSON content as a string.

```
j.getObjectAt(path, artifact) : object
```

path (**List**) : the path to the required object

artifact (**JSONArtifact**) : the starting artifact or **None**

Returns the object at the specified path. The supplied root artifact may be **None** in which case the root of the content is used. The returned value may be a literal string, integer, real or boolean, or a JSON artifact (either a JSON object or a JSON array).

Exceptions:

Exception : if there is an error parsing the JSON or when accessing specific content

Related information

- [Content Management](#)

PairwiseStatsContentModel Objects

Subclass of **ContentModel**.

An interface that provides a mechanism for accessing correlations between columns.

```
p.getAvailablePrimaryColumns() : List
```

Returns the names of the primary columns that can be queried. If the statistics are comparing values within a column then only a single primary column will be returned.

```
p.getAvailablePrimaryValues() : List
```

Returns the values of the primary column that can be queried.

```
p.getAvailableSecondaryColumns() : List
```

Returns the names of the secondary columns that can be queried.

```
p.getAvailableStatistics() : List
```

Returns the statistics which have been computed. Note that not all column pairs may have values for all available statistics.

```
p.getStatistic(primaryColumn, secondaryColumn, statistic) : Number
```

primaryColumn (string) : the primary column

secondaryColumn (string) : the secondary column

statistic (StatisticType) : the statistic

Returns the value of the statistic for the specified pair of columns. Note that the method always returns null if the primary and secondary columns are the same.

```
p.getStatistic(primaryColumn, primaryValue, secondaryColumn, statistic) : Number
```

primaryColumn (string) : the primary column

primaryValue (object) : the primary column value

secondaryColumn (string) : the secondary column

statistic (StatisticType) : the statistic

Returns the value of the statistic for the specified value in the primary column associated with the secondary column. Note that the method always returns null if the primary and secondary columns are the same.

Related information

- [Content Management](#)
-

StatisticType Objects

Defines the statistics that can be computed either for a single column or for combinations of columns/column values.

Constants:

Count (StatisticType) : Represents the number of non-null values.

Covariance (StatisticType) : Represents the covariance between 2 columns.

FTest (StatisticType) : Represents the F-test.

Kurtosis (StatisticType) : Represents the kurtosis.

KurtosisStandardError (StatisticType) : Represents the standard error of the kurtosis.

Max (StatisticType) : Represents the maximum value.

Mean (StatisticType) : Represents the mean value.

MeanStandardError (StatisticType) : Represents the standard error of the mean value.

Median (StatisticType) : Represents the median (middle) value.

Min (StatisticType) : Represents the minimum value.

Mode (StatisticType) : Represents the modal (most common) value.

Pearson (StatisticType) : Represents the Pearson correlation between 2 columns.

Range (StatisticType) : Represents the range value.

```

Skewness (StatisticType) : Represents the skewness.

SkewnessStandardError (StatisticType) : Represents the standard error of the skewness.

StandardDeviation (StatisticType) : Represents the standard deviation.

StandardErrorOfMean (StatisticType) : Represents the standard error of the mean.

Sum (StatisticType) : Represents the sum of values.

TTest (StatisticType) : Represents the t-test.

UniqueCount (StatisticType) : Represents the number of distinct values.

ValidCount (StatisticType) : Represents the number of valid values.

Variance (StatisticType) : Represents the variance.

s.isPairwise() : boolean

Returns whether the statistic is only appropriate when comparing more than one value.

valueOf(name) : StatisticType

name (string) :

values() : StatisticType[]

```

Related information

- [Content Management](#)
-

TableContentModel Objects

Subclass of **ContentModel**.

An interface that provides a mechanism for accessing the tabular content of a **ContentContainer**. Values are arranged in rows and named columns where values in a particular column have the same storage type.

t.getColumnName(columnIndex) : int

Returns the number of columns in this content model..

t.getColumnName(columnIndex) : string

columnIndex (int) : the column index

Returns the name of a specified column in this content model. Returns the empty string if the column does not have a name. The column index must be in the range: `0 <= index < getRowCount ()`.

Exceptions:

IndexOutOfBoundsException: unless the column index is in range

t.getRowCount () : int

Returns the number of rows in this content model.

t.getStorageType(columnIndex) : StorageType

columnIndex (int) : the column index

Returns the storage type of objects in a specified column of this content model. The column index must be in the range: `0 <= index < getRowCount ()`.

Exceptions:

IndexOutOfBoundsException: unless the column index is in range

t.getValueAt(rowIndex, columnIndex) : object

rowIndex (int) : the row index

`columnIndex (int) : the column index`

Returns the value from a specified row and column in this content model. The row and column indexes must be in the range: `0 <= rowIndex < getRowCount() && 0 <= columnIndex < getColumnCount()`. The returned value will either be `None` or an instance of the class returned by `getColumnClass` for the same column index.

Exceptions:

`IndexOutOfBoundsException`: unless the column indexes are in range

Related information

- [Content Management](#)
-

XMLContentModel Objects

Subclass of `ContentModel`.

An interface that provides a mechanism for accessing the XML content of a ContentContainer. Content is accessed using XPath syntax without having to configure the additional parsers although callers can access the underlying XML text if they prefer to use a different mechanism.

`x.getBooleanValue(xpath) : boolean`

`xpath (string) : the XPath expression`

Returns the boolean result of evaluating the specified path expression.

Exceptions:

`Exception`:

`x.getNumericValue(xpath) : Number`

`xpath (string) : the XPath expression`

Returns the result of evaluating the path with return type of numeric. For example, count the number of elements that match the path expression.

Exceptions:

`Exception`:

`x.getStringValue(xpath, attribute) : string`

`xpath (string) : the XPath expression`

`attribute (string) : the name of the attribute to be returned or None if the XML node value is to be returned`

Evaluates the XPath expression to an XML node and returns either the value of the specified attribute in that node if the attribute name is a non-zero length string or the node value otherwise.

Exceptions:

`Exception`:

`x.getStringValues(xpath, attribute) : List`

`xpath (string) : the XPath expression`

`attribute (string) : the name of the attribute to be returned or None if the XML node value is to be returned`

Evaluates the XPath expression to a collection of XML nodes and returns a list containing either the value of the specified attribute in that node if the attribute name is a non-zero length string or the node value otherwise.

Exceptions:

`Exception`:

`x.getValuesList(xpath, attributes, includeValue) : List`

`xpath (string) : the XPath expression`

attributes (`List`) : the list of attribute names whose values are to be returned in each sublist

includeValue (`boolean`) : whether the XML node value should be included at the end of each sublist

Evaluates the XPath expression to obtain a list of XML nodes and returns a list of lists where each sublist contains the specified values from a particular node. The values of the named attributes are added to each sublist and the node value is added to the end of the sublist if the `includeValue` flag is set to `True`.

Exceptions:

Exception:

`x.getValuesMap(xpath, keyAttribute, attributes, includeValue) : Map`

`xpath (string)` : the XPath expression

`keyAttribute (string)` :

`attributes (List)` : the list of attribute names whose values are to be returned in each table entry list

`includeValue (boolean)` : whether the XML node value should be included at the end of each table entry list

Evaluates the XPath expression to obtain a list of XML nodes and returns a hash table of the specified attributes. The key for each entry is either the value of the specified key attribute in that node if the key attribute name is a non-zero length string or the node value otherwise. The value for each entry in the table is a list containing the specified values from the key node. The node value is added to the end of each list if the `includeValue` flag is set to `True`.

Exceptions:

Exception:

`x.getXMLAsString() : string`

Returns the XML as a string.

`x.isNamespaceAware() : boolean`

Returns `True` if the content model is aware of XML namespaces when parsing XML documents. The default value is `False`.

`x.setNamespaceAware(isAware)`

`isAware (boolean)` : whether the content model should be namespace aware

Sets whether the content model is aware of XML namespaces when parsing XML documents. Modifying this value can affect the syntax that should be used in XPath expressions. By default, XML content models are not namespace aware. When the value is changed, `reset()` is called to ensure that all internal storage is flushed to ensure any documents are re-parsed with the new setting.

ASCredentialDescriptor Objects

Define credential to log in the Analytic Server

```
a.getPassword() : string
```

Get password

```
a.getUserName() : string
```

Get user name

Related information

- [Core Objects](#)

ApplicationData Objects

Some features of the Modeler API include information such as the name and version of the application that built them. This supports the ability to brand the Modeler API. By changing this information held by the `SessionFactory`, an application can modify the apparent source of an attribute. Note however that this does not affect "internal" version information associated with some Modeler API features (e.g., persistence).

```
a.getApplicationName() : string
```

Returns the name of the application e.g., "Predictive Server API".

```
a.getApplicationVersion() : string
```

Returns the version of the application e.g., "16.0.0".

```
a.getCopyright() : string
```

Returns the application copyright information e.g., "Copyright (c) 2004-2013, IBM Corp.".

```
a.getVendorName() : string
```

Returns the name of the vendor e.g., "IBM Corp.".

Related information

- [Core Objects](#)

ContentFormat Objects

Subclass of [Enum](#).

Enumerates the valid content formats for content containers.

Constants:

```
BINARY (ContentFormat) : Indicates that the format is binary.
```

```
UTF8 (ContentFormat) : Indicates that the format is UTF8.
```

```
getEnum(name) : ContentFormat
```

```
name (string) : the enumeration name
```

Returns the enumeration with the supplied name or `None` if no enumeration exists for the supplied name.

```
getValues() : ContentFormat[]
```

Returns an array containing all the valid values for this enumeration class.

Related information

- [Core Objects](#)

ContentContainer Objects

Defines the functionality associated with a content container. A content container is used to hold objects (typically generated as a result of executing a stream) which are stored as part of a node or output object.

```
c.getContent() : object
```

Returns the content. The return value will either be a string if the content format is `ContentFormat.UTF8` or a byte array if the content format is `ContentFormat.BINARY`. An empty container will return `None`.

```
c.getContentAsBinary() : byte[]
```

Returns the binary content if the content format is `ContentFormat.BINARY` or `None` otherwise.

```
c.getContentAsUTF8() : string
```

Returns the UTF8 content if the content format is `ContentFormat.UTF8` or `None` otherwise.

```
c.getContentFormat() : ContentFormat
```

Returns the format used to store the component's content. An empty container will return `None`.

```
c.getName() : string
```

Returns the name of this container.

```
c.getTypeID() : string
```

Returns the ID of the container type declaration.

```
c.isEmpty() : boolean
```

Returns true if this container is empty; that is, it has no content associated with it.

```
c.readContainer(inputStream, contentFormat)
```

```
 inputStream (InputStream) :
```

```
contentFormat (ContentFormat) : the content format to be used for storing the input
```

Reads the container from the specified input stream. The input stream is read as a byte array. If the content format is `ContentFormat.BINARY` then the byte array is stored as-is. If the content format is `ContentFormat.UTF8` then the byte array is encoded as a UTF-8 string.

Exceptions:

```
java.io.IOException : if the implementing code throws an IOException.
```

```
c.writeContainer(outputStream)
```

```
 outputStream (OutputStream) : the output stream
```

Writes the container to the specified output stream.

Exceptions:

```
java.io.IOException : if the implementing code throws an IOException.
```

Related information

- [Core Objects](#)

ContentContainerProvider Objects

An interface that provides the basic mechanism for accessing and updating generated objects.

```
c.getContainerTagIterator() : Iterator
```

Returns an iterator for the container tags where each tag is a string.

```
c.getContainerTags() : List[]
```

Returns a list of the container tags.

```
c.getContainerTypeID(tag) : string
```

```
tag (string) : the container tag
```

Returns the type ID associated with the container tag or `None` if the container is unknown or has no type ID.

```
c.getContentContainer(tag) : ContentContainer
```

```
tag (string) : the container tag
```

Returns the container associated with the supplied tag or `None`.

```
c.getContentModel(tag) : ContentModel
```

```
tag (string) : the content model tag
```

Returns the content model associated with the content tags or `None` if content model tag is unknown.

```
c.getContentModelTags() : List
```

Returns a list of the content models supported by this object.

```
c.putContentContainer(tag, container)
```

```
tag (string) : the container tag
```

`container (ContentContainer)` : the container or `None`.

Adds or updates the container component with the supplied tag.

ContentProvider Objects

Stores and retrieves content for an application. Content is identified using *tags* defined by the application. It is the application's responsibility to ensure that tags are unique, and a class-like naming scheme is recommended, e.g. `x.y.z....`

`c.getContent(tag) : Object`

`tag (string)` : the content tag

Returns the content identified by the specified tag or `None` if the tag is unknown to this provider. The type of the result is determined by the content format.

`c.getContentAsBinary(tag) : byte[]`

`tag (string)` : the content tag

Returns the binary content identified by the specified tag or `None` if the tag is unknown to this provider or the content does not have binary format.

`c.getContentAsUTF8(tag) : string`

`tag (string)` : the content tag

Returns the string content identified by the specified tag or `None` if the tag is unknown to this provider or the content does not have string format.

`c.getContentFormat(tag) : ContentFormat`

`tag (string)` : the content tag

Returns the format of the content identified by the specified tag or `None` if the tag is unknown to this provider. The format determines the content type.

`c.getContentTagIterator() : Iterator`

Returns an iterator over the content tags known to this provider.

`c.isContentCurrent(tag) : boolean`

`tag (string)` : the content tag

Returns `True` if the specified content is considered current (up-to-date) with respect to its context, e.g. its containing stream. Returns `False` if the content tag is unknown to this provider, or as a hint that the content may be stale.

`c.putContent(tag, format, content)`

`tag (string)` : the content tag

`format (ContentFormat)` : the content format

`content (Object)` : the content

Stores content in this provider with the specified tag and format. The content must not be `None` and its type must be compatible with the format. Any existing content with the same tag is replaced.

`c.putContentAsBinary(tag, content)`

`tag (string)` : the content tag

`content (byte[])` : the content

Stores binary content in this provider under the specified tag. The content must not be `None`.

`c.putContentAsUTF8(tag, content)`

`tag (string)` : the content tag

```
content (string) : the content
```

Stores string content in this provider under the specified tag. The content must not be **None**.

```
c.removeContent(tag)
```

```
tag (string) : the content tag
```

Removes any content stored by this provider under the specified tag.

Related information

- [Core Objects](#)

CredentialDescriptor Objects

This defines the credentials to log into DataBase.

```
c.getDefinitionName() : string
```

Returns the credential definition name.

```
c.getDomain() : string
```

Returns the domain associated with this credential.

```
c.getPassword() : string
```

Returns the password.

```
c.getUserName() : string
```

Returns the user name.

Related information

- [Core Objects](#)

FileFormat Objects

Subclass of **Enum**.

This class defines constants for the different file formats supported by objects in the Modeler API.

Constants:

```
BITMAP (FileFormat) : Identifier for bitmap image format.
```

```
COGNOS_ACTIVE_REPORT (FileFormat) : Identifier for Cognos Active Report format.
```

```
COMMA_DELIMITED (FileFormat) : Identifier for comma-delimited text.
```

```
COMPOSITE_PROCESSOR (FileFormat) : Identifier for the native SuperNode format.
```

```
DOCUMENT_OUTPUT (FileFormat) : Identifier for the native DocumentOutput format.
```

```
EMF (FileFormat) : Identifier for Enhanced Metafile format.
```

```
EPS (FileFormat) : Identifier for Encapsulated PostScript format.
```

```
EXTERNAL_MODULE_SPECIFICATION (FileFormat) : Identifier for the native external module specification format.
```

```
HTML (FileFormat) : Identifier for HTML format.
```

```
HTMLC (FileFormat) : Identifier for HTMLC format.
```

```
JAR (FileFormat) : Identifier for JAR (Java archive) format.
```

```
JPEG (FileFormat) : Identifier for JPEG image format.
```

MODEL_OUTPUT (**FileFormat**) : Identifier for the native **ModelOutput** format.

MODEL_OUTPUT_SET (**FileFormat**) : Identifier for the native **ModelOutput** set format.

MS_EXCEL (**FileFormat**) : Identifier for MS Excel format.

MS_EXCEL2007 (**FileFormat**) : Identifier for MS Excel 2007 format.

MS_EXCEL2007_M (**FileFormat**) : Identifier for MS Excel 2007 macro-enabled format.

MS_POWERPOINT (**FileFormat**) : Identifier for MS PowerPoint format.

MS_POWERPOINT2007 (**FileFormat**) : Identifier for MS PowerPoint 2007 format.

MS_WORD (**FileFormat**) : Identifier for MS Word format.

MS_WORD2007 (**FileFormat**) : Identifier for MS Word 2007 format.

PASW_RULE (**FileFormat**) : Identifier for PASW RULE format.

PDF (**FileFormat**) : Identifier for PDF format.

PLAIN_TEXT (**FileFormat**) : Identifier for plain text format.

PNG (**FileFormat**) : Identifier for PNG image format.

PROCESSOR (**FileFormat**) : Identifier for the native **Node** format.

PROCESSOR_STREAM (**FileFormat**) : Identifier for the native **Stream** format.

PROJECT (**FileFormat**) : Identifier for the native **Project** format.

PUBLISHED_IMAGE (**FileFormat**) : Identifier for the native image format produced by a Publisher node.

PUBLISHED_PARAMETERS (**FileFormat**) : Identifier for the native image parameter format produced by a Publisher node.

RTF (**FileFormat**) : Identifier for Rich Text Format.

SPSS_APPLICATION_VIEW (**FileFormat**) : Identifier for SPSS application view format.

SPSS_DATA (**FileFormat**) : Identifier for SPSS .sav data format.

SPSS_DATA_PROVIDER (**FileFormat**) : Identifier for SPSS data provider format.

SPSS_SCENARIO (**FileFormat**) : Identifier for SPSS scenario format.

SPSS_SCENARIO_TEMPLATE (**FileFormat**) : Identifier for SPSS scenario template format.

SPSS_WEB_REPORT (**FileFormat**) : Identifier for SPSS Web Report format.

SPV (**FileFormat**) : Identifier for SPV format.

SPW (**FileFormat**) : Identifier for SPW format.

STATE (**FileFormat**) : Identifier for the native combined **ModelOutput** and **Stream** format.

TAB_DELIMITED (**FileFormat**) : Identifier for tab-delimited text.

TIFF (**FileFormat**) : Identifier for TIFF format.

UNKNOWN (**FileFormat**) : Identifier for an unknown file format.

VIZ (**FileFormat**) : Identifier for VIZ format.

VIZML (**FileFormat**) : Identifier for VIZML format.

XML (**FileFormat**) : Identifier for XML format.

ZIP (**FileFormat**) : Identifier for Zip (compressed archive) format.

f.equals(object) : **boolean**

object (**Object**) :

Returns **True** if the supplied object is equal to this. Two file formats are considered equal if the names are equal ignoring the case of the name.

f.getDefaultExtension() : **string**

Returns the default file extension for this file format or an empty string if no file extensions are defined for this file format. The file extension includes the leading ":".

f.getEnum(name) : FileFormat

name (string) : the enumeration name

Returns the enumeration with the supplied name or **None** if no enumeration exists for the supplied name. The lookup is not case-sensitive.

f.getExtensionAt(index) : string

index (int) : the file extension index

Returns the file extension at the supplied index. The first (0'th) extension is assumed to be the default extension. The file extension includes the leading ":".

f.getExtensionCount() : int

Returns the number of file extensions associated with this file format.

f.getFileFilterPattern() : string

Returns a file filter pattern suitable for use with a file chooser dialog that includes all the file extensions associated with this file type. An empty string is returned if no file extensions are defined for this file type.

getFileFormatForExtension(extension) : FileFormat

extension (string) : the file extension

Returns the default file format for the supplied extension or **None** if no matching file format can be found. The extension search is not case-sensitive.

getFileFormatForMIMEType(mimeType) : FileFormat

mimeType (string) : the mime type to be searched for

Returns the file format for the supplied MIME type or **None** if no matching file format can be found.

getFileFormatsForExtension(extension) : List

extension (string) : the file extension

Returns a list of all file formats with the supplied extension. The extension search is not case-sensitive.

f.getMIMEType() : string

Returns the MIME type associated with this file format or an empty string if no MIME type has been defined.

getValues() : FileFormat[]

Returns an array containing all the valid values for this enumeration class.

f.isUnknown() : boolean

Returns **True** if this value is **UNKNOWN**.

f.isValidExtension(extension) : boolean

extension (string) : the file extension

Returns **True** if the supplied extension is valid for this file format or **False** otherwise. **None** values and the empty string always return **False**.

Related information

- [Core Objects](#)
-

IncompatibleServerException Objects

Subclass of **ServerConnectionException**.

An exception thrown while attempting to connect to an incompatible server version.

A message string is always created for this exception.

i.getServerMajorVersion() : int

Returns the major version returned by the server being connected to.

```
i.getServerMinorVersion() : int
```

Returns the minor version returned by the server being connected to.

```
i.getServerPatchVersion() : int
```

Returns the patch version returned by the server being connected to.

Related information

- [Core Objects](#)

InvalidPropertyException Objects

Subclass of [ModelerException](#).

An exception thrown when an invalid property is accessed or an invalid value is supplied for a property.

A message string is always created for this exception.

```
i.getProperty() : string
```

Returns the property name.

```
i.getValue() : Object
```

Returns the value being assigned or `None`.

Related information

- [Core Objects](#)

ModelFieldRole Objects

Subclass of [Enum](#).

This class enumerates the valid model output roles.

Constants:

`ADJUSTED_PROBABILITY (ModelFieldRole)` : Indicates a field containing the adjusted probability of the target value.

`ENTITY_AFFINITY (ModelFieldRole)` : Indicates a field containing the affinity or distance of the value from the entity.

`ENTITY_ID (ModelFieldRole)` : Indicates a field containing the entity ID associated with the cluster, tree node, neuron or rule.

`LOWER_CONFIDENCE_LIMIT (ModelFieldRole)` : Indicates a field containing the lower confidence limit of a numeric prediction.

`PREDICTED_DISPLAY_VALUE (ModelFieldRole)` : Indicates a field containing a displayed-friendly representation of the predicted value.

`PREDICTED_VALUE (ModelFieldRole)` : Indicates a field containing the predicted value.

`PROBABILITY (ModelFieldRole)` : Indicates a field containing the probability of the target value.

`PREDICTED_SEQUENCE (ModelFieldRole)` : Indicates a field containing the predicted sequence.

`PREDICTED_SEQUENCE_PROBABILITY (ModelFieldRole)` : Indicates a field containing the probability associated with the predicted sequence.

`PROPENSITY (ModelFieldRole)` : Indicates a field containing the propensity of the prediction.

`RESIDUAL (ModelFieldRole)` : Indicates a field containing the residual of the predicted numeric value.

`STANDARD_DEVIATION (ModelFieldRole)` : Indicates a field containing the standard deviation of the target value.

`STANDARD_ERROR (ModelFieldRole)` : Indicates a field containing the standard error of the predicted numeric value.

SUPPLEMENTARY (`ModelFieldRole`) : Indicates a field containing some additional information about the value that cannot be categorized into one of the other model field roles.

SUPPORT (`ModelFieldRole`) : Indicates a field containing the support associated with an association model rule.

UNKNOWN (`ModelFieldRole`) : Indicates that the role cannot be determined.

UPPER_CONFIDENCE_LIMIT (`ModelFieldRole`) : Indicates a field containing the upper confidence limit of a numeric prediction.

VALUE (`ModelFieldRole`) : Indicates a field containing the model output value for non-predictive models.

VARIANCE (`ModelFieldRole`) : Indicates a field containing the variance of the target value.

`getEnum(name) : ModelFieldRole`

`name (string) : the enumeration name`

Returns the enumeration with the supplied name or None if no enumeration exists for the supplied name.

`getValues() : ModelFieldRole[]`

Returns an array containing all the valid values for this enumeration class.

`m.isUnknown() : boolean`

Returns True if this value is UNKNOWN.

Related information

- [Core Objects](#)

ObjectCreationException Objects

Subclass of `ModelerException`.

An exception thrown when an instance of an object cannot be created.

No message string is set for this exception.

Related information

- [Core Objects](#)

ObjectLockedException Objects

Subclass of `ModelerException`.

An exception thrown when an attempt is made to lock or modify an object that is already locked. Locking an object prevents an updates to that object while the lock is in effect. A `Stream` and all its `Nodes` are locked by the `Session` during execution.

No message string is set for this exception.

`o.getObject() : Object`

Returns the object.

Related information

- [Core Objects](#)

OwnerException Objects

Subclass of `ModelerException`.

An exception thrown when an object owner requires an owned object.

No message string is set for this exception.

`o.getOwner() : Object`

Returns the object owner.

`o.getUnownedObject() : Object`

Returns the object that is not owned by the owner.

Related information

- [Core Objects](#)
-

ParameterDefinition Objects

Describes a parameter which affects the behaviour of some Modeler API objects. A parameter definition is obtained from a **ParameterProvider**. The parameter name is unique within the provider.

Parameters are modified through the provider. A **ParameterDefinition** instance may be a snapshot of a parameter definition at the time it was obtained from the provider and need not reflect subsequent modifications.

`p.getFalseFlag() : Object`

Returns the *false* indicator for this flag parameter. Returns `None` if the parameter type is other than **ParameterType.FLAG** or if no false value has been declared for the flag.

`p.getLowerBound() : Object`

Returns a lower bound on the valid values of this parameter. Returns `None` if the parameter type is other than **ParameterType.RANGE** or if no lower bound has been declared for the range.

`p.getParameterLabel() : string`

Returns a label for this parameter. The default label is the empty string.

`p.getParameterName() : string`

Returns the name of this parameter. The name is unique within the parameter provider.

`p.getParameterStorage() : ParameterStorage`

Returns the storage type of this parameter.

`p.getParameterType() : ParameterType`

Returns the measure of this parameter.

`p.getParameterValue() : Object`

Returns the value of this parameter.

`p.getSetValues() : Object[]`

Returns the valid values of this parameter. Returns `None` if the parameter type is other than **ParameterType.SET** or if no values have been declared for the set.

`p.getTrueFlag() : Object`

Returns the *true* indicator for this flag parameter. Returns `None` if the parameter type is other than **ParameterType.FLAG** or if no true value has been declared for the flag.

`p.getUpperBound() : Object`

Returns an upper bound on the valid values of this parameter. Returns `None` if the parameter type is other than **ParameterType.RANGE** or if no upper bound has been declared for the range.

`p.isValidValue(value) : boolean`

`value (Object) : the value`

Returns `True` if the specified value is valid for this parameter. The value must be compatible with the parameter storage type and with the parameter values when they are specified.

Related information

- [Core Objects](#)
-

ParameterProvider Objects

Identifies objects that contain parameters. Parameters do not control the behaviour of the implementing class directly but provide a look-up mechanism for values that may affect the behaviour of other objects.

`p.getParameterDefinition(parameterName) : ParameterDefinition`

`parameterName (string) : the parameter name`

Returns the parameter definition for the parameter with the specified name or `None` if no such parameter exists in this provider. The result may be a snapshot of the definition at the time the method was called and need not reflect any subsequent modifications made to the parameter through this provider.

`p.getParameterLabel(parameterName) : string`

`parameterName (string) : the parameter name`

Returns the label of the named parameter or `None` if no such parameter exists.

`p.getParameterStorage(parameterName) : ParameterStorage`

`parameterName (string) : the parameter name`

Returns the storage of the named parameter or `None` if no such parameter exists.

`p.getParameterType(parameterName) : ParameterType`

`parameterName (string) : the parameter name`

Returns the type of the named parameter or `None` if no such parameter exists.

`p.getParameterValue(parameterName) : Object`

`parameterName (string) : the parameter name`

Returns the value of the named parameter or `None` if no such parameter exists.

`p.parameterIterator() : Iterator`

Returns an iterator of parameter names for this object.

`p.setParameterLabel(parameterName, label)`

`parameterName (string) : the parameter name`

`label (string) : the parameter label`

Sets the label of the named parameter.

Exceptions:

`ObjectLockedException` : if the parameter provider is locked

`p.setParameterStorage(parameterName, storage)`

`parameterName (string) : the parameter name`

`storage (ParameterStorage) : the parameter storage`

Sets the storage of the named parameter.

Exceptions:

`ObjectLockedException` : if the parameter provider is locked

`p.setParameterType(parameterName, type)`

`parameterName (string) : the parameter name`

`type (ParameterType) : the parameter type`

Sets the type of the named parameter.

Exceptions:

`ObjectLockedException` : if the parameter provider is locked

`p.setParameterValue(parameterName, value)`

`parameterName (string)` : the parameter name

`value (Object)` : the parameter value

Sets the value of the named parameter.

Exceptions:

`ObjectLockedException` : if the parameter provider is locked

Related information

- [Core Objects](#)

ParameterStorage Objects

Subclass of `Enum`.

This class enumerates the valid storage types for columns in a `DataModel` or parameters.

Constants:

`DATE (ParameterStorage)` : Indicates that the storage type is a date type.

`INTEGER (ParameterStorage)` : Indicates that the storage type is an integer.

`REAL (ParameterStorage)` : Indicates that the storage type is a floating point number.

`STRING (ParameterStorage)` : Indicates that the storage type is a string.

`TIME (ParameterStorage)` : Indicates that the storage type is a time type.

`TIMESTAMP (ParameterStorage)` : Indicates that the storage type is a combined time and date type.

`UNKNOWN (ParameterStorage)` : Indicates that the storage type is unknown.

`getEnum(name) : ParameterStorage`

`name (string)` : the enumeration name

Returns the enumeration with the supplied name or `None` if no enumeration exists for the supplied name.

`p.getStorageClass() : Class`

Returns the Java class that parameter values with this storage will be returned as.

`getValues() : ParameterStorage[]`

Returns an array containing all the valid values for this enumeration class.

Related information

- [Core Objects](#)

ParameterType Objects

Subclass of `Enum`.

This class enumerates the valid types of parameter support by a `ParameterProvider`.

Constants:

FLAG (ParameterType) : Indicates that the parameter value is one of two values.

RANGE (ParameterType) : Indicates that the parameter value lies between two points on a scale.

SET (ParameterType) : Indicates that the parameter value is one of a (small) set of discrete values.

TYPELESS (ParameterType) : Indicates that the parameter can have any value compatible with its storage.

getEnum(name) : ParameterType

name (string) : the enumeration name

Returns the enumeration with the supplied name or **None** if no enumeration exists for the supplied name.

getValues() : ParameterType[]

Returns an array containing all the valid values for this enumeration class.

Related information

- [Core Objects](#)

PropertyiedObject Objects

This encapsulates the functionality of objects that contain settable properties. Properties are split into two sub-groups:

- **Simple properties:** these are basic name/value pairs
- **Keyed properties:** these are properties associated with specific objects

An example of a simple property is a Boolean value that specifies to a data file reader whether column names are included in the first line of a file:

```
myDataReader.setPropertyValue("read_field_names", Boolean.TRUE);
```

An example of a keyed property is used in an object that allows fields or columns to be removed from the data model. Here the setting is made up of both the property name and the key which is the column name:

```
// Remove "DateOfBirth" column  
myColumnFilter.setKeyedPropertyValue("include", "DateOfBirth", Boolean.FALSE);
```

Finally note that properties which correspond with **Enum** values must be converted to strings by calling `getName()` before being passed to one of the setter methods:

```
typeProcessor.setKeyedPropertyValue("role", "Drug", ModelingRole.OUT.getName());
```

Similarly, the getter methods will return Strings which can then be converted to the appropriate **Enum** value:

```
String value = (String) typeProcessor.getKeyedPropertyValue("role", "Drug");  
ModelingRole role = ModelingRole.getValue(value);
```

p.getKeyedPropertyKeys(propertyName) : List

propertyName (string) : the property name

Returns the keys currently defined for the supplied keyed property name.

p.getKeyedPropertyValue(propertyName, keyName) : Object

propertyName (string) : the property name

keyName (string) : the key name

Returns the value of the named property and key or **None** if no such property or key exists.

p.getLabel() : string

Returns the object's display label. The label is the value of the property "`custom_name`" if that is a non-empty string and the "`use_custom_name`" property is not set; otherwise, it is the value of `getName()`.

p.getName() : string

Returns the object's name.

p.getPropertyValue(propertyName) : Object

`propertyName (string) : the property name`

Returns the value of the named property or None if no such property exists.

`p.getSavedByVersion() : double`

Return the object's saved by version.

Exceptions:

`Exception` : if the information cannot be accessed for some reason

`p.isKeyedProperty(propertyName) : boolean`

`propertyName (string) : the property name`

Returns True if the supplied property name is a keyed property.

`p.isServerConnectionRequiredProperty(propertyName) : boolean`

`propertyName (string) : the property name`

Returns True if the supplied property name should only be set if there is a valid server connection.

`p.propertyIterator() : Iterator`

Returns an iterator of property names for this object.

`p.setKeyedPropertyValue(propertyName, keyName, value)`

`propertyName (string) : the property name`

`keyName (string) : the key name`

`value (Object) : the property value`

Sets the value of the named property and key.

Exceptions:

`ObjectLockedException` : if the propertied object is locked

`InvalidPropertyException` : if the property name is unknown or the supplied value is not valid for the property

`p.setLabel(label)`

`label (string) : the object's display label`

Sets the object's display label. If the new label is a non-empty string it is assigned to the property "custom_name", and False is assigned to the property "use_custom_name" so that the specified label takes precedence; otherwise, an empty string is assigned to the property "custom_name", and True is assigned to the property .

`p.setPropertyValue(propertyName, value)`

`propertyName (string) : the property name`

`value (Object) : the property value`

Sets the value of the named property.

Exceptions:

`ObjectLockedException` : if the propertied object is locked

`InvalidPropertyException` : if the property name is unknown or the supplied value is not valid for the property

`p.setPropertyValues(properties)`

`properties (Map) : the property/value pairs to be assigned`

Sets the values of the named properties. Each entry in the Map consists of a key representing the property name and the value which should be assigned to that property.

Exceptions:

`ObjectLockedException` : if the propertied object is locked

`InvalidPropertyException` : if one of the property names is unknown or one the supplied values is not valid for that property

`p.setPropertyValuesFrom(otherObject)`

`otherObject (PropertiedObject)` : the other object whose properties are to be copied

Sets the values of the properties that are in both this object and the supplied other object.

Exceptions:

`ObjectLockedException` : if the propertied object is locked

Related information

- [Core Objects](#)

RepositoryConnectionDescriptor Objects

Defines the basic data elements required to connect to a content repository.

`r.getDomainName() : string`

Returns the domain name to be used when logging into the content repository (if applicable) or the empty string.

`r.getHostNames() : string`

Returns the host name or IP address of the content repository machine.

`r.getPassword() : string`

Returns the user's password in plain text. An empty string indicates that there is no password.

`r.getPortNumber() : int`

Returns the port number which the content repository is listening on.

`r.getUseSSL() : boolean`

Returns `True` if the connection should use a secure socket.

`r.getUserName() : string`

Returns the user's login name.

Related information

- [Core Objects](#)

RepositoryConnectionDescriptor2 Objects

Subclass of `RepositoryConnectionDescriptor`.

Extends the repository connection details for applications which are aware of PASW platform services.

`r.getSsoToken() : Object`

Returns the SSO security token or `None` if there is no token.

`r.getSubject() : Object`

Returns the platform security subject or `None` if there is no subject.

Related information

- [Core Objects](#)

RepositoryConnectionDescriptor3 Objects

Subclass of `RepositoryConnectionDescriptor2`.

```
r.getContextRoot() : string
```

Return the context root of the content repository service.

Related information

- [Core Objects](#)

ServerConnectionDescriptor Objects

Subclass of **SystemServerConnectionDescriptor**.

Defines the basic data elements required to connect to a remote server.

```
s.getPassword() : string
```

Returns the user's password in plain text. An empty string indicates that there is no password.

```
s.isSSOConnect() : boolean
```

Returns `True` if the connection should use SSO.

```
s.isUseSSL() : boolean
```

Returns `True` if the connection should use SSL.

Related information

- [Core Objects](#)

ServerConnectionException Objects

Subclass of **ModelerException**.

An exception thrown while connecting or using a **ServerConnectionDescriptor**.

A message string is always created for this exception.

Related information

- [Core Objects](#)

ServerVersionInfo Objects

Version information for a connected server.

A server version has four components, in decreasing order of priority:

- major
- minor
- release
- fix pack

```
s.getServerVersionFixPack() : int
```

Returns the server fix pack number.

```
s.getServerVersionMajor() : int
```

Returns the server major version number.

```
s.getServerVersionMinor() : int
```

Returns the server minor version number.

```
s.getServerVersionRelease() : int
```

Returns the server release number.

Related information

- [Core Objects](#)

StructureAttributeType Objects

Subclass of **Enum**.

This class enumerates the valid types of attribute supported by a **ParameterProvider**.

Constants:

```
BOOLEAN (StructureAttributeType) :
```

```
DATE (StructureAttributeType) :
```

```
DOUBLE (StructureAttributeType) :
```

```
INTEGER (StructureAttributeType) :
```

```
STRING (StructureAttributeType) :
```

```
getEnum(name) : StructureAttributeType
```

```
name (string) : the enumeration name
```

Returns the enumeration with the supplied name or **None** if no enumeration exists for the supplied name.

```
s.getStorageClass() : Class
```

Returns the basic Java class used to represent this attribute's value. One of:

- **string**
- **int**
- **float**
- **boolean**
- **Date**

```
getValues() : StructureAttributeType[]
```

Returns an array containing all the valid values for this enumeration class.

Related information

- [Core Objects](#)

StructuredValue Objects

This interface defines a structured value. A structured value consists of a number of simple attributes.

```
s.changeAttributeValue(index, value) : StructuredValue
```

```
index (int) : the index
```

```
value (Object) : the new value
```

Returns a new structured value with the attribute value at the specified index changed to the new value. An attribute value cannot be **None** -- if the supplied value is **None**, it will be ignored.

```
s.getAttributeCount() : int
```

Returns the number of attribute values in the structure.

```
s.getAttributeValue(index) : Object
```

```
index (int) : the index
```

Returns the attribute value at the specified index.

Related information

- [Core Objects](#)

SystemServerConnectionDescriptor Objects

Defines the basic data elements that describes a server connection. Note that for security reasons, the user's password is not accessible through this interface.

`s.getDataDirectory() : string`

Returns the data directory for this connection descriptor.

`s.getDomainName() : string`

Returns the domain name to be used when logging into the server (if applicable) or the empty string.

`s.getHostNames() : string`

Returns the host name or IP address of the server machine.

`s.getPortNumber() : int`

Returns the port number which the server is listening on.

`s.getServerMajorVersion() : int`

Returns the major version of server required by this descriptor.

`s.getServerMinorVersion() : int`

Returns the minor version of server required by this descriptor.

`s.getServerPatchVersion() : int`

Returns the patch version of server required by this descriptor.

`s.getUserName() : string`

Returns the user's login name.

Column Objects

This defines the properties of a set of columns. Applications that wish to construct `Column` instances must do so using the `DataModelFactory` rather than implementing the interface directly.

`c.getColumnLabel() : string`

Returns the label of the column or an empty string if there is no label associated with the column.

`c.getColumnName() : string`

Returns the name of the column.

`c.getFalseFlag() : Object`

Returns the "false" indicator value for the column, or `None` if either the value is not known or the column is not a flag.

`c.getLowerBound() : Object`

Returns the lower bound value for the values in the column, or `None` if either the value is not known or the column is not continuous.

`c.getMeasureType() : MeasureType`

Returns the measure type for the column.

`c.getMissingValueDefinition() : MissingValueDefinition`

Returns the missing value definition for the column or `None`.

`c.getModelOutputMetadata() : ModelOutputMetadata`

Returns the model output column role for the column if it is a model output column or `None`.

`c.getModelingRole() : ModelingRole`

Returns the modeling role for the column.

`c.getSetValues() : Object[]`

Returns an array of valid values for the column, or `None` if either the values are not known or the column is not a set.

`c.getStorageType() : StorageType`

Returns the storage type for the column.

`c.getTrueFlag() : Object`

Returns the "true" indicator value for the column, or `None` if either the value is not known or the column is not a flag.

`c.getUpperBound() : Object`

Returns the upper bound value for the values in the column, or `None` if either the value is not known or the column is not continuous.

`c.getValueLabel(value) : string`

`value (Object) : the value`

Returns the label for the value in the column or an empty string if there is no label associated with the value.

`c.hasMissingValueDefinition() : boolean`

Returns `True` if the column has a missing value definition.

`c.isMeasureDiscrete() : boolean`

Returns `True` if the column is discrete. Columns that are either a set or a flag are considered discrete.

`c.isModelOutputColumn() : boolean`

Returns `True` if this is a model output column.

`c.isStorageDatetime() : boolean`

Returns `True` if the column's storage is a time, date or timestamp value.

`c.isStorageNumeric() : boolean`

Returns `True` if the column's storage is an integer or a real number.

`c.isValidValue(value) : boolean`

`value (Object) : the value`

Returns `True` if the specified value is valid for this storage and valid when the valid column values are known.

`d.getExtendedMeasure(name) : ExtendedMeasure`

`name (string) : the column name`

Returns additional metadata that is specific for this field. For example, geospatial fields may return a geospatial-specific descriptor that defines the metadata necessary for the correct interpretation of the values.

Exceptions:

`DataModelError : if the named column does not exist`

`d.getExtendedStorage(name) : ExtendedStorage`

`name (string) : the field name`

Returns additional metadata for this field's storage or `None` if no additional storage metadata is defined.

`d.isList(name) : boolean`

`name (string) :`

Returns `True` if this field is a list field.

Related information

- [Data and Metadata](#)
-

ColumnCountException Objects

Subclass of `DataModelError`.

A `ColumnCountException` is thrown when the number of columns in the data did not match the number of columns specified in the data model.

No message string is set for this exception.

`c.getValues() : List`

Returns the list of values that were being converted.

Related information

- [Data and Metadata](#)

ColumnGroup Objects

This defines the properties of a column group. A column group is typically used to identify related columns e.g. that represent a multi response set.

```
c.getColumnGroupLabel() : string
```

Returns the label of the column group or an empty string if there is no label associated with the column group.

```
c.getColumnGroupName() : string
```

Returns the name of the column group.

```
c.getColumnGroupType() : ColumnGroupType
```

Returns the type of column group.

```
c.getColumnNames() : List
```

Returns the list of column names in this group. The list is a copy of the list in the group and can be modified without affecting the group definition.

```
c.getCountedValue() : string
```

Returns the counted value for this column group. The counted value only has meaning for multi dichotomy sets and represents the "true" or "selected" value of the column. Note that the value is represented as a string even if the columns named by the column group have storage other than string and it is the responsibility of the calling application to convert the string representation into a valid value.

Related information

- [Data and Metadata](#)

ColumnGroupType Objects

Subclass of [Enum](#).

This class enumerates the valid types for a ColumnGroup.

Constants:

- **GENERAL** (`ColumnGroupType`) : Indicates that the there are no special semantics associated with this column group.
- **MULTI_CATEGORY_SET** (`ColumnGroupType`) : Indicates that this column group represents a multi category set.
- **MULTI_DICHOTOMY_SET** (`ColumnGroupType`) : Indicates that this column group represents a multi dichotomy set.
- **SPLIT_GROUP** (`ColumnGroupType`) : A group representing the split fields. Ideally the application will keep the fields in the split group consistent with the fields whose role is "split". However, components will use the group to determine the order for the split fields and will typically ignore the "split" role. There should be at most one split group in the data model.

```
getEnum(name) : ColumnGroupType
```

```
name (string) : the enumeration name
```

Returns the enumeration with the supplied name or None if no enumeration exists for the supplied name.

```
getValues() : ColumnGroupType[]
```

Returns an array containing all the valid values for this enumeration class.

Related information

- [Data and Metadata](#)

DataModel Objects

This defines the properties of a set of columns. Applications that wish to construct data model instances must do so using the **DataModelFactory** rather than implementing the interface directly.

d.columnGroupIterator() : Iterator

Returns an iterator that returns each column group in turn.

d.columnIterator() : Iterator

Returns an iterator that returns each column in the "natural" insert order. The iterator returns instances of Column.

d.contains(name) : boolean

name (string) : the column name

Returns **True** if a column with the supplied name exists in this **DataModel**, **False** otherwise.

d.getColumn(name) : Column

name (string) :

Returns the column with the specified name.

Exceptions:

DataModelError : if the named column does not exist

d.getColumnCount() : int

Returns the number of columns in this set.

d.getColumnGroup(name) : ColumnGroup

name (string) :

Returns the named column group or **None** if no such column group exists.

d.getColumnGroupCount() : int

Returns the number of column groups in this data model.

d.getColumnLabel(name) : string

name (string) : the column name

Returns the label of the named column or an empty string if there is no label associated with the column.

Exceptions:

DataModelError : if the named column does not exist

d.getFalseFlag(name) : Object

name (string) : the column name

Returns the "false" indicator value for the column, or **None** if either the value is not known or the column is not a flag.

Exceptions:

DataModelError : if the named column does not exist

d.getLowerBound(name) : Object

name (string) : the column name

Returns the lower bound value for the values in the named column, or **None** if either the value is not known or the column is not continuous.

Exceptions:

DataModelError : if the named column does not exist

d.getMeasureType(name) : MeasureType

name (string) : the column name

Returns the measure type for values in the named column.

Exceptions:

DataModelError : if the named column does not exist

d.getMissingValueDefinition(name) : MissingValueDefinition

name (string) : the column name

Returns the missing value definition for the column or **None**.

Exceptions:

DataModelError : if the named column does not exist

d.getModelingRole(name) : ModelingRole

name (string) : the column name

Returns the modeling role for the named column.

Exceptions:

DataModelError : if the named column does not exist

d.getSetValues(name) : Object[]

name (string) : the column name

Returns an array of valid values for the column, or **None** if either the values are not known or the column is not a set.

Exceptions:

DataModelError : if the named column does not exist

d.getStorageType(name) : StorageType

name (string) : the column name

Returns the storage type for values in the named column.

Exceptions:

DataModelError : if the named column does not exist

d.isTrueFlag(name) : Object

name (string) : the column name

Returns the "true" indicator value for the column, or **None** if either the value is not known or the column is not a flag.

Exceptions:

DataModelError : if the named column does not exist

d.getUpperBound(name) : Object

name (string) : the column name

Returns the upper bound value for the values in the named column, or **None** if either the value is not known or the column is not continuous.

Exceptions:

DataModelError : if the named column does not exist

d.getValueLabel(name, value) : string

name (string) : the column name

value (Object) : the value

Returns the label for the value in the named column or an empty string if there is no label associated with the value.

Exceptions:

DataModelError : if the named column does not exist

d.hasMissingValueDefinition(name) : boolean

name (string) : the column name

Returns **True** if the column has a missing value definition.

Exceptions:

DataModelError : if the named column does not exist

d.isMeasureDiscrete(name) : boolean

name (string) : the column name

Returns **True** if the column is discrete. Columns that are either a set or a flag are considered discrete.

Exceptions:

DataModelError : if the named column does not exist

d.isModelOutputColumn(name) : boolean

name (string) : the column name

Returns **True** if this is a model output column.

Exceptions:

DataModelError : if the named column does not exist

d.isStorageDatetime(name) : boolean

name (string) : the column name

Returns **True** if the column's storage is a time, date or timestamp value.

Exceptions:

DataModelError : if the named column does not exist

d.isStorageNumeric(name) : boolean

name (string) : the column name

Returns **True** if the column's storage is an integer or a real number.

Exceptions:

DataModelError : if the named column does not exist

d.isValidValue(name, value) : boolean

name (string) : the column name

value (Object) : the value

Returns **True** if the specified value is valid for this storage and valid when the valid column values are known.

Exceptions:

DataModelError : if the named column does not exist

d.nameIterator() : Iterator

Returns an iterator that returns the name of each column in the "natural" insert order.

d.toArray() : Column[]

Returns the data model as an array of columns. The columns are ordered in their natural/insert order.

Related information

- [Data and Metadata](#)
-

DataModelError Objects

Subclass of **ModelerException**.

An exception thrown when there is a mismatch between physical set of data and its expected data model.

No message string is set for this exception.

```
d.getDataModel() : DataModel
```

Returns the data model that was being used to convert the values.

Related information

- [Data and Metadata](#)

DataModelFactory Objects

A factory class that creates and manipulates instances of `Column` and `DataModel`.

```
d.createCollectionType(valueMeasure) : CollectionType
```

`valueMeasure (MeasureType)` : the measure that should be applied to each value in the list.

Creates a new `CollectionType` object. The definition specifies the measurement associated with individual values in the list. The storage cannot be either `MeasureType.COLLECTION` or `MeasureType.GEOSPATIAL`, and should also be consistent with the storage type associated with the simple values in the list column that this metadata is to be associated with.

```
d.createColumn(name, label, storageType, measureType, modelingRole) : Column
```

`name (string)` : the column name

`label (string)` : the column label (may be `None`)

`storageType (StorageType)` : the storage definition

`measureType (MeasureType)` : the measure definition (may be `None`)

`modelingRole (ModelingRole)` : the model role definition for each column (may be `None`)

Returns a `Column` with the supplied attributes.

```
d.createColumn(name, label, extendedStorage) : Column
```

`name (string)` : the column name

`label (string)` : the column label (may be `None`)

`extendedStorage (ExtendedStorage)` : the extended storage definition

Returns a `Column` with the supplied attributes. The measure type is set to `MeasureType.TYPELESS`.

```
d.createColumn(name, label, extendedStorage, extendedMeasure) : Column
```

`name (string)` : the column name

`label (string)` : the column label (may be `None`)

`extendedStorage (ExtendedStorage)` : the extended storage definition

`extendedMeasure (ExtendedMeasure)` : the extended measure definition

Returns a `Column` with the supplied attributes. The measure type is set to `MeasureType.TYPELESS`.

```
d.createColumn(name, label, sourceColumn) : Column
```

`name (string)` : the column name

`label (string)` : the column label (may be `None`)

`sourceColumn (Column)` : the source column

Returns a `Column` with the specified name and labels but with all other attributes the same as source column.

Exceptions:

`DataModelError` : if the source column was not created by the `DataModelFactory`.

```
d.createDataModel() : DataModel
```

Returns an empty `DataModel`.

```
d.createFlagColumn(name, label, storageType, falseValue, trueValue) : Column
```

name (string) : the column name

label (string) : the column label (may be **None**)

storageType (StorageType) : the storage definition

falseValue (object) : the false value

trueValue (object) : the true value

Returns a **Column** with the supplied attributes.

```
d.createGeoType(geometryType, coordinates, wellKnownID, coordinateSystemName) : GeoType
```

geometryType (GeometryType) : the type of geometry object

coordinates (int) : a positive integer representing the number

WellKnownID (int) : the "well-known ID" of the coordinate system or 0 if this is not known

coordinateSystemName (string) : the name of the coordinate system or the empty string if this is not known.

Creates a new **GeoType** object. The definition specifies the type of geometry object, the number of coordinates (typically 2 or 3) required to represent the geometry object, and the "well-known ID" and/or the coordinate system name.

```
d.createListStorage(depth, valueType) : ListStorage
```

depth (int) : how deeply nested the simple values are in the list

valueType (StorageType) : the type of the simple values

Creates a new **ListStorage** object. The definition specifies the depth of the list starting at 0 for a list of simple values, and the basic storage of the underlying values. The storage cannot be either **StorageType.UNKNOWN** or **StorageType.LIST**.

```
d.createModelOutputColumn(prefix, basename, storageType, measureType, modelOutputMetadata) : Column
```

prefix (string) : the column prefix (may not contain "-" characters)

basename (string) : the column base name

storageType (StorageType) : the storage type

measureType (MeasureType) : the measure type

modelOutputMetadata (ModelOutputMetadata) : the model output metadata

Returns a new **Column** with the specified type metadata and associated model output metadata.

Exceptions:

DataModelError : if the prefix is invalid

```
d.createModelOutputColumn(prefix, basename, sourceColumn, modelOutputMetadata) : Column
```

prefix (string) : the column prefix (may not contain "-" characters)

basename (string) : the column base name

sourceColumn (Column) : the source column specifying the column type

modelOutputMetadata (ModelOutputMetadata) : the model output metadata

Returns a new **Column** with the same type metadata as the source column along with the associated model output metadata.

Exceptions:

DataModelError : if the source column was not created by the **DataModelFactory** or the prefix is invalid.

```
d.createModelOutputMetadata(modelFieldRole, targetColumn, value, group, tag) : ModelOutputMetadata
```

modelFieldRole (ModelFieldRole) : the mode column role

targetColumn (string) : the target column (may be **None**)

value (object) : the specific value associated with this column (may be **None**). If supplied, this must be an instance of **string**, **int**, or **float**.

group (List) : the column group definition (may be **None**). If supplied this must be a list on **int** values which are ≥ 1 .

tag (**string**) : the tag (may be **None**)

Returns a new model output metadata object with the specified attributes.

d.createRangeColumn(name, label, storageType, lowerBound, upperBound) : Column

name (**string**) : the column name

label (**string**) : the column label (may be **None**)

storageType (**StorageType**) : the storage definition

lowerBound (**object**) : the lower range bound

upperBound (**object**) : the upper range bound

Returns a **Column** with the supplied attributes.

d.createSetColumn(name, label, storageType, values) : Column

name (**string**) : the column name

label (**string**) : the column label (may be **None**)

storageType (**StorageType**) : the storage definition

values (**object[]**) : the valid values for the column

Returns a **Column** with the supplied attributes.

d.dataModelToXML(dataModel) : string

dataModel (**DataModel**) : the data model

Returns an XML format string containing the supplied data model in a serializable format. The data model can be recreated by calling **xmlToDataModel**.

Exceptions:

com.spss.psapi.data.DataModelException : if the data model XML cannot be created

d.extendDataModel(column, initialDataModel) : DataModel

column (**Column**) : the column

initialDataModel (**DataModel**) :

Returns a **DataModel** consisting of the column appended to the supplied data model. The supplied array must not contain **None** values.

Exceptions:

com.spss.psapi.data.DataModelException : if the column was not created by the **DataModelFactory**.

d.extendDataModel(addition, initialDataModel) : DataModel

addition (**DataModel**) : the data model to be appended

initialDataModel (**DataModel**) :

Returns a **DataModel** consisting of the initial data model with the additions appended.

Exceptions:

com.spss.psapi.data.DataModelException : if the data models were not created by the **DataModelFactory**.

d.extendDataModel(columns, initialDataModel) : DataModel

columns (**Column[]**) : the columns

initialDataModel (**DataModel**) :

Returns a **DataModel** consisting of the columns appended to the supplied data model. The supplied array must not contain **None** values.

Exceptions:

com.spss.psapi.data.DataModelException : if the columns array contains **None** values.

d.extractDataModel(names, initialDataModel) : DataModel

names (**string[]**) : the column names

`initialDataModel (DataModel) : the source data model`

Returns a `DataModel` consisting of the named columns extracted from the source data model. If the source data model does not include a specified column name, that column will be ignored.

Exceptions:

`com.spss.psapi.data.DataModelException` : if the array contains `None` values.

`d.extractDataModel(storageTypes, initialDataModel) : DataModel`

`storageTypes (StorageType[])` : the storage types

`initialDataModel (DataModel) : the source data model`

Returns a `DataModel` consisting of columns in the source data model that have the supplied storage type(s).

Exceptions:

`com.spss.psapi.data.DataModelException` : if the array contains `None` values.

`d.extractDataModel(measureTypes, initialDataModel) : DataModel`

`measureTypes (MeasureType[])` : the measure types

`initialDataModel (DataModel) : the source data model`

Returns a `DataModel` consisting of columns in the source data model that have the supplied measure type(s).

Exceptions:

`com.spss.psapi.data.DataModelException` : if the array contains `None` values.

`d.extractDataModel(modelingRoles, initialDataModel) : DataModel`

`modelingRoles (ModelingRole[])` : the modeling roles types

`initialDataModel (DataModel) : the source data model`

Returns a `DataModel` consisting of columns in the source data model that have the supplied modeling role(s).

Exceptions:

`com.spss.psapi.data.DataModelException` : if the array contains `None` values.

`d.modifyColumns(modifiedColumns) : DataModel`

`modifiedColumns (Collection)` : the columns to be modified

Creates and returns a new data model based on this data model with the specified columns modified. The supplied columns will be used to replace any existing column with the same name meaning that this method cannot be used to change the name of columns in the data model. If a supplied column name does not match an existing column, it will be ignored.

`d.removeColumns(columnNames) : DataModel`

`columnNames (Collection)` :

Creates and returns a new data model based on this data model with the specified columns modified. The supplied columns will be used to replace any existing column with the same name meaning that this method cannot be used to change the name of columns in the data model. If a supplied column does not match an existing column, it will be added to the end of the data model.

Exceptions:

`DataModelError` : if the modified columns are invalid

`d.removeFromDataModel(names, initialDataModel) : DataModel`

`names (String[])` : the column names

`initialDataModel (DataModel) : the source data model`

Returns a `DataModel` consisting of the source data model with the named columns removed.

Exceptions:

`com.spss.psapi.data.DataModelError` : if the array contains `None` values.

`d.removeFromDataModel(storageTypes, initialDataModel) : DataModel`

`storageTypes (StorageType[])` : the storage types

`initialDataModel (DataModel)` : the source data model

Returns a `DataModel` consisting of the source data model with columns of the supplied storage type(s) removed.

Exceptions:

`com.spss.psapi.data.DataModelError` : if the array contains `None` values.

`d.removeFromDataModel(measureTypes, initialDataModel) : DataModel`

`measureTypes (MeasureType[])` : the measure types

`initialDataModel (DataModel)` : the source data model

Returns a `DataModel` consisting of the source data model with columns of the supplied measure type(s) removed.

Exceptions:

`com.spss.psapi.data.DataModelError` : if the array contains `None` values.

`d.removeFromDataModel(modelingRoles, initialDataModel) : DataModel`

`modelingRoles (ModelingRole[])` : the modeling roles types

`initialDataModel (DataModel)` : the source data model

Returns a `DataModel` consisting of the source data model with columns of the supplied modeling roles(s) removed.

Exceptions:

`com.spss.psapi.data.DataModelError` : if the array contains `None` values.

`d.renameColumns(modifiedNames) : DataModel`

`modifiedNames (Map)` : a map containing the original column names as the key and the new name as the associated value

Creates and returns a new data model based on this data model with the specified columns renamed. If the map contains keys that do not correspond to columns in the data model, the key will be ignored.

Exceptions:

`DataModelError` : if the new column names are invalid, for example cause the data model to have duplicate names.

`d.toDataModel(columns) : DataModel`

`columns (Column[])` : Returns a `DataModel` containing the supplied columns. The columns are inserted in array order.

Exceptions:

`DataModelError` : if the source columns are not the system defined implementation

`d.xmlToDataModel(xml) : DataModel`

`xml (string)` : the data model XML

Returns a `DataModel` defined by the supplied XML string. It is assumed the string was generated by calling `dataModelToXML`.

Exceptions:

`DataModelError` : if the data model cannot be recreated

ExtendedMeasure Objects

This is an empty marker interface which identifies classes that provide extended measure metadata.

Related information

- [Data and Metadata](#)

ExtendedStorage Objects

This is an empty marker interface which identifies classes that provide extended storage metadata.

Related information

- [Data and Metadata](#)

GeoType Objects

Subclass of **ExtendedMeasure**.

Defines the different categories of geo objects.

g.getCoordinates() : int

Returns a positive integer, usually 2 or 3, which is the number of coordinates that define a point.

g.getCsname() : string

Returns a string containing the name of the coordinate system if the “well-known ID” is ≥ 0 or **None**.

g.getGeometryType() : GeometryType

Returns the type of object represented by this definition.

g.getWkid() : int

Returns an integer representing the “well-known ID” of the coordinate system or -1. If the attribute is -1, then the coordinate system is assumed to be a non-standard one.

g.getWkt() : string

Returns a string containing the “well-known text” for the coordinate system corresponding to the “well-known ID”.

g.isProjected() : boolean

For valid “well-known ID” values, this indicates whether the coordinate system is projected or geographic.

Related information

- [Data and Metadata](#)

GeometryType Objects

Defines the different categories of geo objects.

Constants:

LineString (GeometryType) : Defines that the values describe lines.

MultiLineString (GeometryType) : Defines that the values describe multiple lines.

MultiPoint (GeometryType) : Defines that the values describe multiple points.

MultiPolygon (GeometryType) : Defines that the values describe multiple polygons.

Point (GeometryType) : Defines that the values describe points.

Polygon (GeometryType) : Defines that the values describe polygons.

g.getDepth() : int

Returns the list depth that this geometry type uses.

```
valueOf(name) : GeometryType
name(string) :
values() : GeometryType[]
```

Related information

- [Data and Metadata](#)

GlobalValues Objects

This defines the set of global values which are usually computed by a stream via a "setglobals" node.

```
g.fieldNameIterator() : Iterator
```

Returns an iterator for each field name with at least one global value.

```
g.getValue(type, fieldName) : Object
```

type (GlobalValues.Type) : the type of value

fieldName (string) : the field name

Returns the global value for the specified type and field name or **None** if no value can be located. The returned value is generally expected to be a number although future functionality may return different value types.

```
g.getValues(fieldName) : Map
fieldName (string) :
```

Returns a map containing the known entries for the specified field name or **None** of no entries for the field exist.

Related information

- [Data and Metadata](#)

GlobalValues.Type Objects

This defines the set of global value types than can be accessed from the global values table.

Constants:

- MAX (GlobalValues.Type) :
- MEAN (GlobalValues.Type) :
- MIN (GlobalValues.Type) :
- STDDEV (GlobalValues.Type) :
- SUM (GlobalValues.Type) :

```
g.getFunctionName() : string
valueOf(name) : GlobalValues.Type
name(string) :
values() : GlobalValues.Type[]
```

Related information

- [Data and Metadata](#)

InvalidColumnExceptionValues Objects

Subclass of **DataModelError**.

An **InvalidColumnValueException** is thrown when the value supplied for a column is not consistent with its storage type.

No message string is set for this exception.

`i.getColumnName() : string`
Returns the name of the unknown column.

`i.getValue() : Object`
Returns the invalid value.

Related information

- [Data and Metadata](#)
-

ListStorage Objects

Subclass of `ExtendedStorage`.

Defines the storage metadata associated with lists

`l.getDepth() : int`
Returns the depth of the list. A list consisting of simple values has a depth of 0.

`l.getValueStorage() : StorageType`
Returns the simple storage of the values held in the list. The return value will not be `Storage.UNKNOWN` or `Storage.LIST`.

Related information

- [Data and Metadata](#)
-

MeasureType Objects

Subclass of `Enum`.

This class enumerates the valid measures for columns in a `DataModel`.

Constants:

- `AUTOMATIC (MeasureType)` : Indicates that the column value will be auto-selected as RANGE or DISCRETE according to its storage.
- `COLLECTION (MeasureType)` : Indicates that the column value should be interpreted as a collection of values.
- `DISCRETE (MeasureType)` : Indicates that the column value is like SET but can be treated as FLAG if there are only two values.
- `FLAG (MeasureType)` : Indicates that the column value is one of two values.
- `GEOSPATIAL (MeasureType)` : Indicates that the column value should be interpreted as a geospatial value.
- `ORDERED_SET (MeasureType)` : Indicates that the column value is like SET but with an implied order on the values.
- `RANGE (MeasureType)` : Indicates that the column value lies between two points on a scale.
- `SET (MeasureType)` : Indicates that the column value is one of a (small) set of discrete values.
- `TYPELESS (MeasureType)` : Indicates that the column can have any value compatible with its storage.

`getEnum(name) : MeasureType`
`name (string) : the enumeration name`
Returns the enumeration with the supplied name or `None` if no enumeration exists for the supplied name.

`getValues() : MeasureType[]`
Returns an array containing all the valid values for this enumeration class.

Related information

- [Data and Metadata](#)
-

MissingValueDefinition Objects

This defines the attributes associated with missing values.

`m.getValueCount() : int`

Returns the number of values specified as missing in this definition, excluding **None** and whitespace values. The result is the length of the list returned by `getValues`.

`m.getValues() : List`

Returns the list of values specified as missing in this definition. The list cannot be modified; the mutator methods on the list throw `UnsupportedOperationException`.

`m.isEnabled() : boolean`

Returns **True** if this definition is enabled. A definition which is not enabled recognizes no values as missing.

`m.isNullIncluded() : boolean`

Returns **True** if the **None** value is recognized as missing by this definition.

`m.isWhitespaceIncluded() : boolean`

Returns **True** if whitespace values are recognized as missing by this definition.

Related information

- [Data and Metadata](#)
-

ModelOutputMetadata Objects

This defines the metadata associated with a Column generated by a model.

Constants:

- **ADJUSTED** (`string`) : Used by binary classifiers as the tag value indicating that the column indicates adjusted propensity.
- **RAW** (`string`) : Used by binary classifiers as the tag value indicating that the column indicates raw propensity.
- **X** (`string`) : Used by Kohonen models as the tag value indicating the X component of the cluster id.
- **Y** (`string`) : Used by Kohonen models as the tag value indicating the Y component of the cluster id.

`m.getRole() : ModelFieldRole`

Returns the model output column role for the column if it is a model output column or **None**.

`m.getTag() : string`

Returns the tag associated with this model output column or **None** if the column is not a model output column or the tag has not been defined.

`m.getTargetColumn() : string`

Returns the target column name associated with this model output column or **None** if the column is not a model output column or the target column has not been defined.

`m.getValue() : Object`

Returns the value associated with this model output column or **None** if the column is not a model output column or no value has been defined. The value is typically used in combination with the target column e.g. when a model can generate probabilities for each value specified by the target field.

Related information

- [Data and Metadata](#)
-

ModelingRole Objects

Subclass of `Enum`.

This class enumerates the valid modeling roles for columns in a `DataModel`.

Constants:

- **BOTH** (`ModelingRole`) : Indicates that this column can be either an antecedent or a consequent.
- **FREQ_WEIGHT** (`ModelingRole`) : Indicates that this column is used to be as frequency weight but won't be showed for user.
- **IN** (`ModelingRole`) : Indicates that this column is a predictor or an antecedent.
- **NONE** (`ModelingRole`) : Indicates that this column is not used directly during modeling.
- **OUT** (`ModelingRole`) : Indicates that this column is predicted or a consequent.
- **PARTITION** (`ModelingRole`) : Indicates that this column is used to identify the data partition.
- **RECORD_ID** (`ModelingRole`) : Indicates that this column is used to identify the record id.
- **SPLIT** (`ModelingRole`) : Indicates that this column is used to split the data.

`getEnum(name) : ModelingRole`

`name (string)` : the enumeration name

Returns the enumeration with the supplied name or `None` if no enumeration exists for the supplied name.

`getValues() : ModelingRole[]`

Returns an array containing all the valid values for this enumeration class.

Related information

- [Data and Metadata](#)

RowSet Objects

This defines the properties of a tabular dataset.

`r.getColumnClass(columnIndex) : Class`

`columnIndex (int)` : the column index

Returns the class of objects in a specified column of this dataset. The column index must be in the range:

`0 <= index < getColumnCount()`

Exceptions:

`IndexOutOfBoundsException` : unless the column index is in range

`r.getColumnCount() : int`

Returns the number of columns in this dataset.

`r.getColumnName(columnIndex) : string`

`columnIndex (int)` : the column index

Returns the name of a specified column in this dataset. Returns the empty string if the column does not have a name. The column index must be in the range:

`0 <= index < getColumnCount()`

Exceptions:

`IndexOutOfBoundsException` : unless the column index is in range

`r.getRowCount() : int`

Returns the number of rows in this dataset.

`r.getValueAt(rowIndex, columnIndex) : Object`

`rowIndex (int)` : the row index

`columnIndex (int)` : the column index

Returns the value from a specified row and column in this dataset. The row and column indexes must be in the range:

`0 <= rowIndex < getRowCount() && 0 <= columnIndex < getColumnCount()`

The returned value will either be `None` or an instance of the class returned by `getColumnClass` for the same column index.

Exceptions:

`IndexOutOfBoundsException` : unless the row and column indexes are in range

-

StorageType Objects

Subclass of `Enum`.

This class enumerates the valid storage types for columns in a `DataModel` or parameters.

Constants:

- `DATE (StorageType)` : Indicates that the storage type is a date type.
- `INTEGER (StorageType)` : Indicates that the storage type is an integer.
- `LIST (StorageType)` : Indicates that the storage type is a list of primitive values.
- `REAL (StorageType)` : Indicates that the storage type is a floating point number.
- `STRING (StorageType)` : Indicates that the storage type is a string.
- `TIME (StorageType)` : Indicates that the storage type is a time type.
- `TIMESTAMP (StorageType)` : Indicates that the storage type is a combined time and date type.
- `UNKNOWN (StorageType)` : Indicates that the storage type is unknown.

`getEnum(name) : StorageType`

`name (string)` : the enumeration name

Returns the enumeration with the supplied name or `None` if no enumeration exists for the supplied name.

`getValues() : StorageType[]`

Returns an array containing all the valid values for this enumeration class.

Related information

- [Data and Metadata](#)
-

UnknownColumnException Objects

Subclass of `DataModelError`.

An `UnknownColumnException` is thrown when a column name is used that does not exist in the data model.

No message string is set for this exception.

`u.getColumnName() : string`

Returns the name of the unknown column.

 - [ParserException Objects](#)
-

Expression Objects

This interface encapsulates details of a CLEM expression.

```
e.getReferencedFields() : set
```

Returns the **Set** of field names referenced by the expression.

```
e.getStorageType() : StorageType
```

Returns the **StorageType** of the expression.

Related information

- [Expressions](#)
-

Parser Objects

This interface encapsulates the functionality for parsing CLEM expressions.

```
p.parseExpression(expressionString, dataModel) : Expression
```

expressionString (**string**) :- the **string** to parse

dataModel (**DataModel**) :- the data model

Attempts to parse the **string** argument to an **Expression**. Parsing checks for syntax, lexical and semantic errors. The **dataModel** argument is used to check for fields referenced in the expression. Parsing using this method will fail if the **string** contains reference to **Node** or **Stream** related functions and values such as GlobalValues, Parameters and database functions.

Exceptions

ParserException: - if the **string** does not contain a parsable Expression.

Related information

- [Expressions](#)
-

ParserException Objects

Subclass of **ModelerException**.

A **ParserException** is thrown to indicate that an attempt to parse a **string** to an **Expression** failed. Parsing can fail due to syntax, lexical or semantic errors.

```
p.getEndPosition() : int
```

Returns the end position in the parsed **string** of the text relating to the error. Returns -1 if start position is not valid.

```
p.getStartPosition() : int
```

Returns the start position in the parsed **string** of the text relating to the error. Returns -1 if start position is not valid.

- [Expressions](#)
-

Model information

This provides support for accessing information about data mining models.

- [CompositeModelDetail Objects](#)
- [ModelDetail Objects](#)
- [ModelType Objects](#)
- [PMMLModelType Objects](#)

Related information

- [CompositeModelDetail Objects](#)
- [ModelDetail Objects](#)
- [ModelType Objects](#)
- [PMMLModelType Objects](#)

CompositeModelDetail Objects

Subclass of [ModelDetail](#).

This interface encapsulates the representation detail of a composite model.

`c.canUseMultipleModels() : boolean`

Returns `True` if multiple models can be used by the composite model.

`c.getIndividualModelResults() : Iterator`

Returns the individual model results of this composite model.

Related information

- [Model information](#)

ModelDetail Objects

This interface encapsulates the representation detail of a data mining model.

`m.getAlgorithmName() : string`

Returns the name of the model builder algorithm.

`m.getApplicationName() : string`

Returns the name of the model builder application.

`m.getApplicationVersion() : string`

Returns the version of the model builder application.

`m.getBuildDate() : Date`

Returns the date this model was built.

`m.getCopyright() : string`

Returns the model copyright.

`m.getInputDataModel() : DataModel`

Returns the input data model required by the model. Note that the `ModelingRole` for each field in the input data model is `ModelingRole.IN`, even for fields that had been specified as `ModelingRole.BOTH` for association or sequence models.

`m.getModelID() : string`

Returns the model ID. For models within a composite model, it is assumed that each model has a unique ID.

```
m.getModelType() : ModelType
```

Returns the type of the model.

```
m.getOutputDataModel() : DataModel
```

Returns the output data model produced by the model. Note that the **ModelingRole** for each field in the output data model is **ModelingRole.OUT**, even for fields that had been specified as **ModelingRole.BOTH** for association or sequence models.

It is also important to note that this is not same as the output column set produced by the **ModelApplier** that applies the model to data. The transformer output column set will usually include additional fields from the input and may include property settings that modify the number or type of outputs produced (for example, a transformer that applies a clustering model may produce the cluster ID as an integer or a string depending on the property settings).

```
m.getPMMLModelType() : PMMLModelType
```

For a model which is represented internally using PMML (one for which **isPMMLModel()** returns **True**) this returns the PMML model type from the underlying PMML that was generated by the modeling algorithm. For a model which is not represented using PMML this returns **None**.

```
m.getPMMLText() : string
```

For a model which is represented internally using PMML (one for which **isPMMLModel()** returns **True**) this returns a string representing the PMML generated from the model building algorithm. For non-PMML models this returns **None**. When this returns **None** you may be able to obtain an alternative representation of the model as PMML using the export function: **TaskRunner.exportModelToFile()**.

```
m.getSplitColumnNames() : List
```

Returns the list of split column names if this is a split model or **None** for non-split models.

```
m.getSplitModelCount() : int
```

Returns the number of split models if this is a split model or **0** otherwise.

```
m.getSplitModelKey(index) : List
```

index (int) : the model index

Returns the values of the split fields at the specified index for split models or **None** for non-split models. When present, the values are in the order specified by the split output columns.

```
m.getSplitModelPMMLText(index) : string
```

index (int) : the model index

Returns the PMML representation of the split model at the specified index for split models or **None** for non-split models or if the split model is not represented as PMML.

```
m.getUserName() : string
```

Returns the name of the account used to build the model.

```
m.isOutputColumnAuxiliary(name) : boolean
```

name (string) : the column name

Returns **True** if the supplied column name is an auxiliary column in the output data model or **False**. An auxiliary output column is a column that provides additional information about the output of the model, for example, the confidence of the prediction or distance from the cluster center.

```
m.isPMMLModel() : boolean
```

Returns **True** if this model is represented using PMML, or **False** otherwise.

```
m.isSplitModel() : boolean
```

Returns **True** if this model is a split model, **False** otherwise.

Related information

- [Model information](#)
-

ModelType Objects

Subclass of **Enum**.

This class enumerates the valid model types. These are largely based on the JDM 1.1 and draft JDM 2.0 data mining functions definition.

Constants:

- **ANOMALY_DETECTION** (`ModelType`) : Indicates an anomaly detection model.
- **APPROXIMATION** (`ModelType`) : Indicates that the model predicts a continuous value.
- **ASSOCIATION** (`ModelType`) : Indicates that the model identifies frequently occurring sets of items.
- **ATTRIBUTE_IMPORTANCE** (`ModelType`) : Indicates an attribute importance model.
- **CATEGORIZE** (`ModelType`) : Indicates a text categorize model.
- **CLASSIFICATION** (`ModelType`) : Indicates that the model predicts a discrete value.
- **CLUSTERING** (`ModelType`) : Indicates that the model groups similar rows of data together.
- **CONCEPT_EXTRACTION** (`ModelType`) : Indicates that the model identifies concepts from textual data.
- **REDUCTION** (`ModelType`) : Indicates that the model reduces the complexity of data.
- **SEQUENCE** (`ModelType`) : Indicates that the model identifies frequently occurring sequences of events.
- **SUPERVISED_MULTITARGET** (`ModelType`) : Indicates a supervised multi-target model.
- **SURVIVAL_ANALYSIS** (`ModelType`) : Indicates a survival analysis model.
- **TIME_SERIES** (`ModelType`) : Indicates a time series model.
- **UNKNOWN** (`ModelType`) : Indicates that the model type cannot be determined. This value should never be returned for any built-in model.

`getEnum(name) : ModelType`

`name (string)` : the enumeration name

Returns the enumeration with the supplied name or `None` if no enumeration exists for the supplied name.

`getValues() : ModelType[]`

Returns an array containing all the valid values for this enumeration class.

`m.isUnknown() : boolean`

Returns `True` if this value is `ModelType.UNKNOWN`.

Related information

- [Model information](#)
-

PMMMLModelType Objects

Subclass of `Enum`.

Enumerates the model types specified by PMML 4.0.

Constants:

- **ASSOCIATION** (`PMMMLModelType`) : PMML AssociationModel
- **CLUSTERING** (`PMMMLModelType`) : PMML ClusteringModel
- **GENERAL_REGRESSION** (`PMMMLModelType`) : PMML GeneralRegressionModel
- **MINING** (`PMMMLModelType`) : PMML MiningModel
- **NAIVE_BAYES** (`PMMMLModelType`) : PMML NaiveBayesModel
- **NEURAL_NETWORK** (`PMMMLModelType`) : PMML NeuralNetwork
- **REGRESSION** (`PMMMLModelType`) : PMML RegressionModel
- **RULE_SET** (`PMMMLModelType`) : PMML RuleSetModel
- **SEQUENCE** (`PMMMLModelType`) : PMML SequenceModel
- **SUPPORT_VECTOR_MACHINE** (`PMMMLModelType`) : PMML SupportVectorMachineModel
- **TEXT** (`PMMMLModelType`) : PMML TextModel
- **TIME_SERIES** (`PMMMLModelType`) : PMML TimeSeriesModel
- **TREE** (`PMMMLModelType`) : PMML TreeModel

`getEnum(name) : PMMMLModelType`

`name (string)` : the PMML model type name

Returns the `PMMMLModelType` corresponding to the specified PMML model type name, or `None` if there is no such model type. The name must be one specified by PMML 4.0.

`getValues() : PMMMLModelType[]`

Returns an array containing all the valid values for this enumeration class.

```
p.isUnknown() : boolean
```

Returns **False** always. All the values in this class represent known model types; there is no "unknown".

ServerDatabaseConnection Objects

This encapsulates the functionality of an object that represents a connection to a database.

```
s.dropTable(tableName)
tableName (string) :
s.getDBQueryColumns(queryText) : RowSet
queryText (string) : the text of the query
```

Returns a list of the columns returned by a specified database query. The list is returned in the form of a dataset where the first column contains the column name as a string.

Exceptions:

```
ServerResourceException : if the server resource cannot be accessed
s.getDBTableColumns(catalogName, schemaName, tableName) : RowSet
catalogName (string) : the catalog name
schemaName (string) : the schema name
tableName (string) : the base table name
```

Returns a list of the columns in a specified database table. The list is returned in the form of a dataset where the first column contains the column name as a string and the second column contains **StorageType** constants that provide the closest match for the storage types for the columns in the database table.

Exceptions:

```
ServerResourceException : if the server resource cannot be accessed
s.getDBTables(catalogName, schemaName, tableName, includeUserTables, includeSystemTables, includeViews,
includeSynonyms) : RowSet
catalogName (string) : pattern for the catalog name
schemaName (string) : pattern for the schema name
tableName (string) : pattern for the table name
includeUserTables (boolean) : indicates whether user tables should be included
```

```
includeSystemTables (boolean) : indicates whether system tables should be included
```

```
includeViews (boolean) : indicates whether views should be included
```

```
includeSynonyms (boolean) : indicates whether synonyms should be included
```

Returns a summary of the tables available on this database connection which match the specified arguments. The summary is returned in the form of a dataset with at least two columns, of which the first two columns are the schema name and table name, both as strings.

Exceptions:

```
ServerResourceException : if the server resource cannot be accessed
```

```
s.isDBTableVisible(catalogName, schemaName, tableName) : boolean
```

```
catalogName (string) : the catalog name
```

```
schemaName (string) : the schema name
```

```
tableName (string) : the table name
```

Returns **True** if the specified table is visible to this connection.

Exceptions:

```
ServerResourceException : if the server resource cannot be accessed
```

Related information

- [Server resources](#)

ServerFile Objects

This encapsulates the representation of a file on the server file system. A server file always uses / to separate directory paths since this is valid for both UNIX and Windows file systems.

```
s.getName() : string
```

Returns the name of the file.

```
s.getParent() : string
```

Returns the pathname of the parent directory.

```
s.getParentServerFile() : ServerFile
```

Returns a file representing the parent directory.

```
s.getPath() : string
```

Returns the pathname of the file.

```
s.isAbsolute() : boolean
```

Returns whether the pathname is absolute.

```
s.isDirectory() : boolean
```

Returns whether this file is a directory.

Related information

- [Server resources](#)

ServerFileSystem Objects

This encapsulates the functionality for representing the file system on the data mining server's host.

```
s.createTemporaryFile(name) : ServerFile
```

`name (string)` : the suggested name of the new file

Creates a new file with a unique name in the server's temporary file space. The file is empty and can be written by the creator. The specified name will be used as the starting point for generating a unique name for the file, and if the name has an extension it will be left unchanged. The file must be deleted when it is no longer needed.

Exceptions:

`ServerResourceException` : if the file cannot be created for any reason

`s.deleteFile(file)`

`file (ServerFile)` : the file to delete

Deletes the specified file from this file system. The caller must have permission to delete the file.

Calling this method has the same effect as creating and running a delete file task.

Exceptions:

`ServerResourceException` : if the file cannot be deleted

`s.directoryOrFileExists(path, isDirectory) : boolean`

`path (ServerFile)` : Pathname to check

`isDirectory (boolean)` : Set to True if the path to be tested should be a directory

Returns whether a directory or file exists.

Exceptions:

`ServerResourceException` : if the server file system cannot be accessed

`s.exists(file) : boolean`

`file (ServerFile)` :

Returns whether a file exists.

Exceptions:

`ServerResourceException` : if the server file system cannot be accessed

`s.getAbsolutePath(file) : string`

`file (ServerFile)` : a `ServerFile` object

Returns the absolute pathname or `None` if the absolute path cannot be determined.

Exceptions:

`ServerResourceException` : if the server file system cannot be accessed

`s.getAbsoluteServerFile(file) : ServerFile`

`file (ServerFile)` : a `ServerFile` object

Returns a file representing the absolute pathname or `None` if the absolute path cannot be determined.

Exceptions:

`ServerResourceException` : if the server file system cannot be accessed

`s.getChild(parent, filename) : ServerFile`

`parent (ServerFile)` : a `ServerFile` object representing a directory or special folder

`filename (string)` : a name of a file or folder which exists in `parent`

Returns the named child in the supplied parent.

Exceptions:

`ServerResourceException` : if the server file system cannot be accessed

`s.getDefaultDirectory() : ServerFile`

Returns the server's default directory.

Exceptions:

ServerResourceException : if the server file system cannot be accessed

s.GetFiles(directory) : ServerFile[]

directory (ServerFile) : the directory

Returns the list of files in the specified directory of the file system.

Exceptions:

ServerResourceException : if the server file system cannot be accessed

s.getParentDirectory(file) : ServerFile

file (ServerFile) : a **ServerFile** object

Returns the parent directory of a file in the file system.

s.getPathSeparator() : string

Returns a string version of the path separator character.

s.getPathSeparatorChar() : char

Returns the path separator character for this file system. On Windows, this is ; and on UNIX, this is :.

s.getRoots() : ServerFile[]

Returns the roots of the file system.

Exceptions:

ServerResourceException : if the server file system cannot be accessed

s.getSeparator() : string

Returns a string version of the separator character.

s.getSeparatorChar() : char

Returns the separator character for this file system. On Windows, this is \ and on UNIX, this is /.

s.getServerFile(filename) : ServerFile

filename (string) : a name of a file or folder

Returns a server file for the corresponding file name.

s.getSize(file) : long

file (ServerFile) : the file

Returns the size, in bytes, of the specified file in this file system. Returns 0 if the file does not exist or is not accessible, or -1 if the file is accessible but the server does not support the file size operation. The result is undefined when the file denotes a directory.

Exceptions:

ServerResourceException : if the file system cannot be accessed

LocaleInfo Objects

This interface defines locale-sensitive information associated with a **Session**.

```
l.getLocale() : Locale
```

Returns the locale associated with this locale information object.

```
l.getLocalizedProcessorDescription(nodeType) : string
```

```
nodeType (string) : the node type
```

Returns a locale-sensitive string describing the supplied node type name or **None** if a description cannot be found.

```
l.getLocalizedProcessorName(nodeType) : string
```

```
nodeType (string) : the node type name
```

Returns a locale-sensitive string representing the supplied node type name or **None** if a name cannot be found.

Related information

- [Server resources](#)

Repository Objects

This defines the basic functionality for a content repository. Unlike the file persistence tasks defined by **TaskFactory**, these are executed synchronously through the repository object rather than indirectly via the Session.

```
r.createFolder(parentFolder, newFolder) : string
```

```
parentFolder (string) : the path to the parent folder
```

```
newFolder (string) : the new folder name
```

Creates a new folder with the specified name.

Exceptions:

```
SessionException : if the folder cannot be created
```

```
r.createRetrieveURI(path, version, label) : URI
```

path (string) : the full path to the object to be retrieved

version (string) : the version marker or **None**

label (string) : the label or **None**

A utility function to create a repository URI that is valid for retrieving an object from the specified location. Either a version or label may be specified if a specific version is required. If both are **None** then the LATEST version will be returned.

Exceptions:

URISyntaxException : if the method cannot construct a valid URI

```
r.createStoreURI(path, label) : URI
```

path (string) : the full path to the store location

label (string) : the label to be applied to the object or **None**

A utility function to create a repository URI that is valid for storing an object at the specified location and with an optional label to be applied to the object when it is stored.

Exceptions:

URISyntaxException : if the method cannot construct a valid URI

```
r.deleteFolder(folder)
```

folder (string) : the folder to be deleted

Deletes the specified folder and any content within it.

Exceptions:

SessionException : if the folder cannot be deleted

```
rgetRepositoryHandle() : Object
```

Returns the underlying repository handle. The handle will be an instance of the Java class
`com.spss.repository.client.application.Repository`.

```
r.renameFolder(folder, newName)
```

folder (string) : the path of the folder to be renamed

newName (string) : the new folder name

Renames the specified folder.

Exceptions:

SessionException : if the folder cannot be renamed

```
r.retrieveDocument(path, version, label, autoManage) : DocumentOutput
```

path (string) : the full path to the object

version (string) : the version marker or **None**

label (string) : the label or **None**

autoManage (boolean) : whether the document should be added to the output manager

Retrieves an output document (in COU format) from the specified path. Either a version or label may be specified if a specific version is required. If both are **None** then the LATEST version is returned. Code that needs to open documents privately without having them made visible to the user should set the **autoManage** flag to **False**.

Exceptions:

URISyntaxException : if the method cannot construct a valid URI

SessionException : if the document output cannot be retrieved for some reason

```
r.retrieveModel(path, version, label, autoManage) : ModelOutput
```

path (string) : the full path to the object

`version (string) : the version marker or None`

`label (string) : the label or None`

`autoManage (boolean) : whether the model should be added to the model manager`

Retrieves a model output from the specified path. Either a version or label may be specified if a specific version is required. If both are **None** then the LATEST version is returned. Code that needs to open models privately without having them made visible to the user should set the `autoManage` flag to **False**.

Exceptions:

`URISyntaxException : if the method cannot construct a valid URI`

`SessionException : if the model output cannot be retrieved for some reason`

`r.retrieveProcessor(path, version, label, diagram) : Node`

`path (string) : the full path to the object`

`version (string) : the version marker or None`

`label (string) : the label or None`

`diagram (Diagram) : the diagram that the node should be added to`

Retrieves a node from the specified path and inserts it into the supplied diagram. Either a version or label may be specified if a specific version is required. If both are **None** then the LATEST version is returned.

Exceptions:

`URISyntaxException : if the method cannot construct a valid URI`

`SessionException : if the node cannot be retrieved for some reason`

`r.retrieveStream(path, version, label, autoManage) : Stream`

`path (string) : the full path to the object`

`version (string) : the version marker or None`

`label (string) : the label or None`

`autoManage (boolean) : whether the stream should be added to the stream manager`

Retrieves a stream from the specified path. Either a version or label may be specified if a specific version is required. If both are **None** then the LATEST version is returned. Code that needs to open streams privately without having them made visible to the user should set the `autoManage` flag to **False**.

Exceptions:

`URISyntaxException : if the method cannot construct a valid URI`

`SessionException : if the stream cannot be retrieved for some reason`

`r.storeDocument(documentOutput, path, label) : string`

`documentOutput (DocumentOutput) : the document output to be stored`

`path (string) : the path`

`label (string) : the label or None`

Stores a document output to the specified location. If the label is provided then it is applied to the new version.

Exceptions:

`URISyntaxException : if the method cannot construct a valid URI`

`SessionException : if the document output cannot be stored for some reason`

`r.storeModel(modelOutput, path, label) : string`

`modelOutput (ModelOutput) : the model output to be stored`

`path (string) : the path`

`label (string) : the label or None`

Stores a model output to the specified location. If the label is provided then it is applied to the new version.

Exceptions:

URISyntaxException : if the method cannot construct a valid URI

SessionException : if the model output cannot be stored for some reason

r.storeProcessor(node, path, label) : string

node (Node) : the node to be stored

path (string) : the path

label (string) : the label or **None**

Stores a node to the specified location. If the label is provided then it is applied to the new version.

Exceptions:

URISyntaxException : if the method cannot construct a valid URI

SessionException : if the node cannot be stored for some reason

r.storeStream(stream, path, label) : string

stream (Stream) : the stream to be stored

path (string) : the path

label (string) : the label or **None**

Stores a stream to the specified location. If the label is provided then it is applied to the new version.

Exceptions:

URISyntaxException : if the method cannot construct a valid URI

SessionException : if the stream cannot be stored for some reason

Session Objects

Subclass of **SystemSession**.

A session is the main interface through which users of the Modeler API access the API features. Each session has its own connection to a data mining server.

A data mining server is typically a remote server identified by a **ServerConnectionDescriptor**. From Modeler API 2.0 a server can also be a local server instance spawned as a child process of the Modeler API host process (see `connect()`). This local server mode requires a local server installation, such as a Modeler client installation, on the local machine. The installation directory is located through the system property

com.spss.psapi.session.serverInstallationDirectory

This property must point to a valid installation directory and must be set before the session factory is instantiated otherwise connections to the local server will fail.

s.close()

Closes this session. This automatically interrupts any task currently running, closes any current **Stream** and invalidates any other objects created by this session.

s.connect(serverDescriptor)

serverDescriptor (ServerConnectionDescriptor) : identifies a remote data mining server

Connects this session to the remote server identified by the specified server descriptor.

Exceptions:

ServerConnectionException : if a connection to the server cannot be established or if the Session already has a connection
s.connect()

Connects this session to a local server instance. Spawns a new local server process.

Exceptions:

ServerConnectionException : if a local server instance cannot be created or if the session already has a connection

s.connect(stream)

stream (Stream) : the stream to be connected

Connects the stream to the session's server.

Exceptions:

ServerConnectionException : if the Session is not connected or if the stream is already connected

OwnerException : if the stream was not created by this session

s.createServerDatabaseConnection(datasourceName, credentialName, catalogName) :
ServerDatabaseConnection

datasourceName (string) : the datasource name

credentialName (string) : the stored credential name

catalogName (string) : the catalog name

Creates a **ServerDatabaseConnection**. The datasource name must visible to the data mining server.

Exceptions:

ServerConnectionException : if the session is not connected to a server

ServerResourceException : if the connection task fails.

s.createServerDatabaseConnection(datasourceName, userName, password, catalogName) :
ServerDatabaseConnection

datasourceName (string) : the datasource name

userName (string) : the user name

password (string) : the password

catalogName (string) : the catalog name

Creates a **ServerDatabaseConnection**. The datasource name must visible to the data mining server.

Exceptions:

ServerConnectionException : if the session is not connected to a server

ServerResourceException : if the connection task fails.

s.getASCredentialDescriptor() : ASCredentialDescriptor

Returns the credential descriptor used to log in to the Analytic Server.

s.getAttribute(name) : Object

name (string) : an attribute name

Returns the value of the specified attribute in this session, or **None** if there is no such attribute. Attributes are created by the application, not by the Modeler API.

s.getAttributeNames() : Collection

Returns the names of the attributes defined in this session.

s.getParameters() : ParameterProvider

Returns the parameter provider for this session. The parameter provider provides access to session parameters.

s.getParser() : Parser

Returns the shared parser for this session.

```
s.getRepository() : Repository
```

Returns the repository object that provides simple mechanisms for storing and retrieving objects.

```
s.getRepositoryConnectionDescriptor() : RepositoryConnectionDescriptor
```

Returns the repository connection descriptor.

```
s.getServerConnectionDescriptor() : ServerConnectionDescriptor
```

Returns the `ServerConnectionDescriptor` used to connect this session to a remote server. Returns `None` if the session is connected to a local server or has not yet been connected.

```
s.getServerDataSourceNames() : RowSet
```

Returns a row set that lists the available system DSNs visible on the data mining server host. The list is returned in the form of a row set where the first column contains the data source name as a string and the second column contains a string description.

Exceptions:

```
ServerConnectionException : if the session is not connected to a server
```

```
ServerResourceException : if access to the server data sources was denied
```

```
s.getServerFileSystem() : ServerFileSystem
```

Returns the server file system.

Exceptions:

```
ServerConnectionException : if the session is not connected to a server
```

```
ServerResourceException : if access to the server file system was denied
```

```
s.getServerVersionInfo() : ServerVersionInfo
```

Returns information about the connected server version or `None` if the session is not connected.

```
s.getTaskFactory() : TaskFactory
```

Returns the `TaskFactory` for this session.

```
s.getTaskRunner() : TaskRunner
```

Returns the `TaskRunner` for this session.

```
s.getUIResources() : UIResources
```

Returns the interface that provides access to UI-related resources.

```
s.interrupt()
```

Interrupts any synchronous task which is currently executing. The call returns immediately while the task is interrupted. It has no effect if the session is not busy.

This method may be called from any thread.

```
s.isBusy() : boolean
```

Returns `True` if this session is currently executing a synchronous task (even if the task is in the process of being interrupted).

This method may be called from any thread.

```
s.isClosed() : boolean
```

Returns `True` if this has been closed.

```
s.isConnected() : boolean
```

Returns `True` if this session has a server connection.

```
s.isValidASCredentialDescriptor(asConnectionDescriptor) : boolean
```

```
asConnectionDescriptor (ASCredentialDescriptor) : the credential descriptor
```

Check whether the credential descriptor is a valid.

```
s.isValidRepositoryConnectionDescriptor(descriptor) : boolean
```

```
descriptor (RepositoryConnectionDescriptor) : the repository connection descriptor
```

Returns **True** if the supplied repository connection descriptor is valid i.e. can connect to a content repository.

```
s.publish(node) : ExecutionHandle  
node (DataWriter) : the DataWriter to be published
```

Executes the specified **DataWriter** in publish mode to obtain a **PublishedImage**. This overrides the execution mode set in the node and retrieves the published image from the server on completion. Execution is synchronous. The result is an **ExecutionHandle** which can be used to determine the exit status of the task and, if the task completes successfully, to obtain the result of the task which is a **PublishedImage**.

Exceptions:

OwnerException : if the node was not created by this session

ObjectLockedException : if the node or its containing stream is locked

ServerConnectionException : if the stream is not connected to a server

SessionException : if the session is already running another task, or cannot execute the task for some other reason, or if execution completes in a state other than **SUCCESS**

```
s.publish(node, inline) : ExecutionHandle
```

node (TerminalNode) : the TerminalNode to be published. Must be a **DataWriter** if not publishing inline

inline (boolean) : **True** to prepare the image for inline scoring

Executes the specified node in publish mode to obtain a **PublishedImage** ready for inline scoring.

If inline is **False**, this is equivalent to calling **publish (DataWriter)** and the node must be a data writer. Otherwise, the node may be any terminal node and the stream is modified in place to replace the input and output nodes with ones suitable for inline scoring.

Execution is synchronous. The result is an **ExecutionHandle** which can be used to determine the exit status of the publishing task and, if the task completes successfully, to obtain the result of the task which is a **PublishedImage**.

Exceptions:

OwnerException : if the node was not created by this session

ObjectLockedException : if the node or its containing stream is locked

ServerConnectionException : if the stream is not connected to a server

SessionException : if the session is already running another task, or cannot execute the task for some other reason, or if the stream cannot be prepared for inline scoring, or if execution completes in a state other than **SUCCESS**

```
s.removeAttribute(name)
```

name (string) : an attribute name

Deletes the specified attribute from this session. If there is no such attribute, the call has no effect.

```
s.run(stream, results) : ExecutionHandle
```

stream (Stream) : the Stream to be executed

results (Collection) : an empty collection that will contain any built objects once execution has completed

Executes the supplied stream synchronously and waits for it to complete. Returns an **ExecutionHandle** which can be used to access the exit status and any result from the task.

Exceptions:

OwnerException : if the stream was not created by this session

ObjectLockedException : if the stream is locked

ServerConnectionException : if the stream is not connected to a server

SessionException : if the session is already running another task, cannot execute the task or if execution completes in a state other than **SUCCESS**

```
s.run(nodes, results) : ExecutionHandle
```

nodes (Node[]) : the array of **Node** objects to be executed

results (Collection) : an empty collection that will contain any built objects once execution has completed

Executes the supplied array of nodes synchronously and waits for them to complete. There must be at least one node in the array. Returns an **ExecutionHandle** which can be used to access the exit status and any result from the task.

Exceptions:

OwnerException : if the nodes' stream was not created by this session or the nodes are not all owned by the same stream

ObjectLockedException : if the nodes' owner stream is locked

ServerConnectionException : if the nodes' stream is not connected to a server

SessionException : if the session is already running another task, cannot execute the task or if execution completes in a state other than **SUCCESS**

IllegalArgumentException : if the array is empty

s.runTask(task) : ExecutionHandle

task (Task) : the Task to be executed

Executes the supplied task synchronously and waits for it to complete. Returns an **ExecutionHandle** which can be used to access the exit status and any result from the task.

Exceptions:

OwnerException : if the task was not created by this session's **TaskFactory**

ObjectLockedException : if the task is already executing or any object referenced by the task is locked for updating

SessionException : if the session cannot execute the task or if execution completes in a state other than **SUCCESS**

s.setASCredentialDescriptor(asConnectionDescriptor)

asConnectionDescriptor (ASCredentialDescriptor) : the credential descriptor

Sets the credential descriptor used to log in Analytic Server.

s.setAttribute(name, value)

name (string) : an attribute name

value (Object) : the attribute value

Assigns a value to the specified attribute in this session. If the attribute already has a value, it is replaced. If the value is **None**, the attribute is deleted from the session.

s.setRepositoryConnectionDescriptor(descriptor)

descriptor (RepositoryConnectionDescriptor) : the new repository connection descriptor

Sets the repository connection descriptor to be used when a connection to a content repository is required. Any existing connection is closed although a new connection will not be created until it is required.

s.spawn(stream, results) : ExecutionHandle

stream (Stream) : the Stream to be executed

results (Collection) : an empty collection that will contain any built objects once execution has completed

Executes the supplied stream asynchronously. Returns an **ExecutionHandle** which can be used to monitor and control the progress of the task.

Exceptions:

OwnerException : if the stream was not created by this session

ObjectLockedException : if the stream is locked

ServerConnectionException : if the stream is not connected to a server

s.spawn(nodes, builtObjects) : ExecutionHandle

nodes (Node[]) : the array of Node objects to be executed

builtObjects (Collection) : an empty collection that will be populated by built objects created by the execution

Executes the supplied array of nodes asynchronously. Returns an **ExecutionHandle** which can be used to monitor and control the progress of the task. There must be at least one node in the array.

Exceptions:

OwnerException : if the nodes' stream was not created by this session or the nodes are not all owned by the same stream

ObjectLockedException : if the nodes' stream is locked

ServerConnectionException : if the nodes' stream is not connected to a server

IllegalArgumentException : if the array is empty

s.spawnPublish(node) : ExecutionHandle

node (DataWriter) : the **DataWriter** to be published

Executes the specified **DataWriter** asynchronously in publish mode to obtain a **PublishedImage**. This overrides the execution mode set in the node and retrieves the published image from the server on completion. Returns an **ExecutionHandle** which can be used to monitor and control the progress of the publishing task and, if it completes successfully, to obtain the task result which is a **PublishedImage**.

Exceptions:

OwnerException : if the node was not created by this session

ObjectLockedException : if the node or its containing stream is locked

ServerConnectionException : if the stream is not connected to a server

s.spawnPublish(node, inline) : ExecutionHandle

node (TerminalNode) : the **TerminalNode** to be published. Must be a **DataWriter** if not publishing inline

inline (boolean) : **True** to prepare the image for inline scoring

Executes the specified node asynchronously in *publish* mode to obtain a **PublishedImage** ready for inline scoring.

If **inline** is **False**, this is equivalent to calling **publish(DataWriter)** and the node must be a data writer. Otherwise, the node may be any terminal node and the stream is modified in place to replace the input and output nodes with ones suitable for inline scoring.

Returns an **ExecutionHandle** which can be used to monitor and control the progress of the publishing task and, if it completes successfully, to obtain the task result which is a **PublishedImage**.

Exceptions:

OwnerException : if the node was not created by this session

ObjectLockedException : if the node or its containing stream is locked

ServerConnectionException : if the stream is not connected to a server

SessionException : if the stream cannot be prepared for inline scoring

s.spawnTask(task) : ExecutionHandle

task (Task) : the **Task** to be executed

Executes the supplied task asynchronously. Returns an **ExecutionHandle** which can be used to monitor and control the progress of the task.

Exceptions:

OwnerException : if the task was not created by this session's **TaskFactory**

ObjectLockedException : if the task is already executing or any object referenced by the task is locked for updating

s.waitForAllTasksToFinish()

Waits for all tasks in progress on this session to complete.

Related information

-

SessionException Objects

Subclass of **ModelerException**.

An exception thrown while creating a **Session** or performing a task within a **Session**.

A message string is always created for this exception.

Related information

- [Server resources](#)
-

SystemSession Objects

Defines the functionality of a system session. Sessions define the basic context that other operations work within.

```
sgetLocale() : Locale
```

Returns the locale specified for this session.

```
s.getLocaleInfo() : LocaleInfo
```

Returns the `LocaleInfo` for this session.

```
s.isLocalSession() : boolean
```

Returns `True` if the session is connected to a local or desktop execution engine, `False` otherwise.

Related information

- [Server resources](#)
-

UIResources Objects

This interface provides access to UI-related resources.

```
u.getBaseProcessorIcon(nodeType) : ImageIcon
```

`nodeType` (`string`) : the node type

Returns the base icon used to represent this node type or `None`. The base icon does not include any background.

```
u.getProcessorIcon(nodeType) : ImageIcon
```

`nodeType` (`string`) : the node type

Returns the default icon used to represent this node type or `None`.

ExecutionFeedbackEvent Objects

Feedback received from an execution task. Feedback is only received from tasks executing a **Node** or **Stream**.

Constants:

- **MESSAGE_ID_EXECUTION_STARTED** (int) : Message ID: execution started.
- **MESSAGE_ID_EXECUTION_STOPPED** (int) : Message ID: execution stopped.
- **MESSAGE_ID_INTERRUPTED** (int) : Message ID: interrupted.
- **MESSAGE_ID_OPTIMIZATION_STARTED** (int) : Message ID: optimization started.
- **MESSAGE_ID_OPTIMIZATION_STOPPED** (int) : Message ID: optimization stopped.
- **MESSAGE_ID_OTHER** (int) : Message ID: other.
- **MESSAGE_ID_PREPARATION_STARTED** (int) : Message ID: preparation started.
- **MESSAGE_ID_PREPARATION_STOPPED** (int) : Message ID: preparation stopped.
- **MESSAGE_ID_PROCESS_EXECUTION_STARTED** (int) : Message ID: external process execution started.
- **MESSAGE_ID_PROCESS_EXECUTION_STOPPED** (int) : Message ID: external process execution stopped.
- **MESSAGE_ID_SQL_EXECUTION_STARTED** (int) : Message ID: SQL execution started.
- **MESSAGE_ID_SQL_EXECUTION_STOPPED** (int) : Message ID: SQL execution stopped.
- **SEVERITY_ERROR** (int) : Severity level: error.
- **SEVERITY_INFORMATION** (int) : Severity level: information.
- **SEVERITY_WARNING** (int) : Severity level: warning.
- **TYPE_DIAGNOSTIC** (int) : Event type: diagnostic message.
- **TYPE_PROGRESS** (int) : Event type: percentage progress.
- **TYPE_RECORD_COUNT** (int) : Event type: record count.

createExecutionFeedbackEvent(handle, type, severity, message) : ExecutionFeedbackEvent

handle (**ExecutionHandle**) : the **ExecutionHandle** which originated the event

type (int) : the type of event

severity (int) : the severity level of the event

message (string) : the message associated with the event

Creates a new execution feedback event. **get messageId()** returns **MESSAGE_ID_OTHER**.

createExecutionFeedbackEvent(handle, type, severity, messageId, message) : ExecutionFeedbackEvent

handle (**ExecutionHandle**) : the **ExecutionHandle** which originated the event

type (int) : the type of event

severity (int) : the severity level of the event

messageId (int) : the message ID associated with the event

message (string) : the message associated with the event

Creates a new execution feedback event. If the value of **messageId** is not recognised, **get messageId()** returns **MESSAGE_ID_OTHER**.

e.getExecutionHandle() : ExecutionHandle

Returns the **ExecutionHandle** that raised the event. This is the source of the event cast to type **ExecutionHandle**.

e.getMessage() : string

Returns the message associated with this event.

For an event of type **TYPE_DIAGNOSTIC** the result is the diagnostic message localized for the session.

For an event of type **TYPE_RECORD_COUNT** the result consists of two decimal integers separated by a space, representing, respectively, the number of records read and written. For example:

```
"15000 0"
```

(15000 records read, none written).

For an event of type **TYPE_PROGRESS** the result consists of a single floating point number in the range

```
0.0 <= n <= 100.0
```

representing (an estimate of) the percentage of work completed. For example:

```
"26.3"
```

(26.3% completed).

```
e.getMessageId() : int
```

Returns the message ID associated with this event. This is one of the **MESSAGE_ID** constants.

```
e.getSeverity() : int
```

Returns the severity level of this event. The result is one of the **SEVERITY** constants declared above. The severity levels **SEVERITY_WARNING** and **SEVERITY_ERROR** are associated with the event type **TYPE_DIAGNOSTIC** and indicate a warning or error condition on the server. An error event ultimately causes execution to fail.

```
e.getType() : int
```

Returns the type of feedback represented by this event. The result is one of the **TYPE** constants declared above.

Related information

- [Tasks and execution](#)
-

ExecutionFeedbackListener Objects

Subclass of **EventListener**.

Listener for **ExecutionFeedbackEvent**.

```
e.executionFeedback(event)
event (ExecutionFeedbackEvent) :
```

Called when execution feedback is produced.

Related information

- [Tasks and execution](#)
-

ExecutionHandle Objects

Monitors and controls execution of a **Task** by a **Session**. A new handle is created for each execution.

```
e.getErrorMessag() : string
```

Returns an error message if execution terminated with an error and a message is available; returns **None** otherwise.

```
e.getExecutionState() : ExecutionState
```

Returns the latest **ExecutionState** of the associated task.

```
e.getExitCode() : int
```

Returns the exit code from executing the task. Typically this is either 0 to indicate success or 1 to indicate failure although some tasks may use different conventions. The result of querying the exit code before the task has finished executing is undefined.

```
e.getResult() : Object
```

Returns the result of the task if execution terminated with success and the task produced a result. Returns **None** if the task is still executing, or if it terminated in a state other than **SUCCESS**, or if it did not return a result.

```
e.getTask() : Task
```

Returns the **Task** being executed.

```
e.terminate() : ExecutionState
```

Terminates execution of the associated task and returns its final **ExecutionState**. The call blocks until the task has finished. The return value may not be **TERMINATED** if execution had completed before the termination request was sent.

```
e.terminate(milliseconds) : ExecutionState
```

```
milliseconds (long) : the maximum time to wait for the task to complete
```

Terminates execution of the associated task, waits until the task has finished or until the specified timeout has expired (whichever is sooner) and returns the execution state of the task. The result may not be **TERMINATED** if execution had completed before the termination request was sent or if execution had not completed before the timeout expired. A timeout of 0 or less means to wait forever.

```
e.waitForCompletion() : ExecutionState
```

Waits until the associated task has finished executing and returns its final **ExecutionState**.

```
e.waitForCompletion(milliseconds) : ExecutionState
```

```
milliseconds (long) : the maximum time to wait for completion
```

Waits until the associated task has finished executing, or until the specified timeout has expired (whichever is sooner) and returns the **ExecutionState** of the task. A timeout of 0 or less means to wait forever.

Related information

- [Tasks and execution](#)
-

ExecutionState Objects

Subclass of **Enum**.

This class enumerates the task execution states.

Constants:

- **ERROR (ExecutionState)** : The task has completed with an error.
- **EXECUTING (ExecutionState)** : The task is still executing.
- **SUBMITTED (ExecutionState)** : The task has been submitted for execution but not yet started.
- **SUCCESS (ExecutionState)** : The task has completed successfully.
- **TERMINATED (ExecutionState)** : The task has completed prematurely as the result of a terminate request.
- **TERMINATING (ExecutionState)** : A terminate request has been issued but the task has not yet completed.

```
getEnum(name) : ExecutionState
```

```
name (string) : the enumeration name
```

Returns the enumeration with the supplied name or **None** if no enumeration exists for the supplied name.

```
getValues() : ExecutionState[]
```

Returns an array containing all the valid values for this enumeration class.

```
e.isCompletedState() : boolean
```

Returns **True** if this state represents a task that is no longer executing. This true for **SUCCESS**, **TERMINATED** and **ERROR** states.

Related information

- [Tasks and execution](#)
-

ExecutionStateEvent Objects

Indicates a state change in a task. An event is fired when a task moves into a new state, and the new state is obtained from the event by calling `getExecutionState`.

```
createExecutionStateEvent(handle, state) : ExecutionStateEvent
```

`handle (ExecutionHandle)` : the `ExecutionHandle` for the event

`state (ExecutionState)` : the new execution state.

Creates a new execution state event.

```
e.getExecutionHandle() : ExecutionHandle
```

Returns the `ExecutionHandle` that raised the event.

```
e.getExecutionState() : ExecutionState
```

Returns the new execution state which caused this event to be raised. The return value is one of the constants defined by `ExecutionState`. Note: This may not correspond with the state that the task is now in since a subsequent state change may have occurred.

Related information

- [Tasks and execution](#)

ExecutionStateListener Objects

Subclass of `EventListener`.

Listener for `ExecutionStateEvent`.

```
e.executionStateChanged(event)
event (ExecutionStateEvent) :
```

Called when the execution state changes.

Related information

- [Tasks and execution](#)

Task Objects

A `Task` represents an operation that can be performed by the Modeler API.

```
t.getResult() : Object
```

Returns any object produced as a result of executing the task. This may be `None` if the task has not been executed yet, or there was an error during execution or if the task does not produce a result.

Related information

- [Tasks and execution](#)

TaskFactory Objects

The `TaskFactory` is used to create instances of `Task`. A task can be executed synchronously or asynchronously by the `Session`. Session-owned objects that are passed to `TaskFactory` methods must be executed by the session that owns them.

```
t.createDeleteFileTask(filePath) : Task
```

`filePath (string)` :- The path of file on server.

Create a task that delete the file using the specified file path.

```
t.createDownloadFileTask(path, outputStream) : Task
```

```

path (string) : the path of the remote file on server
outputStream (OutputStream) : the output stream

Creates a task that copies the content of a file on server to the specified output stream. The task will fail if the file cannot be read.

t.createDropTableTask(conn, tableName) : Task

conn (ServerDatabaseConnection) : - The ServerDatabaseConnection used for connect to the database.

tableName (string) : - The name of the table which you want to delete.

Create a task that drop the table using the specified table name.

t.createExportDocumentTask(document, outputStream, fileFormat) : Task

document (DocumentOutput) : the DocumentOutput object

outputStream (OutputStream) : the output stream

fileFormat (FileFormat) : the FileFormat to be used

Creates a task that exports a DocumentOutput object to an output stream using the specified FileFormat name. Calling getResult() on the completed task returns None.

Exceptions:

OwnerException : if the output is not owned by the same session that owns the task factory

ExportFormatException : if the document does not support the export format

t.createExportModelTask(model, outputStream, fileFormat) : Task

model (ModelOutput) : the ModelOutput object

outputStream (OutputStream) : the output stream

fileFormat (FileFormat) : the FileFormat to be used

Creates a task that exports a ModelOutput object to an output stream using the specified FileFormat name. Calling getResult() on the completed task returns None.

Exceptions:

OwnerException : if the output is not owned by the same session that owns the task factory

ExportFormatException : if the model does not support the export format

t.createExportModelTask(modelApplier, outputStream, fileFormat) : Task

modelApplier (Node) : the Node object

outputStream (OutputStream) : the output stream

fileFormat (FileFormat) : the FileFormat to be used

Creates a task that exports a Node to an output stream using the specified FileFormat name. Calling getResult() on the completed task returns None.

Exceptions:

OwnerException : if the output is not owned by the same session that owns the task factory

ExportFormatException : if the model does not support the export format

t.createExportStreamTask(stream, outputStream, fileFormat) : Task

stream (Stream) : the stream to be exported

outputStream (OutputStream) : the output stream

fileFormat (FileFormat) : the export file format

Creates a task that export a stream description to an output stream using specified file format.

Exceptions:

OwnerException : if the node is not owned by the same session that owns the task factory

```

ExportFormatException : if the stream does not support the export format

```
t.createImportPMMLModelTask(inputStream) : Task
```

inputStream (`InputStream`) : the input stream

Creates a task that imports a `ModelOutput` object from an input stream. Calling `getResultSet()` on the completed task returns an instance of `ModelOutput`.

```
t.createOpenDocumentTask(inputStream) : Task
```

inputStream (`InputStream`) : the input stream

Creates a task that reads a `DocumentOutput` object from an input stream. Calling `getResultSet()` on the completed task returns an instance of `DocumentOutput`. The document is not added to the output manager.

```
t.createOpenDocumentTask(inputStream, autoManage) : Task
```

inputStream (`InputStream`) : the input stream

autoManage (`boolean`) : whether the document should be added to the output manager

Creates a task that reads a `DocumentOutput` object from an input stream. Calling `getResultSet()` on the completed task returns an instance of `DocumentOutput`. Code that needs to open documents privately without having them made visible to the user should set the `autoManage` flag to `False`.

```
t.createOpenModelTask(inputStream) : Task
```

inputStream (`InputStream`) : the input stream

Creates a task that reads a `ModelOutput` object from an input stream. Calling `getResultSet()` on the completed task returns an instance of `ModelOutput`. The model is not added to the model manager.

```
t.createOpenModelTask(inputStream, autoManage) : Task
```

inputStream (`InputStream`) : the input stream

autoManage (`boolean`) : whether the model should be added to the model manager

Creates a task that reads a `ModelOutput` object from an input stream. Calling `getResultSet()` on the completed task returns an instance of `ModelOutput`. Code that needs to open models privately without having them made visible to the user should set the `autoManage` flag to `False`.

```
t.createOpenProcessorTask(inputStream, stream) : Task
```

inputStream (`InputStream`) : the input stream

stream (`Stream`) : the `Stream`

Creates a task that reads a `Node` object from an input stream and inserts it into the supplied `Stream`. Calling `getResultSet()` on the completed task returns an instance of `Node`.

Exceptions:

OwnerException : if the stream is not owned by the same session that owns the task factory

```
t.createOpenStreamTask(inputStream) : Task
```

inputStream (`InputStream`) : the input stream

Creates a task that reads a `Stream` object from an input stream. Calling `getResultSet()` on the completed task returns an instance of `Stream`.

```
t.createOpenStreamTask(inputStream, autoManage) : Task
```

inputStream (`InputStream`) : the input stream

autoManage (`boolean`) : whether the opened stream should be added to the stream manager

Creates a task that reads a `Stream` object from an input stream. Calling `getResultSet()` on the completed task returns an instance of `Stream`. Code that needs to open streams privately without having them made visible to the user should set the `autoManage` flag to `False`.

```
t.createSaveDocumentTask(document, outputStream) : Task
```

document (`DocumentOutput`) : the `DocumentOutput` object

outputStream (`OutputStream`) : the output stream

Creates a task that saves a `DocumentOutput` object to an output stream. Calling `getResultSet()` on the completed task returns `None`.

Exceptions:

OwnerException : if the document output is not owned by the same session that owns the task factory

t.createSaveModelTask(model, outputStream) : Task

model (ModelOutput) : the **ModelOutput** object

outputStream (OutputStream) : the output stream

Creates a task that saves a **ModelOutput** object to an output stream. Calling **getResult()** on the completed task returns **None**.

Exceptions:

OwnerException : if the model output is not owned by the same session that owns the task factory

t.createSaveProcessorTask(node, outputStream) : Task

node (Node) : the **Node** object

outputStream (OutputStream) : the output stream

Creates a task that saves a **Node** object to an output stream. Calling **getResult()** on the completed task returns **None**.

Exceptions:

OwnerException : if the node is not owned by the same session that owns the task factory

t.createSaveStreamTask(stream, outputStream) : Task

stream (Stream) : the **Stream** object

outputStream (OutputStream) : the output stream

Creates a task that saves a **Stream** object to an output stream. Calling **getResult()** on the completed task returns **None**.

Exceptions:

OwnerException : if the stream is not owned by the same session that owns the task factory

t.createUpdatePMMLModelTask(modelOutput, inputStream) : Task
modelOutput (ModelOutput) :
inputStream (InputStream) :

Creates a task that updates the **ModelOutput** object with PMML read from an input stream. The task will fail if the **ModelOutput** is not based on a PMML model or the **ModelOutput** and the PMML algorithms are not the same.

Exceptions:

OwnerException : if the model output is not owned by the same session that owns the task factory

t.createUploadFileTask(path, inputStream) : Task

path (string) : the path of the remote file on server

inputStream (InputStream) : the input stream

Creates a task that copies the content of the specified input stream to a file on server, replacing any existing file content. The task will fail if the file cannot be written.

Related information

- [Tasks and execution](#)
-

TaskRunner Objects

The **TaskRunner** provides a convenient way of creating and running tasks synchronously.

t.createStream(name, autoConnect, autoManage) : Stream

name (string) : the object's name

autoConnect (boolean) : whether the stream should be auto-connected to the server

`autoManage (boolean)` : whether the stream should be added to the stream manager

Creates and returns a new `Stream`. Note that code that needs to create streams privately without having them made visible to the user should set the `autoManage` flag to `False`.

Exceptions:

`ServerConnectionException` : if the Session is already connected and the auto-connect flag is `True` but a new connection could not be created for the stream

t.exportDocumentToFile(documentOutput, filename, fileFormat)

`documentOutput (DocumentOutput)` : the document to be exported

`filename (string)` : the exported file path

`fileFormat (FileFormat)` : the export file format

Exports the stream description to a file using the specified file format.

Exceptions:

`OwnerException` : if the document is not owned by the task runner session

`SessionException` : if the document cannot be exported for some reason

`ExportFormatException` : if the document does not support the export format

t.exportModelSummaryToFile(modelOutput, filename, fileFormat)

`modelOutput (ModelOutput)` : the model to be exported

`filename (string)` : the exported file path

`fileFormat (FileFormat)` : the export file format which is either `FileFormat.PLAIN_TEXT` or `FileFormat.HTML`.

Exports the model summary to a file using the specified file format. Model summaries can only be exported as text or HTML.

Exceptions:

`OwnerException` : if the model is not owned by the task runner session

`SessionException` : if the model cannot be exported for some reason

`ExportFormatException` : if the model does not support the export format

t.exportModelSummaryToFile(node, filename, fileFormat)

`modelOutput (Node)` : the model applier node to be exported

`filename (string)` : the exported file path

`fileFormat (FileFormat)` : the export file format which is either `FileFormat.PLAIN_TEXT` or `FileFormat.HTML`.

Exports the model summary in the supplied node to a file using the specified file format. Model summaries can only be exported as text or HTML.

Exceptions:

`OwnerException` : if the model is not owned by the task runner session

`SessionException` : if the model cannot be exported for some reason

`ExportFormatException` : if the model does not support the export format

t.exportModelToFile(modelOutput, filename, fileFormat)

`modelOutput (ModelOutput)` : the model to be exported

`filename (string)` : the exported file path

`fileFormat (FileFormat)` : the export file format

Exports the model to a file using the specified file format.

Exceptions:

`OwnerException` : if the model is not owned by the task runner session

`SessionException` : if the model cannot be exported for some reason

`ExportFormatException` : if the model does not support the export format

t.exportModelToFile(node, filename, fileFormat)

`modelOutput (Node)` : the model applier node to be exported

`filename (string)` : the exported file path

`fileFormat (FileFormat)` : the export file format

Exports the model in the supplied node to a file using the specified file format.

Exceptions:

`OwnerException` : if the model is not owned by the task runner session

`SessionException` : if the model cannot be exported for some reason

`ExportFormatException` : if the model does not support the export format

t.exportOutputToFile(object, filename, fileFormat, options)

`object (PropertiedObject)` : the object with the output content

`filename (string)` : the file name where the output should be exported to

`fileFormat (FileFormat)` : the file format

`options (Map)` : either None or a hash table of attribute values

Exports the output content from the supplied object to the specified file and format. The following document formats are supported:

- `FileFormat.PLAIN_TEXT`
- `FileFormat.HTML`
- `FileFormat.RTF`
- `FileFormat.SPV`
- `FileFormat.SPW`
- `FileFormat.SPSS_WEB_REPORT`
- `FileFormat.COGNOS_ACTIVE_REPORT`
- `FileFormat.PDF`
- `FileFormat.MS_EXCEL`
- `FileFormat.MS_EXCEL2007`
- `FileFormat.MS_EXCEL2007_M`
- `FileFormat.MS_POWERPOINT`

The following image formats are supported:

- `FileFormat.BITMAP`
- `FileFormat.PNG`
- `FileFormat.JPEG`
- `FileFormat.TIFF`

If `options` are supplied, the value is a table of attribute/value pairs. For document exports, the options are:

- `alternate_log_file_location` (string): the location of the log file if this is to be expored separately
- `custom_report_title` (string): a custom title for a web report

- `excel_location_option` ("AddColumns", "AddRows", "OverwriteAtCellRef"): where the content should be exported to in Excel
- `excel_operation_option` ("CreateWorkbook", "CreateWorksheet", "ModifyWorksheet"): how the content should be exported to Excel
- `excel_sheetname` (string): the Excel sheet name
- `excel_starting_cell_ref` (string): the Excel starting cell references
- `export_html_headers` (Boolean): whether to export HTML headers
- `export_image_maps` (Boolean): whether to create image maps
- `export_images` (Boolean): whether images should be exported separately for formats that don't support images
- `html_with_style` (Boolean): whether style information should be saved
- `include_footnotes_and_captions` (Boolean): whether footnotes and captions should be included
- `interactive_layer` (Boolean): whether an interactive layer should be included in formats that support them
- `is_logs_excluded` (Boolean): whether exclude logs
- `is_notes_excluded` (Boolean): whether to exclude notes
- `is_text_excluded` (Boolean): whether to exclude text content
- `javascript_file_name` (string): for interactive output, the location of the JavaScript file if separate
- `model_view_option` ("MVExportAll", "MVExportVisible", "MVPrintSetting"): which model views should be exported
- `page_break_between_table` (Boolean): whether to create a page break between tables
- `page_setup` (Map): the page setup settings (see below)
- `pdf_embed_bookmarks` (Boolean): whether to embed bookmarks in PDF document
- `pdf_embed_fonts` (Boolean): whether to embed fonts in the PDF document
- `pivot_table_option` ("PTEExportAllLayers", "PTEExportVisibleLayers", "PTUsePrintLayerSetting"): how pivot tables should be handled
- `ppt_use_viewer_outlines` (Boolean): whether to use viewer outlines in the PowerPoint
- `preserve_break_points` (Boolean): whether to preserve break points
- `table_style` (string): the name of the table style
- `text_encoding` ("utf8", "utf16"): what text encoding to use in text files
- `text_doc_option` ("TxtUseSpaces", "TxtUseTabs"): whether to uses spaces or tabs in text files
- `text_width_autofit` (Boolean): whether to make table columns fit the content in text files
- `txt_column_width` (integer): if table columns are not fitted to their content in text files, defines the column width
- `col_txt_border_character` (character): the table column character when exporting to a text file
- `row_txt_border_character` (character): the table column character when exporting to a text file
- `viewer_doc_name` (string): the name of the document which should be displayed in the viewer
- `wide_tables_option` ("WT_Extend", "WT_Shrink", "WT_Wrap"): defines how wide tables should be handled

For graph exports, the options are:

- `bmp_compress_image` (Boolean): whether to compress bitmap images
- `graph_image_size` (integer): how much to scale the exported image as a percentage of the original
- `graph_invert_colors` (Boolean): whether to invert the colors
- `graph_type` ("BMP", "JPG", "PNG", "TIF"): defines the graph type to be used when exporting images separately from the non-image content
- `model_view_option` ("MVExportAll", "MVExportVisible", "MVPrintSetting"): which model views should be exported
- `png_color_depth` ("BlackWhite", "Grays", "SixteenColors", "TrueColor24", "TrueColor36", "TwoFiftySixColors"): the color depth when exporting to PNG
- `tiff_color_space` ("CMYK", "RGB"): the color space when exporting to TIF
- `tiff_compress_image` (Boolean): whether to compress TIF images

For the `page_setup`, the options are:

- `height` (Double): the page height
- `width` (Double): the page width
- `bottom_margin` (Double): the bottom margin
- `left_margin` (Double): the left margin
- `right_margin` (Double): the right margin
- `top_margin` (Double): the top margin
- `orientation` (Integer): 0 for portrait, 1 for landscape
- `units` ("Centimeters", "Millimeters", "Inches", "PrintPoints"): the units that the margin and dimension values represent

Exceptions:

`OwnerException` : if the object is not owned by the current session

`ExportFormatException` : if the export format is not supported

`SessionException` : if some other error occurs

t.exportStreamToFile(stream, filename, fileFormat)

`stream` (`Stream`) : the stream to be exported

`filename` (string) : the exported file path

fileFormat (FileFormat) : the export file format

Exports the stream description to a file using the specified file format.

Exceptions:

OwnerException : if the stream is not owned by the task runner session

SessionException : if the stream cannot be exported for some reason

ExportFormatException : if the stream does not support the export format

t.insertNodeFromFile(filename, diagram) : Node

filename (string) : the file path

diagram (Diagram) : the diagram that the node should be inserted into

Reads and returns a node from the specified file, inserting it into the supplied diagram. Note that this can be used to read both **Node** and **SuperNode** objects.

Exceptions:

OwnerException : if the diagram is not owned by the task runner session

SessionException : if the node cannot be loaded for some reason

ObjectLockedException : if the stream that the node is being added to is locked

t.openDocumentFromFile(filename, autoManage) : DocumentOutput

filename (string) : the document file path

autoManage (boolean) : whether the document should be added to the output manager

Reads and returns a document from the specified file.

Exceptions:

SessionException : if the document cannot be loaded for some reason

t.openModelFromFile(filename, autoManage) : ModelOutput

filename (string) : the model file path

autoManage (boolean) : whether the model should be added to the model manager

Reads and returns a model from the specified file.

Exceptions:

SessionException : if the model cannot be loaded for some reason

t.openStreamFromFile(filename, autoManage) : Stream

filename (string) : the stream file path

autoManage (boolean) : whether the stream should be added to the stream manager

Reads and returns a stream from the specified file.

Exceptions:

SessionException : if the stream cannot be loaded for some reason

t.saveDocumentToFile(documentOutput, filename)

documentOutput (DocumentOutput) : the document to be saved

filename (string) : the document file path

Saves the document to the specified file location.

Exceptions:

OwnerException : if the document is not owned by the task runner session

SessionException : if the document cannot be saved for some reason

t.saveModelToFile(modelOutput, filename)

modelOutput (ModelOutput) : the model to be saved

filename (string) : the model file path

Saves the model to the specified file location.

Exceptions:

OwnerException : if the model is not owned by the task runner session

SessionException : if the model cannot be saved for some reason

t.saveNodeToFile(node, filename)

node (Node) : the node to be saved

filename (string) : the node file path

Saves the model to the specified file location.

Exceptions:

OwnerException : if the node is not owned by the task runner session

SessionException : if the node cannot be saved for some reason

t.saveStreamToFile(stream, filename)

stream (Stream) : the stream to be saved

filename (string) : the stream file path

Saves the stream to the specified file location.

Exceptions:

OwnerException : if the stream is not owned by the task runner session

SessionException : if the stream cannot be saved for some reason

Streams and SuperNodes

BuiltObject Objects

Subclass of **PropertiedObject**.

This encapsulates the concrete results of executing **objectBuilder** nodes.

b.close()

Closes this built object and releases its external resources. Closing an object which is already closed has no effect, otherwise the behaviour of a method applied to a closed object is undefined except where stated.

b.getBuilderProcessorID() : string

Returns the ID of the object builder node that built this object. The empty string is returned if this information is not available.

b.getBuilderStreamID() : string

Returns the temporary session ID of the stream containing the object builder node that built this object. If the stream is closed and subsequently re-opened, the re-opened stream's ID will be different from the value returned here.

The empty string is returned if this information is not available.

b.getID() : string

Returns the temporary session ID of this object. A new ID is allocated each time a new built object is created or opened and the ID is not persisted. This means that if the same object is re-opened multiple times, each object will include a different ID.

b.isClosed() : boolean

Returns **True** if this object has been closed.

b.isExportable(fileFormat) : boolean

fileFormat (FileFormat) : the FileFormat

Returns **True** if this object can be exported using the supplied **FileFormat** or **False** otherwise.

Related information

- [Streams and SuperNodes](#)

CFNode Objects

Subclass of **Node**.

This identifies **Node** objects that are implemented via the Component Framework.

c.getFeature() : Object

Return the underlying CF feature of the CF node.

Related information

- [Streams and SuperNodes](#)

CompositeModelApplier Objects

Subclass of **ModelApplier**, **CompositeModelOwner**.

This encapsulates the auto-model applier nodes **ModelApplier** that can ensemble the scores from multiple models into a single score.

Related information

- [Streams and SuperNodes](#)

CompositeModelBuilder Objects

Subclass of `ModelBuilder`.

This encapsulates the auto-model builder nodes `ModelBuilder` that can build and evaluate multiple models using different modeling algorithms and settings.

```
c.getAllModelAlgorithms() : List
```

Returns the model builder node ids that are available in this `CompositeModelBuilder`.

```
c.isAlgorithmEnabled(modelBuilderId) : boolean
```

```
modelBuilderId (string) : build model id
```

Returns whether the supplied algorithm is enabled. If the supplied algorithm ID is not one of the algorithms available for this model builder, the method returns `False`. An algorithm may be enabled in the model builder, but invalid due to other settings (see `isAlgorithmInvalid(String)`).

```
c.isAlgorithmInvalid(algorithmID) : boolean
```

```
algorithmID (string) :
```

Returns whether the supplied algorithm is invalid. An algorithm may be enabled (see `isAlgorithmEnabled(String)`) in this model builder, but be invalid due to other settings. For instance, the target measure may not be valid for the algorithm. If the algorithm is invalidated in this way it will not be built, even if it is enabled.

```
c.setAlgorithmEnabled(modelBuilderId, value)
```

```
modelBuilderId (string) : build model id
```

```
value (boolean) : the enabled value
```

Sets whether the supplied algorithm is enabled. If the supplied algorithm ID is not one of the algorithms available for this model builder, the method call will have no effect.

Related information

- [Streams and SuperNodes](#)

CompositeModelOutput Objects

Subclass of `ModelOutput`, `CompositeModelOwner`.

This encapsulates the concrete results of executing `ModelBuilder` nodes or by opening or importing Composite models. This will be the results of the auto models.

```
c.getModelDetail() : CompositeModelDetail
```

Returns the underlying composite model representation.

Related information

- [Streams and SuperNodes](#)

CompositeModelOwner Objects

This encapsulates objects that own auto-built models. These models can be ensembled and the scores from multiple models combined into a single score.

```
c.getCompositeModelDetail() : CompositeModelDetail
```

Returns the underlying composite model representation.

```
c.getModelResult(resultId) : CompositeModelResult
```

```
resultId (string) :
```

Returns the model results for the specified ID or `None` if no such model result exists.

```
c.getModelResultIDs() : List
```

Returns the list of model result IDs. The result ID is the same as the name of the individual composite model result.

```
c.isModelResultUsed(resultId) : boolean  
resultId (string) :
```

Returns whether the specified model result ID is enabled/active.

```
c.removeModelResults(resultIds)
```

```
resultIds (List) : the list of result IDs to be removed
```

Permanently removes the supplied model results from this composite model object owner.

```
c.setModelResultUsed(resultId, value)
```

```
resultId (string) : the result ID
```

```
value (boolean) : True if the model should be enabled, False if not
```

Sets whether the specified model result ID is active. Note that supplying model results that have previously been removed will have no effect i.e. they will not be re-added into the composite model object owner.

Related information

- [Streams and SuperNodes](#)
-

CompositeModelResults Objects

This encapsulates the concrete results for the individual models forming the Composite Model.

```
c.getModelMeasureLabel(measure) : string
```

```
measure (string) : the evaluation measure name
```

Returns a descriptive label for the specified evaluation measure or `None` if the measure is not valid for this result.

```
c.getModelMeasurePartitionCount() : int
```

Returns the number of partitions for which evaluation measures exist. Partitions (where they exist) are numbered: 0=Training, 1=Testing, 2=Validation.

```
c.getModelMeasureType(measure) : StorageType
```

```
measure (string) : the evaluation measure name
```

Returns the data type of the specified evaluation measure or `None` if the measure is not valid for this result.

```
c.getModelMeasureValue(measure, partition) : Object
```

```
measure (string) : the evaluation measure name
```

```
partition (int) : the partition index
```

Returns the value of the specified evaluation measure in the specified partition, or `None` if either the measure or the partition is not valid for this result.

```
c.getModelMeasures() : List
```

Returns the list of measures used to evaluate this model result.

```
c.getModelName() : string
```

Returns the name of this model result. The model name is expected to be unique within a set of composite model result objects.

```
c.getModelOutput() : ModelOutput
```

Returns the model output of the composite model result.

```
c.isUsed() : boolean
```

Returns `True` if this composite model result is used.

Related information

-

SuperNode Objects

Subclass of **Node**, **ParameterProvider**.

This encapsulates the functionality of any SuperNode whose behaviour is determined by its constituent nodes.

s.getChildDiagram() : SuperNodeDiagram

Returns the diagram containing the nodes encapsulated by this SuperNode.

s.getCompositeProcessorType() : SuperNodeType

Returns the type of this SuperNode.

s.isPasswordNeeded() : boolean

If the SuperNode is not locked or a password has been entered then return **False**, otherwise return **True**.

s.setCompositeProcessorType(type)

type (SuperNodeType) : the SuperNode type

Sets the type of this SuperNode.

Exceptions:

ObjectLockedException : if the diagram is currently locked

s.verifyPassword(password) : boolean

password (string) : the password to be tested

Check whether the supplied password is valid or not.

Related information

- [Streams and SuperNodes](#)
-

SuperNodeDiagram Objects

Subclass of **Diagram**.

This is the diagram used by **SuperNode** objects to store nodes. It allows connections between the two pseudo nodes, (the input connector and output connector) and other nodes in the diagram to be edited.

s.disconnectInputConnector()

Removes any direct links between the diagram's input connector and other nodes in the diagram. If the SuperNode is an initial node and therefore doesn't have an input connector, this method does nothing.

Exceptions:

ObjectLockedException : if the diagram is currently locked

s.disconnectOutputConnector()

Removes any direct links between the diagram's output connector and other nodes in the diagram. If the SuperNode is an terminal node and therefore doesn't have an input connector, this method does nothing.

Exceptions:

ObjectLockedException : if the diagram is currently locked

s.getInputConnector() : Node

Returns the input connector from this diagram, or **None** if the diagram belongs to an initial node and has no input connector.

```
s.getOutputConnector() : Node
```

Returns the output connector from this diagram, or **None** if the diagram belongs to a terminal node and has no output connector.

```
s.linkFromInputConnector(node)
node (Node) :
```

Creates a link from the input connector to the supplied node.

Exceptions:

OwnerException : if any objects in the path are not owned by this diagram

ObjectLockedException : if the diagram is currently locked

InvalidEditException : if the connection would be invalid

```
s.linkToOutputConnector(node)
node (Node) :
```

Creates a link from the supplied node to the output connector.

Exceptions:

OwnerException : if any objects in the path are not owned by this diagram

ObjectLockedException : if the diagram is currently locked

InvalidEditException : if the connection would be invalid

```
s.runAll(results) : ExecutionHandle
```

results (Collection) : an empty collection that will contain any built objects once execution has completed

Executes the executable nodes within this sub-stream synchronously and waits for it to complete. Returns an **ExecutionHandle** which can be used to access the exit status and any result from the task.

Note that this should only be called on a terminal **SuperNode**.

Exceptions:

OwnerException : if the stream was not created by this session

ObjectLockedException : if the stream is locked

ServerConnectionException : if the stream is not connected to a server

SessionException : if the session is already running another task, cannot execute the task or if execution completes in a state other than **SUCCESS**

```
s.runSelected(nodes, results) : ExecutionHandle
```

nodes (Node[]) : the array of **Node** objects to be executed

results (Collection) : an empty collection that will contain any built objects once execution has completed

Executes the supplied array of nodes synchronously and waits for them to complete. There must be at least one node in the array. Returns an **ExecutionHandle** which can be used to access the exit status and any result from the task.

Note that this should only be called on a terminal **SuperNode**.

Exceptions:

OwnerException : if the nodes are not all owned by this stream

ObjectLockedException : if the stream is locked

ServerConnectionException : if the stream is not connected to a server

SessionException : if the session is already running a stream, another task, cannot execute the task or if execution completes in a state other than **SUCCESS**

IllegalArgumentException : if the array is empty

```
s.unlinkFromInputConnector(node)
node (Node) :
```

Removes any direct link from the input connector to the supplied node.

Exceptions:

`OwnerException` : if any objects in the path are not owned by this diagram

`ObjectLockedException` : if the diagram is currently locked

`InvalidEditException` : if the connection would be invalid

```
s.unlinkToOutputConnector(node)
node (Node) :
```

Removes any direct link from the supplied node to the output connector.

Exceptions:

`OwnerException` : if any objects in the path are not owned by this diagram

`ObjectLockedException` : if the diagram is currently locked

`InvalidEditException` : if the connection would be invalid

SuperNodeType Objects

Subclass of `Enum`.

This class enumerates the types of SuperNodes.

Constants:

- `INITIAL (SuperNodeType)` : Represents a `SuperNode` that begins a sequence of nodes.
- `PROCESS (SuperNodeType)` : Represents a `SuperNode` that allows data to flow through it.
- `TERMINAL (SuperNodeType)` : Represents a `SuperNode` that ends a sequence of nodes.

```
getEnum(name) : SuperNodeType
```

`name (string)` : the enumeration name

Returns the enumeration with the supplied name or `None` if no enumeration exists for the supplied name.

```
getValues() : SuperNodeType[]
```

Returns an array containing all the valid values for this enumeration class.

Related information

- [Streams and SuperNodes](#)
-

DataReader Objects

Subclass of `InitialNode`.

This encapsulates the functionality of a data node that reads records e.g. from a file or database table.

Related information

- [Streams and SuperNodes](#)
-

DataTransformer Objects

Subclass of **ProcessNode**.

This encapsulates the functionality of a standard inline data node.

Related information

- [Streams and SuperNodes](#)
-

DataWriter Objects

Subclass of **TerminalNode**.

This encapsulates the functionality of a node that writes records e.g. to a file or database table.

```
d.getExportDataModel() : DataModel
```

Returns the **DataModel** being exported by this node.

Related information

- [Streams and SuperNodes](#)
-

DiagramConnector Objects

Subclass of **ProcessNode**.

A node which provides a connection point between a **SuperNodeDiagram** and its containing diagram. A connector routes data between diagrams.

Related information

- [Streams and SuperNodes](#)
-

DocumentBuilder Objects

Subclass of **ObjectBuilder**.

This encapsulates the functionality of a node that builds a viewable output object such as a table, graph or report.

Related information

- [Streams and SuperNodes](#)
-

DocumentOutput Objects

Subclass of **BuiltObject**.

This encapsulates the concrete results of executing **DocumentBuilder** nodes that produce generic document-type outputs.

```
d.getDocumentOutputType() : DocumentOutputType
```

Returns the **DocumentOutputType** of this output. The returned value corresponds with one of the output-type constants defined by **DocumentOutputType**.

```
d.getTypeName() : string
```

Returns the name of this type of output object.

Related information

- [Streams and SuperNodes](#)

DocumentOutputType Objects

Subclass of **Enum**.

This class enumerates the types of document outputs that are generated by the different **NodeType** that are **DocumentBuilders** or which can be imported.

Constants:

- **ANALYSIS** (**DocumentOutputType**) :
- **COLLECTION** (**DocumentOutputType**) :
- **CUSTOM_TABLE** (**DocumentOutputType**) :
- **DATA_AUDIT** (**DocumentOutputType**) :
- **DISTRIBUTION** (**DocumentOutputType**) :
- **ENSEMBLE** (**DocumentOutputType**) :
- **EVALUATION** (**DocumentOutputType**) :
- **GRAPH_BOARD** (**DocumentOutputType**) :
- **HISTOGRAM** (**DocumentOutputType**) :
- **MATRIX** (**DocumentOutputType**) :
- **MEANS** (**DocumentOutputType**) :
- **MULTI_PLOT** (**DocumentOutputType**) :
- **QUALITY** (**DocumentOutputType**) :
- **REPORT** (**DocumentOutputType**) :
- **REPORT_DOCUMENT** (**DocumentOutputType**) :
- **SCATTER_PLOT** (**DocumentOutputType**) :
- **SPSS_PROCEDURE** (**DocumentOutputType**) :
- **STATISTICS** (**DocumentOutputType**) :
- **TABLE** (**DocumentOutputType**) :
- **TIME_PLOT** (**DocumentOutputType**) :
- **TRANSFORM** (**DocumentOutputType**) :
- **UNKNOWN** (**DocumentOutputType**) : Represents a document output object whose type cannot be determined.
- **WEB** (**DocumentOutputType**) :

addDocumentOutputType(identifier) : DocumentOutputType
identifier (string) :

Adds a the type with the supplied name. Returns the new type or **None** if a type with the supplied name already exists. This method is for system use only and is only public as an implementation detail.

getEnum(name) : DocumentOutputType

name (string) : the enumeration name

Returns the enumeration with the supplied name or **None** if no enumeration exists for the supplied name.

getValues() : DocumentOutputType[]

Returns an array containing all the valid values for this enumeration class.

d.isUnknown() : boolean

Returns **True** if this value is **UNKNOWN**.

removeDocumentOutputType(identifier)

identifier (string) : the type to be removed

Removes the specified type. The type should have been created with **addDocumentOutputType()**. This method is for system use only and is only public as an implementation detail.

Related information

- [Streams and SuperNodes](#)

ExportFormatException Objects

Subclass of **ModelerException**.

Indicates that an attempt was made to export a built object using an unsupported file format.

No message string is set for this exception.

```
e.getFileFormat() : FileFormat
```

Returns the unsupported export format.

```
e.getObject() : BuiltObject
```

Returns the built object.

Related information

- [Streams and SuperNodes](#)

GraphBuilder Objects

Subclass of **DocumentBuilder**.

This encapsulates the functionality of a node that builds a graph output.

```
g.getGraphOutput() : GraphOutput
```

Returns the most recent **GraphOutput** produced by this node, or None if this **GraphBuilder** has either not been executed before or failed to produce an object during the most recent execution.

Related information

- [Streams and SuperNodes](#)

GraphOutput Objects

Subclass of **DocumentOutput**.

This encapsulates the concrete results of executing **DocumentBuilder** nodes that produce objects that are based on graphs.

Related information

- [Streams and SuperNodes](#)

InitialNode Objects

Subclass of **Node**.

This encapsulates the functionality of any node that begins a sequence of nodes. These typically import data from a data source such as a database or file.

Related information

- [Streams and SuperNodes](#)

ProcessNode Objects

Subclass of **Node**.

This encapsulates the functionality of any node that allows data to flow through it i.e., a **Node** that is neither a **InitialNode** nor a **TerminalNode**.

Related information

- [Streams and SuperNodes](#)
-

InvalidEditException Objects

Subclass of **ModelerException**.

An exception thrown when an invalid attempt is made to edit the links between two or more nodes.

No message string is set for this exception.

`i.getProcessorDiagram() : Diagram`

Returns the **Diagram** that generated the exception.

`i.getProcessorStream() : Stream`

Returns the **Stream** that generated the exception.

Related information

- [Streams and SuperNodes](#)
-

ModelApplier Objects

Subclass of **ProcessNode**.

This encapsulates the functionality of an inline node that applies models.

`m.getBuilderProcessorID() : string`

Returns the ID of the model builder node that built the underlying model. The empty string is returned if this information is not available.

`m.getBuilderStreamID() : string`

Returns the ID of the stream of the model builder node that built the underlying model. The empty string is returned if this information is not available.

`m.getLocalizedName() : string`

Returns the localized algorithm name.

`m.getModelDetail() : ModelDetail`

Returns the underlying model representation.

Related information

- [Streams and SuperNodes](#)
-

ModelBuilder Objects

Subclass of **ObjectBuilder**.

This encapsulates the functionality of a node that builds a model output object.

```
m.getModelOutputType() : ModelOutputType
```

Returns the type of `ModelOutput` that is produced by this type of model builder. The returned value corresponds to one of the model-type constants defined by `ModelOutputType`.

Related information

- [Streams and SuperNodes](#)

ModelOutput Objects

Subclass of `BuiltObject`.

This encapsulates the concrete results of executing `ModelBuilder` nodes or by opening or importing models.

```
m.getLocalizedAlgorithmName() : string
```

Returns the localized algorithm name.

```
m.getModelApplierID() : string
```

Returns the ID of `ModelApplier` that corresponds with this model output or `None` if this model output cannot be applied directly to data.

```
m.getModelDetail() : ModelDetail
```

Returns the underlying model representation.

```
m.getModelOutputType() : ModelOutputType
```

Returns the `ModelOutputType` of this model output. The returned value corresponds with one of the model-type constants defined by `ModelOutputType`.

```
m.getTypeName() : string
```

Returns the name of this type of output object.

Related information

- [Streams and SuperNodes](#)

ModelOutputType Objects

Subclass of `Enum`.

This class enumerates the types of model outputs that are generated by the different `NodeType` that are `ModelBuilders` or which can be imported.

Constants:

- `ANOMALY_DETECTION` (`ModelOutputType`) :
- `APRIORI` (`ModelOutputType`) :
- `ASSOCIATION` (`ModelOutputType`) :
- `AUTO_CLUSTER` (`ModelOutputType`) :
- `BACK_PROPAGATION` (`ModelOutputType`) :
- `BINARY_CLASSIFIER` (`ModelOutputType`) :

- ORACLE_KMEANS (ModelOutputType) :
- ORACLE_NAIVE_BAYES (ModelOutputType) :
- ORACLE_NMF (ModelOutputType) :
- ORACLE_OCLUSTER (ModelOutputType) :
- ORACLE_SVM (ModelOutputType) :
- QUEST (ModelOutputType) :
- QUEST_SPLIT (ModelOutputType) :
- RULE (ModelOutputType) :
- SEQUENCE (ModelOutputType) :
- SPSS_MODEL (ModelOutputType) :
- TEXT_EXTRACTION (ModelOutputType) :
- TIME_SERIES (ModelOutputType) :
- TWOSTEP (ModelOutputType) :
- UNKNOWN (ModelOutputType) : Represents a model output object whose type cannot be determined.

addModelOutputType(identifier) : ModelOutputType

`identifier (string) :`

Adds a type with the supplied name. Returns the new type or `None` if a type with the supplied name already exists. This method is for system use only and is only public as an implementation detail.

getEnum(name) : ModelOutputType

`name (string) : the enumeration name`

Returns the enumeration with the supplied name or `None` if no enumeration exists for the supplied name.

getValues() : ModelOutputType[]

Returns an array containing all the valid values for this enumeration class.

m.isUnknown() : boolean

Returns `True` if this value is `UNKNOWN`.

removeModelOutputType(identifier)

`identifier (string) : the type to be removed.`

Removes the specified type. The type should have been created with `addModelOutputType()`. This method is for system use only and is only public as an implementation detail.

Related information

- [Streams and SuperNodes](#)

ObjectBuilder Objects

Subclass of `TerminalNode`.

This encapsulates the functionality of a node that builds an output object such as a model or graph.

`o.getBuiltObject() : BuiltObject`

Returns the most recent `BuiltObject` produced by this node, or `None` if this `ObjectBuilder` has either not been executed before or failed to produce an object during the most recent execution.

Related information

- [Streams and SuperNodes](#)

Node Objects

Subclass of `PropertiedObject`, `ContentContainerProvider`.

This is the base interface for all nodes.

`n.flushCache()`

Flushes the cache of this object. Has no effect if the cache is not enabled or is not full.

`n.getID() : string`

Returns the ID of this object. A new ID is created each time a new node is created. The ID is persisted with the node when it is saved as part of a stream so that when the stream is opened, the node IDs are preserved. However, if a saved node is inserted into a stream, the insert node is considered to be a new object and will be allocated a new ID.

`n.getInputDataModel() : DataModel`

Returns the `DataModel` coming into this node.

`n.getOutputDataModel() : DataModel`

Returns the `DataModel` output by this node.

`n.getProcessorDiagram() : Diagram`

Returns the `Diagram` that owns this node.

`n.getProcessorStream() : Stream`

Returns the `Stream` that owns this node.

`n.getTypeName() : string`

Returns the name of this type of node.

`n.getXPosition() : int`

Returns the x position offset of the node in the `Diagram`.

`n.getYPosition() : int`

Returns the y position offset of the node in the `Diagram`.

```

n.isCacheEnabled() : boolean

```

Returns **True** if the cache is enabled, **False** otherwise.

```

n.isCacheFull() : boolean

```

Returns **True** if the cache is full, **False** otherwise.

```

n.isInitial() : boolean

```

Returns **True** if this is an initial node i.e. one that occurs at the start of a stream.

```

n.isInline() : boolean

```

Returns **True** if this is an in-line node i.e. one that occurs mid-stream.

```

n.isTerminal() : boolean

```

Returns **True** if this is a terminal node i.e. one that occurs at the end of a stream.

```

n.run(results) : ExecutionHandle
results (Collection) :

```

Executes this node synchronously and waits for execution to complete. Returns an **ExecutionHandle** which can be used to access the exit status and any result from the task. Equivalent to calling:

```

node.getProcessorStream().runSelected(new Processor[] {node}, results);

```

Exceptions:

- OwnerException** : if there is inconsistent ownership
- ObjectLockedException** : if the owner stream is locked for some reason (for example, it is already executing)
- ServerConnectionException** : if the connection to the server cannot be established
- SessionException** : if some other exception occurs

```

n.setCacheEnabled(val)
val (boolean) :

```

Enables or disables the cache for this object. If the cache is full and the caching becomes disabled, the cache is flushed.

```

n.setPositionBetween(source, target)

```

source (Node) : the predecessor

target (Node) : the successor

Sets the position of the node in the **Diagram** so it is positioned between the supplied nodes.

```

n.setXYPosition(x, y)

```

x (int) : the x offset

y (int) : the y offset

Sets the position of the node in the **Diagram**.

Related information

- [Streams and SuperNodes](#)
-

Diagram Objects

This is the container used to assemble **Node** objects into a connected flow or well-formed sequence of nodes.

```
d.clear()
```

Deletes all nodes from this diagram.

Exceptions:

```
ObjectLockedException : if the diagram is currently locked
```

`d.create(nodeType, name) : Node`

`nodeType (string) : the node type name`

`name (string) : the object's name`

Creates a `Node` of the specified type and adds it to this diagram.

Exceptions:

`ObjectCreationException : if the node cannot be created for some reason`

`ObjectLockedException : if the node cannot be added to the stream`

`d.createAt(nodeType, name, x, y) : Node`

`nodeType (string) : the node type name`

`name (string) : the object's name`

`x (int) : the x location`

`y (int) : the y location`

Creates a `Node` of the specified type and adds it to this diagram at the specified location. If either `x < 0` or `y < 0`, the location is not set.

Exceptions:

`ObjectCreationException : if the node cannot be created for some reason`

`ObjectLockedException : if the node cannot be added to the stream`

`d.createModelApplier(modelOutput, name) : Node`

`modelOutput (ModelOutput) : the model output object`

`name (string) : the new object's name`

Creates a `ModelApplier` derived from the supplied model output object.

Exceptions:

`ObjectCreationException : if the node cannot be created for some reason`

`ObjectLockedException : if the node cannot be added to the stream`

`d.delete(node)`

`node (Node) : the node to be removed`

Deletes the specified node from this diagram. The node must be owned by this diagram.

Exceptions:

`OwnerException : if the node is not owned by this diagram`

`ObjectLockedException : if the diagram is currently locked`

`d.deleteAll(nodes)`

`nodes (Collection) : the collection of nodes to be removed`

Deletes all the specified nodes from this diagram. All nodes in the collection must belong to this diagram.

Exceptions:

`OwnerException : if any node parameters are not owned by this diagram`

`ObjectLockedException : if the diagram is currently locked`

`ClassCastException : if any item in the collection is not of type Node`

`d.disconnect(node)`

`node (Node) : the node to be disconnected`

Removes any links between the supplied node and any other nodes in this diagram.

Exceptions:

OwnerException : if any objects in the path are not owned by this diagram

ObjectLockedException : if the diagram is currently locked

d.findAll(type, label) : Collection

type (string) : the node type

label (string) : the node label

Returns a list of all nodes with the specified type and name. Either the type or name may be **None** in which case the other parameter is used.

d.findAll(filter, recursive) : Collection

filter (NodeFilter) : the node filter

recursive (boolean) : if **True** then composite nodes should be recursively searched

Returns a collection of all nodes accepted by the specified filter. If the recursive flag is **True** then any SuperNodes within this diagram are also searched.

d.findById(id) : Node

id (string) : the node ID

Returns the node with the supplied ID or **None** if no such node exists. The search is limited to the current diagram.

d.findByType(type, label) : Node

type (string) : the node type

label (string) : the node label

Returns the node with the supplied type and/or label. Either the type or name may be **None** in which case the other parameter is used. If multiple nodes match then an arbitrary one is chosen and returned. If no nodes match then the return value is **None**.

d.findDownstream(fromNodes) : List

fromNodes (List) : the start point of the search

Searches from the supplied list of nodes and returns the set of nodes downstream of the supplied nodes. The returned list includes the originally supplied nodes.

d.findUpstream(fromNodes) : List

fromNodes (List) : the start point of the search

Searches from the supplied list of nodes and returns the set of nodes upstream of the supplied nodes. The returned list includes the originally supplied nodes.

d.flushCaches()

Flushes the caches of any cache-enabled **Node** objects in the diagram. Has no effect if caches are not enabled or are not full.

d.insert(source, nodes, newIDs) : List

source (Diagram) : the diagram that owns the nodes to be inserted

nodes (List) : the nodes to be copied

newIDs (boolean) : **True** if new IDs should be generated for each node or **False** if the existing IDs should be re-used

Inserts copies of the nodes in the supplied list. It is assumed that all nodes in the supplied list are contained within the specified diagram. The new IDs flag indicates whether new IDs should be generated for each node, or whether the existing ID should be copied across. It is assumed that all nodes in a diagram have a unique ID so this flag must be set **True** if the source diagram is the same as this diagram. The method returns the list of newly inserted nodes where the order of the nodes is undefined (i.e. the ordering is not necessarily the same as the order of nodes in the input list).

Exceptions:

ObjectLockedException : if the diagram has been locked because of another operation

InvalidEditException : if the edit would be invalid

d.isEnabled(node) : boolean

node (Node) : the node

Returns **True** if the supplied node is enabled.

Exceptions:

OwnerException : if the node is not owned by this diagram

d.isOwner(node) : boolean

node (Node) : the node

Returns **True** if the node is owned by this diagram.

d.isValidLink(source, target) : boolean

source (Node) : the source node

target (Node) : the target node

Returns **True** if it would be valid to create a link between the specified source and target nodes. This checks that both objects belong to this diagram, that the source can supply a link and the target can receive a link, and that creating such a link will not cause a circularity in the diagram.

Exceptions:

OwnerException : if the source or target node are not owned by this diagram

d.iterator() : Iterator

Returns an iterator over the **Node** objects contained in this diagram. The behaviour of the iterator if the diagram is modified between calls of **next()** is undefined.

Note: The iterator returns "top-level" nodes and does not recursively descend into any composite nodes.

d.link(source, target)

source (Node) : the source node

target (Node) : the target node

Creates a new link between the source and the target.

Exceptions:

OwnerException : if any node parameters are not owned by this diagram

ObjectLockedException : if the diagram is currently locked

InvalidEditException : if the connection would be invalid

d.link(source, targets)

source (Node) : the source node

targets (List) : the list of target nodes

Creates new links between the source and each target node in the supplied list.

Exceptions:

OwnerException : if any node parameters are not owned by this diagram

ObjectLockedException : if the diagram is currently locked

InvalidEditException : if a connection would be invalid

ClassCastException : if targets does not contain instances of **Node**

d.linkBetween(inserted, source, target)

inserted (Node) : the node to be inserted

source (Node) : the source node

target (Node) : the target node

Connects a **Node** between two other instances and sets the position of the inserted node to be between those. Any direct link between the source and target is removed first. If any link would be invalid (the source is a terminal node, the target is a source node or the target cannot accept any more links), a **ModelerException** is thrown and no changes are made to the diagram.

Exceptions:

OwnerException : if any of the nodes are not owned by the diagram

ObjectLockedException : if the diagram has been locked because of another operation

InvalidEditException : if the edit is invalid e.g., the target already has the maximum number of input connections

d.linkPath(path)

path (List) : the set of **Node** instances

Creates a new path between **Node** instances. The first node is linked to the second, the second is linked to the third etc. If any link would be invalid (for example, the nodes are already linked, the source is a terminal node, the target is a source node or the target cannot accept any more links), a **ModelerException** is thrown and no changes are made to the diagram.

Exceptions:

OwnerException : if any objects in the path are not owned by this diagram

ObjectLockedException : if the diagram is currently locked

InvalidEditException : if a link between two adjacent nodes in the path cannot be created.

d.linkUpdater(updater, updatable)

updater (Node) : the updater node

updatable (Node) : the updatable node

Creates a new update link between the updater and the updatable. It is expected that updater implements the **Updater** interface while the updatable implements the **Updatable** interface.

Exceptions:

OwnerException : if any node parameters are not owned by this diagram

ObjectLockedException : if the diagram is currently locked

InvalidEditException : if the connection would be invalid

d.predecessorAt(node, index) : Node

node (Node) : the node

index (int) : which predecessor to return

Returns the specified immediate predecessor of the supplied node or **None** if the index is out of bounds.

Exceptions:

OwnerException : if the node is not owned by this diagram

d.predecessorCount(node) : int

node (Node) : the node

Returns the number of immediate predecessors of the supplied node.

Exceptions:

OwnerException : if the node is not owned by this diagram

d.predecessors(node) : List

node (Node) : the node

Returns the immediate predecessors of the supplied node.

Exceptions:

OwnerException : if the node is not owned by this diagram

d.replace(originalNode, replacementNode, discardOriginal)

originalNode (Node) : the node to be replaced

replacementNode (Node) : the new node

discardOriginal (boolean) : if **True**, the id of the original node is assigned to the new node and the original node is automatically deleted from the diagram. If **False**, the original node is retained and the replacement node id is unchanged

Replaces the specified node from this diagram. The both nodes must be owned by this diagram.

Exceptions:

OwnerException : if any node is not owned by this diagram
ObjectLockedException : if the diagram is currently locked
InvalidEditException : is the link operation is invalid
d.setEnabled(node, enabled)

node (Node) : the node

enabled (boolean) : whether the node should be enabled

Sets the enabled state of the supplied node.

Exceptions:

OwnerException : if the node is not owned by this diagram

d.size() : int

Returns the number of **Node** objects contained in this diagram.

d.successorAt(node, index) : Node

node (Node) : the successor

index (int) : which successor to return

Returns the specified immediate successor of the supplied node or **None** if the index is out of bounds.

Exceptions:

OwnerException : if the node is not owned by this diagram

d.successorCount(node) : int

node (Node) : the node

Returns the number of immediate successors of the supplied node.

Exceptions:

OwnerException : if the node is not owned by this diagram

d.successors(node) : List

node (Node) : the node

Returns the immediate successors of the supplied node.

Exceptions:

OwnerException : if the node is not owned by this diagram

d.unlink(source, target)

source (Node) : the source node

target (Node) : the target node

Removes any direct link between the source and the target.

Exceptions:

OwnerException : if any node parameters are not owned by this diagram

ObjectLockedException : if the diagram is currently locked

d.unlink(source, targets)

source (Node) : the source node

targets (List) : the list of target nodes

Removes any direct links between the source and each object in the targets list.

Exceptions:

OwnerException : if any node parameters are not owned by this diagram

ObjectLockedException : if the diagram is currently locked

ClassCastException : if targets does not contain instances of **Node**

d.unlinkPath(path)

path (List) : the list of **Node** instances

Removes any path that exists between **Node** instances. If no link exists between two adjacent nodes in the path, these are silently ignored i.e., no exception will be thrown.

Exceptions:

ObjectLockedException : if the diagram is currently locked

OwnerException : if any objects in the path are not owned by this diagram

d.unlinkUpdater(updater, updatable)

updater (Node) : the updater node

updatable (Node) : the target node

Removes any update link between the updater and the updatable. It is expected that updater implements the **Updater** interface while the updatable implements the **Updatable** interface.

Exceptions:

OwnerException : if any node parameters are not owned by this diagram

ObjectLockedException : if the diagram is currently locked

Related information

- [Streams and SuperNodes](#)

NodeFilter Objects

This is used to define arbitrary criteria for filtering nodes e.g. during searches.

n.accept(node) : boolean

node (Node) : the node

Returns **True** if the node should be included by the filter.

Related information

- [Streams and SuperNodes](#)

Stream Objects

Subclass of **Diagram**, **PropertiedObject**, **ParameterProvider**.

This is the top-level container used to assemble **Node** objects into a connected "flow". It also provides the environment for setting which may be used to modify node behaviour.

s.close()

Closes the current stream. If the stream is already closed, this method does nothing. No further operations can be applied to a closed stream.

s.getContentProvider() : ContentProvider

Returns the **ContentProvider** for this stream. The content provider manages additional content on behalf of applications.

```
s.getGlobalValues() : GlobalValues
```

Returns the global values computed for this stream. Global values are constructed and updated by executing a Set Globals node.

```
s.getID() : string
```

Returns the temporary session ID of this object. A new ID is allocated each time a new stream is created or opened and the ID is not persisted when the stream is saved. This means that if the same persisted object is re-opened multiple times, each object will have a different ID.

```
s.getServerConnectionDescriptor() : ServerConnectionDescriptor
```

Returns the **ServerConnectionDescriptor** used to connect this stream to a server or **None** if the stream has not yet been connected or if the owner session was not created using **SessionFactory**.

```
s.isClosed() : boolean
```

Returns **True** if the stream has been closed, **False** otherwise.

```
s.isConnected() : boolean
```

Returns **True** if this has a server connection.

```
s.isExportable(format) : boolean  
format (FileFormat) :
```

Returns **True** if this stream can be exported using the supplied **FileFormat** or **False** otherwise.

```
s.runAll(results) : ExecutionHandle
```

results (Collection) : an empty collection that will contain any built objects once execution has completed

Executes the stream synchronously and waits for it to complete. Returns an **ExecutionHandle** which can be used to access the exit status and any result from the task.

Exceptions:

OwnerException : if the stream was not created by this session

ObjectLockedException : if the stream is locked

ServerConnectionException : if the stream is not connected to a server

SessionException : if the session is already running another task, cannot execute the task or if execution completes in a state other than **SUCCESS**

```
s.runScript(results) : ExecutionHandle
```

results (Collection) : an empty collection that will contain any built objects once execution has completed

Executes the stream script synchronously and waits for it to complete. The stream script is always run regardless of whether script execution is set as the default behaviour. Returns an **ExecutionHandle** which can be used to access the exit status and any result from the task.

Exceptions:

OwnerException : if the stream was not created by this session

ObjectLockedException : if the stream is locked

ServerConnectionException : if the stream is not connected to a server

SessionException : if the session is already running another task, cannot execute the task or if execution completes in a state other than **SUCCESS**

```
s.runSelected(nodes, results) : ExecutionHandle
```

nodes (Node[]) : the array of **Node** objects to be executed

results (Collection) : an empty collection that will contain any built objects once execution has completed

Executes the supplied array of nodes synchronously and waits for them to complete. There must be at least one node in the array. Returns an **ExecutionHandle** which can be used to access the exit status and any result from the task.

Exceptions:

OwnerException : if the nodes are not all owned by this stream

ObjectLockedException : if the stream is locked

ServerConnectionException : if the stream is not connected to a server

SessionException : if the session is already running a stream, another task, cannot execute the task or if execution completes in a state other than **SUCCESS**

IllegalArgumentException : if the array is empty

- [Streams and SuperNodes](#)

PublishedImage Objects

The result of publishing a **DataWriter**.

p.getImageContent() : byte[]

Returns the contents of the image file.

p.getMetadataContent() : byte[]

Returns the contents of the metadata file, or **None** if there is no metadata file.

p.getOutputDataModel() : DataModel

Returns a data model which describes the fields exported by the image. This is the server-side data model and differs from the export data model of the published node in that fields typically have known storage but default measure.

p.getParameterContent() : byte[]

Returns the contents of the parameter file.

Related information

- [Streams and SuperNodes](#)

RowSetBuilder Objects

Subclass of **DocumentBuilder**.

This encapsulates the functionality of a node that builds an output based on a **RowSet**.

r.getRowSetOutput() : RowSetOutput

Returns the most recent **RowSetOutput** produced by this node, or **None** if this **RowSetBuilder** has either not been executed before or failed to produce an object during the most recent execution.

Related information

- [Streams and SuperNodes](#)

RowSetOutput Objects

Subclass of **DocumentOutput**.

This encapsulates the concrete results of executing **DocumentBuilder** nodes that produce objects that are based on underlying **RowSet** such as tables and matrices.

r.getRowSet() : RowSet

Returns the **RowSet** underlying this output object.

Related information

- [Streams and SuperNodes](#)

TerminalNode Objects

Subclass of **Node**.

This encapsulates the functionality of any node that terminates a particular sequence of nodes.

Related information

- [Streams and SuperNodes](#)

Updatable Objects

Subclass of **Node**.

This represents **Node** objects that can be updated by **Updating** objects. Updating can happen either by modifying the contents of an updatable object, or by replacing it in the stream. An updatable object can only be associated with one updater at a time.

u.getUpdater() : Node

Returns the **Node** that is updating this one or **None** if there is no updater.

u.getUpdaterID() : string

Returns the id of the node that is updating this one or the empty string if there is no updater.

u.isUpdatingEnabled() : boolean

Returns **True** if this node can be updated by an updater. This value can be set or returned regardless of whether an updater has been specified.

u.setUpdatingEnabled(canUpdate)
canUpdate (boolean) :

Sets whether this node can be updated by any associated updater.

Related information

- [Streams and SuperNodes](#)
-

Updater Objects

Subclass of **Node**.

This represents **Node** objects that update **Updatable** objects. Updating can happen either by modifying the contents of an updatable object, or by replacing it in the stream. An updater can have multiple updatable objects associated with it.

u.getUpdatableCount() : int

Returns the number of **Updatable** nodes that this is updating.

u.getUpdatables() : Iterator

Returns an iterator for the **Updatable** nodes that this is updating.

Database Modeling Overview

IBM® SPSS® Modeler Server supports integration with data mining and modeling tools that are available from database vendors, including IBM Netezza, Oracle Data Miner, and Microsoft Analysis Services. You can build, score, and store models inside the database—all from within the IBM SPSS Modeler application. This allows you to combine the analytical capabilities and ease-of-use of IBM SPSS Modeler with the power and performance of a database, while taking advantage of database-native algorithms provided by these vendors. Models are built inside the database, which can then be browsed and scored through the IBM SPSS Modeler interface in the normal manner and can be deployed using IBM SPSS Modeler Solution Publisher if needed. Supported algorithms are on the Database Modeling palette in IBM SPSS Modeler.

Using IBM SPSS Modeler to access database-native algorithms offers several advantages:

- In-database algorithms are often closely integrated with the database server and may offer improved performance.
- Models built and stored “in database” may be more easily deployed to and shared with any application that can access the database.

SQL generation. In-database modeling is distinct from SQL generation, otherwise known as “SQL pushback”. This feature allows you to generate SQL statements for native IBM SPSS Modeler operations that can be “pushed back” to (that is, executed in) the database in order to improve performance. For example, the Merge, Aggregate, and Select nodes all generate SQL code that can be pushed back to the database in this manner. Using SQL generation in combination with database modeling may result in streams that can be run from start to finish in the database, resulting in significant performance gains over streams run in IBM SPSS Modeler.

Note: Database modeling and SQL optimization require that IBM SPSS Modeler Server connectivity be enabled on the IBM SPSS Modeler computer. With this setting enabled, you can access database algorithms, push back SQL directly from IBM SPSS Modeler, and access IBM SPSS Modeler Server. To verify the current license status, choose the following from the IBM SPSS Modeler menu.

Help > About > Additional Details

If connectivity is enabled, you see the option Server Enablement in the License Status tab.

See [Connecting to IBM SPSS Modeler Server](#) for more information.

For information on supported algorithms, see the subsequent sections on specific vendors.

-

What you need

To perform database modeling, you need the following setup:

- An ODBC connection to an appropriate database, with required analytical components installed (Microsoft Analysis Services or Oracle Data Miner).
- In IBM® SPSS® Modeler, database modeling must be enabled in the Helper Applications dialog box (Tools > Helper Applications).
- The Generate SQL and SQL Optimization settings should be enabled in the User Options dialog box in IBM SPSS Modeler as well as on IBM SPSS Modeler Server (if used). Note that SQL optimization is not strictly required for database modeling to work but is highly recommended for performance reasons.

Note: Database modeling and SQL optimization require that IBM SPSS Modeler Server connectivity be enabled on the IBM SPSS Modeler computer. With this setting enabled, you can access database algorithms, push back SQL directly from IBM SPSS Modeler, and access IBM SPSS Modeler Server. To verify the current license status, choose the following from the IBM SPSS Modeler menu.

Help > About > Additional Details

If connectivity is enabled, you see the option Server Enablement in the License Status tab.

See [Connecting to IBM SPSS Modeler Server](#) for more information.

For detailed information, see the subsequent sections on specific vendors.

Model Building

The process of building and scoring models by using database algorithms is similar to other types of data mining in IBM® SPSS® Modeler. The general process of working with nodes and modeling "nuggets" is similar to any other stream when working in IBM SPSS Modeler. The only difference is that the actual processing and model building is pushed back to the database.

A Database modelling stream is conceptually identical to other data streams in IBM SPSS Modeler; however, this stream performs all operations in a database, including, for example, model-building using the Microsoft Decision Tree node. When you run the stream, IBM SPSS Modeler instructs the database to build and store the resulting model, and details are downloaded to IBM SPSS Modeler. In-database execution is indicated by the use of purple-shaded nodes in the stream.

Data Preparation

Whether or not database-native algorithms are used, data preparations should be pushed back to the database whenever possible in order to improve performance.

- If the original data is stored in the database, the goal is to keep it there by making sure that all required upstream operations can be converted to SQL. This will prevent data from being downloaded to IBM® SPSS® Modeler—avoiding a bottleneck that might nullify any gains—and allow the entire stream to be run in the database.
 - If the original data are *not* stored in the database, database modeling can still be used. In this case, the data preparation is conducted in IBM SPSS Modeler and the prepared dataset is automatically uploaded to the database for model building.
-

Model scoring

Models generated from IBM® SPSS® Modeler by using in-database mining are different from regular IBM SPSS Modeler models. Although they appear in the Model manager as generated model "nuggets," they are actually remote models held on the remote data mining or database server. What you see in IBM SPSS Modeler are simply references to these remote models. In other words, the IBM SPSS Modeler model you see is a "hollow" model that contains information such as the database server hostname, database name, and the model name. This is an important distinction to understand as you browse and score models created using database-native algorithms.

Once you have created a model, you can add it to the stream for scoring like any other generated model in IBM SPSS Modeler. All scoring is done within the database, even if upstream operations are not. (Upstream operations may still be pushed back to the database if possible to improve performance, but this is not a requirement for scoring to take place.) You can also browse the generated model in most cases using the standard browser provided by the database vendor.

For both browsing and scoring, a live connection to the server running Oracle Data Miner or Microsoft Analysis Services is required.

Viewing results and specifying settings

To view results and specify settings for scoring, double-click the model on the stream canvas. Alternatively, you can right-click the model and choose Browse or Edit. Specific settings depend on the type of model.

Exporting and saving database models

Database models and summaries can be exported from the model browser in the same manner as other models created in IBM® SPSS® Modeler, using options on the File menu.

1. From the File menu in the model browser, choose any of the following options:

- Export Text exports the model summary to a text file
- Export HTML exports the model summary to an HTML file
- Export PMML (supported for IBM Db2 IM models only) exports the model as predictive model markup language (PMML), which can be used with other PMML-compatible software.

Note: You can also save a generated model by choosing Save Node from the File menu.

Model Consistency

For each generated database model, IBM® SPSS® Modeler stores a description of the model structure, along with a reference to the model with the same name that is stored within the database. The Server tab of a generated model displays a unique key generated for that model, which matches the actual model in the database.

IBM SPSS Modeler uses this randomly generated key to check that the model is still consistent. This key is stored in the description of a model when it is built. It is a good idea to check that keys match before running a deployment stream.

1. To check the consistency of the model stored in the database by comparing its description with the random key stored by IBM SPSS Modeler, click the Check button. If the database model cannot be found or the key does not match, an error is reported.

- [Building Models with Analysis Services](#)
- [Scoring Analysis Services Models](#)
- [Analysis Services Mining Examples](#)

IBM SPSS Modeler and Microsoft Analysis Services

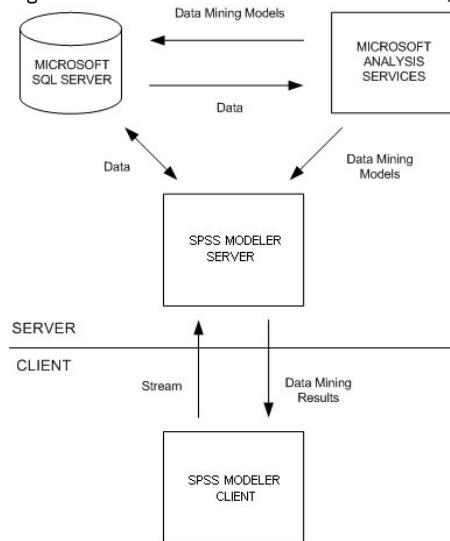

IBM® SPSS® Modeler supports integration with Microsoft SQL Server Analysis Services. This functionality is implemented as modeling nodes in IBM SPSS Modeler and is available from the Database Modeling palette. If the palette is not visible, you can activate it by enabling MS Analysis Services integration, available on the Microsoft tab, from the Helper Applications dialog box. See the topic [Enabling Integration with Analysis Services](#) for more information.

IBM SPSS Modeler supports integration of the following Analysis Services algorithms:

- Decision Trees
- Clustering
- Association Rules
- Naïve Bayes
- Linear Regression
- Neural Network
- Logistic Regression
- Time Series
- Sequence Clustering

The following diagram illustrates the flow of data from client to server where in-database mining is managed by IBM SPSS Modeler Server. Model building is performed using Analysis Services. The resulting model is stored by Analysis Services. A reference to this model is maintained within IBM SPSS Modeler streams. The model is then downloaded from Analysis Services to either Microsoft SQL Server or IBM SPSS Modeler for scoring.

Figure 1. Data flow between IBM SPSS Modeler, Microsoft SQL Server, and Microsoft Analysis Services during model building

Note: The IBM SPSS Modeler Server is not required, though it can be used. IBM SPSS Modeler client is capable of processing in-database mining calculations itself.

Requirements for Integration with Microsoft Analysis Services

The following are prerequisites for conducting in-database modeling using Analysis Services algorithms with IBM® SPSS® Modeler. You may need to consult with your database administrator to ensure that these conditions are met.

- IBM SPSS Modeler running against an IBM SPSS Modeler Server installation (distributed mode) on Windows. UNIX platforms are not supported in this integration with Analysis Services.
Important: IBM SPSS Modeler users must configure an ODBC connection using the SQL Native Client driver available from Microsoft at the URL listed below under *Additional IBM SPSS Modeler Server Requirements*. *The driver provided with the IBM SPSS Data Access Pack (and typically recommended for other uses with IBM SPSS Modeler) is not recommended for this purpose.* The driver should be configured to use SQL Server With Integrated Windows Authentication enabled, since IBM SPSS Modeler does not support SQL Server authentication. If you have questions about creating or setting permissions for ODBC data sources, contact your database administrator.
- SQL Server must be installed, although not necessarily on the same host as IBM SPSS Modeler. IBM SPSS Modeler users must have sufficient permissions to read and write data and drop and create tables and views.

Note: SQL Server Enterprise Edition is recommended. The Enterprise Edition provides additional flexibility by providing advanced parameters to tune algorithm results. The Standard Edition version provides the same parameters but does not allow users to edit some of the advanced parameters.

- Microsoft SQL Server Analysis Services must be installed on the same host as SQL Server.

Additional IBM SPSS Modeler Server Requirements

To use Analysis Services algorithms with IBM SPSS Modeler Server, the following components must be installed on the IBM SPSS Modeler Server host machine.

Note: If SQL Server is installed on the same host as IBM SPSS Modeler Server, these components will already be available.

- Microsoft SQL Server Analysis Services 10.0 OLE DB Provider (be sure to select the correct variant for your operating system)
- Microsoft SQL Server Native Client (be sure to select the correct variant for your operating system)
- If you are using Microsoft SQL Server 2008 or 2012, you might also require Microsoft Core XML Services (MSXML) 6.0.

To download these components, go to www.microsoft.com/downloads, search for .NET Framework or (for all other components) SQL Server Feature Pack, and select the latest pack for your version of SQL Server.

These may require other packages to be installed first, which should also be available on the Microsoft Downloads web site.

Additional IBM SPSS Modeler Requirements

To use Analysis Services algorithms with IBM SPSS Modeler, the same components must be installed as above, with the addition of the following at the client:

- Microsoft SQL Server Datamining Viewer Controls (be sure to select the correct variant for your operating system) - this also requires:
- Microsoft ADOMD.NET

To download these components, go to www.microsoft.com/downloads, search for SQL Server Feature Pack, and select the latest pack for your version of SQL Server.

Note: Database modeling and SQL optimization require that IBM SPSS Modeler Server connectivity be enabled on the IBM SPSS Modeler computer. With this setting enabled, you can access database algorithms, push back SQL directly from IBM SPSS Modeler, and access IBM SPSS Modeler Server. To verify the current license status, choose the following from the IBM SPSS Modeler menu.

Help > About > Additional Details

If connectivity is enabled, you see the option Server Enablement in the License Status tab.

See [Connecting to IBM SPSS Modeler Server](#) for more information.

Related information

- [Enabling Integration with Analysis Services](#)
 - [Building Models with Analysis Services](#)
 - [Scoring Analysis Services Models](#)

Enabling Integration with Analysis Services

To enable IBM® SPSS® Modeler integration with Analysis Services, you will need to configure SQL Server and Analysis Services, create an ODBC source, enable the integration in the IBM SPSS Modeler Helper Applications dialog box, and enable SQL generation and optimization.

Note: Microsoft SQL Server and Microsoft Analysis Services must be available. See the topic [Requirements for Integration with Microsoft Analysis Services](#) for more information.

Configuring SQL Server

Configure SQL Server to allow scoring to take place within the database.

1. Create the following registry key on the SQL Server host machine:

`HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\MSSQLServer\Providers\MSOLAP`

2. Add the following **DWORD** value to this key:

`AllowInProcess 1`

3. Restart SQL Server after making this change.

Configuring Analysis Services

Before IBM SPSS Modeler can communicate with Analysis Services, you must first manually configure two settings in the Analysis Server Properties dialog box:

1. Log in to the Analysis Server through the MS SQL Server Management Studio.
2. Access the Properties dialog box by right-clicking the server name and choosing Properties.
3. Select the Show Advanced (All) Properties check box.
4. Change the following properties:
 - Change the value for **DataMining\AllowAdHocOpenRowsetQueries** to **True** (the default value is **False**).
 - Change the value for **DataMining\AllowProvidersInOpenRowset** to **[all]** (there is no default value).

Creating an ODBC DSN for SQL Server

To read or write to a database, you must have an ODBC data source installed and configured for the relevant database, with read or write permissions as needed. The Microsoft SQL Native Client ODBC driver is required and automatically installed with SQL Server. *The driver provided with the IBM SPSS Data Access Pack (and typically recommended for other uses with IBM SPSS Modeler) is not recommended for this purpose.* If IBM SPSS Modeler and SQL Server reside on different hosts, you can download the Microsoft SQL Native Client ODBC driver. See the topic [Requirements for Integration with Microsoft Analysis Services](#) for more information.

If you have questions about creating or setting permissions for ODBC data sources, contact your database administrator.

1. Using the Microsoft SQL Native Client ODBC driver, create an ODBC DSN that points to the SQL Server database used in the data mining process. The remaining default driver settings should be used.
2. For this DSN, ensure that With Integrated Windows Authentication is selected.
 - If IBM SPSS Modeler and IBM SPSS Modeler Server are running on different hosts, create the same ODBC DSN on each of the hosts. Ensure that the same DSN name is used on each host.

Enabling the Analysis Services Integration in IBM SPSS Modeler

To enable IBM SPSS Modeler to use Analysis Services, you must first provide server specifications in the Helper Applications dialog box.

1. From the IBM SPSS Modeler menus choose:
Tools > Options > Helper Applications
2. Click the Microsoft tab.
 - **Enable Microsoft Analysis Services Integration.** Enables the Database Modeling palette (if not already displayed) at the bottom of the IBM SPSS Modeler window and adds the nodes for Analysis Services algorithms.
 - **Analysis Server Host.** Specify the name of the machine on which Analysis Services is running.
 - **Analysis Server Database.** Select the desired database by clicking the ellipsis (...) button to open a subdialog box in which you can choose from available databases. The list is populated with databases available to the specified Analysis server. Since Microsoft Analysis Services stores data mining models within named databases, you should select the appropriate database in which Microsoft models built by IBM SPSS Modeler are stored.
 - **SQL Server Connection.** Specify the DSN information used by the SQL Server database to store the data that are passed into the Analysis server. Choose the ODBC data source that will be used to provide the data for building Analysis Services data mining models. If you are building Analysis Services models from data supplied in flat files or ODBC data sources, the data will be automatically uploaded to a temporary table created in the SQL Server database to which this ODBC data source points.
 - **Warn when about to overwrite a data mining model.** Select to ensure that models stored in the database are not overwritten by IBM SPSS Modeler without warning.

Note: Settings made in the Helper Applications dialog box can be overridden inside the various Analysis Services nodes.

Enabling SQL Generation and Optimization

1. From the IBM SPSS Modeler menus choose:
Tools > Stream Properties > Options
2. Click the Optimization option in the navigation pane.
3. Confirm that the Generate SQL option is enabled. This setting is required for database modeling to function.
4. Select Optimize SQL Generation and Optimize other execution (not strictly required but strongly recommended for optimized performance).

Building Models with Analysis Services

Analysis Services model building requires that the training dataset be located in a table or view within the SQL Server database. If the data is not located in SQL Server or need to be processed in IBM® SPSS® Modeler as part of data preparation that cannot be performed in SQL Server, the data is automatically uploaded to a temporary table in SQL Server before model building.

Managing Analysis Services Models

Building an Analysis Services model via IBM® SPSS® Modeler creates a model in IBM SPSS Modeler and creates or replaces a model in the SQL Server database. The IBM SPSS Modeler model references the content of a database model stored on a database server. IBM SPSS Modeler can perform consistency checking by storing an identical generated model key string in both the IBM SPSS Modeler model and the SQL Server model.

	The MS Decision Tree modeling node is used in predictive modeling of both categorical and continuous attributes. For categorical attributes, the node makes predictions based on the relationships between input columns in a dataset. For example, in a scenario to predict which customers are likely to purchase a bicycle, if nine out of ten younger customers buy a bicycle but only two out of ten older customers do so, the node infers that age is a good predictor of bicycle purchase. The decision tree makes predictions based on this tendency toward a particular outcome. For continuous attributes, the algorithm uses linear regression to determine where a decision tree splits. If more than one column is set to predictable, or if the input data contains a nested table that is set to predictable, the node builds a separate decision tree for each predictable column.
	The MS Clustering modeling node uses iterative techniques to group cases in a dataset into clusters that contain similar characteristics. These groupings are useful for exploring data, identifying anomalies in the data, and creating predictions. Clustering models identify relationships in a dataset that you might not logically derive through casual observation. For example, you can logically discern that people who commute to their jobs by bicycle do not typically live a long distance from where they work. The algorithm, however, can find other characteristics about bicycle commuters that are not as obvious. The clustering node differs from other data mining nodes in that no target field is specified. The clustering node trains the model strictly from the relationships that exist in the data and from the clusters that the node identifies.
	The MS Association Rules modeling node is useful for recommendation engines. A recommendation engine recommends products to customers based on items they have already purchased or in which they have indicated an interest. Association models are built on datasets that contain identifiers both for individual cases and for the items that the cases contain. A group of items in a case is called an itemset . An association model is made up of a series of itemsets and the rules that

	<p>describe how those items are grouped together within the cases. The rules that the algorithm identifies can be used to predict a customer's likely future purchases, based on the items that already exist in the customer's shopping cart.</p>
	<p>The MS Naive Bayes modeling node calculates the conditional probability between target and predictor fields and assumes that the columns are independent. The model is termed naïve because it treats all proposed prediction variables as being independent of one another. This method is computationally less intense than other Analysis Services algorithms and therefore useful for quickly discovering relationships during the preliminary stages of modeling. You can use this node to do initial explorations of data and then apply the results to create additional models with other nodes that may take longer to compute but give more accurate results.</p>
	<p>The MS Linear Regression modeling node is a variation of the Decision Trees node, where the MINIMUM_LEAF_CASES parameter is set to be greater than or equal to the total number of cases in the dataset that the node uses to train the mining model. With the parameter set in this way, the node will never create a split and therefore performs a linear regression.</p>
	<p>The MS Neural Network modeling node is similar to the MS Decision Tree node in that the MS Neural Network node calculates probabilities for each possible state of the input attribute when given each state of the predictable attribute. You can later use these probabilities to predict an outcome of the predicted attribute, based on the input attributes.</p>
	<p>The MS Logistic Regression modeling node is a variation of the MS Neural Network node, where the HIDDEN_NODE_RATIO parameter is set to 0. This setting creates a neural network model that does not contain a hidden layer and therefore is equivalent to logistic regression.</p>
	<p>The MS Time Series modeling node provides regression algorithms that are optimized for the forecasting of continuous values, such as product sales, over time. Whereas other Microsoft algorithms, such as decision trees, require additional columns of new information as input to predict a trend, a time series model does not. A time series model can predict trends based only on the original dataset that is used to create the model. You can also add new data to the model when you make a prediction and automatically incorporate the new data in the trend analysis. See the topic MS Time Series Node for more information.</p>
	<p>The MS Sequence Clustering modeling node identifies ordered sequences in data, and combines the results of this analysis with clustering techniques to generate clusters based on the sequences and other attributes. See the topic MS Sequence Clustering Node for more information.</p>

You can access each node from the Database Modeling palette at the bottom of the IBM SPSS Modeler window.

Model Options

In order to build the most basic model, you need to specify options on the Model tab before proceeding. Scoring method and other advanced options are available on the Expert tab.

The following basic modeling options are available:

Model name. Specifies the name assigned to the model that is created when the node is executed.

- **Auto.** Generates the model name automatically based on the target or ID field names or the name of the model type in cases where no target is specified (such as clustering models).
- **Custom.** Allows you to specify a custom name for the model created.

Use partitioned data. Splits the data into separate subsets or samples for training, testing, and validation based on the current partition field. Using one sample to create the model and a separate sample to test it may provide an indication of how well the model will generalize to larger datasets that are similar to the current data. If no partition field is specified in the stream, this option is ignored.

With Drillthrough. If shown, this option enables you to query the model to learn details about the cases included in the model.

Unique field. From the drop-down list, select a field that uniquely identifies each case. Typically, this is an ID field, such as CustomerID.

MS Association Rules Node

The MS Association Rules modeling node is useful for recommendation engines. A recommendation engine recommends products to customers based on items they have already purchased or in which they have indicated an interest. Association models are built on datasets that contain identifiers both for individual cases and for the items that the cases contain. A group of items in a case is called an **itemset**.

An association model is made up of a series of itemsets and the rules that describe how those items are grouped together within the cases. The rules that the algorithm identifies can be used to predict a customer's likely future purchases, based on the items that already exist in the customer's shopping cart.

For tabular format data, the algorithm creates scores that represent probability (*\$MP-field*) for each generated recommendation (*\$M-field*). For transactional format data, scores are created for support (*\$MS-field*), probability (*\$MP-field*) and adjusted probability (*\$MAP-field*) for each generated recommendation (*\$M-field*).

Requirements

The requirements for a transactional association model are as follows:

- **Unique field.** An association rules model requires a key that uniquely identifies records.
- **ID field.** When building an MS Association Rules model with transactional format data, an ID field that identifies each transaction is required. ID fields can be set to the same as the unique field.
- **At least one input field.** The Association Rules algorithm requires at least one input field.
- **Target field.** When building an MS Association model with transactional data, the target field must be the transaction field, for example products that a user bought.

MS Time Series Node

The MS Time Series modeling node supports two types of predictions:

- future
- historical

Future predictions estimate target field values for a specified number of time periods beyond the end of your historical data, and are always performed. **Historical predictions** are estimated target field values for a specified number of time periods for which you have the actual values in your historical data. You can use historical predictions to assess the quality of the model, by comparing the actual historical values with the predicted values. The value of the start point for the predictions determines whether historical predictions are performed.

Unlike the IBM® SPSS® Modeler Time Series node, the MS Time Series node does not need a preceding Time Intervals node. A further difference is that by default, scores are produced only for the predicted rows, not for all the historical rows in the time series data.

Requirements

The requirements for an MS Time Series model are as follows:

- **Single key time field.** Each model must contain one numeric or date field that is used as the case series, defining the time slices that the model will use. The data type for the key time field can be either a datetime data type or a numeric data type. However, the field must contain continuous values, and the values must be unique for each series.
 - **Single target field.** You can specify only one target field in each model. The data type of the target field must have continuous values. For example, you can predict how numeric attributes, such as income, sales, or temperature, change over time. However, you cannot use a field that contains categorical values, such as purchasing status or level of education, as the target field.
 - **At least one input field.** The MS Time Series algorithm requires at least one input field. The data type of the input field must have continuous values. Non-continuous input fields are ignored when building the model.
 - **Dataset must be sorted.** The input dataset must be sorted (on the key time field), otherwise model building will be interrupted with an error.

MS Time Series Expert Options

The options available on the Expert tab can fluctuate depending on the structure of the selected stream. Refer to the user interface field-level help for full details regarding expert options for the selected Analysis Services model node.

If you are making historical predictions, the number of historical steps that can be included in the scoring result is decided by the value of (HISTORIC_MODEL_COUNT * HISTORIC_MODEL_GAP). By default, this limitation is 10, meaning that only 10 historical predictions will be made. In this case, for example, an error occurs if you enter a value of less than -10 for Historical prediction on the Settings tab of the model nugget (see [MS Time Series Model Nugget Settings Tab](#)). If you want to see more historical predictions, you can increase the value of HISTORIC_MODEL_COUNT or HISTORIC_MODEL_GAP, but this will increase the build time for the model.

MS Time Series Settings Options

Begin Estimation. Specify the time period where you want predictions to start.

- Start From: New Prediction. The time period at which you want future predictions to start, expressed as an offset from the last time period of your historical data. For example, if your historical data ended at 12/99 and you wanted to begin predictions at 01/00, you would use a value of 1; however, if you wanted predictions to start at 03/00, you would use a value of 3.
- Start From: Historical Prediction. The time period at which you want historical predictions to start, expressed as a negative offset from the last time period of your historical data. For example, if your historical data ended at 12/99 and you wanted to make historical predictions for the last five time periods of your data, you would use a value of -5.

End Estimation. Specify the time period where you want predictions to stop.

- End step of the prediction. The time period at which you want predictions to stop, expressed as an offset from the last time period of your historical data. For example, if your historical data end at 12/99 and you want predictions to stop at 6/00, you would use a value of 6 here. For future predictions, the value must always be greater than or equal to the Start From value.

MS Sequence Clustering Node

The MS Sequence Clustering node uses a sequence analysis algorithm that explores data containing events that can be linked by following paths, or *sequences*. Some examples of this might be the click paths created when users navigate or browse a Web site, or the order in which a customer adds items to a shopping cart at an online retailer. The algorithm finds the most common sequences by grouping, or *clustering*, sequences that are identical.

Requirements

The requirements for a Microsoft Sequence Clustering model are:

- **ID field.** The Microsoft Sequence Clustering algorithm requires the sequence information to be stored in transactional format. For this, an ID field that identifies each transaction is required.
- **At least one input field.** The algorithm requires at least one input field.
- **Sequence field.** The algorithm also requires a sequence identifier field, which must have a measurement level of Continuous. For example, you can use a Web page identifier, an integer, or a text string, as long as the field identifies the events in a sequence. Only one sequence identifier is allowed for each sequence, and only one type of sequence is allowed in each model. The Sequence field must be different from the ID and Unique fields.
- **Target field.** A target field is required when building a sequence clustering model.
- **Unique field.** A sequence clustering model requires a key field that uniquely identifies records. You can set the Unique field to be the same as the ID field.

MS Sequence Clustering Fields Options

All modeling nodes have a Fields tab, where you specify the fields to be used in building the model.

Before you can build a sequence clustering model, you need to specify which fields you want to use as targets and as inputs. Note that for the MS Sequence Clustering node, you cannot use field information from an upstream Type node; you must specify the field settings here.

ID. Select an ID field from the list. Numeric or symbolic fields can be used as the ID field. Each unique value of this field should indicate a specific unit of analysis. For example, in a market basket application, each ID might represent a single customer. For a Web log analysis application, each ID might represent a computer (by IP address) or a user (by login data).

Inputs. Select the input field or fields for the model. These are the fields that contain the events of interest in sequence modeling.

Sequence. Choose a field from the list, to be used as the sequence identifier field. For example, you can use a Web page identifier, an integer, or a text string, provided that the field identifies the events in a sequence. Only one sequence identifier is allowed for each sequence, and only one type of sequence is allowed in each model. The Sequence field must be different from the ID field (specified on this tab) and the Unique field (specified on the Model tab).

Target. Choose a field to be used as the target field, that is, the field whose value you are trying to predict based on the sequence data.

Scoring Analysis Services Models

Model scoring occurs within SQL Server and is performed by Analysis Services. The dataset may need to be uploaded to a temporary table if the data originates within IBM® SPSS® Modeler or needs to be prepared within IBM SPSS Modeler. Models that you create from IBM SPSS Modeler, using in-database mining, are actually a remote model held on the remote data mining or database server. This is an important distinction to understand as you browse and score models created using Microsoft Analysis Services algorithms.

In IBM SPSS Modeler, generally only a single prediction and associated probability or confidence is delivered.

For model scoring examples, see [Analysis Services Mining Examples](#).

Analysis Services Model Nugget Server Tab

The Server tab is used to specify connections for in-database mining. The tab also provides the unique model key. The key is randomly generated when the model is built and is stored both within the model in IBM® SPSS® Modeler and also within the description of the model object stored in the Analysis Services database.

On the Server tab, you can configure the Analysis server host and database and the SQL Server data source for the scoring operation. Options specified here overwrite those specified in the Helper Applications or Build Model dialog boxes in IBM SPSS Modeler. See the topic [Enabling Integration with Analysis Services](#) for more information.

Model GUID. The model key is shown here. The key is randomly generated when the model is built and is stored both within the model in IBM SPSS Modeler and also within the description of the model object stored in the Analysis Services database.

Check. Click this button to check the model key against the key in the model stored in the Analysis Services database. This allows you to verify that the model still exists within the Analysis server and indicates that the structure of the model has not changed.

Note: The Check button is available only for models added to the stream canvas in preparation for scoring. If the check fails, investigate whether the model has been deleted or replaced by a different model on the server.

View. Click for a graphical view of the decision tree model. The Decision Tree Viewer is shared by other decision tree algorithms in IBM SPSS Modeler and the functionality is identical.

Analysis Services Model Nugget Summary Tab

The Summary tab of a model nugget displays information about the model itself (*Analysis*), fields used in the model (*Fields*), settings used when building the model (*Build Settings*), and model training (*Training Summary*).

When you first browse the node, the Summary tab results are collapsed. To see the results of interest, use the expander control to the left of an item to unfold it or click the Expand All button to show all results. To hide the results when you have finished viewing them, use the expander control to collapse the specific results you want to hide or click the Collapse All button to collapse all results.

Analysis. Displays information about the specific model. If you have executed an Analysis node attached to this model nugget, information from that analysis will also appear in this section.

Fields. Lists the fields used as the target and the inputs in building the model.

Build Settings. Contains information about the settings used in building the model.

Training Summary. Shows the type of model, the stream used to create it, the user who created it, when it was built, and the elapsed time for building the model.

MS Time Series Model Nugget

The MS Time Series model produces scores for only for the predicted time periods, not for the historical data.

The following table shows the fields that are added to the model.

Table 1. Fields added to the model

Field Name	Description
\$M-field	Predicted value of <i>field</i>
\$Var-field	Computed variance of <i>field</i>
\$Stdev-field	Standard deviation of <i>field</i>

MS Time Series Model Nugget Server Tab

The Server tab is used to specify connections for in-database mining. The tab also provides the unique model key. The key is randomly generated when the model is built and is stored both within the model in IBM® SPSS® Modeler and also within the description of the model object stored in the Analysis Services database.

On the Server tab, you can configure the Analysis server host and database and the SQL Server data source for the scoring operation. Options specified here overwrite those specified in the Helper Applications or Build Model dialog boxes in IBM SPSS Modeler. See the topic [Enabling Integration with Analysis Services](#) for more information.

Model GUID. The model key is shown here. The key is randomly generated when the model is built and is stored both within the model in IBM SPSS Modeler and also within the description of the model object stored in the Analysis Services database.

Check. Click this button to check the model key against the key in the model stored in the Analysis Services database. This allows you to verify that the model still exists within the Analysis server and indicates that the structure of the model has not changed.

Note: The Check button is available only for models added to the stream canvas in preparation for scoring. If the check fails, investigate whether the model has been deleted or replaced by a different model on the server.

View. Click for a graphical view of the time series model. Analysis Services displays the completed model as a tree. You can also view a graph that shows the historical value of the target field over time, together with predicted future values.

For more information, see the description of the Time Series viewer in the MSDN library at <http://msdn.microsoft.com/en-us/library/ms175331.aspx>.

MS Time Series Model Nugget Settings Tab

Begin Estimation. Specify the time period where you want predictions to start.

- Start From: New Prediction. The time period at which you want future predictions to start, expressed as an offset from the last time period of your historical data. For example, if your historical data ended at 12/99 and you wanted to begin predictions at 01/00, you would use a value of 1; however, if you wanted predictions to start at 03/00, you would use a value of 3.
- Start From: Historical Prediction. The time period at which you want historical predictions to start, expressed as a negative offset from the last time period of your historical data. For example, if your historical data ended at 12/99 and you wanted to make historical predictions for the last five time periods of your data, you would use a value of -5.

End Estimation. Specify the time period where you want predictions to stop.

- End step of the prediction. The time period at which you want predictions to stop, expressed as an offset from the last time period of your historical data. For example, if your historical data end at 12/99 and you want predictions to stop at 6/00, you would use a value of 6 here. For future predictions, the value must always be greater than or equal to the Start From value.

Exporting Models and Generating Nodes

You can export a model summary and structure to text and HTML format files. You can generate the appropriate Select and Filter nodes where appropriate.

Similar to other model nuggets in IBM® SPSS® Modeler, the Microsoft Analysis Services model nuggets support the direct generation of record and field operations nodes. Using the model nugget Generate menu options, you can generate the following nodes:

- Select node (only if an item is selected on the Model tab)
- Filter node

Analysis Services Mining Examples

Included are a number of sample streams that demonstrate the use of MS Analysis Services data mining with IBM® SPSS® Modeler. These streams can be found in the IBM SPSS Modeler installation folder under:

|Demos|Database_Modelling|Microsoft

Note: The Demos folder can be accessed from the IBM SPSS Modeler program group on the Windows Start menu.

-

Example Streams: Decision Trees

The following streams can be used together in sequence as an example of the database mining process using the Decision Trees algorithm provided by MS Analysis Services.

Table 1. Decision Trees - example streams

Stream	Description
<code>1_upload_data.str</code>	Used to clean and upload data from a flat file into the database.
<code>2_explore_data.str</code>	Provides an example of data exploration with IBM® SPSS® Modeler
<code>3_build_model.str</code>	Builds the model using the database-native algorithm.
<code>4_evaluate_model.str</code>	Used as an example of model evaluation with IBM SPSS Modeler
<code>5_deploy_model.str</code>	Deploys the model for in-database scoring.

Note: In order to run the example, streams must be executed in order. In addition, source and modeling nodes in each stream must be updated to reference a valid data source for the database you want to use.

The dataset used in the example streams concerns credit card applications and presents a classification problem with a mixture of categorical and continuous predictors. For more information about this dataset, see the `crx.names` file in the same folder as the sample streams.

This dataset is available from the UCI Machine Learning Repository at <ftp://ftp.ics.uci.edu/pub/machine-learning-databases/credit-screening/>.

- [Example Stream: Explore Data](#)
- [Example Stream: Build Model](#)
- [Example Stream: Evaluate Model](#)
- [Example Stream: Deploy Model](#)

Example Stream: Upload Data

The first example stream, `1_upload_data.str`, is used to clean and upload data from a flat file into SQL Server.

Since Analysis Services data mining requires a key field, this initial stream uses a Derive node to add a new field to the dataset called `KEY` with unique values 1,2,3 using the IBM® SPSS® Modeler `@INDEX` function.

The subsequent Filler node is used for missing-value handling and replaces empty fields read in from the text file `crx.data` with `NULL` values.

- [Analysis Services Mining Examples](#)
- [Example Streams: Decision Trees](#)
- [Example Stream: Explore Data](#)
- [Example Stream: Build Model](#)
- [Example Stream: Evaluate Model](#)
- [Example Stream: Deploy Model](#)

Example Stream: Explore Data

The second example stream, `2_explore_data.str`, is used to demonstrate use of a Data Audit node to gain a general overview of the data, including summary statistics and graphs.

Double-clicking a graph in the Data Audit Report produces a more detailed graph for deeper exploration of a given field.

- [Analysis Services Mining Examples](#)
- [Example Streams: Decision Trees](#)
- [Example Stream: Upload Data](#)
- [Example Stream: Build Model](#)
- [Example Stream: Evaluate Model](#)
- [Example Stream: Deploy Model](#)

Example Stream: Build Model

The third example stream, `3_build_model.str`, illustrates model building in IBM® SPSS® Modeler. You can attach the database model to the stream and double-click to specify build settings.

On the Model tab of the dialog box, you can specify the following:

1. Select the Key field as the Unique ID field.

On the Expert tab, you can fine-tune settings for building the model.

Before running, ensure that you have specified the correct database for model building. Use the Server tab to adjust any settings.

Related information

- [Analysis Services Mining Examples](#)
- [Example Streams: Decision Trees](#)
- [Example Stream: Upload Data](#)
- [Example Stream: Explore Data](#)
- [Example Stream: Evaluate Model](#)
- [Example Stream: Deploy Model](#)

Example Stream: Evaluate Model

The fourth example stream, `4_evaluate_model.str`, illustrates the advantages of using IBM® SPSS® Modeler for in-database modeling. Once you have executed the model, you can add it back to your data stream and evaluate the model using several tools offered in IBM SPSS Modeler.

Viewing Modeling Results

You can double-click the model nugget to explore your results. The Summary tab provides a rule-tree view of your results. You can also click the View button, located on the Server tab, for a graphical view of the Decision Trees model.

Evaluating Model Results

The Analysis node in the sample stream creates a coincidence matrix showing the pattern of matches between each predicted field and its target field. Execute the Analysis node to view the results.

The Evaluation node in the sample stream can create a gains chart designed to show accuracy improvements made by the model. Execute the Evaluation node to view the results.

Related information

- [Analysis Services Mining Examples](#)
 - [Example Streams: Decision Trees](#)
 - [Example Stream: Upload Data](#)
 - [Example Stream: Explore Data](#)
 - [Example Stream: Build Model](#)
 - [Example Stream: Deploy Model](#)
-

Example Stream: Deploy Model

Once you are satisfied with the accuracy of the model, you can deploy it for use with external applications or for publishing back to the database. In the final example stream, `5_deploy_model.str`, data is read from the table `CREDIT` and then scored and published to the table `CREDITSCORES` using a Database Export node.

Running the stream generates the following SQL:

```
DROP TABLE CREDITSCORES

CREATE TABLE CREDITSCORES ( "field1" varchar(1), "field2" varchar(255), "field3" float, "field4" varchar(1), "field5" varchar(2), "field6" varchar(2), "field7" varchar(2), "field8" float, "field9" varchar(1), "field10" varchar(1), "field11" int, "field12" varchar(1), "field13" varchar(1), "field14" int, "field15" int, "field16" varchar(1), "KEY" int, "$M-field16" varchar(9), "$MC-field16" float )

INSERT INTO CREDITSCORES ("field1", "field2", "field3", "field4", "field5", "field6", "field7", "field8", "field9", "field10", "field11", "field12", "field13", "field14", "field15", "field16", "KEY", "$M-field16", "$MC-field16")

About Oracle Data Mining

IBM® SPSS® Modeler supports integration with Oracle Data Mining (ODM), which provides a family of data mining algorithms tightly embedded within the Oracle RDBMS. These features can be accessed through the IBM SPSS Modeler graphical user interface and workflow-oriented development environment, allowing customers to use the data mining algorithms offered by ODM.

IBM SPSS Modeler supports integration of the following algorithms from Oracle Data Mining:

- Naive Bayes
- Adaptive Bayes
- Support Vector Machine (SVM)
- Generalized Linear Models (GLM)*
- Decision Tree
- O-Cluster
- k-Means
- Nonnegative Matrix Factorization (NMF)
- Apriori
- Minimum Descriptor Length (MDL)
- Attribute Importance (AI)

* 11g R1 only

Requirements for Integration with Oracle

The following conditions are prerequisites for conducting in-database modeling using Oracle Data Mining. You may need to consult with your database administrator to ensure that these conditions are met.

- IBM® SPSS® Modeler running in local mode or against an IBM SPSS Modeler Server installation on Windows or UNIX.
- Oracle 10gR2 or 11gR1 (10.2 Database or higher) with the Oracle Data Mining option.

Note: 10gR2 provides support for all database modeling algorithms except Generalized Linear Models (requires 11gR1).

- An ODBC data source for connecting to Oracle. See the topic [Enabling Integration with Oracle](#) for more information.

Note: Database modeling and SQL optimization require that IBM SPSS Modeler Server connectivity be enabled on the IBM SPSS Modeler computer. With this setting enabled, you can access database algorithms, push back SQL directly from IBM SPSS Modeler, and access IBM SPSS Modeler Server. To verify the current license status, choose the following from the IBM SPSS Modeler menu.

Help > About > Additional Details

If connectivity is enabled, you see the option Server Enablement in the License Status tab.

See [Connecting to IBM SPSS Modeler Server](#) for more information.

Enabling Integration with Oracle

To enable the IBM® SPSS® Modeler integration with Oracle Data Mining, you'll need to configure Oracle, create an ODBC source, enable the integration in the IBM SPSS Modeler Helper Applications dialog box, and enable SQL generation and optimization.

Configuring Oracle

To install and configure Oracle Data Mining, see the Oracle documentation—in particular, the *Oracle Administrator's Guide*—for more details.

Creating an ODBC Source for Oracle

To enable the connection between Oracle and IBM SPSS Modeler, you need to create an ODBC system data source name (DSN).

Before creating a DSN, you should have a basic understanding of ODBC data sources and drivers, and database support in IBM SPSS Modeler.

If you are running in distributed mode against IBM SPSS Modeler Server, create the DSN on the server computer. If you are running in local (client) mode, create the DSN on the client computer.

1. Install the ODBC drivers. These are available on the IBM SPSS Data Access Pack installation disk shipped with this release. Run the *setup.exe* file to start the installer, and select all the relevant drivers. Follow the on-screen instructions to install the drivers.
 - a. Create the DSN.

Note: The menu sequence depends on your version of Windows.

 - Windows XP. From the Start menu, choose Control Panel. Double-click Administrative Tools, and then double-click Data Sources (ODBC).
 - Windows Vista. From the Start menu, choose Control Panel, then System Maintenance. Double-click Administrative Tools, selectData Sources (ODBC), then click Open.
 - Windows 7. From the Start menu, choose Control Panel, then System & Security, then Administrative Tools. SelectData Sources (ODBC), then click Open.
 - b. Go to the System DSN tab, and then click Add.
2. Select the SPSS OEM 6.0 Oracle Wire Protocol driver.
3. Click Finish.
4. In the ODBC Oracle Wire Protocol Driver Setup screen, enter a data source name of your choosing, the hostname of the Oracle server, the port number for the connection, and the SID for the Oracle instance you are using.

The hostname, port, and SID can be obtained from the *tnsnames.ora* file on the server machine if you have implemented TNS with a *tnsnames.ora* file. Contact your Oracle administrator for more information.
5. Click the Test button to test the connection.

Enabling Oracle Data Mining Integration in IBM SPSS Modeler

1. From the IBM SPSS Modeler menus choose:
Tools > *Options* > *Helper Applications*

2. Click the Oracle tab.

Enable Oracle Data Mining Integration. Enables the Database Modeling palette (if not already displayed) at the bottom of the IBM SPSS Modeler window and adds the nodes for Oracle Data Mining algorithms.

Oracle Connection. Specify the default Oracle ODBC data source used for building and storing models, along with a valid user name and password. This setting can be overridden on the individual modeling nodes and model nuggets.

Note: The database connection used for modeling purposes may or may not be the same as the connection used to access data. For example, you might have a stream that accesses data from one Oracle database, downloads the data to IBM SPSS Modeler for cleaning or other manipulations, and then uploads the data to a different Oracle database for modeling purposes. Alternatively, the original data might reside in a flat file or other (non-Oracle) source, in which case it would need to be uploaded to Oracle for modeling. In all cases, the data will be automatically uploaded to a temporary table created in the database that is used for modeling.

Warn when about to overwrite an Oracle Data Mining model. Select this option to ensure that models stored in the database are not overwritten by IBM SPSS Modeler without warning.

List Oracle Data Mining Models. Displays available data mining models.

Enable launch of Oracle Data Miner. (optional) When enabled, allows IBM SPSS Modeler to launch the Oracle Data Miner application. Refer to [Oracle Data Miner](#) for more information.

Path for Oracle Data Miner executable. (optional) Specifies the physical location of the Oracle Data Miner for Windows executable file (for example, C:\odm\bin\odminerw.exe). Oracle Data Miner is not installed with IBM SPSS Modeler; you must download the correct version from the Oracle Web site (<http://www.oracle.com/technology/products/bi/odm/odminer.html>) and install it at the client.

Enabling SQL Generation and Optimization

1. From the IBM SPSS Modeler menus choose:
Tools > *Stream Properties* > *Options*
2. Click the Optimization option in the navigation pane.
3. Confirm that the Generate SQL option is enabled. This setting is required for database modeling to function.
4. Select Optimize SQL Generation and Optimize other execution (not strictly required but strongly recommended for optimized performance).

Building Models with Oracle Data Mining

Oracle model-building nodes work just like other modeling nodes in IBM® SPSS® Modeler, with a few exceptions. You can access these nodes from the Database Modeling palette across the bottom of the IBM SPSS Modeler window.

Data Considerations

Oracle requires that categorical data be stored in a string format (either CHAR or VARCHAR2). As a result, IBM SPSS Modeler will not allow numeric storage fields with a measurement level of *Flag* or *Nominal* (categorical) to be specified as input to ODM models. If necessary, numbers can be converted to strings in IBM SPSS Modeler by using the Reclassify node.

Target field. Only one field may be selected as the output (target) field in ODM classification models.

Model name. From Oracle 11gR1 onwards, the name `unique` is a keyword and cannot be used as a custom model name.

Unique field. Specifies the field used to uniquely identify each case. For example, this might be an ID field, such as *CustomerID*. IBM SPSS Modeler imposes a restriction that this key field must be numeric.

Note: This field is optional for all Oracle nodes except Oracle Adaptive Bayes, Oracle O-Cluster and Oracle Apriori.

General Comments

- PMML Export/Import is not provided from IBM SPSS Modeler for models created by Oracle Data Mining.
- Model scoring always happens within ODM. The dataset may need to be uploaded to a temporary table if the data originate, or need to be prepared, within IBM SPSS Modeler.
- In IBM SPSS Modeler, generally only a single prediction and associated probability or confidence is delivered.
- IBM SPSS Modeler restricts the number of fields that can be used in model building and scoring to 1,000.
- IBM SPSS Modeler can score ODM models from within streams published for execution by using IBM SPSS Modeler Solution Publisher.

Oracle Models Server Options

Specify the Oracle connection that is used to upload data for modeling. If necessary, you can select a connection on the Server tab for each modeling node to override the default Oracle connection specified in the Helper Applications dialog box. See the topic [Enabling Integration with Oracle](#) for more information.

Comments

- The connection used for modeling may or may not be the same as the connection used in the source node for a stream. For example, you might have a stream that accesses data from one Oracle database, downloads the data to IBM® SPSS® Modeler for cleaning or other manipulations, and then uploads the data to a different Oracle database for modeling purposes.
- The ODBC data source name is effectively embedded in each IBM SPSS Modeler stream. If a stream that is created on one host is executed on a different host, the name of the data source must be the same on each host. Alternatively, a different data source can be selected on the Server tab in each source or modeling node.

Misclassification Costs

In some contexts, certain kinds of errors are more costly than others. For example, it may be more costly to classify a high-risk credit applicant as low risk (one kind of error) than it is to classify a low-risk applicant as high risk (a different kind of error). Misclassification costs allow you to specify the relative importance of different kinds of prediction errors.

Misclassification costs are basically weights applied to specific outcomes. These weights are factored into the model and may actually change the prediction (as a way of protecting against costly mistakes).

With the exception of C5.0 models, misclassification costs are not applied when scoring a model and are not taken into account when ranking or comparing models using an Auto Classifier node, evaluation chart, or Analysis node. A model that includes costs may not produce fewer errors than one that doesn't and may not rank any higher in terms of overall accuracy, but it is likely to perform better in practical terms because it has a built-in bias in favor of *less expensive* errors.

The cost matrix shows the cost for each possible combination of predicted category and actual category. By default, all misclassification costs are set to 1.0. To enter custom cost values, select Use misclassification costs and enter your custom values into the cost matrix.

To change a misclassification cost, select the cell corresponding to the desired combination of predicted and actual values, delete the existing contents of the cell, and enter the desired cost for the cell. Costs are not automatically symmetrical. For example, if you set the cost of misclassifying *A* as *B* to be 2.0, the cost of misclassifying *B* as *A* will still have the default value of 1.0 unless you explicitly change it as well.

Note: Only the Decision Trees model allows costs to be specified at build time.

Oracle Naive Bayes

Naive Bayes is a well-known algorithm for classification problems. The model is termed *naïve* because it treats all proposed prediction variables as being independent of one another. Naive Bayes is a fast, scalable algorithm that calculates conditional probabilities for combinations of attributes and the target attribute. From the training data, an independent probability is established. This probability gives the likelihood of each target class, given the occurrence of each value category from each input variable.

- Cross-validation is used to test model accuracy on the same data that were used to build the model. This is particularly useful when the number of cases available to build a model is small.
- The model output can be browsed in a matrix format. The numbers in the matrix are conditional probabilities that relate the predicted classes (columns) and predictor variable-value combinations (rows).

Naive Bayes Expert Options

When the model is built, individual predictor attribute values or value pairs are ignored unless there are enough occurrences of a given value or pair in the training data. The thresholds for ignoring values are specified as fractions based on the number of records in the training data.

Adjusting these thresholds may reduce noise and improve the model's ability to generalize to other datasets.

- **Singleton Threshold.** Specifies the threshold for a given predictor attribute value. The number of occurrences of a given value must equal or exceed the specified fraction or the value is ignored.
- **Pairwise Threshold.** Specifies the threshold for a given attribute and predictor value pair. The number of occurrences of a given value pair must equal or exceed the specified fraction or the pair is ignored.

Prediction probability. Allows the model to include the probability of a correct prediction for a possible outcome of the target field. To enable this feature, choose Select, click the Specify button, choose one of the possible outcomes, and then click Insert.

Use Prediction Set. Generates a table of all the possible results for all possible outcomes of the target field.

Oracle Adaptive Bayes

Adaptive Bayes Network (ABN) constructs Bayesian Network classifiers by using Minimum Description Length (MDL) and automatic feature selection. ABN does well in certain situations where Naive Bayes does poorly and does at least as well in most other situations, although performance may be slower. The ABN algorithm provides the ability to build three types of advanced, Bayesian-based models, including simplified decision tree (single-feature), pruned Naive Bayes, and boosted multifeature models.

Note: The Oracle Adaptive Bayes algorithm has been dropped in Oracle 12C and is not supported in IBM® SPSS® Modeler when using Oracle 12C. See http://docs.oracle.com/database/121/DMPRG/release_changes.htm#DMPRG726.

Generated Models

In single-feature build mode, ABN produces a simplified decision tree, based on a set of human-readable rules, that allows the business user or analyst to understand the basis of the model's predictions and act or explain to others accordingly. This may be a significant advantage over Naive Bayes and multifeature models. These rules can be browsed like a standard rule set in IBM SPSS Modeler. A simple set of rules might look like this:

```
IF MARITAL_STATUS = "Married"  
AND EDUCATION_NUM = "13-16"
```

```
THEN CHURN= "TRUE"
Confidence = .78, Support = 570 cases
```

Pruned Naive Bayes and multifeature models cannot be browsed in IBM SPSS Modeler.

Adaptive Bayes Model Options

Model name. You can generate the model name automatically based on the target or ID field (or model type in cases where no such field is specified) or specify a custom name.

Use partitioned data. If a partition field is defined, this option ensures that data from only the training partition is used to build the model.

Unique field. Specifies the field used to uniquely identify each case. For example, this might be an ID field, such as *CustomerID*. IBM® SPSS® Modeler imposes a restriction that this key field must be numeric.

Note: This field is optional for all Oracle nodes except Oracle Adaptive Bayes, Oracle O-Cluster and Oracle Apriori.

Model Type

You can choose from three different modes for building the model.

- **Multi-feature.** Builds and compares a number of models, including an NB model and single and multifeature product probability models. This is the most exhaustive mode and typically takes the longest to compute as a result. Rules are produced only if the single feature model turns out to be best. If a multifeature or NB model is chosen, no rules are produced.
- **Single-feature.** Creates a simplified decision tree based on a set of rules. Each rule contains a condition together with probabilities associated with each outcome. The rules are mutually exclusive and are provided in a format that can be read by humans, which may be a significant advantage over Naive Bayes and multifeature models.
- **Naive Bayes.** Builds a single NB model and compares it with the global sample prior (the distribution of target values in the global sample). The NB model is produced as output only if it turns out to be a better predictor of the target values than the global prior. Otherwise, no model is produced as output.

Adaptive Bayes Expert Options

Limit execution time. Select this option to specify a maximum build time in minutes. This makes it possible to produce models in less time, although the resulting model may be less accurate. At each milestone in the modeling process, the algorithm checks whether it will be able to complete the next milestone within the specified amount of time before continuing and returns the best model available when the limit is reached.

Max Predictors. This option allows you to limit the complexity of the model and improve performance by limiting the number of predictors used. Predictors are ranked based on an MDL measure of their correlation to the target as a measure of their likelihood of being included in the model.

Max Naive Bayes Predictors. This option specifies the maximum number of predictors to be used in the Naive Bayes model.

Oracle Support Vector Machine (SVM)

Support Vector Machine (SVM) is a classification and regression algorithm that uses machine learning theory to maximize predictive accuracy without overfitting the data. SVM uses an optional nonlinear transformation of the training data, followed by the search for regression equations in the transformed data to separate the classes (for categorical targets) or fit the target (for continuous targets). Oracle's implementation of SVM allows models to be built by using one of two available kernels, linear or Gaussian. The linear kernel omits the nonlinear transformation altogether so that the resulting model is essentially a regression model.

For more information, see the *Oracle Data Mining Application Developer's Guide* and *Oracle Data Mining Concepts*.

Oracle SVM Model Options

Model name. You can generate the model name automatically based on the target or ID field (or model type in cases where no such field is specified) or specify a custom name.

Unique field. Specifies the field used to uniquely identify each case. For example, this might be an ID field, such as *CustomerID*. IBM® SPSS® Modeler imposes a restriction that this key field must be numeric.

Note: This field is optional for all Oracle nodes except Oracle Adaptive Bayes, Oracle O-Cluster and Oracle Apriori.

Auto Data Preparation. (11g only) Enables (default) or disables the automated data preparation mode of Oracle Data Mining. If this box is checked, ODM automatically performs the data transformations required by the algorithm. For more information, see *Oracle Data Mining Concepts*.

Active Learning. Provides a way to deal with large build sets. With active learning, the algorithm creates an initial model based on a small sample before applying it to the complete training dataset and then incrementally updates the sample and model based on the results. The cycle is repeated until the model converges on the training data or the maximum allowed number of support vectors is reached.

Kernel Function. Select Linear or Gaussian, or leave the default System Determined to allow the system to choose the most suitable kernel. Gaussian kernels are able to learn more complex relationships but generally take longer to compute. You may want to start with the linear kernel and try the Gaussian kernel only if the linear kernel fails to find a good fit. This is more likely to happen with a regression model, where the choice of kernel matters more. Also, note that SVM models built with the Gaussian kernel cannot be browsed in IBM SPSS Modeler. Models built with the linear kernel can be browsed in IBM SPSS Modeler in the same manner as standard regression models.

Normalization Method. Specifies the normalization method for continuous input and target fields. You can choose Z-Score, Min-Max, or None. Oracle performs normalization automatically if the Auto Data Preparation check box is selected. Uncheck this box to select the normalization method manually.

Oracle SVM Expert Options

Kernel Cache Size. Specifies, in bytes, the size of the cache to be used for storing computed kernels during the build operation. As might be expected, larger caches typically result in faster builds. The default is 50MB.

Convergence Tolerance. Specifies the tolerance value that is allowed before termination for the model build. The value must be between 0 and 1. The default value is 0.001. Larger values tend to result in faster building but less-accurate models.

Specify Standard Deviation. Specifies the standard deviation parameter used by the Gaussian kernel. This parameter affects the trade-off between model complexity and ability to generalize to other datasets (overfitting and underfitting the data). Higher standard deviation values favor underfitting. By default, this parameter is estimated from the training data.

Specify Epsilon. For regression models only, specifies the value of the interval of the allowed error in building epsilon-insensitive models. In other words, it distinguishes small errors (which are ignored) from large errors (which aren't). The value must be between 0 and 1. By default, this is estimated from the training data.

Specify Complexity Factor. Specifies the complexity factor, which trades off model error (as measured against the training data) and model complexity in order to avoid overfitting or underfitting the data. Higher values place a greater penalty on errors, with an increased risk of overfitting the data; lower values place a lower penalty on errors and can lead to underfitting.

Specify Outlier Rate. Specifies the desired rate of outliers in the training data. Only valid for One-Class SVM models. Cannot be used with the **Specify Complexity Factor** setting.

Prediction probability. Allows the model to include the probability of a correct prediction for a possible outcome of the target field. To enable this feature, choose Select, click the Specify button, choose one of the possible outcomes, and then click Insert.

Use Prediction Set. Generates a table of all the possible results for all possible outcomes of the target field.

Oracle SVM Weights Options

In a classification model, using weights enables you to specify the relative importance of the various possible target values. Doing so might be useful, for example, if the data points in your training data are not realistically distributed among the categories. Weights enable you to bias the model so that you can compensate for those categories that are less well represented in the data. Increasing the weight for a target value should increase the percentage of correct predictions for that category.

There are three methods of setting weights:

- Based on training data. This is the default. Weights are based on the relative frequencies of the categories in the training data.
- Equal for all classes. Weights for all categories are defined as $1/k$, where k is the number of target categories.
- Custom. You can specify your own weights. Starting values for weights are set as equal for all classes. You can adjust the weights for individual categories to user-defined values. To adjust a specific category's weight, select the Weight cell in the table corresponding to the desired category, delete the contents of the cell, and enter the desired value.

The weights for all categories should sum to 1.0. If they do not sum to 1.0, a warning is displayed, with an option to automatically normalize the values. This automatic adjustment preserves the proportions across categories while enforcing the weight constraint. You can perform this adjustment at any time by clicking the Normalize button. To reset the table to equal values for all categories, click the Equalize button.

Oracle Generalized Linear Models (GLM)

(11g only) Generalized linear models relax the restrictive assumptions made by linear models. These include, for example, the assumptions that the target variable has a normal distribution, and that the effect of the predictors on the target variable is linear in nature. A generalized linear model is suitable for predictions where the distribution of the target is likely to have a non-normal distribution, such as a multinomial or a Poisson distribution. Similarly, a generalized linear model is useful in cases where the relationship, or link, between the predictors and the target is likely to be non-linear.

For more information, see the *Oracle Data Mining Application Developer's Guide* and *Oracle Data Mining Concepts*.

Oracle GLM Model Options

Model name. You can generate the model name automatically based on the target or ID field (or model type in cases where no such field is specified) or specify a custom name.

Unique field. Specifies the field used to uniquely identify each case. For example, this might be an ID field, such as *CustomerID*. IBM® SPSS® Modeler imposes a restriction that this key field must be numeric.

Note: This field is optional for all Oracle nodes except Oracle Adaptive Bayes, Oracle O-Cluster and Oracle Apriori.

Auto Data Preparation. (11g only) Enables (default) or disables the automated data preparation mode of Oracle Data Mining. If this box is checked, ODM automatically performs the data transformations required by the algorithm. For more information, see *Oracle Data Mining Concepts*.

Normalization Method. Specifies the normalization method for continuous input and target fields. You can choose Z-Score, Min-Max, or None. Oracle performs normalization automatically if the Auto Data Preparation check box is selected. Uncheck this box to select the normalization method manually.

Missing Value Handling. Specifies how to process missing values in the input data:

- Replace with mean or mode replaces missing values of numerical attributes with the mean value, and replaces missing values of categorical attributes with the mode.
 - Only use complete records ignores records with missing values.
-

Oracle GLM Expert Options

Use Row Weights. Check this box to activate the adjacent drop-down list, from where you can select a column that contains a weighting factor for the rows.

Save Row Diagnostics to Table. Check this box to activate the adjacent text field, where you can enter the name of a table to contain row-level diagnostics.

Coefficient Confidence Level. The degree of certainty, from 0.0 to 1.0, that the value predicted for the target will lie within a confidence interval computed by the model. Confidence bounds are returned with the coefficient statistics.

Reference Category for Target. Select Custom to choose a value for the target field to use as a reference category, or leave the default value Auto.

Ridge Regression. Ridge regression is a technique that compensates for the situation where there is too high a degree of correlation in the variables. You can use the Auto option to allow the algorithm to control the use of this technique, or you can control it manually by means of the Disable and Enable options. If you choose to enable ridge regression manually, you can override the system default value for the ridge parameter by entering a value in the adjacent field.

Produce VIF for Ridge Regression. Check this box if you want to produce Variance Inflation Factor (VIF) statistics when ridge is being used for linear regression.

Prediction probability. Allows the model to include the probability of a correct prediction for a possible outcome of the target field. To enable this feature, choose Select, click the Specify button, choose one of the possible outcomes, and then click Insert.

Use Prediction Set. Generates a table of all the possible results for all possible outcomes of the target field.

Oracle GLM Weights Options

In a classification model, using weights enables you to specify the relative importance of the various possible target values. Doing so might be useful, for example, if the data points in your training data are not realistically distributed among the categories. Weights enable you to bias the model so that you can compensate for those categories that are less well represented in the data. Increasing the weight for a target value should increase the percentage of correct predictions for that category.

There are three methods of setting weights:

- Based on training data. This is the default. Weights are based on the relative frequencies of the categories in the training data.
- Equal for all classes. Weights for all categories are defined as $1/k$, where k is the number of target categories.
- Custom. You can specify your own weights. Starting values for weights are set as equal for all classes. You can adjust the weights for individual categories to user-defined values. To adjust a specific category's weight, select the Weight cell in the table corresponding to the desired category, delete the contents of the cell, and enter the desired value.

The weights for all categories should sum to 1.0. If they do not sum to 1.0, a warning is displayed, with an option to automatically normalize the values. This automatic adjustment preserves the proportions across categories while enforcing the weight constraint. You can perform this adjustment at any time by clicking the Normalize button. To reset the table to equal values for all categories, click the Equalize button.

Oracle Decision Tree

Oracle Data Mining offers a classic Decision Tree feature, based on the popular Classification and Regression Tree algorithm. The ODM Decision Tree model contains complete information about each node, including Confidence, Support, and Splitting Criterion. The full Rule for each node can be displayed, and in addition, a surrogate attribute is supplied for each node, to be used as a substitute when applying the model to a case with missing values.

Decision trees are popular because they are so universally applicable, easy to apply and easy to understand. Decision trees sift through each potential input attribute searching for the best “splitter,” that is, attribute cutpoint (`AGE > 55`, for example) that splits the downstream data records into more homogeneous populations. After each split decision, ODM repeats the process growing out the entire tree and creating terminal “leaves” that represent similar populations of records, items, or people. Looking down from the root tree node (for example, the total population), decision trees provide human readable rules of `IF A, then B` statements. These decision tree rules also provide the support and confidence for each tree node.

While Adaptive Bayes Networks can also provide short simple rules that can be useful in providing explanations for each prediction, Decision Trees provide full Oracle Data Mining rules for each splitting decision. Decision Trees are also useful for developing detailed profiles of the best customers, healthy patients, factors associated with fraud, and so on.

Decision Tree Model Options

Model name. You can generate the model name automatically based on the target or ID field (or model type in cases where no such field is specified) or specify a custom name.

Unique field. Specifies the field used to uniquely identify each case. For example, this might be an ID field, such as *CustomerID*. IBM® SPSS® Modeler imposes a restriction that this key field must be numeric.

Note: This field is optional for all Oracle nodes except Oracle Adaptive Bayes, Oracle O-Cluster and Oracle Apriori.

Auto Data Preparation. (11g only) Enables (default) or disables the automated data preparation mode of Oracle Data Mining. If this box is checked, ODM automatically performs the data transformations required by the algorithm. For more information, see *Oracle Data Mining Concepts*.

Impurity metric. Specifies which metric is used for seeking the best test question for splitting data at each node. The best splitter and split value are those that result in the largest increase in target value homogeneity for the entities in the node. Homogeneity is measured in accordance with a metric. The supported metrics are **gini** and **entropy**.

Decision Tree Expert Options

Maximum Depth. Sets the maximum depth of the tree model to be built.

Minimum percentage of records in a node. Sets the percentage of the minimum number of records per node.

Minimum percentage of records for a split. Sets the minimum number of records in a parent node expressed as a percent of the total number of records used to train the model. No split is attempted if the number of records is below this percentage.

Minimum records in a node. Sets the minimum number of records returned.

Minimum records for a split. Sets the minimum number of records in a parent node expressed as a value. No split is attempted if the number of records is below this value.

Rule identifier. If checked, includes in the model a string to identify the node in the tree at which a particular split is made.

Prediction probability. Allows the model to include the probability of a correct prediction for a possible outcome of the target field. To enable this feature, choose Select, click the Specify button, choose one of the possible outcomes, and then click Insert.

Use Prediction Set. Generates a table of all the possible results for all possible outcomes of the target field.

Oracle O-Cluster

The Oracle O-Cluster algorithm identifies naturally occurring groupings within a data population. Orthogonal partitioning clustering (O-Cluster) is an Oracle proprietary clustering algorithm that creates a hierarchical grid-based clustering model, that is, it creates axis-parallel (orthogonal) partitions in the input attribute space. The algorithm operates recursively. The resulting hierarchical structure represents an irregular grid that tessellates the attribute space into clusters.

The O-Cluster algorithm handles both numeric and categorical attributes and ODM will automatically select the best cluster definitions. ODM provides cluster detail information, cluster rules, cluster centroid values, and can be used to score a population on their cluster membership.

Oracle k-Means

The Oracle k-Means algorithm identifies naturally occurring groupings within a data population. The k-Means algorithm is a distance-based clustering algorithm that partitions the data into a predetermined number of clusters (provided there are enough distinct cases). Distance-based algorithms rely on a distance metric (function) to measure the similarity between data points. Data points are assigned to the nearest cluster according to the distance metric used. ODM provides an enhanced version of k-Means.

The k-Means algorithm supports hierarchical clusters, handles numeric and categorical attributes, and cuts the population into the user-specified number of clusters. ODM provides cluster detail information, cluster rules, cluster centroid values, and can be used to score a population on their cluster membership.

k-Means Expert Options

Iterations. Sets the number of iterations for the k-Means algorithm.

Convergence tolerance. Sets the convergence tolerance for the k-Means algorithm.

Number of bins. Specifies the number of bins in the attribute histogram produced by k-Means. The bin boundaries for each attribute are computed globally on the entire training dataset. The binning method is equi-width. All attributes have the same number of bins with the exception of attributes with a single value that have only one bin.

Block growth. Sets the growth factor for memory allocated to hold cluster data.

Minimum Percent Attribute Support. Sets the fraction of attribute values that must be non-null in order for the attribute to be included in the rule description for the cluster. Setting the parameter value too high in data with missing values can result in very short or even empty rules.

Oracle Nonnegative Matrix Factorization (NMF)

Nonnegative Matrix Factorization (NMF) is useful for reducing a large dataset into representative attributes. Similar to Principal Components Analysis (PCA) in concept, but able to handle larger amounts of attributes and in an additive representation model, NMF is a powerful, state-of-the-art data mining algorithm that can be used for a variety of use cases.

NMF can be used to reduce large amounts of data, text data for example, into smaller, more sparse representations that reduce the dimensionality of the data (the same information can be preserved using far fewer variables). The output of NMF models can be analyzed using supervised learning techniques such as SVMs or unsupervised learning techniques such as clustering techniques. Oracle Data Mining uses NMF and SVM algorithms to mine unstructured text data.

Oracle Apriori

The Apriori algorithm discovers association rules in data. For example, "if a customer purchases a razor and after shave, then that customer will purchase shaving cream with 80% confidence." The association mining problem can be decomposed into two subproblems:

- Find all combinations of items, called frequent itemsets, whose support is greater than the minimum support.
- Use the frequent itemsets to generate the desired rules. The idea is that if, for example, ABC and BC are frequent, then the rule "A implies BC" holds if the ratio of **support (ABC)** to **support (BC)** is at least as large as the minimum confidence. Note that the rule will have minimum support because ABCD is frequent. ODM Association only supports single consequent rules (ABC implies D).

The number of frequent itemsets is governed by the minimum support parameters. The number of rules generated is governed by the number of frequent itemsets and the confidence parameter. If the confidence parameter is set too high, there may be frequent itemsets in the association model but no rules.

ODM uses an SQL-based implementation of the Apriori algorithm. The candidate generation and support counting steps are implemented using SQL queries. Specialized in-memory data structures are not used. The SQL queries are fine-tuned to run efficiently in the database server by using various hints.

Apriori Fields Options

All modeling nodes have a Fields tab, where you can specify the fields to be used in building the model.

Before you can build an Apriori model, you need to specify which fields you want to use as the items of interest in association modeling.

Use type node settings. This option tells the node to use field information from an upstream Type node. This is the default.

Use custom settings. This option tells the node to use field information specified here instead of that given in any upstream Type node(s). After selecting this option, specify the remaining fields on the dialog, which depend on whether you are using transactional format.

If you are *not* using transactional format, specify:

- **Inputs.** Select the input field(s). This is similar to setting a field role to *Input* in a Type node.
- **Partition.** This field allows you to specify a field used to partition the data into separate samples for the training, testing, and validation stages of model building.

If you are using transactional format, specify:

Use transactional format. Use this option if you want to transform data from a row per item, to a row per case.

Selecting this option changes the field controls in the lower part of this dialog box:

For transactional format, specify:

- **ID.** Select an ID field from the list. Numeric or symbolic fields can be used as the ID field. Each unique value of this field should indicate a specific unit of analysis. For example, in a market basket application, each ID might represent a single customer. For a Web log analysis application, each ID might represent a computer (by IP address) or a user (by login data).
- **Content.** Specify the content field for the model. This field contains the item of interest in association modeling.
- **Partition.** This field allows you to specify a field used to partition the data into separate samples for the training, testing, and validation stages of model building. By using one sample to create the model and a different sample to test it, you can get a good indication of how well the model will generalize to larger datasets that are similar to the current data. If multiple partition fields have been defined by using Type or Partition nodes, a single partition field must be selected on the Fields tab in each modeling node that uses partitioning. (If only one partition is present, it is automatically used whenever partitioning is enabled.) Also note that to apply the selected partition in your analysis, partitioning must also be enabled in the Model Options tab for the node. (Deselecting this option makes it possible to disable partitioning without changing field settings.)

Apriori Model Options

Model name. You can generate the model name automatically based on the target or ID field (or model type in cases where no such field is specified) or specify a custom name.

Unique field. Specifies the field used to uniquely identify each case. For example, this might be an ID field, such as *CustomerID*. IBM® SPSS® Modeler imposes a restriction that this key field must be numeric.

Note: This field is optional for all Oracle nodes except Oracle Adaptive Bayes, Oracle O-Cluster and Oracle Apriori.

Auto Data Preparation. (11g only) Enables (default) or disables the automated data preparation mode of Oracle Data Mining. If this box is checked, ODM automatically performs the data transformations required by the algorithm. For more information, see *Oracle Data Mining Concepts*.

Maximum rule length. Sets the maximum number of preconditions for any rule, an integer from 2 to 20. This is a way to limit the complexity of the rules. If the rules are too complex or too specific, or if your rule set is taking too long to train, try decreasing this setting.

Minimum confidence. Sets the minimum confidence level, a value between 0 and 1. Rules with lower confidence than the specified criterion are discarded.

Minimum support. Sets the minimum support threshold, a value between 0 and 1. Apriori discovers patterns with frequency above the minimum support threshold.

Oracle Minimum Description Length (MDL)

The Oracle Minimum Description Length (MDL) algorithm helps to identify the attributes that have the greatest influence on a target attribute. Oftentimes, knowing which attributes are most influential helps you to better understand and manage your business and can help simplify modeling activities. Additionally, these attributes can indicate the types of data you may wish to add to augment your models. MDL might be used, for example, to find the process attributes most relevant to predicting the quality of a manufactured part, the factors associated with churn, or the genes most likely involved in the treatment of a particular disease.

Oracle MDL discards input fields that it regards as unimportant in predicting the target. With the remaining input fields it then builds an unrefined model nugget that is associated with an Oracle model, visible in Oracle Data Miner. Browsing the model in Oracle Data Miner displays a chart showing the remaining input fields, ranked in order of their significance in predicting the target.

Negative ranking indicates noise. Input fields ranked at zero or less do not contribute to the prediction and should probably be removed from the data.

To display the chart

1. Right-click on the unrefined model nugget in the Models palette and choose Browse.
2. From the model window, click the button to launch Oracle Data Miner.
3. Connect to Oracle Data Miner. See the topic [Oracle Data Miner](#) for more information.
4. In the Oracle Data Miner navigator panel, expand Models, then Attribute Importance.
5. Select the relevant Oracle model (it will have the same name as the target field you specified in IBM® SPSS® Modeler). If you are not sure which is the correct one, select the Attribute Importance folder and look for a model by creation date.

Oracle Attribute Importance (AI)

The objective of attribute importance is to find out which attributes in the data set are related to the result, and the degree to which they influence the final outcome. The Oracle Attribute Importance node analyzes data, finds patterns, and predicts outcomes or results with an associated level of confidence.

AI Selection Options

The Options tab allows you to specify the default settings for selecting or excluding input fields in the model nugget. You can then add the model to a stream to select a subset of fields for use in subsequent model-building efforts. Alternatively, you can override these settings by selecting or deselecting additional fields in the model browser after generating the model. However, the default settings make it possible to apply the model nugget without further changes, which may be particularly useful for scripting purposes.

The following options are available:

All fields ranked. Selects fields based on their ranking as *important*, *marginal*, or *unimportant*. You can edit the label for each ranking as well as the cutoff values used to assign records to one rank or another.

Top number of fields. Selects the top *n* fields based on importance.

Importance greater than. Selects all fields with importance greater than the specified value.

The target field is always preserved regardless of the selection.

AI Model Nugget Model Tab

The Model tab for an Oracle AI model nugget displays the rank and importance of all inputs, and allows you to select fields for filtering by using the check boxes in the column on the left. When you run the stream, only the checked fields are preserved, together with the target prediction.

The other input fields are discarded. The default selections are based on the options specified in the modeling node, but you can select or deselect additional fields as needed.

- To sort the list by rank, field name, importance, or any of the other displayed columns, click on the column header. Alternatively, select the desired item from the list next to the Sort By button, and use the up and down arrows to change the direction of the sort.
- You can use the toolbar to check or uncheck all fields and to access the Check Fields dialog box, which allows you to select fields by rank or importance. You can also press the Shift or Ctrl keys while clicking on fields to extend the selection.
- The threshold values for ranking inputs as important, marginal, or unimportant are displayed in the legend below the table. These values are specified in the modeling node.

Managing Oracle Models

Oracle models are added to the Models palette just like other IBM® SPSS® Modeler models and can be used in much the same way. However, there are a few important differences, given that each Oracle model created in IBM SPSS Modeler actually references a model stored on a database server.

Oracle Model Nugget Server Tab

Building an ODM model via IBM® SPSS® Modeler creates a model in IBM SPSS Modeler and creates or replaces a model in the Oracle database. An IBM SPSS Modeler model of this kind references the content of a database model stored on a database server. IBM SPSS Modeler can perform consistency checking by storing an identical generated **model key** string in both the IBM SPSS Modeler model and the Oracle model.

The key string for each Oracle model is displayed under the *Model Information* column in the List Models dialog box. The key string for an IBM SPSS Modeler model is displayed as the Model Key on the Server tab of an IBM SPSS Modeler model (when placed into a stream).

The Check button on the Server tab of a model nugget can be used to check that the model keys in the IBM SPSS Modeler model and the Oracle model match. If no model of the same name can be found in Oracle or if the model keys do not match, the Oracle model has been deleted or rebuilt since the IBM SPSS Modeler model was built.

Oracle Model Nugget Summary Tab

The Summary tab of a model nugget displays information about the model itself (*Analysis*), fields used in the model (*Fields*), settings used when building the model (*Build Settings*), and model training (*Training Summary*).

When you first browse the node, the Summary tab results are collapsed. To see the results of interest, use the expander control to the left of an item to unfold it or click the Expand All button to show all results. To hide the results when you have finished viewing them, use the expander control to collapse the specific results you want to hide or click the Collapse All button to collapse all results.

Analysis. Displays information about the specific model. If you have executed an Analysis node attached to this model nugget, information from that analysis will also appear in this section.

Fields. Lists the fields used as the target and the inputs in building the model.

Build Settings. Contains information about the settings used in building the model.

Training Summary. Shows the type of model, the stream used to create it, the user who created it, when it was built, and the elapsed time for building the model.

Listing Oracle Models

The List Oracle Data Mining Models button launches a dialog box that lists the existing database models and allows models to be removed. This dialog box can be launched from the Helper Applications dialog box and from the build, browse, and apply dialog boxes for ODM-related nodes.

The following information is displayed for each model:

- **Model Name.** Name of the model, which is used to sort the list
- **Model Information.** Model key information composed of build date/time and target column name
- **Model Type.** Name of the algorithm that built this model

Oracle Data Miner

Oracle Data Miner is the user interface to Oracle Data Mining (ODM) and replaces the previous IBM® SPSS® Modeler user interface to ODM. Oracle Data Miner is designed to increase the analyst's success rate in properly utilizing ODM algorithms. These goals are addressed in several ways:

- Users need more assistance in applying a methodology that addresses both data preparation and algorithm selection. Oracle Data Miner meets this need by providing Data Mining Activities to step users through the proper methodology.
- Oracle Data Miner includes improved and expanded heuristics in the model building and transformation wizards to reduce the chance of error in specifying model and transformation settings.

Defining an Oracle Data Miner Connection

1. Oracle Data Miner can be launched from all Oracle build, apply nodes, and output dialog boxes via the **Launch Oracle Data Miner** button.

Figure 1. Launch Oracle Data Miner Button

2. The Oracle Data Miner **Edit Connection** dialog box is presented to the user before the Oracle Data Miner external application is launched (provided the Helper Application option is properly defined).

Note: This dialog box only displays in the absence of a defined connection name.

- Provide a Data Miner connection name and enter the appropriate Oracle 10gR1 or 10gR2 server information. The Oracle server should be the same server specified in IBM SPSS Modeler.

3. The Oracle Data Miner **Choose Connection** dialog box provides options for specifying which connection name, defined in the above step, is used.

Refer to [Oracle Data Miner](#) on the Oracle Web site for more information regarding Oracle Data Miner requirements, installation, and usage.

Preparing the Data

Two types of data preparation may be useful when you are using the Naive Bayes, Adaptive Bayes, and Support Vector Machine provided with Oracle Data Mining algorithms in modeling:

- **Binning**, or conversion of continuous numeric range fields to categories for algorithms that cannot accept continuous data.
- **Normalization**, or transformations applied to numeric ranges so that they have similar means and standard deviations.

Binning

IBM® SPSS® Modeler's Binning node offers a number of techniques for performing binning operations. A binning operation is defined that can be applied to one or many fields. Executing the binning operation on a dataset creates the thresholds and allows an IBM SPSS Modeler Derive node to be created. The derive operation can be converted to SQL and applied prior to model building and scoring. This approach creates a dependency between the model and the Derive node that performs the binning but allows the binning specifications to be reused by multiple modeling tasks.

Normalization

Continuous (numeric range) fields that are used as inputs to Support Vector Machine models should be normalized prior to model building. In the case of regression models, normalization must also be reversed to reconstruct the score from the model output. The SVM model settings allow you to choose Z-Score, Min-Max, or None. The normalization coefficients are constructed by Oracle as a step in the model-building process, and the coefficients are uploaded to IBM SPSS Modeler and stored with the model. At apply time, the coefficients are converted into IBM SPSS Modeler derive expressions and used to prepare the data for scoring before passing the data to the model. In this case, normalization is closely associated with the modeling task.

Oracle Data Mining Examples

A number of sample streams are included that demonstrate the use of ODM with IBM® SPSS® Modeler. These streams can be found in the IBM SPSS Modeler installation folder under `|Demos|Database_Modelling|Oracle Data Mining|`.

Note: The Demos folder can be accessed from the IBM SPSS Modeler program group on the Windows Start menu.

The streams in the following table can be used together in sequence as an example of the database mining process, using the Support Vector Machine (SVM) algorithm that is provided with Oracle Data Mining:

Table 1. Database mining - example streams

Stream	Description
<code>1_upload_data.str</code>	Used to clean and upload data from a flat file into the database.
<code>2_explore_data.str</code>	Provides an example of data exploration with IBM SPSS Modeler
<code>3_build_model.str</code>	Builds the model using the database-native algorithm.
<code>4_evaluate_model.str</code>	Used as an example of model evaluation with IBM SPSS Modeler
<code>5_deploy_model.str</code>	Deploys the model for in-database scoring.

Note: In order to run the example, streams must be executed in order. In addition, source and modeling nodes in each stream must be updated to reference a valid data source for the database you want to use.

The dataset used in the example streams concerns credit card applications and presents a classification problem with a mixture of categorical and continuous predictors. For more information about this dataset, see the `crx.names` file in the same folder as the sample streams.

This dataset is available from the UCI Machine Learning Repository at <ftp://ftp.ics.uci.edu/pub/machine-learning-databases/credit-screening/>.

Example Stream: Upload Data

The first example stream, `1_upload_data.str`, is used to clean and upload data from a flat file into Oracle.

Since Oracle Data Mining requires a unique ID field, this initial stream uses a Derive node to add a new field to the dataset called `ID`, with unique values 1,2,3, using the IBM® SPSS® Modeler @INDEX function.

The Filler node is used for missing-value handling and replaces empty fields that are read from the text file `crx.data` with `NULL` values.

Example Stream: Explore Data

The second example stream, *2_explore_data.str*, is used to demonstrate use of a Data Audit node to gain a general overview of the data, including summary statistics and graphs.

Double-clicking a graph in the Data Audit Report produces a more detailed graph for deeper exploration of a given field.

Example Stream: Build Model

The third example stream, *3_build_model.str*, illustrates model building in IBM® SPSS® Modeler. Double-click the Database source node (labeled CREDIT) to specify the data source. To specify build settings, double-click the build node (initially labeled CLASS, which changes to FIELD16 when the data source is specified).

On the Model tab of the dialog box:

1. Ensure that ID is selected as the Unique field.
2. Ensure that Linear is selected as the kernel function and Z-Score is the normalization method.

-

Example Stream: Evaluate Model

The fourth example stream, *4_evaluate_model.str*, illustrates the advantages of using IBM® SPSS® Modeler for in-database modeling. Once you have executed the model, you can add it back to your data stream and evaluate the model by using several tools offered in IBM SPSS Modeler.

Viewing Modeling Results

Attach a Table node to the model nugget to explore your results. The \$O-field16 field shows the predicted value for *field16* in each case, and the \$OC-field16 field shows the confidence value for this prediction.

Evaluating Model Results

You can use the Analysis node to create a coincidence matrix showing the pattern of matches between each predicted field and its target field. Run the Analysis node to see the results.

You can use the Evaluation node to create a gains chart designed to show accuracy improvements made by the model. Run the Evaluation node to see the results.

SPSS Modeler with IBM Data Warehouse and IBM Netezza Analytics

IBM® SPSS® Modeler supports integration with IBM Data Warehouse and IBM Netezza® Analytics, which provides the ability to run advanced analytics on those IBM servers. These features can be accessed through the IBM SPSS Modeler graphical user interface and workflow-oriented development environment, allowing you to run the data mining algorithms directly in the IBM Netezza or IBM Data Warehouse environment.

SPSS Modeler supports integration of the following algorithms from **IBM Netezza Analytics**:

- Decision Trees
- K-Means
- TwoStep
- Bayes Net
- Naive Bayes
- KNN
- Divisive Clustering
- PCA
- Regression Tree
- Linear Regression
- Time Series
- Generalized Linear

For more information about these algorithms, see the *IBM Netezza Analytics Developer's Guide* and the *IBM Netezza Analytics Reference Guide*.

SPSS Modeler supports integration of the following algorithms from **IBM Data Warehouse** (Bayes Net, Divisive Clustering, and Time Series are not supported):

- Decision Trees
- K-Means
- TwoStep
- Naive Bayes
- KNN
- PCA
- Regression Tree
- Linear Regression
- Generalized Linear

Note: AIX isn't supported.

Integration requirements

The following conditions are prerequisites for conducting in-database modeling using IBM® Netezza® Analytics or IBM Data Warehouse. You may need to consult with your database administrator to ensure that these conditions are met.

- IBM SPSS® Modeler running against an IBM SPSS Modeler Server installation on Windows or UNIX (except zLinux, for which IBM Netezza ODBC drivers are not available).
- IBM Netezza Performance Server, running the IBM Netezza Analytics package.

Note: The minimum version of Netezza Performance Server (NPS) that is required depends on the version of INZA that is required and is as follows:

- Anything greater than NPS 6.0.0 P8 will support INZA versions prior to 2.0.
- To use INZA 2.0 or greater requires NPS 6.0.5 P5 or greater.

Netezza Generalized Linear and Netezza Time Series require INZA 2.0 and above to be functional. All the other Netezza In-Database nodes need INZA 1.1 or later.

- An ODBC data source for connecting to an IBM Netezza database. See the topic [Enabling integration](#) for more information.
- An ODBC data source for connecting to an IBM Data Warehouse database.

- SQL generation and optimization enabled in IBM SPSS Modeler. See the topic [Enabling integration](#) for more information.

Note: Database modeling and SQL optimization require that IBM SPSS Modeler Server connectivity be enabled on the IBM SPSS Modeler computer. With this setting enabled, you can access database algorithms, push back SQL directly from IBM SPSS Modeler, and access IBM SPSS Modeler Server. To verify the current license status, choose the following from the IBM SPSS Modeler menu.
Help>About>Additional Details

If connectivity is enabled, you see the option Server Enablement in the License Status tab.

See [Connecting to IBM SPSS Modeler Server](#) for more information.

Enabling integration

Enabling integration with IBM® Netezza® Analytics or IBM Data Warehouse consists of the following steps.

- Configuring IBM Netezza Analytics or IBM Data Warehouse
- Creating an ODBC source
- Enabling the integration in IBM SPSS® Modeler
- Enabling SQL generation and optimization in IBM SPSS Modeler

These are described in the sections that follow.

- [Configuring IBM Netezza Analytics or IBM Data Warehouse](#)
- [Creating an ODBC Source for IBM Netezza Analytics](#)
- [Enabling integration in SPSS Modeler](#)
- [Enabling SQL Generation and Optimization](#)

Configuring IBM Netezza Analytics or IBM Data Warehouse

To install and configure IBM® Netezza® Analytics or IBM Data Warehouse, refer to the appropriate IBM documentation. For example, for IBM Netezza Analytics, see the *IBM Netezza Analytics Installation Guide* provided with that product. The section *Setting Database Permissions* in that guide contains details of scripts that need to be run to allow IBM SPSS® Modeler streams to write to the database.

Note: If you will be using nodes that rely on matrix calculation, the Matrix Engine must be initialized by running `CALL NZM..INITIALIZE()`; otherwise execution of stored procedures will fail. Initialization is a one-time setup step for each database.

Creating an ODBC Source for IBM Netezza® Analytics

To enable the connection between the IBM Netezza database and IBM® SPSS® Modeler, you need to create an ODBC system data source name (DSN).

Before creating a DSN, you should have a basic understanding of ODBC data sources and drivers, and database support in IBM SPSS Modeler.

If you are running in distributed mode against IBM SPSS Modeler Server, create the DSN on the server computer. If you are running in local (client) mode, create the DSN on the client computer.

Windows clients

1. From your *Netezza Client* CD, run the *nzodbcsetup.exe* file to start the installer. Follow the on-screen instructions to install the driver. For full instructions, see the *IBM Netezza ODBC, JDBC, and OLE DB Installation and Configuration Guide*.
 - a. Create the DSN.
Note: The menu sequence depends on your version of Windows.
 - Windows XP. From the Start menu, choose Control Panel. Double-click Administrative Tools, and then double-click Data Sources (ODBC).
 - Windows Vista. From the Start menu, choose Control Panel, then System Maintenance. Double-click Administrative Tools, selectData Sources (ODBC), then click Open.
 - Windows 7. From the Start menu, choose Control Panel, then System & Security, then Administrative Tools. SelectData Sources (ODBC), then click Open.
 - b. Go to the System DSN tab, and then click Add.
2. Select *NetezzaSQL* from the list and click Finish.
3. On the DSN Options tab of the Netezza ODBC Driver Setup screen, type a data source name of your choosing, the hostname or IP address of the IBM Netezza server, the port number for the connection, the database of the IBM Netezza instance you are using, and your

- username and password details for the database connection. Click the Help button for an explanation of the fields.
4. Click the Test Connection button and ensure that you can connect to the database.
 5. When you have a successful connection, click OK repeatedly to exit from the ODBC Data Source Administrator screen.

Windows servers

The procedure for Windows Server is the same as the client procedure for Windows XP.

UNIX or Linux servers

The following procedure applies to UNIX or Linux servers (except zLinux, for which IBM Netezza ODBC drivers are not available).

1. From your Netezza Client CD/DVD, copy the relevant <platform>.cli.package.tar.gz file to a temporary location on the server.
2. Extract the archive contents by means of the **gunzip** and **tar** commands.
3. Add execute permissions to the *unpack* script that is extracted.
4. Run the script, answering the on-screen prompts.
5. Edit the modelersrv.sh file to include the following lines.

```
. <SDAP Install Path>/odbc.sh  
LD_LIBRARY_PATH_64=$LD_LIBRARY_PATH:/usr/local/nz/lib64; export LD_LIBRARY_PATH_64  
NZ_ODBC_INI_PATH=<SDAP Install Path>; export NZ_ODBC_INI_PATH
```

For example:

```
. /usr/IBM/SPSS/SDAP/odbc.sh  
LD_LIBRARY_PATH_64=$LD_LIBRARY_PATH:/usr/local/nz/lib64; export LD_LIBRARY_PATH_64  
NZ_ODBC_INI_PATH=/usr/IBM/SPSS/SDAP; export NZ_ODBC_INI_PATH
```

6. Locate the file /usr/local/nz/lib64/odbc.ini and copy its contents into the odbc.ini file that is installed with SDAP (the one defined by the \$ODBCINI environment variable).

Note: For 64-bit Linux systems, the Driver parameter incorrectly references the 32-bit driver. When you copy the odbc.ini contents in the previous step, edit the path within this parameter accordingly, for example:

```
/usr/local/nz/lib64/libnzodbc.so
```

7. Edit the parameters in the Netezza DSN definition to reflect the database to be used.
8. Restart IBM SPSS Modeler Server and test the use of the Netezza in-database mining nodes on the client.

Enabling integration in SPSS Modeler

1. From the IBM® SPSS® Modeler main menu, choose Tools->Options->Helper Applications.
2. Click the IBM Data Warehouse tab.

Enable IBM Data Warehouse Analytics Integration. Enables the Database Modeling palette (if not already displayed) at the bottom of the IBM SPSS Modeler window and adds the nodes for IBM Data Warehouse and Netezza Data Mining algorithms.

IBM Data Warehouse Connection. Click the Edit button and choose the IBM Data Warehouse connection string that you set up when creating the ODBC source. For more information, see the IBM Data Warehouse admin console.

Enabling SQL Generation and Optimization

Because of the likelihood of working with very large data sets, for performance reasons you should enable the SQL generation and optimization options in IBM® SPSS® Modeler.

1. From the IBM SPSS Modeler menus choose: Tools->Stream Properties->Options
2. Click the Optimization option in the navigation pane.
3. Confirm that the Generate SQL option is enabled. This setting is required for database modeling to function.
4. Select Optimize SQL Generation and Optimize other execution (not strictly required but strongly recommended for optimized performance).

Building models with IBM Netezza® Analytics and IBM Data Warehouse

Each of the supported algorithms has a corresponding modeling node. You can access the IBM Data Warehouse and IBM Netezza modeling nodes from the Database Modeling tab on the nodes palette.

Data considerations

Fields in the data source can contain variables of various data types, depending on the modeling node. In IBM® SPSS® Modeler, data types are known as *measurement levels*. The Fields tab of the modeling node uses icons to indicate the permitted measurement level types for its input and target fields.

Target field The target field is the field whose value you are trying to predict. Where a target can be specified, only one of the source data fields can be selected as the target field.

Record ID field Specifies the field used to uniquely identify each case. For example, this might be an ID field, such as *CustomerID*. If the source data does not include an ID field, you can create this field by means of a Derive node, as the following procedure shows.

1. Select the source node.
2. From the Field Ops tab on the nodes palette, double-click the Derive node.
3. Open the Derive node by double-clicking its icon on the canvas.
4. In the Derive field field, type (for example) **ID**.
5. In the Formula field, type **@INDEX** and click OK.
6. Connect the Derive node to the rest of the stream.

Note: If you retrieve long numeric data from a Netezza database by using the **NUMERIC(18, 0)** data type, SPSS Modeler can sometimes round up the data during import. To avoid this issue, store your data using either the **BIGINT**, or **NUMERIC(36, 0)** data type.

Note: Due to the limitations on the types of fields that can be used, a field with a typeless Measurement level and a role of Record ID does not appear in a Netezza In-Database modeling node (for example, K-Means).

Handling null values

If the input data contains null values, use of some Netezza nodes may result in error messages or long-running streams, so we recommend removing records containing null values. Use the following method.

1. Attach a Select node to the source node.
2. Set the Mode option of the Select node to Discard.
3. Enter the following in the Condition field:

```
@NULL(field1) [or @NULL(field2) [...] or @NULL(fieldN)]
```

Be sure to include every input field.

4. Connect the Select node to the rest of the stream.

Model output

It is possible for a stream containing a Data Warehouse or Netezza modeling node to produce slightly different results each time it is run. This is because the order in which the node reads the source data is not always the same, as the data is read into temporary tables before model building. However, the differences produced by this effect are negligible.

General comments

- In IBM SPSS Collaboration and Deployment Services, it is not possible to create scoring configurations using streams containing IBM Data Warehouse or IBM Netezza database modeling nodes.
- PMML export or import is not possible for models created by the Data Warehouse or Netezza nodes.
- [Field options](#)
- [Server options](#)
- [Model options](#)
- [Managing models](#)
- [Listing database models](#)

Field options

On the Fields tab, you choose whether you want to use the field role settings already defined in upstream nodes, or make the field assignments manually.

Use predefined roles. This option uses the role settings (targets, predictors and so on) from an upstream Type node (or the Types tab of an upstream source node).

Use custom field assignments. Choose this option if you want to assign targets, predictors and other roles manually on this screen.

Fields. Use the arrow buttons to assign items manually from this list to the various role fields on the right of the screen. The icons indicate the valid measurement levels for each role field.

Click the All button to select all the fields in the list, or click an individual measurement level button to select all fields with that measurement level.

Target. Choose one field as the target for the prediction. For Generalized Linear models, see also the Trials field on this screen.

Record ID. The field that is to be used as the unique record identifier.

Predictors (Inputs). Choose one or more fields as inputs for the prediction.

Server options

On the Server tab, you specify the IBM Data Warehouse database where the model is to be built.

IBM Data Warehouse Server Details. Here you specify the connection details for the database you want to use for the model.

- Use upstream connection. (default) Uses the connection details specified in an upstream node, for example the Database source node. This option works only if all upstream nodes are able to use SQL pushback. In this case there is no need to move the data out of the database, as the SQL fully implements all of the upstream nodes.
- Move data to connection. Moves the data to the database you specify here. Doing so allows modeling to work if the data is in another IBM Data Warehouse database, or a database from another vendor, or even if the data is in a flat file. In addition, data is moved back to the database specified here if the data has been extracted because a node did not perform SQL pushback. Click the Edit button to browse for and select a connection.

CAUTION:

IBM® Netezza® Analytics and IBM Data Warehouse is typically used with very large data sets. Transferring large amounts of data between databases, or out of and back into a database, can be very time-consuming and should be avoided where possible.

Note: The ODBC data source name is effectively embedded in each IBM SPSS® Modeler stream. If a stream that is created on one host is executed on a different host, the name of the data source must be the same on each host. Alternatively, a different data source can be selected on the Server tab in each source or modeling node.

Model options

On the Model Options tab, you can choose whether to specify a name for the model, or generate a name automatically. You can also set default values for scoring options.

Model name. You can generate the model name automatically based on the target or ID field (or model type in cases where no such field is specified) or specify a custom name.

Replace existing if the name has been used. If you select this check box, any existing model of the same name will be overwritten.

Make Available for Scoring. You can set the default values here for the scoring options that appear on the dialog for the model nugget. For details of the options, see the help topic for the Settings tab of that particular nugget.

Managing models

Building an IBM Netezza or IBM Data Warehouse model via SPSS® Modeler creates a model in SPSS Modeler and creates or replaces a model in the IBM Data Warehouse database. The SPSS Modeler model of this kind references the content of a database model stored on a database server. SPSS Modeler can perform consistency checking by storing an identical generated model key string in both the SPSS Modeler model and the Netezza or Data Warehouse model.

The model name for each Netezza or Data Warehouse model is displayed under the *Model Information* column in the Listing Database Models dialog box. The model name for an SPSS Modeler model is displayed as the Model Key on the Server tab of an SPSS Modeler model (when placed into a stream).

The Check button can be used to check that the model keys in the SPSS Modeler model and the Netezza or Data Warehouse model match. If no model of the same name can be found in Netezza or Data Warehouse, or if the model keys do not match, the Netezza or Data Warehouse model has been deleted or rebuilt since the SPSS Modeler model was built.

Listing database models

SPSS® Modeler provides a dialog box for listing the models that are stored in IBM Data Warehouse and enables models to be deleted. This dialog box is accessible from the IBM Helper Applications dialog box and from the build, browse, and apply dialog boxes for IBM Data Warehouse and IBM Netezza data mining-related nodes. The following information is displayed for each model:

- Model name (name of the model, which is used to sort the list).
 - Owner name.
 - The algorithm used in the model.
 - The current state of the model; for example, Complete.
 - The date on which the model was created.
-

IBM Data WH Regression Tree

A regression tree is a tree-based algorithm that splits a sample of cases repeatedly to derive subsets of the same kind, based on values of a numeric target field. As with decision trees, regression trees decompose the data into subsets in which the leaves of the tree correspond to sufficiently small or sufficiently uniform subsets. Splits are selected to decrease the dispersion of target attribute values, so that they can be reasonably well predicted by their mean values at leaves.

- [IBM Data WH Regression Tree Build Options - Tree Growth](#)
 - [IBM Data WH Tree Build Options - Tree Pruning](#)
-

IBM Data WH Regression Tree Build Options - Tree Growth

You can set build options for tree growth and tree pruning.

The following build options are available for tree growth:

Maximum tree depth. The maximum number of levels to which the tree can grow below the root node, that is, the number of times the sample is split recursively. The default is 62, which is the maximum tree depth for modeling purposes.

Note: If the viewer in the model nugget shows the textual representation of the model, a maximum of 12 levels of the tree is displayed.

Splitting Criteria. These options control when to stop splitting the tree. If you do not want to use the default values, click Customize and change the values.

- **Split evaluation measure.** This class evaluation measure evaluates the best place to split the tree.
Note: Currently, variance is the only possible option.
- **Minimum improvement for splits.** The minimum amount by which impurity must be reduced before a new split is created in the tree. The goal of tree building is to create subgroups with similar output values to minimize the impurity within each node. If the best split for a branch reduces the impurity by less than the amount that is specified by the splitting criteria, the branch is not split.
- **Minimum number of instances for a split.** The minimum number of records that can be split. When fewer than this number of unsplittable records remain, no further splits are made. You can use this field to prevent the creation of small subgroups in the tree.

Statistics. This parameter defines how many statistics are included in the model. Select one of the following options:

- **All.** All column-related statistics and all value-related statistics are included.
Note: This parameter includes the maximum number of statistics and might therefore affect the performance of your system. If you do not want to view the model in graphical format, specify None.
 - **Columns.** Column-related statistics are included.
 - **None.** Only statistics that are required to score the model are included.
-

IBM Data WH Tree Build Options - Tree Pruning

You can use the pruning options to specify pruning criteria for the regression tree. The intention of pruning is to reduce the risk of overfitting by removing overgrown subgroups that do not improve the expected accuracy on new data.

Pruning measure. The pruning measure ensures that the estimated accuracy of the model remains within acceptable limits after removing a leaf from the tree. You can select one of the following measures.

- **mse.** Mean squared error - (default) measures how close a fitted line is to the data points.
- **r2.** R-squared - measures the proportion of variation in the dependent variable explained by the regression model.
- **Pearson.** Pearson's correlation coefficient - measures the strength of relationship between linearly dependent variables that are normally distributed.
- **Spearman.** Spearman's correlation coefficient - detects nonlinear relationships that appear weak according to Pearson's correlation, but which may actually be strong.

Data for pruning. You can use some or all of the training data to estimate the expected accuracy on new data. Alternatively, you can use a separate pruning dataset from a specified table for this purpose.

- Use all training data. This option (the default) uses all the training data to estimate the model accuracy.
- Use % of training data for pruning. Use this option to split the data into two sets, one for training and one for pruning, using the percentage specified here for the pruning data.
Select Replicate results if you want to specify a random seed to ensure that the data is partitioned in the same way each time you run the stream. You can either specify an integer in the Seed used for pruning field, or click Generate, which will create a pseudo-random integer.
- Use data from an existing table. Specify the table name of a separate pruning dataset for estimating model accuracy. Doing so is considered more reliable than using training data. However, this option may result in the removal of a large subset of data from the training set, thus reducing the quality of the decision tree.

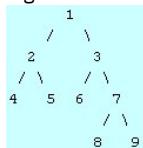

Netezza Divisive Clustering

Divisive clustering is a method of cluster analysis in which the algorithm is run repeatedly to divide clusters into subclusters until a specified stopping point is reached.

Cluster formation begins with a single cluster containing all training instances (records). The first iteration of the algorithm divides the data set into two subclusters, with subsequent iterations dividing these into further subclusters. The stopping criteria are specified as a maximum number of iterations, a maximum number of levels to which the data set is divided, and a minimum required number of instances for further partitioning.

The resulting hierarchical clustering tree can be used to classify instances by propagating them down from the root cluster, as in the following example.

Figure 1. Example of a divisive clustering tree

At each level, the best matching subcluster is chosen with respect to the distance of the instance from the subcluster centers.

When the instances are scored with an applied hierarchy level of -1 (the default), the scoring returns only a leaf cluster, as leaves are designated by a negative number. In the example, this would be one of clusters 4, 5, 6, 8, or 9. However, if the hierarchy level is set to 2, for example, scoring would return one of the clusters at the second level below the root cluster, namely 4, 5, 6, or 7.

- [Netezza Divisive Clustering Field Options](#)
- [Netezza Divisive Clustering Build Options](#)

Related information

- [Netezza Divisive Clustering Model Nuggets](#)

Netezza Divisive Clustering Field Options

On the Fields tab, you choose whether you want to use the field role settings already defined in upstream nodes, or make the field assignments manually.

Use predefined roles. This option uses the role settings (targets, predictors and so on) from an upstream Type node (or the Types tab of an upstream source node).

Use custom field assignments. Choose this option if you want to assign targets, predictors and other roles manually on this screen.

Fields. Use the arrow buttons to assign items manually from this list to the various role fields on the right of the screen. The icons indicate the valid measurement levels for each role field.

Click the All button to select all the fields in the list, or click an individual measurement level button to select all fields with that measurement level.

Record ID. The field that is to be used as the unique record identifier.

Predictors (Inputs). Choose one or more fields as inputs for the prediction.

Related information

- [Netezza Divisive Clustering](#)
 - [Netezza Divisive Clustering Model Nuggets](#)
-

Netezza Divisive Clustering Build Options

The Build Options tab is where you set all the options for building the model. You can, of course, just click the Run button to build a model with all the default options, but normally you will want to customize the build for your own purposes.

Distance measure. The method to be used for measuring the distance between data points; greater distances indicate greater dissimilarities. The options are:

- Euclidean. (default) The distance between two points is computed by joining them with a straight line.
- Manhattan. The distance between two points is calculated as the sum of the absolute differences between their co-ordinates.
- Canberra. Similar to Manhattan distance, but more sensitive to data points closer to the origin.
- Maximum. The distance between two points is calculated as the greatest of their differences along any coordinate dimension.

Maximum number of iterations. The algorithm operates by performing several iterations of the same process. This option allows you to stop model training after the number of iterations specified.

Maximum depth of cluster trees. The maximum number of levels to which the data set can be subdivided.

Replicate results. Check this box if you want to set a random seed, which will enable you to replicate analyses. You can either specify an integer or click Generate, which creates a pseudo-random integer.

Minimum number of instances for a split. The minimum number of records that can be split. When fewer than this number of unsplit records remain, no further splits will be made. You can use this field to prevent the creation of very small subgroups in the cluster tree.

IBM Data WH Generalized Linear

Linear regression is a long-established statistical technique for classifying records based on the values of numeric input fields. Linear regression fits a straight line or surface that minimizes the discrepancies between predicted and actual output values. Linear models are useful in modeling a wide range of real-world phenomena owing to their simplicity in both training and model application. However, linear models assume a normal distribution in the dependent (target) variable and a linear impact of the independent (predictor) variables on the dependent variable.

There are many situations where a linear regression is useful but the above assumptions do not apply. For example, when modeling consumer choice between a discrete number of products, the dependent variable is likely to have a multinomial distribution. Equally, when modeling income against age, income typically increases as age increases, but the link between the two is unlikely to be as simple as a straight line.

For these situations, a generalized linear model can be used. Generalized linear models expand the linear regression model so that the dependent variable is related to the predictor variables by means of a specified link function, for which there is a choice of suitable functions. Moreover, the model allows for the dependent variable to have a non-normal distribution, such as Poisson.

The algorithm iteratively seeks the best-fitting model, up to a specified number of iterations. In calculating the best fit, the error is represented by the sum of squares of the differences between the predicted and actual value of the dependent variable.

- [IBM Data WH Generalized Linear Model Field Options](#)
- [IBM Data WH Generalized Linear Model Options - General](#)
- [IBM Data WH Generalized Linear Model Options - Interaction](#)

- [IBM Data WH Generalized Linear Model Options - Scoring Options](#)

IBM Data WH Generalized Linear Model Field Options

On the Fields tab, you choose whether you want to use the field role settings that are already defined in upstream nodes, or make the field assignments manually.

Use predefined roles. This option uses the role settings, such as targets or predictors from an upstream Type node, or the Types tab of an upstream source node.

Use custom field assignments. Choose this option if you want to assign targets, predictors, and other roles manually on this screen.

Fields. Use the arrow buttons to assign items manually from this list to the various role fields on the right of the screen. The icons indicate the valid measurement levels for each role field.

Click the All button to select all the fields in the list, or click an individual measurement level button to select all fields with that measurement level.

Target. Choose one field as the target for the prediction.

Record ID. The field that is to be used as the unique record identifier. The values of this field must be unique for each record, for example, customer ID numbers.

Instance Weight. Specify a field to use instance weights. An instance weight is a weight per row of input data. By default, all input records are assumed to have equal relative importance. You can change the importance by assigning individual weights to the input records. The field that you specify must contain a numeric weight for each row of input data.

Predictors (Inputs). Select the input field or fields. This action is similar to setting the field role to *Input* in a Type node.

IBM Data WH Generalized Linear Model Options - General

On the Model Options tab, you can choose whether to specify a name for the model, or generate a name automatically. You can also make various settings relating to the model, the link function, the input field interactions (if any), and set default values for scoring options.

Model name. You can generate the model name automatically based on the target or ID field (or model type in cases where no such field is specified) or specify a custom name.

Field options. You can specify the roles of the input fields for building the model.

General Settings. These settings relate to the stopping criteria for the algorithm.

- **Maximum number of iterations.** The maximum number of iterations the algorithm will perform; minimum is 1, default is 20.
- **Maximum error (1e).** The maximum error value (in scientific notation) at which the algorithm should stop finding the best fit model. Minimum is 0, default is -3, meaning 1E-3, or 0.001.
- **Insignificant error values threshold (1e).** The value (in scientific notation) below which errors are treated as having a value of zero. Minimum is -1, default is -7, meaning that error values below 1E-7 (or 0.0000001) are counted as insignificant.

Distribution Settings. These settings relate to the distribution of the dependent (target) variable.

- **Distribution of response variable.** The distribution type; one of Bernoulli (default), Gaussian, Poisson, Binomial, Negative binomial, Wald (Inverse Gaussian), and Gamma.
- **Parameters.** (Poisson or binomial distribution only) You must specify one of the following options in the Specify parameter field:
 - To automatically have the parameter estimated from data, select Default.
 - To allow optimization of the distribution quasi-likelihood, select Quasi.
 - To explicitly specify the parameter value, select Explicit.(Binomial distribution only) You must specify the input table column that is to be used as the trials field as required by binomial distribution. This column contains the number of trials for the binomial distribution.
(Negative binomial distribution only) You can use the default of -1 or specify a different parameter value.

Link Function Settings. These settings relate to the link function, which relates the dependent variable to the predictor variables.

- **Link function.** The function to be used; one of Identity, Inverse, Invnegative, Invsquare, Sqrt, Power, Oddspower, Log, Clog, Loglog, Cloglog, Logit (default), Probit, Gaussit, Cauchit, Canbinom, Cangeom, Cannegbinom.
- **Parameters.** (Power or Oddspower link functions only) You can specify a parameter value if the link function is Power or Oddspower. Choose to either specify a value, or use the default of 1.

IBM Data WH Generalized Linear Model Options - Interaction

The Interaction panel contains the options for specifying interactions (that is, multiplicative effects between input fields).

Column Interaction. Select this check box to specify interactions between input fields. Leave the box cleared if there are no interactions.

Enter interactions into the model by selecting one or more fields in the source list and dragging to the interactions list. The type of interaction created depends upon the hotspot onto which you drop the selection.

- **Main.** Dropped fields appear as separate main interactions at the bottom of the interactions list.
- **2-way.** All possible pairs of the dropped fields appear as 2-way interactions at the bottom of the interactions list.
- **3-way.** All possible triplets of the dropped fields appear as 3-way interactions at the bottom of the interactions list.
- *****. The combination of all dropped fields appear as a single interaction at the bottom of the interactions list.

Include Intercept. The intercept is usually included in the model. If you can assume the data passes through the origin, you can exclude the intercept.

Dialog box buttons

The buttons to the right of the display enable you to make changes to the terms used in the model.

Figure 1. Delete button

Delete terms from the model by selecting the terms you want to delete and clicking the delete button.

Figure 2. Reorder buttons

Reorder the terms within the model by selecting the terms you want to reorder and clicking the up or down arrow.

Figure 3. Custom interaction button

- [Add a Custom Term](#)

Add a Custom Term

You can specify custom interactions in the form $n1*x1*x1*x1...$ Select a field from the Fields list, click the right-arrow button to add the field to Custom Term, click By*, select the next field, click the right-arrow button, and so on. When you have built the custom interaction, click Add term to return it to the Interaction panel.

IBM Data WH Generalized Linear Model Options - Scoring Options

Make Available for Scoring. You can set the default values here for the scoring options that appear on the dialog for the model nugget. See the topic [IBM Data WH Generalized Linear Model Nugget - Settings tab](#) for more information.

- **Include input fields.** Select this check box if you want to display the input fields in the model output as well as the predictions.

IBM Data WH Decision Trees

A decision tree is a hierarchical structure that represents a classification model. With a decision tree model, you can develop a classification system to predict or classify future observations from a set of training data. The classification takes the form of a tree structure in which the branches represent split points in the classification. The splits break the data down into subgroups recursively until a stopping point is reached. The tree nodes at the stopping points are known as **leaves**. Each leaf assigns a label, known as a **class label**, to the members of its subgroup, or class.

- [Instance weights and class weights](#)
 - [Netezza Decision Tree Field Options](#)
 - [IBM Data WH Decision Tree Build Options](#)
-

Instance weights and class weights

By default, all input records and classes are assumed to have equal relative importance. You can change this by assigning individual weights to the members of either or both of these items. Doing so might be useful, for example, if the data points in your training data are not realistically distributed among the categories. Weights enable you to bias the model so that you can compensate for those categories that are less well represented in the data. Increasing the weight for a target value should increase the percentage of correct predictions for that category.

In the Decision Tree modeling node, you can specify two types of weights. **Instance weights** assign a weight to each row of input data. The weights are typically specified as 1.0 for most cases, with higher or lower values given only to those cases that are more or less important than the majority, as shown in the following table.

Table 1. Instance weight example

Record ID	Target	Instance Weight
1	drugA	1.1
2	drugB	1.0
3	drugA	1.0
4	drugB	0.3

Class weights assign a weight to each category of the target field, as shown in the following table.

Table 2. Class weight example

Class	Class Weight
drugA	1.0
drugB	1.5

Both types of weights can be used at the same time, in which case they are multiplied together and used as instance weights. Thus if the two previous examples were used together, the algorithm would use the instance weights as shown in the following table.

Table 3. Instance weight calculation example

Record ID	Calculation	Instance Weight
1	1.1*1.0	1.1
2	1.0*1.5	1.5
3	1.0*1.0	1.0
4	0.3*1.5	0.45

Netezza Decision Tree Field Options

On the Fields tab, you choose whether you want to use the field role settings already defined in upstream nodes, or make the field assignments manually.

Use predefined roles This option uses the role settings (targets, predictors and so on) from an upstream Type node (or the Types tab of an upstream source node).

Use custom field assignments. To manually assign targets, predictors and other roles, select this option.

Fields. Use the arrow buttons to assign items manually from this list to the various role fields on the right of the screen. The icons indicate the valid measurement levels for each role field.

To select all the fields in the list, click the All button, or click an individual measurement level button to select all fields with that measurement level.

Target. Select one field as the target for the prediction.

Record ID. The field that is to be used as the unique record identifier. The values of this field must be unique for each record (for example, customer ID numbers).

Instance Weight. Specifying a field here enables you to use instance weights (a weight per row of input data) instead of, or in addition to, the default, class weights (a weight per category for the target field). The field you specify here must be one that contains a numeric weight for each row of input data. See the topic [Instance weights and class weights](#) for more information.

Predictors (Inputs). Select the input field or fields. This is similar to setting the field role to *Input* in a Type node.

IBM Data WH Decision Tree Build Options

The following build options are available for tree growth:

Growth Measure. These options control the way tree growth is measured.

- **Impurity Measure.** This measure evaluates the best place to split the tree. It is a measurement of the variability in a subgroup or segment of data. A low impurity measurement indicates a group where most members have similar values for the criterion or target field. The supported measurements are Entropy and Gini. These measurements are based on probabilities of category membership for the branch.
- **Maximum tree depth.** The maximum number of levels to which the tree can grow below the root node, that is, the number of times the sample is split recursively. The default value of this property is 10, and the maximal value that you can set for this property is 62. Note: If the viewer in the model nugget shows the textual representation of the model, a maximum of 12 levels of the tree is displayed.

Splitting Criteria. These options control when to stop splitting the tree.

- **Minimum improvement for splits.** The minimum amount by which impurity must be reduced before a new split is created in the tree. The goal of tree building is to create subgroups with similar output values to minimize the impurity within each node. If the best split for a branch reduces the impurity by less than the amount that is specified by the splitting criteria, the branch is not split.
- **Minimum number of instances for a split.** The minimum number of records that can be split. When fewer than this number of unsplittable records remain, no further splits are made. You can use this field to prevent the creation of small subgroups in the tree.

Statistics. This parameter defines how many statistics are included in the model. Select one of the following options:

- **All.** All column-related statistics and all value-related statistics are included.
Note: This parameter includes the maximum number of statistics and might therefore affect the performance of your system. If you do not want to view the model in graphical format, specify None.
 - **Columns.** Column-related statistics are included.
 - **None.** Only statistics that are required to score the model are included.
 - [IBM Data WH Decision Tree Node - Class Weights](#)
 - [IBM Data WH Decision Tree Node - Tree Pruning](#)
-

IBM Data WH Decision Tree Node - Class Weights

Here you can assign weights to individual classes. The default is to assign a value of 1 to all classes, making them equally weighted. By specifying different numerical weights for different class labels, you instruct the algorithm to weight the training sets of particular classes accordingly.

To change a weight, double-click it in the Weight column and make the changes you want.

Value. The set of class labels, derived from the possible values of the target field.

Weight. The weighting to be assigned to a particular class. Assigning a higher weight to a class makes the model more sensitive to that class relative to the other classes.

You can use class weights in combination with instance weights. See the topic [Instance weights and class weights](#) for more information.

IBM Data WH Decision Tree Node - Tree Pruning

You can use the pruning options to specify pruning criteria for the decision tree. The intention of pruning is to reduce the risk of overfitting by removing overgrown subgroups that do not improve the expected accuracy on new data.

Pruning measure. The default pruning measure, Accuracy, ensures that the estimated accuracy of the model remains within acceptable limits after removing a leaf from the tree. Use the alternative, Weighted Accuracy, if you want to take the class weights into account while applying pruning.

Data for pruning. You can use some or all of the training data to estimate the expected accuracy on new data. Alternatively, you can use a separate pruning dataset from a specified table for this purpose.

- Use all training data. This option (the default) uses all the training data to estimate the model accuracy.
- Use % of training data for pruning. Use this option to split the data into two sets, one for training and one for pruning, using the percentage specified here for the pruning data.

Select Replicate results if you want to specify a random seed to ensure that the data is partitioned in the same way each time you run the stream. You can either specify an integer in the Seed used for pruning field, or click Generate, which will create a pseudo-random integer.

- Use data from an existing table. Specify the table name of a separate pruning dataset for estimating model accuracy. Doing so is considered more reliable than using training data. However, this option may result in the removal of a large subset of data from the training set, thus reducing the quality of the decision tree.

IBM Data WH Linear Regression

Linear models predict a continuous target based on linear relationships between the target and one or more predictors. While limited to directly modeling linear relationships only, linear regression models are relatively simple and give an easily interpreted mathematical formula for scoring. Linear models are fast, efficient and easy to use, although their applicability is limited compared to those produced by more refined regression algorithms.

- [IBM Data WH Linear Regression Build Options](#)

IBM Data WH Linear Regression Build Options

The Build Options tab is where you set all the options for building the model. You can, of course, just click the Run button to build a model with all the default options, but normally you will want to customize the build for your own purposes.

Use Singular Value Decomposition to solve equations. Using the Singular Value Decomposition matrix instead of the original matrix has the advantage of being more robust against numerical errors, and can also speed up computation.

Include intercept in the model. Including the intercept increases the overall accuracy of the solution.

Calculate model diagnostics. This option causes a number of diagnostics to be calculated on the model. The results are stored in matrices or tables for later review. The diagnostics include r-squared, residual sum-of-squares, estimation of variance, standard deviation, *p*-value, and *t*-value.

These diagnostics relate to the validity and usefulness of the model. You should run separate diagnostics on the underlying data to ensure that it meets linearity assumptions.

IBM Data WH KNN

Nearest Neighbor Analysis is a method for classifying cases based on their similarity to other cases. In machine learning, it was developed as a way to recognize patterns of data without requiring an exact match to any stored patterns, or cases. Similar cases are near each other and dissimilar cases are distant from each other. Thus, the distance between two cases is a measure of their dissimilarity.

Cases that are near each other are said to be “neighbors.” When a new case (holdout) is presented, its distance from each of the cases in the model is computed. The classifications of the most similar cases – the nearest neighbors – are tallied and the new case is placed into the category that contains the greatest number of nearest neighbors.

You can specify the number of nearest neighbors to examine; this value is called *k*. The pictures show how a new case would be classified using two different values of *k*. When *k* = 5, the new case is placed in category 1 because a majority of the nearest neighbors belong to category 1. However, when *k* = 9, the new case is placed in category 0 because a majority of the nearest neighbors belong to category 0.

Nearest neighbor analysis can also be used to compute values for a continuous target. In this situation, the average or median target value of the nearest neighbors is used to obtain the predicted value for the new case.

- [IBM Data WH KNN Model Options - General](#)
- [IBM Data WH KNN Model Options - Scoring Options](#)

IBM Data WH KNN Model Options - General

On the Model Options - General tab, you can choose whether to specify a name for the model, or generate a name automatically. You can also set options that control how the number of nearest neighbors is calculated, and set options for enhanced performance and accuracy of the model.

Model name. You can generate the model name automatically based on the target or ID field (or model type in cases where no such field is specified) or specify a custom name.

Neighbors

Distance measure. The method to be used for measuring the distance between data points; greater distances indicate greater dissimilarities. The options are:

- Euclidean. (default) The distance between two points is computed by joining them with a straight line.
- Manhattan. The distance between two points is calculated as the sum of the absolute differences between their co-ordinates.
- Canberra. Similar to Manhattan distance, but more sensitive to data points closer to the origin.
- Maximum. The distance between two points is calculated as the greatest of their differences along any coordinate dimension.

Number of Nearest Neighbors (k). The number of nearest neighbors for a particular case. Note that using a greater number of neighbors will not necessarily result in a more accurate model.

The choice of k controls the balance between the prevention of overfitting (this may be important, particularly for "noisy" data) and resolution (yielding different predictions for similar instances). You will usually have to adjust the value of k for each data set, with typical values ranging from 1 to several dozen.

Enhance Performance and Accuracy

Standardize measurements before calculating distance. If selected, this option standardizes the measurements for continuous input fields before calculating the distance values.

Use coresets to increase performance for large datasets. If selected, this option uses core set sampling to speed up the calculation when large data sets are involved.

IBM Data WH KNN Model Options - Scoring Options

On the Model Options - Scoring Options tab, you can set the default value for a scoring option, and assign relative weights to individual classes.

Make Available for Scoring

Include input fields. Specifies whether the input fields are included in scoring by default.

Class Weights

Use this option if you want to change the relative importance of individual classes in building the model.

Note: This option is enabled only if you are using KNN for classification. If you are performing regression (that is, if the target field type is Continuous), the option is disabled.

The default is to assign a value of 1 to all classes, making them equally weighted. By specifying different numerical weights for different class labels, you instruct the algorithm to weight the training sets of particular classes accordingly.

To change a weight, double-click it in the Weight column and make the changes you want.

Value. The set of class labels, derived from the possible values of the target field.

Weight. The weighting to be assigned to a particular class. Assigning a higher weight to a class makes the model more sensitive to that class relative to the other classes.

IBM Data WH K-Means

The K-Means node implements the k -means algorithm, which provides a method of cluster analysis. You can use this node to cluster a data set into distinct groups.

The algorithm is a distance-based clustering algorithm that relies on a distance metric (function) to measure the similarity between data points. The data points are assigned to the nearest cluster according to the distance metric used.

The algorithm operates by performing several iterations of the same basic process, in which each training instance is assigned to the closest cluster (with respect to the specified distance function, applied to the instance and cluster center). All cluster centers are then recalculated as

the mean attribute value vectors of the instances assigned to particular clusters.

- [IBM Data WH K-Means Field Options](#)
 - [IBM Data WH K-Means Build Options Tab](#)
-

IBM Data WH K-Means Field Options

On the Fields tab, you choose whether you want to use the field role settings already defined in upstream nodes, or make the field assignments manually.

Use predefined roles. This option uses the role settings (targets, predictors and so on) from an upstream Type node (or the Types tab of an upstream source node).

Use custom field assignments. Choose this option if you want to assign targets, predictors and other roles manually on this screen.

Fields. Use the arrow buttons to assign items manually from this list to the various role fields on the right of the screen. The icons indicate the valid measurement levels for each role field.

Click the All button to select all the fields in the list, or click an individual measurement level button to select all fields with that measurement level.

Record ID. The field that is to be used as the unique record identifier.

Predictors (Inputs). Choose one or more fields as inputs for the prediction.

IBM Data WH K-Means Build Options Tab

By setting the build options, you can customize the build of the model for your own purposes.

If you want to build a model with the default options, click Run.

Distance measure. This parameter defines the method of measure for the distance between data points. Greater distances indicate greater dissimilarities. Select one of the following options:

- **Euclidean.** The Euclidean measure is the straight-line distance between two data points.
- **Normalized Euclidean.** The Normalized Euclidean measure is similar to the Euclidean measure but it is normalized by the squared standard deviation. Unlike the Euclidean measure, the Normalized Euclidean measure is also scale-invariant.
- **Mahalanobis.** The Mahalanobis measure is a generalized Euclidean measure that takes correlations of input data into account. Like the Normalized Euclidean measure, the Mahalanobis measure is scale-invariant.
- **Manhattan.** The Manhattan measure is the distance between two data points that is calculated as the sum of the absolute differences between their coordinates.
- **Canberra.** The Canberra measure is similar to the Manhattan measure but it is more sensitive to data points that are closer to the origin.
- **Maximum.** The Maximum measure is the distance between two data points that is calculated as the greatest of their differences along any coordinate dimension.

Number of clusters. This parameter defines the number of clusters to be created.

Maximum number of iterations. The algorithm does several iterations of the same process. This parameter defines the number of iterations after which model training stops.

Statistics. This parameter defines how many statistics are included in the model. Select one of the following options:

- **All.** All column-related statistics and all value-related statistics are included.
Note: This parameter includes the maximum number of statistics and might therefore affect the performance of your system. If you do not want to view the model in graphical format, specify None.
- **Columns.** Column-related statistics are included.
- **None.** Only statistics that are required to score the model are included.

Replicate results. Select this check box if you want to set a random seed to replicate analyses. You can specify an integer, or you can create a pseudo-random integer by clicking Generate.

IBM Data WH Naive Bayes

Naïve Bayes is a well-known algorithm for classification problems. The model is termed *naïve* because it treats all proposed prediction variables as being independent of one another. Naïve Bayes is a fast, scalable algorithm that calculates conditional probabilities for combinations of attributes and the target attribute. From the training data, an independent probability is established. This probability gives the likelihood of each target class, given the occurrence of each value category from each input variable.

Netezza Bayes Net

A Bayesian network is a model that displays variables in a data set and the probabilistic, or conditional, independencies between them. Using the Netezza Bayes Net node, you can build a probability model by combining observed and recorded evidence with common-sense real-world knowledge to establish the likelihood of occurrences by using seemingly unlinked attributes.

 - [Netezza Bayes Net Build Options](#)
-

Netezza Bayes Net Field Options

On the Fields tab, you choose whether you want to use the field role settings already defined in upstream nodes, or make the field assignments manually.

For this node, the target field is needed only for scoring, so it is not displayed on this tab. You can set or change the target on a Type node, on the Model Options tab of this node, or on the Settings tab of the model nugget. See the topic [Netezza Bayes Net Nugget - Settings Tab](#) for more information.

Use predefined roles. This option uses the role settings (targets, predictors and so on) from an upstream Type node (or the Types tab of an upstream source node).

Use custom field assignments. Choose this option if you want to assign targets, predictors and other roles manually on this screen.

Fields. Use the arrow buttons to assign items manually from this list to the various role fields on the right of the screen. The icons indicate the valid measurement levels for each role field.

Click the All button to select all the fields in the list, or click an individual measurement level button to select all fields with that measurement level.

Predictors (Inputs). Choose one or more fields as inputs for the prediction.

Netezza Time Series

A **time series** is a sequence of numerical data values, measured at successive (though not necessarily regular) points in time--for example, daily stock prices or weekly sales data. Analyzing such data can be useful, for example, in highlighting behavior such as trends and seasonality (a repeating pattern), and in predicting future behavior from past events.

Netezza Time Series supports the following time series algorithms.

- spectral analysis
- exponential smoothing
- AutoRegressive Integrated Moving Average (ARIMA)
- seasonal trend decomposition

These algorithms break a time series down into a trend and a seasonal component. These components are then analyzed in order to build a model that can be used for prediction.

Spectral analysis is used to identify periodic behavior in time series. For time series composed of multiple underlying periodicities or when a considerable amount of random noise is present in the data, spectral analysis provides the clearest means of identifying periodic components. This method detects the frequencies of periodic behavior by transforming the series from the time domain into a series of the frequency domain.

Exponential smoothing is a method of forecasting that uses weighted values of previous series observations to predict future values. With exponential smoothing, the influence of observations decreases over time in an exponential way. This method forecasts one point at a time, adjusting its forecasts as new data comes in, taking into account addition, trend, and seasonality.

ARIMA models provide more sophisticated methods for modeling trend and seasonal components than do exponential smoothing models. This method involves explicitly specifying autoregressive and moving average orders as well as the degree of differencing.

Note: In practical terms, ARIMA models are most useful if you want to include predictors that may help to explain the behavior of the series being forecast, such as the number of catalogs mailed or the number of hits to a company Web page. Exponential smoothing models describe the behavior of the time series without attempting to explain why it behaves as it does.

Seasonal trend decomposition removes periodic behavior from the time series in order to perform a trend analysis and then selects a basic shape for the trend, such as a quadratic function. These basic shapes have a number of parameters whose values are determined so as to minimize the mean squared error of the residuals (that is, the differences between the fitted and observed values of the time series).

- [Interpolation of Values in Netezza Time Series](#)
- [Netezza Time Series Field Options](#)
- [Netezza Time Series Build Options](#)
- [Netezza Time Series Model Options](#)

Interpolation of Values in Netezza Time Series

Interpolation is the process of estimating and inserting missing values in time series data.

If the intervals of the time series are regular but some values are simply not present, the missing values can be estimated using linear interpolation. Consider the following series of monthly passenger arrivals at an airport terminal.

Table 1. Monthly arrivals at a passenger terminal

Month	Passengers
3	3,500,000
4	3,900,000
5	-
6	3,400,000
7	4,500,000
8	3,900,000
9	5,800,000
10	6,000,000

In this case, linear interpolation would estimate the missing value for month 5 as 3,650,000 (the mid-point between months 4 and 6).

Irregular intervals are handled differently. Consider the following series of temperature readings.

Table 2. Temperature readings

Date	Time	Temperature
2011-07-24	7:00	57
2011-07-24	14:00	75
2011-07-24	21:00	72
2011-07-25	7:15	59

Date	Time	Temperature
2011-07-25	14:00	77
2011-07-25	20:55	74
2011-07-27	7:00	60
2011-07-27	14:00	78
2011-07-27	22:00	74

Here we have readings taken at three points during three days, but at various times, only some of which are common between days. In addition, only two of the days are consecutive.

This situation can be handled in one of two ways: calculating aggregates, or determining a step size.

Aggregates might be daily aggregates calculated according to a formula based on semantic knowledge of the data. Doing so could result in the following data set.

Table 3. Temperature readings (aggregated)

Date	Time	Temperature
2011-07-24	24:00	69
2011-07-25	24:00	71
2011-07-26	24:00	null
2011-07-27	24:00	72

Alternatively, the algorithm can treat the series as a distinct series and determine a suitable step size. In this case, the step size determined by the algorithm might be 8 hours, resulting in the following.

Table 4. Temperature readings with step size calculated

Date	Time	Temperature
2011-07-24	6:00	
2011-07-24	14:00	75
2011-07-24	22:00	
2011-07-25	6:00	
2011-07-25	14:00	77
2011-07-25	22:00	
2011-07-26	6:00	
2011-07-26	14:00	
2011-07-26	22:00	
2011-07-27	6:00	
2011-07-27	14:00	78
2011-07-27	22:00	74

Here, only four readings correspond to the original measurements, but with the help of the other known values from the original series, the missing values can again be calculated by interpolation.

Netezza Time Series Field Options

On the Fields tab, you specify roles for the input fields in the source data.

Fields. Use the arrow buttons to assign items manually from this list to the various role fields on the right of the screen. The icons indicate the valid measurement levels for each role field.

Target. Choose one field as the target for the prediction. This must be a field with a measurement level of Continuous.

(Predictor) Time Points. (required) The input field containing the date or time values for the time series. This must be a field with a measurement level of Continuous or Categorical and a data storage type of Date, Time, Timestamp, or Numeric. The data storage type of the field you specify here also defines the input type for some fields on other tabs of this modeling node.

(Predictor) Time Series IDs (By). A field containing time series IDs; use this if the input contains more than one time series.

Netezza Time Series Build Options

There are two levels of build options:

- Basic - settings for the algorithm choice, interpolation, and time range to be used.
- Advanced - settings for forecasting

This section describes the basic options.

The Build Options tab is where you set all the options for building the model. You can, of course, just click the Run button to build a model with all the default options, but normally you will want to customize the build for your own purposes.

Algorithm

These are the settings relating to the time series algorithm to be used.

Algorithm Name. Choose the time series algorithm you want to use. The available algorithms are Spectral Analysis, Exponential Smoothing (default), ARIMA, or Seasonal Trend Decomposition. See the topic [Netezza Time Series](#) for more information.

Trend. (Exponential Smoothing only) Simple exponential smoothing does not perform well if the time series exhibits a trend. Use this field to specify the trend, if any, so that the algorithm can take account of it.

- **System Determined.** (default) The system attempts to find the optimal value for this parameter.
- **None(N).** The time series does not exhibit a trend.
- **Additive(A).** A trend that steadily increases over time.
- **Damped Additive(DA).** An additive trend that eventually disappears.
- **Multiplicative(M).** A trend that increases over time, typically more rapidly than a steady additive trend.
- **Damped Multiplicative(DM).** A multiplicative trend that eventually disappears.

Seasonality. (Exponential Smoothing only) Use this field to specify whether the time series exhibits any seasonal patterns in the data.

- **System Determined.** (default) The system attempts to find the optimal value for this parameter.
- **None(N).** The time series does not exhibit seasonal patterns.
- **Additive(A).** The pattern of seasonal fluctuations exhibits a steady upward trend over time.
- **Multiplicative(M).** Same as additive seasonality, but in addition the amplitude (the distance between the high and low points) of the seasonal fluctuations increases relative to the overall upward trend of the fluctuations.

Use system determined settings for ARIMA. (ARIMA only) Choose this option if you want the system to determine the settings for the ARIMA algorithm.

Specify. (ARIMA only) Choose this option and click the button to specify the ARIMA settings manually.

Interpolation

If the time series source data has missing values, choose a method for inserting estimated values to fill the gaps in the data. See the topic [Interpolation of Values in Netezza Time Series](#) for more information.

- **Linear.** Choose this method if the intervals of the time series are regular but some values are simply not present.
- **Exponential Splines.** Fits a smooth curve where the known data point values increase or decrease at a high rate.
- **Cubic Splines.** Fits a smooth curve to the known data points to estimate the missing values.

Time Range

Here you can choose whether to use the full range of data in the time series, or a contiguous subset of that data, to create the model. Valid input for these fields is defined by the data storage type of the field specified for Time Points on the Fields tab. See the topic [Netezza Time Series Field Options](#) for more information.

- **Use earliest and latest times available in data.** Choose this option if you want to use the full range of the time series data.
- **Specify time window.** Choose this option if you want to use only a portion of the time series. Use the Earliest time (from) and Latest time (to) fields to specify the boundaries.
- [**ARIMA Structure**](#)
- [**Netezza Time Series Build Options - Advanced**](#)

Related information

- [Netezza Time Series](#)
- [Netezza Time Series Model Nugget](#)

ARIMA Structure

Specify the values of the various non-seasonal and seasonal components of the ARIMA model. In each case, set the operator to = (equal to) or <= (less than or equal to), then specify the value in the adjacent field. Values must be non-negative integers specifying the degrees.

Non seasonal. The values for the various nonseasonal components of the model.

- **Degrees of autocorrelation (p).** The number of autoregressive orders in the model. Autoregressive orders specify which previous values from the series are used to predict current values. For example, an autoregressive order of 2 specifies that the value of the series two time periods in the past be used to predict the current value.
- **Derivation (d).** Specifies the order of differencing applied to the series before estimating models. Differencing is necessary when trends are present (series with trends are typically nonstationary and ARIMA modeling assumes stationarity) and is used to remove their effect. The order of differencing corresponds to the degree of series trend--first-order differencing accounts for linear trends, second-order differencing accounts for quadratic trends, and so on.
- **Moving average (q).** The number of moving average orders in the model. Moving average orders specify how deviations from the series mean for previous values are used to predict current values. For example, moving-average orders of 1 and 2 specify that deviations from the mean value of the series from each of the last two time periods be considered when predicting current values of the series.

Seasonal. Seasonal autocorrelation (SP), derivation (SD), and moving average (SQ) components play the same roles as their nonseasonal counterparts. For seasonal orders, however, current series values are affected by previous series values separated by one or more seasonal periods. For example, for monthly data (seasonal period of 12), a seasonal order of 1 means that the current series value is affected by the series value 12 periods prior to the current one. A seasonal order of 1, for monthly data, is then the same as specifying a nonseasonal order of 12.

The seasonal settings are considered only if seasonality is detected in the data, or if you specify Period settings on the Advanced tab.

Netezza Time Series Build Options - Advanced

You can use the advanced settings to specify options for forecasting.

Use system determined settings for model build options. Choose this option if you want the system to determine the advanced settings.

Specify. Choose this option if you want to specify the advanced options manually. (The option is not available if the algorithm is Spectral Analysis.)

- **Period/Units for period.** The period of time after which some characteristic behavior of the time series repeats itself. For example, for a time series of weekly sales figures you would specify 1 for the period and Weeks for the units. Period must be a non-negative integer; Units for period can be one of Milliseconds, Seconds, Minutes, Hours, Days, Weeks, Quarters, or Years. Do not set Units for period if Period is not set, or if the time type is not numeric. However, if you specify Period, you must also specify Units for period.

Settings for forecasting. You can choose to make forecasts up to a particular point in time, or at specific time points. Valid input for these fields is defined by the data storage type of the field specified for Time Points on the Fields tab. See the topic [Netezza Time Series Field Options](#) for more information.

- **Forecast horizon.** Choose this option if you want to specify only an end point for forecasting. Forecasts will be made up to this point in time.
- **Forecast times.** Choose this option to specify one or more points in time at which to make forecasts. Click Add to add a new row to the table of time points. To delete a row, select the row and click Delete.

Netezza Time Series Model Options

On the Model Options tab, you can choose whether to specify a name for the model, or generate a name automatically. You can also set default values for the model output options.

Model name. You can generate the model name automatically based on the target or ID field (or model type in cases where no such field is specified) or specify a custom name.

Make Available for Scoring. You can set the default values here for the scoring options that appear on the dialog for the model nugget.

- **Include historical values in outcome.** By default, the model output does not include the historical data values (the ones used to make the prediction). Select this check box to include these values.
- **Include interpolated values in outcome.** If you choose to include historical values in the output, select this box if you also want to include the interpolated values, if any. Note that interpolation works only on historical data, so this box is unavailable if Include historical values in outcome is not selected. See the topic [Interpolation of Values in Netezza Time Series](#) for more information.

IBM Data WH TwoStep

The TwoStep node implements the TwoStep algorithm that provides a method to cluster data over large data sets.

You can use this node to cluster data while available resources, for example, memory and time constraints, are considered.

The TwoStep algorithm is a database-mining algorithm that clusters data in the following way:

1. A clustering feature (CF) tree is created. This high-balanced tree stores clustering features for hierarchical clustering where similar input records become part of the same tree nodes.
 2. The leaves of the CF tree are clustered hierarchically in-memory to generate the final clustering result. The best number of clusters is determined automatically. If you specify a maximum number of clusters, the best number of clusters within the specified limit is determined.
 3. The clustering result is refined in a second step where an algorithm that is similar to the K-Means algorithm is applied to the data.
- [IBM Data WH TwoStep Field Options](#)
 - [IBM Data WH TwoStep Build Options](#)

IBM Data WH TwoStep Field Options

By setting the field options, you can specify to use the field role settings that are defined in upstream nodes. You can also make the field assignments manually.

Select an item. Choose this option to use the role settings from an upstream Type node or from the Types tab of an upstream source node. Role settings are, for example, targets and predictors.

Use custom field assignments. Choose this option if you want to assign targets, predictors, and other roles manually.

Fields. Use the arrows to assign items manually from this list to the role fields on the right. The icons indicate the valid measurement levels for each role field.

Record ID. The field that is to be used as the unique record identifier.

Predictors (Inputs). Choose one or more fields as inputs for the prediction.

IBM Data WH TwoStep Build Options

By setting the build options, you can customize the build of the model for your own purposes.

If you want to build a model with the default options, click Run.

Distance measure. This parameter defines the method of measure for the distance between data points. Greater distances indicate greater dissimilarities. The options are:

- **Log-likelihood.** The likelihood measure places a probability distribution on the variables. Continuous variables are assumed to be normally distributed, while categorical variables are assumed to be multinomial. All variables are assumed to be independent.
- **Euclidean.** The Euclidean measure is the straight-line distance between two data points.
- **Normalized Euclidean.** The Normalized Euclidean measure is similar to the Euclidean measure but it is normalized by the squared standard deviation. Unlike the Euclidean measure, the Normalized Euclidean measure is also scale-invariant.

Cluster Number. This parameter defines the number of clusters to be created. The options are:

- **Automatically calculate number of clusters.** The number of clusters is calculated automatically. You can specify the maximum number of clusters in the Maximum field.
- **Specify number of clusters.** Specify how many clusters should be created.

Statistics. This parameter defines how many statistics are included in the model. The options are:

- **All.** All column-related statistics and all value-related statistics are included.
Note: This parameter includes the maximum number of statistics and might therefore affect the performance of your system. If you do not want to view the model in graphical format, specify None.
- **Columns.** Column-related statistics are included.
- **None.** Only statistics that are required to score the model are included.

Replicate results. Select this check box if you want to set a random seed to replicate analyses. You can specify an integer, or you can create a pseudo-random integer by clicking Generate.

IBM Data WH PCA

Principal component analysis (PCA) is a powerful data-reduction technique designed to reduce the complexity of data. PCA finds linear combinations of the input fields that do the best job of capturing the variance in the entire set of fields, where the components are orthogonal to (not correlated with) each other. The goal is to find a small number of derived fields (the principal components) that effectively summarize the information in the original set of input fields.

Note: An error may occur when scoring the model if lowercase field names are used. This is a known Db2 Data Warehouse defect, with the workaround being to rename all the fields to uppercase before scoring.

- [IBM Data WH PCA Field Options](#)
 - [IBM Data WH PCA Build Options](#)
-

IBM Data WH PCA Field Options

On the Fields tab, you choose whether you want to use the field role settings already defined in upstream nodes, or make the field assignments manually.

Use predefined roles. This option uses the role settings (targets, predictors and so on) from an upstream Type node (or the Types tab of an upstream source node).

Use custom field assignments. Choose this option if you want to assign targets, predictors and other roles manually on this screen.

Fields. Use the arrow buttons to assign items manually from this list to the various role fields on the right of the screen. The icons indicate the valid measurement levels for each role field.

Click the All button to select all the fields in the list, or click an individual measurement level button to select all fields with that measurement level.

Record ID. The field that is to be used as the unique record identifier.

Predictors (Inputs). Choose one or more fields as inputs for the prediction.

IBM Data WH PCA Build Options

The Build Options tab is where you set all the options for building the model. You can, of course, just click the Run button to build a model with all the default options, but normally you will want to customize the build for your own purposes.

Center data before computing PCA. If checked (default), this option performs data centering (also known as "mean subtraction") before the analysis. Data centering is necessary to ensure that the first principal component describes the direction of maximum variance, otherwise the component might correspond more closely to the mean of the data. You would normally uncheck this option only for performance improvement if the data had already been prepared in this way.

Perform data scaling before computing PCA. This option performs data scaling before the analysis. Doing so can make the analysis less arbitrary when different variables are measured in different units. In its simplest form data scaling can be achieved by dividing each variable by its standard variation.

Use less accurate but faster method to compute PCA. This option causes the algorithm to use a less accurate but faster method (forceEigensolve) of finding the principal components.

Managing IBM Data WH and Netezza Models

IBM Data Warehouse and IBM® Netezza® Analytics models are added to the canvas and the Models palette in the same way as other IBM SPSS® Modeler models, and can be used in much the same way. However, there are a few important differences, given that each IBM Data Warehouse or IBM Netezza Analytics model created in IBM SPSS Modeler actually references a model stored on a database server. Thus for a stream to function correctly, it must connect to the database where the model was created, and the model table must not have been changed by an external process.

 - [Netezza Time Series Model Nugget](#)
 - [IBM Data WH Generalized Linear Model Nugget](#)
 - [IBM Data WH TwoStep Model Nugget](#)
-

Scoring IBM Data Warehouse and IBM® Netezza® Analytics models

Models are represented on the canvas by a gold model nugget icon. The main purpose of a nugget is for scoring data to generate predictions, or to allow further analysis of the model properties. Scores are added in the form of one or more extra data fields that can be made visible by attaching a Table node to the nugget and running that branch of the stream, as described later in this section. Some nugget dialog boxes, such as those for Decision Tree or Regression Tree, additionally have a Model tab that provides a visual representation of the model.

The extra fields are distinguished by the prefix \$<id>- added to the name of the target field, where <id> depends on the model, and identifies the type of information being added. The different identifiers are described in the topics for each model nugget.

To view the scores, complete the following steps:

1. Attach a Table node to the model nugget.
 2. Open the Table node.
 3. Click Run.
 4. Scroll to the right of the table output window to view the extra fields and their scores.
-

IBM Data WH and Netezza model nugget Server tab

On the Server tab, you can set server options for scoring the model. You can either continue to use a server connection that was specified upstream, or you can move the data to another database that you specify here.

IBM Data Warehouse Server Details. Here you specify the connection details for the database you want to use for the model.

- Use upstream connection. (default) Uses the connection details specified in an upstream node, for example the Database source node. This option works only if all upstream nodes are able to use SQL pushback. In this case there is no need to move the data out of the database, as the SQL fully implements all of the upstream nodes.
- Move data to connection. Moves the data to the database you specify here. Doing so allows modeling to work if the data is in another IBM Data Warehouse database, or a database from another vendor, or even if the data is in a flat file. In addition, data is moved back to the database specified here if the data has been extracted because a node did not perform SQL pushback. Click the Edit button to browse for and select a connection.
CAUTION:
IBM® Netezza® Analytics and IBM Data Warehouse is typically used with very large data sets. Transferring large amounts of data between databases, or out of and back into a database, can be very time-consuming and should be avoided where possible.

Model name. The name of the model. The name is shown for your information only; you cannot change it here.

IBM Data WH Decision Tree Model Nuggets

The Decision Tree model nugget displays the output from the modeling operation, and also enables you to set some options for scoring the model.

When you run a stream containing a Decision Tree model nugget, by default the node adds one new field, the name of which is derived from the target name.

Table 1. Model-scoring field for Decision Tree

Name of Added Field	Meaning
---------------------	---------

Name of Added Field	Meaning
<code>\$I-target_name</code>	Predicted value for current record.

If you select the option Compute probabilities of assigned classes for scoring records on either the modeling node or the model nugget and run the stream, a further field is added.

Table 2. Model-scoring field for Decision Tree - additional

Name of Added Field	Meaning
<code>\$IP-target_name</code>	Confidence value (from 0.0 to 1.0) for the prediction.

- [IBM Data WH Decision Tree Nugget - Model Tab](#)
- [IBM Data WH Decision Tree Nugget - Settings Tab](#)
- [IBM Data WH Decision Tree Nugget - Viewer Tab](#)

IBM Data WH Decision Tree Nugget - Model Tab

The Model tab shows the Predictor Importance of the decision tree model in graphical format. The length of the bar represents the importance of the predictor.

Note: When you are working with IBM® Netezza® Analytics Version 2.x or previous, the content of the decision tree model is shown in textual format only.

For these versions, the following information is shown:

- Each line of text corresponds to a node or a leaf.
- The indentation reflects the tree level.
- For a node, the split condition is displayed.
- For a leaf, the assigned class label is shown.

IBM Data WH Decision Tree Nugget - Settings Tab

The Settings tab enables you to set some options for scoring the model.

Include input fields. If selected, this option passes all the original input fields downstream, appending the extra modeling field or fields to each row of data. If you clear this check box, only the Record ID field and the extra modeling fields are passed on, and so the stream runs more quickly.

Compute probabilities of assigned classes for scoring records. (Decision Tree and Naive Bayes only) If selected, this option means that the extra modeling fields include a confidence (that is, a probability) field as well as the prediction field. If you clear this check box, only the prediction field is produced.

Use deterministic input data. If selected, this option ensures that any Netezza algorithm that runs multiple passes of the same view will use the same set of data for each pass. If you clear this check box to show that non-deterministic data is being used a temporary table is created to hold the data output for processing, such as that produced by a partition node; this table is deleted after the model is created.

IBM Data WH Decision Tree Nugget - Viewer Tab

The Viewer tab shows a tree presentation of the tree model in the same way as the SPSS® Modeler does for its decision tree model.

Note: If the model is built with IBM® Netezza® Analytics Version 2.x or previous, the Viewer tab is empty.

IBM Data WH K-Means Model Nugget

K-Means model nuggets contain all of the information captured by the clustering model, as well as information about the training data and the estimation process.

When you run a stream containing a K-Means model nugget, the node adds two new fields containing the cluster membership and distance from the assigned cluster center for that record. The new field with the name `$KM-K-Means` is for the cluster membership and the new field with the name `$KMD-K-Means` is for the distance from the cluster center.

- [IBM Data WH K-Means Nugget - Model Tab](#)

- [IBM Data WH K-Means Nugget - Settings Tab](#)
-

IBM Data WH K-Means Nugget - Model Tab

The Model tab contains various graphic views that show summary statistics and distributions for fields of clusters. You can export the data from the model, or you can export the view as a graphic.

When you are working with IBM® Netezza® Analytics Version 2.x or previous, or when you build the model with Mahalanobis as the distance measure, the content of the K-Means models is shown in textual format only.

For these versions, the following information is shown:

- **Summary Statistics.** For both the smallest and the largest cluster, summary statistics shows the number of records. Summary statistics also shows the percentage of the data set that is taken up by these clusters. The list also shows the size ratio of the largest cluster to the smallest.
 - **Clustering Summary.** The clustering summary lists the clusters that are created by the algorithm. For each cluster, the table shows the number of records in that cluster, together with the mean distance from the cluster center for those records.
-

IBM Data WH K-Means Nugget - Settings Tab

The Settings tab enables you to set some options for scoring the model.

Include input fields. If selected, this option passes all the original input fields downstream, appending the extra modeling field or fields to each row of data. If you clear this check box, only the Record ID field and the extra modeling fields are passed on, and so the stream runs more quickly.

Distance measure. The method to be used for measuring the distance between data points; greater distances indicate greater dissimilarities. The options are:

- Euclidean. (default) The distance between two points is computed by joining them with a straight line.
 - Manhattan. The distance between two points is calculated as the sum of the absolute differences between their co-ordinates.
 - Canberra. Similar to Manhattan distance, but more sensitive to data points closer to the origin.
 - Maximum. The distance between two points is calculated as the greatest of their differences along any coordinate dimension.
-

Netezza Bayes Net Model Nuggets

The Bayes Net model nugget provides a means of setting options for scoring the model.

When you run a stream containing a Bayes Net model nugget, the node adds one new field, the name of which is derived from the target name.

Table 1. Model-scoring field for Bayes Net

Name of Added Field	Meaning
\$BN-target_name	Predicted value for current record.

You can view the extra field by attaching a Table node to the model nugget and running the Table node.

- [Netezza Bayes Net Nugget - Settings Tab](#)
-

Related information

- [Scoring IBM Data Warehouse and IBM Netezza Analytics models](#)
 - [Netezza Bayes Net](#)
-

Netezza Bayes Net Nugget - Settings Tab

On the Settings tab, you can set options for scoring the model.

Target. If you want to score a target field that is different from the current target, choose the new target here.

Record ID. If no Record ID field is specified, choose the field to use here.

Type of prediction. The variation of the prediction algorithm that you want to use:

- **Best (most correlated neighbor).** (default) Uses the most correlated neighbor node.
- **Neighbors (weighted prediction of neighbors).** Uses a weighted prediction of all neighbor nodes.
- **NN-neighbors (non-null neighbors).** Same as the previous option, except that it ignores nodes with null values (that is, nodes corresponding to attributes that have missing values for the instance for which the prediction is calculated).

Include input fields. If selected, this option passes all the original input fields downstream, appending the extra modeling field or fields to each row of data. If you clear this check box, only the Record ID field and the extra modeling fields are passed on, and so the stream runs more quickly.

Related information

- [Scoring IBM Data Warehouse and IBM Netezza Analytics models](#)
 - [Netezza Bayes Net](#)
-

IBM Data WH Naive Bayes Model Nuggets

The Naive Bayes model nugget provides a means of setting options for scoring the model.

When you run a stream containing a Naive Bayes model nugget, by default the node adds one new field, the name of which is derived from the target name.

Table 1. Model-scoring field for Naive Bayes - default

Name of Added Field	Meaning
\$I-target_name	Predicted value for current record.

If you select the option Compute probabilities of assigned classes for scoring records on either the modeling node or the model nugget and run the stream, two further fields are added.

Table 2. Model-scoring fields for Naive Bayes - additional

Name of Added Field	Meaning
\$IP-target_name	The Bayesian numerator of the class for the instance (that is, the product of the prior class probability and the conditional instance attribute value probabilities).
\$ILP-target_name	The natural logarithm of the latter.

You can view the extra fields by attaching a Table node to the model nugget and running the Table node.

- [IBM Data WH Naive Bayes Nugget - Settings Tab](#)
-

IBM Data WH Naive Bayes Nugget - Settings Tab

On the Settings tab, you can set options for scoring the model.

Include input fields. If selected, this option passes all the original input fields downstream, appending the extra modeling field or fields to each row of data. If you clear this check box, only the Record ID field and the extra modeling fields are passed on, and so the stream runs more quickly.

Compute probabilities of assigned classes for scoring records. (Decision Tree and Naive Bayes only) If selected, this option means that the extra modeling fields include a confidence (that is, a probability) field as well as the prediction field. If you clear this check box, only the prediction field is produced.

Improve probability accuracy for small or heavily unbalanced datasets. When computing probabilities, this option invokes the *m*-estimation technique for avoiding zero probabilities during estimation. This kind of estimation of probabilities may be slower but can give better results for small or heavily unbalanced datasets.

IBM Data WH KNN Model Nuggets

The KNN model nugget provides a means of setting options for scoring the model.

When you run a stream containing a KNN model nugget, the node adds one new field, the name of which is derived from the target name.

Table 1. Model-scoring field for KNN

Name of Added Field	Meaning
\$KNN-target_name	Predicted value for current record.

You can view the extra field by attaching a Table node to the model nugget and running the Table node.

- [IBM Data WH KNN Nugget - Settings Tab](#)

IBM Data WH KNN Nugget - Settings Tab

On the Settings tab, you can set options for scoring the model.

Distance measure. The method to be used for measuring the distance between data points; greater distances indicate greater dissimilarities. The options are:

- Euclidean. (default) The distance between two points is computed by joining them with a straight line.
- Manhattan. The distance between two points is calculated as the sum of the absolute differences between their co-ordinates.
- Canberra. Similar to Manhattan distance, but more sensitive to data points closer to the origin.
- Maximum. The distance between two points is calculated as the greatest of their differences along any coordinate dimension.

Number of Nearest Neighbors (k). The number of nearest neighbors for a particular case. Note that using a greater number of neighbors will not necessarily result in a more accurate model.

The choice of k controls the balance between the prevention of overfitting (this may be important, particularly for "noisy" data) and resolution (yielding different predictions for similar instances). You will usually have to adjust the value of k for each data set, with typical values ranging from 1 to several dozen.

Include input fields. If selected, this option passes all the original input fields downstream, appending the extra modeling field or fields to each row of data. If you clear this check box, only the Record ID field and the extra modeling fields are passed on, and so the stream runs more quickly.

Standardize measurements before calculating distance. If selected, this option standardizes the measurements for continuous input fields before calculating the distance values.

Use coresets to increase performance for large datasets. If selected, this option uses core set sampling to speed up the calculation when large data sets are involved.

Netezza Divisive Clustering Model Nuggets

The Divisive Clustering model nugget provides a means of setting options for scoring the model.

When you run a stream containing a Divisive Clustering model nugget, the node adds two new fields, the names of which are derived from the target name.

Table 1. Model-scoring fields for Divisive Clustering

Name of Added Field	Meaning
\$DC-target_name	Identifier of subcluster to which current record is assigned.
\$DCD-target_name	Distance from subcluster center for current record.

You can view the extra fields by attaching a Table node to the model nugget and running the Table node.

- [Netezza Divisive Clustering Nugget - Settings Tab](#)

Related information

-

IBM Data WH PCA Model Nuggets

The PCA model nugget provides a means of setting options for scoring the model.

When you run a stream containing a PCA model nugget, by default the node adds one new field, the name of which is derived from the target name.

Table 1. Model-scoring field for PCA

Name of Added Field	Meaning
\$F-target_name	Predicted value for current record.

If you specify a value greater than 1 in the Number of principal components ... field on either the modeling node or the model nugget and run the stream, the node adds a new field for each component. In this case the field names are suffixed by *-n*, where *n* is the number of the component. For example, if your model is named *pca* and contains three components, the new fields would be named \$F-pca-1, \$F-pca-2, and \$F-pca-3.

You can view the extra fields by attaching a Table node to the model nugget and running the Table node.

Note: An error may occur when scoring the model if lowercase field names are used. This is a known Db2 Data Warehouse defect, with the workaround being to rename all the fields to uppercase before scoring.

- [IBM Data WH PCA Nugget - Settings Tab](#)
-

IBM Data WH PCA Nugget - Settings Tab

On the Settings tab, you can set options for scoring the model.

Number of principal components to be used in projection. The number of principal components to which you want to reduce the data set. This value must not exceed the number of attributes (input fields).

Include input fields. If selected, this option passes all the original input fields downstream, appending the extra modeling field or fields to each row of data. If you clear this check box, only the Record ID field and the extra modeling fields are passed on, and so the stream runs more quickly.

Netezza Regression Tree Model Nuggets

The Regression Tree model nugget provides a means of setting options for scoring the model.

When you run a stream containing a Regression Tree model nugget, by default the node adds one new field, the name of which is derived from the target name.

Table 1. Model-scoring field for Regression Tree

Name of Added Field	Meaning
\$I-target_name	Predicted value for current record.

If you select the option Compute estimated variance on either the modeling node or the model nugget and run the stream, a further field is added.

Table 2. Model-scoring field for Regression Tree - additional

Name of Added Field	Meaning
\$IV-target_name	Estimated variances of the predicted value.

You can view the extra fields by attaching a Table node to the model nugget and running the Table node.

- [Netezza Regression Tree Nugget - Settings Tab](#)
- [Netezza Regression Tree Nugget - Viewer Tab](#)

Related information

- [Scoring IBM Data Warehouse and IBM Netezza Analytics models](#)
- [IBM Data WH Regression Tree](#)

Netezza Regression Tree Nugget - Model Tab

The Model tab shows the Predictor Importance of the regression tree model in graphical format. The length of the bar represents the importance of the predictor.

Note: When you are working with IBM® Netezza® Analytics Version 2.x or previous, the content of the regression tree model is shown in textual format only.

For these versions, the following information is shown:

- Each line of text corresponds to a node or a leaf.
- The indentation reflects the tree level.
- For a node, the split condition is displayed.
- For a leaf, the assigned class label is shown.

Related information

- [Scoring IBM Data Warehouse and IBM Netezza Analytics models](#)
- [IBM Data WH Regression Tree](#)

Netezza Regression Tree Nugget - Settings Tab

On the Settings tab, you can set options for scoring the model.

Include input fields. If selected, this option passes all the original input fields downstream, appending the extra modeling field or fields to each row of data. If you clear this check box, only the Record ID field and the extra modeling fields are passed on, and so the stream runs more quickly.

Compute estimated variance. Indicates whether the variances of assigned classes should be included in the output.

Related information

-

IBM Data WH Linear Regression Model Nuggets

The Linear Regression model nugget provides a means of setting options for scoring the model.

When you run a stream containing a Linear Regression model nugget, the node adds one new field, the name of which is derived from the target name.

Table 1. Model-scoring field for Linear Regression

Name of Added Field	Meaning
\$LR-target_name	Predicted value for current record.

- [IBM Data WH Linear Regression Nugget - Settings Tab](#)
-

IBM Data WH Linear Regression Nugget - Settings Tab

On the Settings tab, you can set options for scoring the model.

Include input fields. If selected, this option passes all the original input fields downstream, appending the extra modeling field or fields to each row of data. If you clear this check box, only the Record ID field and the extra modeling fields are passed on, and so the stream runs more quickly.

Netezza Time Series Model Nugget

The model nugget provides access to the output of the time series modeling operation. The output consists of the following fields.

Table 1. Time Series model output fields

Field	Description
TSID	The identifier of the time series; the contents of the field specified for Time Series IDs on the Fields tab of the modeling node. See the topic Netezza Time Series Field Options for more information.
TIME	The time period within the current time series.
HISTORY	The historical data values (the ones used to make the prediction). This field is included only if the option Include historical values in outcome is selected on the Settings tab of the model nugget.
\$TS-INTERPOLATED	The interpolated values, where used. This field is included only if the option Include interpolated values in outcome is selected on the Settings tab of the model nugget. Interpolation is an option on the Build Options tab of the modeling node.
\$TS-FORECAST	The forecast values for the time series.

To view the model output, attach a Table node (from the Output tab of the node palette) to the model nugget and run the Table node.

- [Netezza Time Series Nugget - Settings tab](#)
-

Netezza Time Series Nugget - Settings tab

On the Settings tab you can specify options for customizing the model output.

Model Name. The name of the model, as specified on the Model Options tab of the modeling node.

The other options are the same as those on the Modeling Options tab of the modeling node.

IBM Data WH Generalized Linear Model Nugget

The model nugget provides access to the output of the modeling operation.

When you run a stream containing a Generalized Linear model nugget, the node adds a new field, the name of which is derived from the target name.

Table 1. Model-scoring field for Generalized Linear

Name of Added Field	Meaning
\$GLM-target_name	Predicted value for current record.

The Model tab displays various statistics relating to the model.

The output consists of the following fields.

Table 2. Output fields from Generalized Linear model

Output Field	Description
Parameter	The parameters (that is, the predictor variables) used by the model. These are the numerical and nominal columns, as well as the intercept (the constant term in the regression model).
Beta	The correlation coefficient (that is, the linear component of the model).
Std Error	The standard deviation for the beta.
Test	The test statistics used to evaluate the validity of the parameter.
p-value	The probability of an error when assuming that the parameter is significant.
Residuals Summary	
Residual Type	The type of residual of the prediction for which summary values are shown.
RSS	The value of the residual.
df	The degrees of freedom for the residual.
p-value	The probability of an error. A high value indicates a poorly-fitting model; a low value indicates a good fit.

- [IBM Data WH Generalized Linear Model Nugget - Settings tab](#)

IBM Data WH Generalized Linear Model Nugget - Settings tab

On the Settings tab you can customize the model output.

The option is the same as that shown for Scoring Options on the modeling node. See the topic [IBM Data WH Generalized Linear Model Options - Scoring Options](#) for more information.

IBM Data WH TwoStep Model Nugget

When you run a stream that contains a TwoStep model nugget, the node adds two new fields that contain the cluster membership and distance from the assigned cluster center for that record. The new field with the name \$TS-Twostep is for the cluster membership, and the new field with the name \$TSP-Twostep is for the distance from the cluster center.

- [IBM Data WH TwoStep Nugget - Model Tab](#)

IBM Data WH TwoStep Nugget - Model Tab

The Model tab contains various graphic views that show summary statistics and distributions for fields of clusters. You can export the data from the model, or you can export the view as a graphic.

IBM SPSS Modeler and IBM Db2 for z/OS

SPSS Modeler supports integration with Db2 for z/OS, which provides the ability to run advanced analytics on Db2 for z/OS servers. You can access these features through the SPSS Modeler graphical user interface and workflow-oriented development environment. This way, you can run the data mining algorithms directly in the Db2 for z/OS environment leveraging IBM Db2 Analytics Accelerator.

SPSS Modeler supports integration of the following algorithms from Db2 for z/OS.

- Decision Trees
 - K-Means
 - Naive Bayes
 - Regression Tree
 - TwoStep
-

Requirements for integration with IBM Db2 for z/OS

The following conditions are prerequisites for conducting in-database modeling by using Db2® for z/OS® and IBM® Db2 Analytics Accelerator for z/OS. To ensure that these conditions are met, you might need to consult with your database administrator. For detailed requirements, including supported versions, see the [Software Product Compatibility Reports](#).

- IBM SPSS® Modeler running in local mode or against an SPSS Modeler Server installation on Windows or UNIX
 - Db2 for z/OS together with Db2 Analytics Accelerator for z/OS
 - IBM SPSS Data Access Pack
 - On the server running SPSS Modeler Server, one of the following systems:
 - IBM Db2 Data Server Driver for ODBC and CLI
 - Any version of Db2 for Linux®, UNIX, and Windows with an ODBC data source that is configured for Db2 for z/OS
 - License for Db2 Connect for System z®
 - SQL generation and optimization enabled in SPSS Modeler
 - Db2 z/OS in-database mining requires either accelerator-only tables (AOT) or accelerated tables, and INZA support. IDAA INZA was introduced in IDAA 5.1. This means that the Db2 z/OS in-database mining nodes will not work with previous versions of IDAA. If you use an IDAA-enabled DSN in Modeler, the only tables that will be displayed in the list of tables returned in the Database source node using that DSN will be AOT or accelerated tables.
-

Enabling integration with IBM Db2 Analytics Accelerator for z/OS

Enabling integration with Db2® Analytics Accelerator for z/OS® consists of the following steps:

- Configuring Db2 for z/OS and Db2 Analytics Accelerator for z/OS
 - Creating an ODBC source
 - Enabling the integration of IBM® Db2 for z/OS in IBM SPSS® Modeler
 - Enabling SQL generation and optimization in SPSS Modeler
 - Enabling IBM SPSS Modeler Server Scoring Adapter for Db2 for z/OS
 - Configuring DSN using IBM Db2 Client in IBM SPSS Modeler
 - [Configuring IBM Db2 for z/OS and IBM Analytics Accelerator for z/OS](#)
 - [Creating an ODBC Source for IBM Db2 for z/OS and IBM Db2 Analytics Accelerator](#)
 - [Enabling the integration of IBM Db2 for z/OS in IBM SPSS Modeler](#)
 - [Enabling SQL Generation and Optimization](#)
 - [Configuring DSN using IBM Db2 Client in IBM SPSS Modeler](#)
-

Configuring IBM® Db2 for z/OS and IBM Analytics Accelerator for z/OS

How to configure Db2® for z/OS® and Analytics Accelerator for z/OS is described on the following website:

[Db2 Analytics Accelerator for z/OS](#).

Creating an ODBC Source for IBM Db2 for z/OS and IBM Db2 Analytics Accelerator

For information about how to enable a connection between Db2® for z/OS® and IBM® Db2 Analytics Accelerator, see the following websites:

- For version 4: [Db2 Analytics Accelerator for z/OS 4.1.0](#)
- For version 3: [Db2 Analytics Accelerator for z/OS 3.1.0](#)
- [Enabling query acceleration with IBM Db2 Analytics Accelerator for ODBC and JDBC applications without modifying the applications](#)
- [SQL error from ODBC driver when running a query in Db2 Analytics Accelerator for z/OS](#)

Enabling the integration of IBM® Db2 for z/OS® in IBM SPSS Modeler

To enable the integration of Db2® for z/OS in SPSS® Modeler, perform the following steps:

1. From the SPSS Modeler config directory, open the `odbc-db2-accelerator-names.cfg` file.
If the file does not exists, you must create it.

2. Add the names of all data sources and the names of all accelerators. For example:

```
dsn1, acceleratorname1  
dsn2, acceleratorname2
```

3. The default CCSID for accelerator only tables (AOT) is Unicode; to override this, modify the entries by adding encoding strings to the accelerator names. For example:

```
dsn1, acceleratorname1, EBCDIC  
dsn2, acceleratorname2, UNICODE
```

4. Save and close the `odbc-db2-accelerator-names.cfg` file, then open the `odbc-db2-custom-properties.cfg` file from the same directory.

5. SPSS Modeler uses SQL to set the IDAA registers. If required, you can override these entries by changing the SQL to the required values.
For example:

```
current_query_sql_acc, "SET CURRENT QUERY ACCELERATION = ELIGIBLE"  
current_get_archive_acc, "SET CURRENT GET_ACCEL_ARCHIVE = NO"
```

6. By default, SPSS Modeler uses SQL to create temporary tables for a database cache. If required, you can override this by specifying the expected database name. For example:

```
[OSZ]  
table_create_temp_sql_acc, 'CREATE TABLE <table-name> <(table-columns)> IN DATABASE  
NAME_OF_DATABASE_FOR_AOT'
```

7. By default, SPSS Modeler considers that SQL queries written in an ODBC source node are non-replayable, meaning that the query is considered to return different results when being executed multiple times. However, in some scenarios, this may prevent Modeler from generating SQL for downstream nodes and can be overridden by changing the relevant value to `Y`. For example:

```
assume_custom_sql_replayable, Y
```

8. From the SPSS Modeler main menu, click Tools > Options > Helper Applications.

9. Click the IBM Db2 for z/OS tab.

10. Select Enable IBM Db2 for z/OS Data Mining Integration and then click OK.

Note: You cannot view IDAA and non-IDAA tables at the same time in Modeler.

Enabling SQL Generation and Optimization

Because of the likelihood of working with very large data sets, for performance reasons you should enable the SQL generation and optimization options in IBM® SPSS® Modeler.

To configure SPSS Modeler, do the following steps:

1. From the IBM SPSS Modeler menus choose Tools > Stream Properties > Options
 2. Click the Optimization option in the navigation pane.
 3. Confirm that the Generate SQL option is enabled. This setting is required for database modeling to function.
 4. Select Optimize SQL Generation and Optimize other execution (not strictly required but strongly recommended for optimized performance).
-

Configuring DSN using IBM® Db2 Client in IBM SPSS Modeler

If required, to configure a data source name (DSN) using Db2® Client for Db2 in SPSS® Modeler, complete the following steps:

1. If not already installed, install Db2 Client on the operating system where Modeler Server is installed.
2. Using the **db2 catalog** command, catalog the database and add a new data source to the db2cli.ini file in Db2 Client. Be sure to point to the defined database alias.
3. Configure data access; detailed steps are available in the Modeler documentation.
For more information, see [Data Access](#).
4. Create a new ODBC data source in odbc.ini by referencing the database alias defined in step 2.
5. For Linux or UNIX users:
 - a. Ensure that the driver library libdb2o.so is used (instead of libdb2.so), and make sure 'DriverUnicodeType=1' is defined for the new data source.
 - b. In the IBM SPSS Data Access Pack installation, ensure that the library path of Db2 Client is added to odbc.sh.
 - c. Ensure that Modeler Server uses an ODBC Driver wrapper library with UTF-16 encoding (this is called 'libspssodbc_datadirect_utf16.so').
6. Make sure that the user who connects to Db2 has the necessary privileges to run the following query:

```
SELECT ACCELERATORNAME FROM SYSACCEL.SYSACCELERATORS
```

Building models with IBM® Db2 for z/OS

Each of the supported algorithms has a corresponding modeling node. You can access the Db2® for z/OS® modeling nodes from the Database Modeling tab on the nodes palette.

Data considerations

Fields in the data source can contain variables of various data types, depending on the modeling node. In SPSS® Modeler, data types are known as *measurement levels*. The Fields tab of the modeling node uses icons to indicate the permitted measurement level types for its input and target fields.

Target field. The target field is the field whose value you are trying to predict. Where a target can be specified, only one of the source data fields can be selected as the target field.

Record ID field. Specifies the field used to uniquely identify each case. For example, this might be an ID field, such as *CustomerID*. If the source data does not include an ID field, you can create this field by means of a Derive node, as the following procedure shows.

1. Select the source node.
2. From the Field Ops tab on the nodes palette, double-click the Derive node.
3. Open the Derive node by double-clicking its icon on the canvas.
4. In the Derive field field, type (for example) *ID*.
5. In the Formula field, type @INDEX and click OK.
6. Connect the Derive node to the rest of the stream.

Handling null values

If the input data contains null values, use of some Db2 for z/OS nodes may result in error messages or long-running streams, so we recommend removing records containing null values. Use the following method.

1. Attach a Select node to the source node.
2. Set the Mode option of the Select node to Discard.
3. Enter the following in the Condition field:

```
@NULL(field1) [or @NULL(field2) [...] or @NULL(fieldN)])
```

Be sure to include every input field.

4. Connect the Select node to the rest of the stream.

Model output

It is possible for a stream containing a Db2 for z/OS modeling node to produce slightly different results each time it is run. This is because the order in which the node reads the source data is not always the same, as the data is read into temporary tables before model building. However, the differences produced by this effect are negligible.

General comments

- In SPSS Collaboration and Deployment Services, it is not possible to create scoring configurations using streams containing Db2 for z/OS modeling nodes.
 - PMML export or import is not possible for models created by the Db2 for z/OS nodes.
 - [IBM Db2 for z/OS models - Field options](#)
 - [IBM Db2 for z/OS Models - Server Options](#)
 - [IBM Db2 for z/OS models - Model options](#)
-

IBM® Db2® for z/OS® models - Field options

On the Fields tab, you choose whether you want to use the field role settings already defined in upstream nodes, or make the field assignments manually.

Use predefined roles. This option uses the role settings (targets, predictors and so on) from an upstream Type node (or the Types tab of an upstream source node).

Use custom field assignments. Choose this option if you want to assign targets, predictors and other roles manually on this screen.

Fields. Use the arrow buttons to assign items manually from this list to the various role fields on the right of the screen. The icons indicate the valid measurement levels for each role field.

Click the All button to select all the fields in the list, or click an individual measurement level button to select all fields with that measurement level.

Target. Choose one field as the target for the prediction. For Generalized Linear models, see also the Trials field on this screen.

Record ID. The field that is to be used as the unique record identifier.

Predictors (Inputs). Choose one or more fields as inputs for the prediction.

IBM Db2 for z/OS Models - Server Options

On the Server tab, you specify the Db2® for z/OS® system where the model is to be built.

- Use upstream connection. (default) Uses the connection details specified in an upstream node, for example the Database source node.
Note: This option works only if all upstream nodes are able to use SQL pushback. In this case, there is no need to move the data out of the database, as the SQL fully implements all of the upstream nodes.
- Move data to connection. Moves the data to the database you specify here. Doing so allows modeling to work if the data is in another IBM® database, or a database from another vendor, or even if the data is in a flat file. In addition, data is moved back to the database specified here if the data has been extracted because a node did not perform SQL pushback. Click the Edit button to browse for and select a connection.

Note: The ODBC data source name is effectively embedded in each SPSS® Modeler stream. If a stream that is created on one host is executed on a different host, the name of the data source must be the same on each host. Alternatively, a different data source can be selected on the Server tab in each source or modeling node.

IBM® Db2® for z/OS® models - Model options

On the Model Options tab, you can choose whether to specify a name for the model, or generate a name automatically.

Model name. You can generate the model name automatically based on the target or ID field (or model type in cases where no such field is specified) or specify a custom name.

Replace existing if the name has been used. If you select this check box, any existing model of the same name will be overwritten.

IBM® Db2® for z/OS® Models - K-Means

The K-Means node implements the *k*-means algorithm, which provides a method of cluster analysis. You can use this node to cluster a data set into distinct groups.

The algorithm is a distance-based clustering algorithm that relies on a distance metric (function) to measure the similarity between data points. The data points are assigned to the nearest cluster according to the distance metric used.

The algorithm operates by performing several iterations of the same basic process, in which each training instance is assigned to the closest cluster (with respect to the specified distance function, applied to the instance and cluster center). All cluster centers are then recalculated as the mean attribute value vectors of the instances assigned to particular clusters.

- [IBM Db2 for z/OS models - K-Means Field options](#)
- [IBM Db2 for z/OS Models - K-Means build options](#)

IBM® Db2® for z/OS® models - K-Means Field options

On the Fields tab, you choose whether you want to use the field role settings already defined in upstream nodes, or make the field assignments manually.

Use predefined roles. This option uses the role settings (targets, predictors and so on) from an upstream Type node (or the Types tab of an upstream source node).

Use custom field assignments. Choose this option if you want to assign targets, predictors and other roles manually on this screen.

Fields. Use the arrow buttons to assign items manually from this list to the various role fields on the right of the screen. The icons indicate the valid measurement levels for each role field.

Click the All button to select all the fields in the list, or click an individual measurement level button to select all fields with that measurement level.

Record ID. The field that is to be used as the unique record identifier.

Predictors (Inputs). Choose one or more fields as inputs for the prediction.

IBM® Db2® for z/OS® Models - K-Means build options

By setting the build options, you can customize the build of the model for your own purposes.

If you want to build a model with the default options, click Run.

Distance measure. This parameter defines the method of measure for the distance between data points. Greater distances indicate greater dissimilarities. Select one of the following options:

- Euclidean. The Euclidean measure is the straight-line distance between two data points.
- Normalized Euclidean. The Normalized Euclidean measure is similar to the Euclidean measure but it is normalized by the squared standard deviation. Unlike the Euclidean measure, the Normalized Euclidean measure is also scale-invariant.

Number of clusters. This parameter defines the number of clusters to be created.

Maximum number of iterations. The algorithm does several iterations of the same process. This parameter defines the number of iterations after which model training stops.

Statistics. This parameter defines how many statistics are included in the model. Select one of the following options:

- All. All column-related statistics and all value-related statistics are included.
Note: This parameter includes the maximum number of statistics and might therefore affect the performance of your system. If you do not want to view the model in graphical format, specify None.
- Columns. Column-related statistics are included.
- None. Only statistics that are required to score the model are included.

Replicate results. Select this check box if you want to set a random seed to replicate analyses. You can specify an integer, or you can create a pseudo-random integer by clicking Generate.

IBM® Db2® for z/OS® models - Naive Bayes

Naive Bayes is a well-known algorithm for classification problems. The model is termed naïve because it treats all proposed prediction variables as being independent of one another. Naive Bayes is a fast, scalable algorithm that calculates conditional probabilities for combinations of attributes and the target attribute. From the training data, an independent probability is established. This probability gives the likelihood of each target class, given the occurrence of each value category from each input variable.

IBM® Db2® for z/OS® Models - Decision Trees

A decision tree is a hierarchical structure that represents a classification model. With a decision tree model, you can develop a classification system to predict or classify future observations from a set of training data. The classification takes the form of a tree structure in which the branches represent split points in the classification. The splits break the data down into subgroups recursively until a stopping point is reached. The tree nodes at the stopping points are known as *leaves*. Each leaf assigns a label, known as a *class label*, to the members of its subgroup, or class.

- [IBM Db2 for z/OS models - Decision Tree field options](#)
- [IBM Db2 for z/OS Models - Decision Tree Build Options](#)
- [IBM Db2 for z/OS Models - Decision Tree Node - Class Weights](#)
- [IBM Db2 for z/OS Models - Decision Tree Node - Tree Pruning](#)

IBM® Db2® for z/OS® models - Decision Tree field options

On the Fields tab, you choose whether you want to use the field role settings already defined in upstream nodes, or make the field assignments manually.

Use predefined roles. This option uses the role settings (targets, predictors and so on) from an upstream Type node (or the Types tab of an upstream source node).

Use custom field assignments. Choose this option if you want to assign targets, predictors and other roles manually on this screen.

Fields. Use the arrow buttons to assign items manually from this list to the various role fields on the right of the screen. The icons indicate the valid measurement levels for each role field.

Click the All button to select all the fields in the list, or click an individual measurement level button to select all fields with that measurement level.

Target. Choose one field as the target for the prediction.

Record ID. The field that is to be used as the unique record identifier. The values of this field must be unique for each record (for example, customer ID numbers).

Instance Weight. Specifying a field here enables you to use instance weights (a weight per row of input data) instead of, or in addition to, the default, class weights (a weight per category for the target field). The field you specify here must be one that contains a numeric weight for each row of input data.

Predictors (Inputs). Select the input field or fields. This is similar to setting the field role to *Input* in a Type node.

IBM® Db2® for z/OS® Models - Decision Tree Build Options

The following build options are available for tree growth:

Growth Measure. These options control the way tree growth is measured.

- Impurity Measure. This measure evaluates the best place to split the tree. It is a measurement of the variability in a subgroup or segment of data. A low impurity measurement indicates a group where most members have similar values for the criterion or target field. The supported measurements are Entropy and Gini. These measurements are based on probabilities of category membership for the branch.
- Maximum tree depth. The maximum number of levels to which the tree can grow below the root node, that is, the number of times the sample is split recursively. The default value of this property is 10, and the maximal value that you can set for this property is 62. Note: If the viewer in the model nugget shows the textual representation of the model, a maximum of 12 levels of the tree is displayed.

Splitting Criteria. These options control when to stop splitting the tree.

- Minimum improvement for splits. The minimum amount by which impurity must be reduced before a new split is created in the tree. The goal of tree building is to create subgroups with similar output values to minimize the impurity within each node. If the best split for a branch reduces the impurity by less than the amount that is specified by the splitting criteria, the branch is not split.
- Minimum number of instances for a split. The minimum number of records that can be split. When fewer than this number of unsplittable records remain, no further splits are made. You can use this field to prevent the creation of small subgroups in the tree.

Statistics. This parameter defines how many statistics are included in the model. Select one of the following options:

- All. All column-related statistics and all value-related statistics are included.
Note: This parameter includes the maximum number of statistics and might therefore affect the performance of your system. If you do not want to view the model in graphical format, specify None.
- Columns. Column-related statistics are included.
- None. Only statistics that are required to score the model are included.

IBM® Db2® for z/OS® Models - Decision Tree Node - Class Weights

Here you can assign weights to individual classes. The default is to assign a value of 1 to all classes, making them equally weighted. By specifying different numerical weights for different class labels, you instruct the algorithm to weight the training sets of particular classes accordingly.

To change a weight, double-click it in the Weight column and make the changes you want.

Value. The set of class labels, derived from the possible values of the target field.

Weight. The weighting to be assigned to a particular class. Assigning a higher weight to a class makes the model more sensitive to that class relative to the other classes.

You can use class weights in combination with instance weights.

IBM® Db2® for z/OS® Models - Decision Tree Node - Tree Pruning

You can use the pruning options to specify pruning criteria for the decision tree. The intention of pruning is to reduce the risk of overfitting by removing overgrown subgroups that do not improve the expected accuracy on new data.

Pruning measure. The default pruning measure, Accuracy, ensures that the estimated accuracy of the model remains within acceptable limits after removing a leaf from the tree. Use the alternative, Weighted Accuracy, if you want to take the class weights into account while applying pruning.

Data for pruning. You can use some or all of the training data to estimate the expected accuracy on new data. Alternatively, you can use a separate pruning dataset from a specified table for this purpose.

- **Use all training data.** This option (the default) uses all the training data to estimate the model accuracy.
- **Use % of training data for pruning.** Use this option to split the data into two sets, one for training and one for pruning, using the percentage specified here for the pruning data.
- Select Replicate results if you want to specify a random seed to ensure that the data is partitioned in the same way each time you run the stream. You can either specify an integer in the Seed used for pruning field, or click Generate, which will create a pseudo-random integer.
- **Use data from an existing table.** Specify the table name of a separate pruning data set for estimating model accuracy. Doing so is considered more reliable than using training data.

IBM® Db2® for z/OS® models - Regression Tree

A regression tree is a tree-based algorithm that splits a sample of cases repeatedly to derive subsets of the same kind, based on values of a numeric target field. As with decision trees, regression trees decompose the data into subsets in which the leaves of the tree correspond to sufficiently small or sufficiently uniform subsets. Splits are selected to decrease the dispersion of target attribute values, so that they can be reasonably well predicted by their mean values at leaves.

IBM® Db2® for z/OS® Models - Regression Tree Build Options - Tree Growth

You can set build options for tree growth and tree pruning.

The following build options are available for tree growth:

Maximum tree depth. The maximum number of levels to which the tree can grow below the root node, that is, the number of times the sample is split recursively. The default is 62, which is the maximum tree depth for modeling purposes.

Note: If the viewer in the model nugget shows the textual representation of the model, a maximum of 12 levels of the tree is displayed. Splitting Criteria. These options control when to stop splitting the tree.

- Split evaluation measure. This class evaluation measure evaluates the best place to split the tree.
Note: Currently, variance is the only possible option.
- Minimum improvement for splits. The minimum amount by which impurity must be reduced before a new split is created in the tree. The goal of tree building is to create subgroups with similar output values to minimize the impurity within each node. If the best split for a branch reduces the impurity by less than the amount that is specified by the splitting criteria, the branch is not split.
- Minimum number of instances for a split. The minimum number of records that can be split. When fewer than this number of unsplit records remain, no further splits are made. You can use this field to prevent the creation of small subgroups in the tree.

Statistics. This parameter defines how many statistics are included in the model. Select one of the following options:

- All. All column-related statistics and all value-related statistics are included.
Note: This parameter includes the maximum number of statistics and might therefore affect the performance of your system. If you do not want to view the model in graphical format, specify None.
- Columns. Column-related statistics are included.
- None. Only statistics that are required to score the model are included.

IBM® Db2® for z/OS® models - Regression Tree build options - Tree Pruning

You can use the pruning options to specify pruning criteria for the regression tree. The intention of pruning is to reduce the risk of overfitting by removing overgrown subgroups that do not improve the expected accuracy on new data.

Pruning measure. The pruning measure ensures that the estimated accuracy of the model remains within acceptable limits after removing a leaf from the tree. You can select one of the following measures.

- mse. Mean squared error - (default) measures how close a fitted line is to the data points.
- r2. R-squared - measures the proportion of variation in the dependent variable explained by the regression model.
- Pearson. Pearson's correlation coefficient - measures the strength of relationship between linearly dependent variables that are normally distributed.
- Spearman. Spearman's correlation coefficient - detects nonlinear relationships that appear weak according to Pearson's correlation, but which may actually be strong.

Data for pruning. You can use some or all of the training data to estimate the expected accuracy on new data. Alternatively, you can use a separate pruning dataset from a specified table for this purpose.

- Use all training data. This option (the default) uses all the training data to estimate the model accuracy.
- Use % of training data for pruning. Use this option to split the data into two sets, one for training and one for pruning, using the percentage specified here for the pruning data.
Select Replicate results if you want to specify a random seed to ensure that the data is partitioned in the same way each time you run the stream. You can either specify an integer in the Seed used for pruning field, or click Generate, which will create a pseudo-random integer.
- Use data from an existing table. Specify the table name of a separate pruning dataset for estimating model accuracy. Doing so is considered more reliable than using training data.

IBM® Db2® for z/OS® models - TwoStep

The TwoStep node implements the TwoStep algorithm that provides a method to cluster data over large data sets.

You can use this node to cluster data while available resources, for example, memory and time constraints, are considered.

The TwoStep algorithm is a database-mining algorithm that clusters data in the following way:

1. A clustering feature (CF) tree is created. This high-balanced tree stores clustering features for hierarchical clustering where similar input records become part of the same tree nodes.
2. The leaves of the CF tree are clustered hierarchically in-memory to generate the final clustering result. The best number of clusters is determined automatically. If you specify a maximum number of clusters, the best number of clusters within the specified limit is

determined.

3. The clustering result is refined in a second step where an algorithm that is similar to the K-Means algorithm is applied to the data.

- [IBM Db2 for z/OS models - TwoStep field options](#)
 - [IBM Db2 for z/OS Models - TwoStep Build Options](#)
 - [IBM Db2 for z/OS Models - TwoStep nugget - Model tab](#)
-

IBM® Db2® for z/OS® models - TwoStep field options

By setting the field options, you can specify to use the field role settings that are defined in upstream nodes. You can also make the field assignments manually.

Select an item. Choose this option to use the role settings from an upstream Type node or from the Types tab of an upstream source node. Role settings are, for example, targets and predictors.

Use custom field assignments. Choose this option if you want to assign targets, predictors, and other roles manually.

Fields. Use the arrows to assign items manually from this list to the role fields on the right. The icons indicate the valid measurement levels for each role field.

Record ID. The field that is to be used as the unique record identifier.

Predictors (Inputs). Choose one or more fields as inputs for the prediction.

IBM® Db2® for z/OS® Models - TwoStep Build Options

By setting the build options, you can customize the build of the model for your own purposes.

If you want to build a model with the default options, click Run.

Distance measure. This parameter defines the method of measure for the distance between data points. Greater distances indicate greater dissimilarities. The option is:

- Log-likelihood. The likelihood measure places a probability distribution on the variables. Continuous variables are assumed to be normally distributed, while categorical variables are assumed to be multinomial. All variables are assumed to be independent.

Cluster Number. This parameter defines the number of clusters to be created. The options are:

- Automatically calculate number of clusters. The number of clusters is calculated automatically. You can specify the maximum number of clusters in the Maximum field.
- Specify number of clusters. Specify how many clusters should be created.

Statistics. This parameter defines how many statistics are included in the model. The options are:

- All. All column-related statistics and all value-related statistics are included.
Note: This parameter includes the maximum number of statistics and might therefore affect the performance of your system. If you do not want to view the model in graphical format, specify None.
- Columns. Column-related statistics are included.
- None. Only statistics that are required to score the model are included.

Replicate results. Select this check box if you want to set a random seed to replicate analyses. You can specify an integer, or you can create a pseudo-random integer by clicking Generate.

IBM® Db2® for z/OS® Models - TwoStep nugget - Model tab

The Model tab contains various graphic views that show summary statistics and distributions for fields of clusters. You can export the data from the model, or you can export the view as a graphic.

Managing IBM Db2 for z/OS Models

Db2® for z/OS® models are added to the canvas and the Models palette in the same way as other IBM® SPSS® Modeler models, and can be used in much the same way.

To score the data directly in Db2 for z/OS, do the following steps:

1. Install SPSS Scoring Adapter in the Db2 for z/OS database where the data is located.
2. Ensure that the stream connects to the Db2 for z/OS database where the data is located.

- [Scoring IBM Db2 for z/OS Models](#)
- [IBM Db2 for z/OS Decision Tree Model Nuggets](#)
- [IBM Db2 for z/OS K-Means model nugget](#)
- [IBM Db2 for z/OS Naïve Bayes model nuggets](#)
- [IBM Db2 for z/OS Regression Tree model nuggets](#)
- [IBM Db2 for z/OS TwoStep model nugget](#)

Scoring IBM® Db2® for z/OS® Models

Models are represented on the canvas by a gold model nugget icon. The main purpose of a nugget is for scoring data to generate predictions, or to allow further analysis of the model properties. Scores are added in the form of one or more extra data fields that can be made visible by attaching a Table node to the nugget and running that branch of the stream, as described later in this section. Some nugget dialog boxes, such as those for Decision Tree or Regression Tree, additionally have a Model tab that provides a visual representation of the model.

The extra fields are distinguished by the prefix \$<id>- added to the name of the target field, where <id> depends on the model, and identifies the type of information being added. The different identifiers are described in the topics for each model nugget.

To view the scores, complete the following steps:

1. Attach a Table node to the model nugget.
2. Open the Table node.
3. Click Run.
4. Scroll to the right of the table output window to view the extra fields and their scores.

Note: The scoring process does not run in the accelerator but in Db2 and consequently requires that the input table for scoring must be physically located in Db2. Therefore, as scoring input, only a Db2-based table or an accelerated table can be used. If the stream uses an accelerator-only table, the following error occurs: "THE STATEMENT CANNOT BE EXECUTED BY DB2 OR IN THE ACCELERATOR."

IBM® Db2 for z/OS Decision Tree Model Nuggets

The Decision Tree model nugget displays the output from the modeling operation and also enables you to set some options for scoring the model.

When you run a stream that contains a Decision Tree model nugget, the node adds two new fields, the names of which are derived from the target.

Table 1. Model-scoring field for Decision Tree

Name of Added Field	Meaning
\$I-target_name	Predicted value for current record.
\$IP-target_name	Confidence value (from 0.0 to 1.0) for the prediction.

Note: Due to limitations in Db2® for z/OS®, the column names might be truncated.

- [IBM Db2 for z/OS Decision Tree Nugget - Model Tab](#)
- [IBM Db2 for z/OS Decision Tree Nugget - Viewer Tab](#)

IBM® Db2® for z/OS® Decision Tree Nugget - Model Tab

The Model tab shows the Predictor Importance of the decision tree model in graphical format. The length of the bar represents the importance of the predictor.

Related information

- [Scoring IBM Db2 for z/OS Models](#)

- [IBM Db2 for z/OS Models - Decision Trees](#)

IBM® Db2® for z/OS® Decision Tree Nugget - Viewer Tab

The Viewer tab shows a tree presentation of the tree model in the same way as the SPSS® Modeler does for its decision tree model.

IBM® Db2 for z/OS K-Means model nugget

K-Means model nuggets contain all of the information captured by the clustering model, as well as information about the training data and the estimation process.

When you run a stream that contains a K-Means model nugget, the node adds two new fields that contain the cluster membership and distance from the assigned cluster center for that record. The new field names are derived from the model name, prefixed by \$KM- for the cluster membership and \$KMD- for the distance from the cluster center. For example, if your model is named Kmeans, the new fields would be named \$KM-Kmeans and \$KMD-Kmeans.

Note: Due to limitations in Db2® for z/OS®, the column names might be truncated.

- [IBM Db2 for z/OS K-Means nugget - Model tab](#)

IBM® Db2® for z/OS® K-Means nugget - Model tab

The Model tab contains various graphic views that show summary statistics and distributions for fields of clusters. You can export the data from the model, or you can export the view as a graphic.

IBM® Db2 for z/OS Naive Bayes model nuggets

When you run a stream that contains a Naive Bayes model nugget, the node adds two new fields, the names of which are derived from the target name.

Table 1. Model-scoring field for Naive Bayes

Name of Added Field	Meaning
\$I-target_name	Predicted value for current record.
\$IP-target_name	Confidence value (from 0.0 to 1.0) for the prediction.

Note: Due to limitations in Db2® for z/OS®, the column names might be truncated.

You can view the extra fields by attaching a Table node to the model nugget and running the Table node.

IBM® Db2 for z/OS Regression Tree model nuggets

When you run a stream that contains a Regression Tree model nugget, the node adds two new fields, the names of which are derived from the target name.

Table 1. Model-scoring field for Regression Tree

Name of Added Field	Meaning
\$I-target_name	Predicted value for current record.
\$IS-target_name	Estimated standard deviation of the predicted value.

Note: Due to limitations in Db2® for z/OS®, the column names might be truncated.

You can view the extra fields by attaching a Table node to the model nugget and running the Table node.

- [IBM Db2 for z/OS Regression Tree nugget - Model tab](#)
- [IBM Db2 for z/OS Regression Tree nugget - Viewer tab](#)

IBM® Db2® for z/OS® Regression Tree nugget - Model tab

The Model tab shows the Predictor Importance of the regression tree model in graphical format. The length of the bar represents the importance of the predictor.

IBM® Db2® for z/OS® Regression Tree nugget - Viewer tab

The Viewer tab shows a tree presentation of the tree model in the same way as the SPSS® Modeler does for its regression tree model.

IBM® Db2® for z/OS® TwoStep model nugget

When you run a stream that contains a TwoStep model nugget, the node adds two new fields that contain the cluster membership and distance from the assigned cluster center for that record. The new field names are derived from the model name, prefixed by \$TS- for the cluster membership and \$TSD- for the distance from the cluster center. For example, if your model is named MDL, the new fields would be named \$TS-MDL and \$TSD-MDL.

Architecture and Hardware Recommendations

- [Architecture Description](#)
- [Hardware Recommendations](#)
- [Data Access](#)

Architecture Description

IBM® SPSS® Modeler Server uses a three-tier, distributed architecture. Software operations are shared between the client and the server computers. The advantages of installing and using IBM SPSS Modeler Server (versus the standalone IBM SPSS Modeler), especially when dealing with large data sets, are numerous:

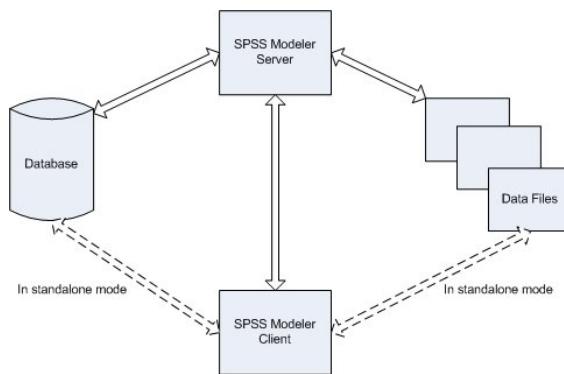

- IBM SPSS Modeler Server can run on UNIX, in addition to Windows, allowing more flexibility in deciding where to install it. On any platform, you can dedicate a faster, larger server computer to data mining processes.
- IBM SPSS Modeler Server is optimized for fast performance. When operations cannot be pushed into the database, IBM SPSS Modeler Server stores the intermediate results as temporary files on disk rather than in RAM. Because servers usually have significant disk space available, IBM SPSS Modeler Server can perform sort, merge, and aggregation operations on very large data sets.
- Using the client-server architecture, you can centralize data-mining processes in your organization. Centralization can help to formalize the role of data mining in your business processes.
- Using administrator tools like the IBM SPSS Modeler Administration Console (included with IBM SPSS Deployment Manager) and IBM SPSS Collaboration and Deployment Services (sold separately), you can monitor data mining processes, ensuring that adequate computing resources are available. With IBM SPSS Collaboration and Deployment Services you can automate certain data mining tasks, manage access to data models, and share results across your organization.

The components of IBM SPSS Modeler's distributed architecture are shown in the "[IBM SPSS Modeler Server Architecture](#)" graphic.

- **IBM SPSS Modeler.** The client software is installed on the end user's computer. It provides the user interface and displays the data mining results. The client is a complete installation of IBM SPSS Modeler software, but when it is connected to IBM SPSS Modeler Server for distributed analysis, its execution engine is inactive. The IBM SPSS Modeler runs on Windows operating systems only.
- **IBM SPSS Modeler Server.** The server software installed on a server computer, with network connectivity to both the IBM SPSS Modeler(s) and the database. IBM SPSS Modeler Server runs as a service (on Windows) or a daemon process (on UNIX), waiting for clients to connect. It handles the execution of streams and scripts created using the IBM SPSS Modeler.
- **Database server.** The database server could be a live data warehouse (for example, Oracle on a large UNIX server) or, to reduce impact on other operational systems, a data mart on a local/departmental server (for example, SQL Server on Windows).

IBM SPSS Modeler Server Architecture

Figure 1. IBM SPSS Modeler Server architecture

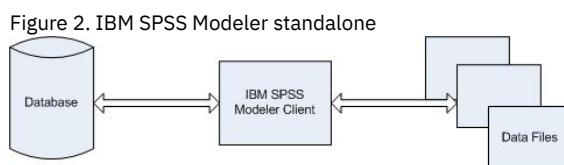

With the distributed architecture, most of the processing occurs on the server computer. When the end user executes a stream, IBM SPSS Modeler sends a description of the stream to the server. The server determines which operations can be executed in SQL and creates the appropriate queries. These queries are executed in the database, and the resulting data are passed to the server for any processing that cannot be expressed using SQL. Once the processing is complete, only the relevant results are passed back to the client.

If necessary, IBM SPSS Modeler Server can execute all IBM SPSS Modeler operations outside of the database. It automatically balances its use of RAM and disk memory to hold data for manipulation. This process makes IBM SPSS Modeler Server fully compatible with flat files.

Load balancing is also available by using a cluster of servers for processing. Clustering is available starting in IBM SPSS Collaboration and Deployment Services 3.5 through the Coordinator of Processes plug-in. See the topic [Load Balancing with Server Clusters](#) for more information. You can connect to a server or cluster managed in the Coordinator of Processes directly through IBM SPSS Modeler's Server Login dialog. See the topic [Connecting to IBM SPSS Modeler Server](#) for more information.

Standalone Client

IBM SPSS Modeler may also be configured to run as a self-contained desktop application, shown in the graphic below. See [IBM SPSS Modeler Support](#) for more information.

Hardware Recommendations

As you plan your IBM® SPSS® Modeler Server installation, you should consider the hardware that you will use. Although IBM SPSS Modeler Server is designed to be speedy, you can maximize its efficiency by using hardware that is sized appropriately for your data mining tasks. Upgrading hardware is often the simplest and most economical way to improve performance across the board.

Dedicated server. Install IBM SPSS Modeler Server on a dedicated server machine where it will not compete for resources with other applications, including any databases to which IBM SPSS Modeler Server may be connecting. Model-building operations in particular are resource-intensive and perform much better when not in competition with other applications.

Note: Although installing IBM SPSS Modeler Server on the same computer as the database can reduce data-transfer time between the database and the server by avoiding network overhead, in most cases the best configuration is to have the server and database on separate machines to avoid competition for resources. Provide a fast connection between the two to minimize the cost of data transfer.

Processors. The number of processors on the machine should be no less than the number of concurrent tasks (simultaneously executing streams) you expect to run on a regular basis. In general, the more processors, the better.

- A single instance of IBM SPSS Modeler Server will accept connections from multiple clients (users), and each client connection can initiate multiple stream executions. One server can therefore have several execution tasks in progress at any one time.
- As a rule of thumb, allow one processor for one or two users, two processors for up to four users, and four processors for up to eight users. Add one additional processor for every two to four users beyond that, depending on the mix of work.
- To the extent that some processing may be pushed back to the database through SQL optimization, it may be possible to share a CPU between two or more users with minimal loss in performance.
- Multithreading capabilities make it possible for a single task to take advantage of multiple processors, so adding processors can improve performance even in cases where only one task is running at a time. Generally, multithreading is used for C5.0 model building and certain data preparation operations (sort, aggregate, and merge). Multithreading is also supported for all nodes that run in IBM SPSS Analytic Server (for example: GLE, Linear-AS, Random Forest, LSVM, Tree-AS, Time Series, TCM, Association Rules, and STP).

64-bit platforms. If you plan to process or build models on very large volumes of data, use a 64-bit machine as your IBM SPSS Modeler Server platform, and maximize the amount of RAM for the machine. For larger data sets, the server can quickly exhaust the per-process memory limits

imposed by 32-bit platforms, forcing data to be spilled to disk and significantly increasing the running time. 64-bit server implementations can take advantage of additional RAM; a minimum of 8 gigabytes (GB) is recommended.

Future needs. Whenever feasible, make sure that server hardware is expandable in terms of memory and CPUs, both to accommodate increases in usage (for example, increased numbers of simultaneous users or increases in the existing users processing requirements) and increased multithreading capabilities of IBM SPSS Modeler Server in the future.

- [Temporary Disk Space and RAM Requirements](#)
-

Temporary Disk Space and RAM Requirements

IBM® SPSS® Modeler Server uses temporary disk space to process large volumes of data. The amount of temporary space that you need depends on the volume and type of data that you process and the type of operations you perform. The data volume is proportional to both the number of rows and the number of columns. The more rows and columns that you process, the more disk space you need.

- [Conditions That Require Temporary Disk Space](#)
 - [Calculating the Amount of Temporary Disk Space](#)
 - [RAM Requirements](#)
-

Conditions That Require Temporary Disk Space

The powerful SQL optimization feature of IBM® SPSS® Modeler Server means that processing can occur in the database (rather than on the server) whenever possible. However, when any of the following conditions are true, SQL optimization cannot be used:

- The data to be processed are held in a flat file rather than in a database.
- SQL optimization is turned off.
- The processing operation cannot be optimized using SQL.

When SQL optimization cannot be used, the following data manipulation nodes and CLEM functions create temporary disk copies of some or all of the data. If the streams used at your site contain these processing commands or functions, you may need to set aside additional disk space on your server.

- Aggregate node
- Distinct node
- Binning node
- Merge node when using the merge-by-key option
- Any modeling node
- Sort node
- Table output node
- @OFFSET functions in which the lookup condition uses @THIS.
- Any @ function, such as @MIN, @MAX, and @AVE, in which the offset parameter is calculated.

Related information

- [Calculating the Amount of Temporary Disk Space](#)
 - [RAM Requirements](#)
-

Calculating the Amount of Temporary Disk Space

In general, IBM® SPSS® Modeler Server needs to be able to write a temporary file that is at least *three times as large* as the original data set. For example, if the data file is 2GB and SQL generation is not used, IBM SPSS Modeler Server will require 6GB of disk space to process the data. Because each concurrent user account creates its own temporary files, you will need to increase the disk space accordingly for each concurrent user.

If you find that your site frequently uses large temporary files, consider using a separate file system for IBM SPSS Modeler's temporary files, created on a separate disk. For best results, a RAID 0 or striped data set that spans multiple physical disks can be used to speed up disk operations, ideally with each disk in the striped file system on a separate disk controller.

Related information

- [Conditions That Require Temporary Disk Space](#)

- [RAM Requirements](#)
-

RAM Requirements

For most processing that cannot be performed in the database, IBM® SPSS® Modeler Server stores the intermediate results as temporary files on disk rather than in memory (RAM). However, for modeling nodes, RAM is used if possible. The Neural Net, Kohonen, and K-Means nodes require large amounts of RAM. If these nodes are frequently used at your site, consider installing more RAM on the server.

In general, the number of bytes of RAM needed can be estimated by

```
(number_of_records * number_of_cells_per_record) * number_of_bytes_per_cell
```

where `number_of_cells_per_record` can become very large when there are nominal fields.

Refer to the system requirements section of the server installation guide for current RAM recommendations. For four or more simultaneous users, even more RAM is recommended. Memory must be shared between concurrent tasks, so scale up accordingly. In general, adding memory is likely to be one of the most cost-effective ways to improve performance across the board.

- [Conditions That Require Temporary Disk Space](#)
 - [Calculating the Amount of Temporary Disk Space](#)
-

Data Access

To read or write to a database, you must have an ODBC data source installed and configured for the relevant database, with read or write permissions as needed. The IBM SPSS Data Access Pack includes a set of ODBC drivers that can be used for this purpose, and these drivers are available from the download site. If you have questions about creating or setting permissions for ODBC data sources, contact your database administrator.

Supported ODBC drivers

For the latest information on which databases and ODBC drivers are supported and tested for use with IBM® SPSS® Modeler, see the product compatibility matrices on the corporate Support site (<http://www.ibm.com/support>).

Where to install drivers

Note: ODBC drivers must be installed and configured on each computer where processing may occur.

- If you are running IBM SPSS Modeler in local (standalone) mode, the drivers must be installed on the local computer.
- If you are running IBM SPSS Modeler in distributed mode against a remote IBM SPSS Modeler Server, the ODBC drivers need to be installed on the computer where IBM SPSS Modeler Server is installed. For IBM SPSS Modeler Server on UNIX systems, see also "Configuring ODBC drivers on UNIX systems" later in this section.
- If you need to access the same data sources from both IBM SPSS Modeler and IBM SPSS Modeler Server, the ODBC drivers must be installed on both computers.
- If you are running IBM SPSS Modeler over Terminal Services, the ODBC drivers need to be installed on the Terminal Services server on which you have IBM SPSS Modeler installed.

Configuring ODBC drivers on UNIX systems

By default, the DataDirect Driver Manager is not configured for IBM SPSS Modeler Server on UNIX systems. To configure UNIX to load the DataDirect Driver Manager, enter the following commands:

```
cd <modeler_server_install_directory>/bin  
rm -f libspssodbc.so
```

Then run this command if you want to use the UTF8 driver wrapper:

```
ln -s libspssodbc_datadirect.so libspssodbc.so
```

Or run this command instead if you want to use the UTF16 driver wrapper:

```
ln -s libspssodbc_datadirect_utf16.so libspssodbc.so
```

Doing so removes the default link and creates a link to the DataDirect Driver Manager.

Note: The UTF16 driver wrapper is required to use SAP HANA or IBM Db2 CLI drivers for some databases. DashDB requires the IBM Db2 CLI driver.

To configure SPSS Modeler Server:

1. Configure the SPSS Modeler Server start up script modelersrv.sh to source the IBM SPSS Data Access Pack odbc.sh environment file by adding the following line to modelersrv.sh:

```
. /<pathtoSDAPinstall>/odbc.sh
```

Where <pathtoSDAPinstall> is the full path to your IBM SPSS Data Access Pack installation.

2. Restart SPSS Modeler Server.

In addition, for SAP HANA and IBM Db2 only, add the following parameter definition to the DSN in your odbc.ini file to avoid buffer overflows during connection:

DriverUnicodeType=1

Note: The libspssodbc_datadirect_utf16.so wrapper is also compatible with the other SPSS Modeler Server supported ODBC drivers.

Note: The above rules apply specifically to accessing data in a database. Other types of file operations, such as opening and saving streams, projects, models, nodes, PMML, output, and script files, are always done on the client and are always specified in terms of the file system of the client computer. In addition, the Set Directory command in SPSS Modeler sets the working directory for *local* client objects (for example, streams) but does not affect the server's working directory.

UNIX and SPSS Statistics

For information about how to configure SPSS Modeler Server on UNIX to work with the IBM SPSS Statistics data access technology, see [Configuring UNIX Startup Scripts](#).

- [Referencing Data Files](#)
 - [Importing IBM SPSS Statistics Data Files](#)
-

Referencing Data Files

Windows. If you store data on the same computer as IBM® SPSS® Modeler Server, we recommend that you give the path to the data from the perspective of the server computer (for example, C:\ServerData\Sales 1998.csv). Performance is faster when the network is not used to locate the file.

If the data is stored on a different host, we recommend using UNC file references (for example, \\mydataserver\ServerData\Sales 1998.csv). Note that UNC names work only when the path contains the name of a shared network resource. The referencing computer must have permission to read the specified file. If you switch frequently from distributed to local analysis mode, use UNC file references because they work regardless of the mode.

UNIX. To reference data files that reside on a UNIX server, use the full file specification and forward slashes (for example, /public/data/ServerData/Sales 1998.csv). Avoid using the backslash character in the UNIX directory and in filenames for data used with IBM SPSS Modeler Server. It does not matter whether a text file uses UNIX or DOS format—both are handled automatically.

Related information

- [Importing IBM SPSS Statistics Data Files](#)
-

Importing IBM SPSS Statistics Data Files

If you are also running IBM® SPSS® Statistics Server at your site, users may want to import or export IBM SPSS Statistics data while in distributed mode. Recall that when the IBM SPSS Modeler runs in distributed mode, it presents the server's file system. The IBM SPSS Statistics client works in the same way. For importing and exporting to take place between the two applications, both clients must be operating in the same mode. If they are not, their views of the file systems will be different and they will not be able to share files. The IBM SPSS Statistics nodes in IBM SPSS Modeler can automatically start the IBM SPSS Statistics client, but users must first ensure that the IBM SPSS Statistics client is operating in the same mode as IBM SPSS Modeler.

IBM SPSS Modeler Support

This section is intended for administrators and help-desk personnel who support users of IBM® SPSS® Modeler. It covers the following topics:

- How to log on to IBM SPSS Modeler Server (or run standalone by disconnecting from a Server)
 - Data and file systems that users may need
 - User accounts and file permissions pertaining to IBM SPSS Modeler Server
 - Differences in results that users may see when switching between IBM SPSS Modeler Server and IBM SPSS Modeler
- [Connecting to IBM SPSS Modeler Server](#)
 - [Data and File Systems](#)
 - [User Authentication](#)
 - [Differences in Results](#)
-

Connecting to IBM SPSS Modeler Server

IBM® SPSS® Modeler can be run as a standalone application, or as a client connected to IBM SPSS Modeler Server directly or to an IBM SPSS Modeler Server or server cluster through the Coordinator of Processes plug-in from IBM SPSS Collaboration and Deployment Services. The current connection status is displayed at the bottom left of the IBM SPSS Modeler window.

Whenever you want to connect to a server, you can manually enter the server name to which you want to connect or select a name that you have previously defined. However, if you have IBM SPSS Collaboration and Deployment Services, you can search through a list of servers or server clusters from the Server Login dialog box. The ability to browse through the Statistics services running on a network is made available through the Coordinator of Processes.

To Connect to a Server

1. On the Tools menu, click Server Login. The Server Login dialog box opens. Alternatively, double-click the connection status area of the IBM SPSS Modeler window.
2. Using the dialog box, specify options to connect to the local server computer or select a connection from the table.
 - Click Add or Edit to add or edit a connection. See the topic [Adding and Editing the IBM SPSS Modeler Server Connection](#) for more information.
 - Click Search to access a server or server cluster in the Coordinator of Processes. See the topic [Searching for Servers in IBM SPSS Collaboration and Deployment Services](#) for more information.

Server table. This table contains the set of defined server connections. The table displays the default connection, server name, description, and port number. You can manually add a new connection, as well as select or search for an existing connection. To set a particular server as the default connection, select the check box in the Default column in the table for the connection.

Default data path. Specify a path used for data on the server computer. Click the ellipsis button (...) to browse to the required location.

Set Credentials. Leave this box unchecked to enable the **single sign-on** feature, which attempts to log you in to the server using your local computer username and password details. If single sign-on is not possible, or if you check this box to disable single sign-on (for example, to log in to an administrator account), the following fields are enabled for you to enter your credentials.

User ID. Enter the user name with which to log on to the server.

Password. Enter the password associated with the specified user name.

Domain. Specify the domain used to log on to the server. A domain name is required only when the server computer is in a different Windows domain than the client computer.

3. Click OK to complete the connection.

To Disconnect from a Server

1. On the Tools menu, click Server Login. The Server Login dialog box opens. Alternatively, double-click the connection status area of the IBM SPSS Modeler window.
 2. In the dialog box, select the Local Server and click OK.
- [Adding and Editing the IBM SPSS Modeler Server Connection](#)
 - [Searching for Servers in IBM SPSS Collaboration and Deployment Services](#)

 - [Adding and Editing the IBM SPSS Modeler Server Connection](#)
 - [Searching for Servers in IBM SPSS Collaboration and Deployment Services](#)

Related information

- [Starting IBM SPSS Modeler](#)

Configuring single sign-on

You can connect to an IBM® SPSS® Modeler Server that is running on any supported platform using Single Sign-On. To connect using Single Sign-On, you must first configure your IBM SPSS Modeler server and client machines.

If you are using Single Sign-On to connect to both IBM SPSS Modeler Server and IBM SPSS Collaboration and Deployment Services, you must connect to IBM SPSS Collaboration and Deployment Services before you connect to IBM SPSS Modeler.

IBM SPSS Modeler Server uses Kerberos for Single Sign-On.

Kerberos is a core component of Windows Active Directory, and the following information assumes an Active Directory infrastructure. In particular:

- The client computer is a Windows computer that is joined to an Active Directory domain
- The client user has logged in to the computer using a domain account. The mechanism used to log in is unimportant and may employ a smart card, fingerprint, etc.
- IBM SPSS Modeler Server can validate the client user's credentials by reference to the Active Directory domain controller

This documentation describes how both Windows and UNIX servers can be configured to authenticate this way. Other configurations may be possible but are untested.

To inter-operate with most modern, secure Active Directory installations, you must install the high-strength encryption pack for Java because the required encryption algorithms are not supported by default. You must install the pack for both client and server. An error message such as **Illegal key size** is displayed on the client when a server connection fails because the pack is not installed. See [Installing unlimited strength encryption](#).

- [The Service Principal Name](#)
- [Configuring IBM SPSS Modeler Server on Windows](#)
- [Configuring IBM SPSS Modeler Server on UNIX and Linux](#)
- [Configuring IBM SPSS Modeler client](#)
- [Getting the SSO user's group membership](#)
- [Single sign-on for data sources](#)

The Service Principal Name

Each server instance must register a unique *service principal name (SPN)* to identify itself, and the client must specify the same SPN when it connects to the server.

An SPN for an instance of SPSS® Modeler Server has the form:

```
modelerserver/<host>:<port>
```

For example:

```
modelerserver/jdoemachine.spss.com:28054
```

Note that the host name must be qualified with its DNS domain (**spss.com** in this example), and the domain must map to the Kerberos realm.

The combination of host name and port number makes the SPN unique (because each instance on a given host must listen on a different port). And both client and server already have the host name and port number and so can construct the appropriate SPN for the instance. The additional configuration step required is to register the SPN in the Kerberos database.

Registering the SPN on Windows

If you are using Active Directory as your Kerberos implementation, use the **setspn** command to register the SPN. To run this command, the following conditions must be satisfied:

- You must be logged on to a domain controller
- You must run the command prompt with elevated privileges (run as administrator)
- You must be a member of the Domain Admins group (or have had the appropriate permission delegated to you by a domain administrator)

For more information, refer to the following articles:

- [Setspn Command-Line Reference](#)
- [Delegating Authority to Modify SPNs](#)

For the default instance, listening on the standard port (28054, for example) and running under the Local System account, you must register the SPN against the server computer name. For example:

```
setspn -s modelerserver/jdoemachine.spss.com:28054 jdoemachine
```

For each subsequent (profile) instance, listening on a custom port (for example, 29000) and running under an arbitrary user account (for example, `jdoe`) with the option `start_process_as_login_user` set to `Y`, you must register the SPN against the service user account name:

```
setspn -s modelerserver/jdoemachine.spss.com:29000 jdoe
```

Note that in this case (when the service account is other than Local System), registering the SPN is not sufficient to enable a client to connect. Additional configuration steps are described in the next section.

To see which SPNs are registered to the account `jdoe`:

```
setspn -l jdoe
```

Registering the SPN on UNIX

If you are using Active Directory as your Kerberos implementation, you can use the `setspn` command as described in the previous Windows section; this assumes you have already created the computer or user account in the directory. Or you can use `ktpass`, as illustrated in [Configuring IBM SPSS Modeler Server on UNIX and Linux](#).

If you are using some other Kerberos implementation, then use the Kerberos administration tool to add the service principal to the Kerberos database. To convert the SPN to a Kerberos principal you must append the name of the Kerberos realm. For example:

```
modelerserver/jdoemachine.spss.com:28054@MODELERSO.COM
```

Add this same principal and password to the server's keytab. The keytab must contain an entry for every instance running on the host.

- [Configuring IBM SPSS Modeler Server on Windows](#)
- [Getting the SSO user's group membership](#)

Configuring IBM® SPSS Modeler Server on Windows

In the default scenario where the SPSS® Modeler Server service runs under the Local System account, it uses native Windows APIs to authenticate the user's credentials and no additional configuration is required on the server.

In the alternative scenario where the SPSS Modeler Server service runs under a dedicated user account and `start_process_as_login_user` is set to `Y`, then it uses Java APIs to authenticate the user's credentials and additional configuration is required on the server.

First, verify that the default scenario works. The client should be able to use SSO to connect to the default instance running under the Local System account. This will validate the client-side configuration (that is unchanged). You will need to register the SPN for the default instance as described earlier.

Then perform the following steps:

1. Create the directory `<MODELERSERVER>\config\sso`.
2. Create a file called `krb5.conf` in the `sso` folder you created in step 1. For instructions on how to create this file, see step 3 under [Configuring IBM SPSS Modeler client](#). The file must be the same on the server and client.
3. Use the following command to create the file `krb5.keytab` in the server SSO directory:

```
<MODELERSERVER>\jre\bin\ktab -a <spn>@<realm> -k krb5.keytab
```

For example:

```
"..\jre\bin\ktab.exe" -a modelerserver/jdoemachine.spss.com:29000@SPSS.COM  
-k krb5.keytab
```

This will prompt you for a password. The password you enter must be the password of the service account. So if the service account is `jdoe`, for example, you must enter the password for the user `jdoe`.

The service account itself is not mentioned in the keytab, but earlier you registered the SPN to that account using `setspn`. This means that the password for the service principal and the password for the service account are one and the same.

For each new instance (profile) you create, you must register the SPN for that instance (using `setspn`; see [Configuring server profiles](#) and [The Service Principal Name](#)) and add an entry to the keytab (using `jre\bin\ktab`). There is only one keytab file, and it must contain an entry for every instance that is not running as Local System. The default instance, or any other instance running as Local System, does not need to be in the keytab because it uses Windows APIs to authenticate. Windows APIs do not use the keytab.

To verify that an instance is included in the keytab:

```
ktab.exe -l -e -k krb5.keytab
```

You may see multiple entries for each principal with different encryption types, but this is normal.

Configuring IBM SPSS Modeler Server on UNIX and Linux

Prerequisites

IBM® SPSS® Modeler Server relies on Windows Active Directory (AD) to enable single sign-on, for which the following prerequisites are essential:

- The SPSS Modeler Client (Windows) computer is a member of an Active Directory (AD) domain.
- The client user logs in to the computer using an AD domain account.
- The SPSS Modeler Server (UNIX) computer is identified by a fully-qualified domain name that is rooted in the AD DNS domain. For example, if the DNS domain is `modelersso.com`, then the server hostname might be `myserver.modelersso.com`.
- The AD DNS domain supports both forward and reverse lookups for the SPSS Modeler Server hostname.

If the SPSS Modeler Server machine is not a member of the AD domain you must create a domain user account to represent the service in the directory. For example, you could create a domain account called `ModelerServer`.

To Configure SPSS Modeler Server on UNIX or Linux

1. In the SPSS Modeler Serverconfig folder, create a subfolder called sso.
2. In the sso folder, create a keytab file. The keytab file's generation can be done on the AD side; however, there are different requirements depending on whether the SPSS Modeler Server machine is a member of the AD domain:
 - If the SPSS Modeler Server machine **is** a member of the AD domain, use the computer account name as the service user name:

```
ktpass -princ <spn>@<realm> -mapUser <domain>\<computer account> -pass <password> -out <output file> -ptype KRB5_NT_PRINCIPAL
```

For example:

```
ktpass -princ modelerserver/myserver.modelersso.com:28054@MODELERSO.COM -mapUser MODELERSO\myserver$ -pass Pass1234 -out c:\myserver.keytab -ptype KRB5_NT_PRINCIPAL
```

- If the SPSS Modeler Server machine **is not** a member of the AD domain, specify the domain user account, that you created as a prerequisite, as the service user:

```
ktpass -princ <spn>@<realm> -mapUser <domain>\<user account> -mapOp set -pass <password> -out <output file> -ptype KRB5_NT_PRINCIPAL
```

For example:

```
ktpass -princ modelerserver/myserver.modelersso.com:28054@MODELERSO.COM -mapUser MODELERSO\MyModelerServer -mapOp set -pass Pass1234 -out c:\myserver.keytab -ptype KRB5_NT_PRINCIPAL
```

For more information, see [Ktpass Command-Line Reference](#).

3. Rename the keytab file in the sso folder to krb5.keytab.

Note: If you re-join the server machine to the domain, generate a new keytab file.

4. Create a file called krb5.conf in the sso folder you created in step 1. For instructions on how to create this file, see step 3 under [Configuring IBM SPSS Modeler client](#). The file must be the same on the server and client.

Configuring IBM SPSS Modeler client

1. Enable Java to access the TGT session key:
 - a. From the Start menu, click Run.
 - b. Enter `regedit` and click OK to open the Registry Editor.

- c. Navigate to the registry location appropriate to the operating system of the local machine:
 - On Windows XP: My Computer\HKEY_LOCAL_MACHINE\System\CurrentControlSet\Control\Lsa\Kerberos
 - On Windows Vista, or Windows 7: My Computer\HKEY_LOCAL_MACHINE\System\CurrentControlSet\Control\Lsa\Kerberos\Parameters
 - d. Right-click the folder and select New > DWORD. The name of the new value should be allowtgtsessionkey.
 - e. Set the value of allowtgtsessionkey to a hexadecimal value of 1, that is 0x00000001.
 - f. Close the Registry Editor.
 - g. Note there is a known issue when the user account is a member of the local Administrators group and User Account Control (UAC) is enabled. In this case, the session key in the retrieved service ticket is empty, which causes SSO authentication to fail. To avoid this issue, perform one of the actions:
 - Run the application as Administrator
 - Disable User Account Control
 - Use an account that is not an Administrator account
2. In the config folder of the IBM® SPSS® Modeler installation location, create a folder called sso.
3. In the sso folder, create a krb5.conf file. Instructions for how to create a krb5.conf file can be found at http://web.mit.edu/kerberos/krb5-current/doc/admin/conf_files/krb5_conf.html. An example of a krb5.conf file is provided below:

```
[libdefaults]
    default_realm = MODELERSSO.COM
    dns_lookup_kdc = true
    dns_lookup_realm = true

[realms]
    MODELERSSO.COM = {
        kdc = ad.modelersso.com:88
        admin_server = ad.modelersso.com:749
        default_domain = modelersso.com
    }

[domain_realm]
    .modelersso.com = MODELERSSO.COM
    modelersso.com = MODELERSSO.COM
```

4. Restart the local machine and the server machine.

Getting the SSO user's group membership

When a user logs on to SPSS® Modeler Server using SSO and the server is running non-root, then the name of the authenticated user is not associated with an operating system user account. The server cannot obtain the user's operating system group membership. So how is group configuration performed in this case?

We assume the user is registered in an LDAP directory (which could be Active Directory) and we can request the group membership from the LDAP server. SPSS Modeler Server can query the LDAP provider in IBM® SPSS Collaboration and Deployment Services for the group membership.

There are two properties in options.cfg on the SPSS Modeler Server that control the server's access to the IBM SPSS Collaboration and Deployment Services Repository:

```
repository_enabled, N
repository_url, ""
```

To enable group lookup, you must set both properties. For example:

```
repository_enabled, Y
repository_url, "http://jdoemachine.spss.ibm.com:9083"
```

The repository connection is only used for SSO group lookup, so you do not need to change these property settings unless you need this feature.

For group lookup to work properly, you must configure your repository first to add an LDAP or Active Directory provider and then to enable SSO using that provider:

1. Start IBM SPSS Deployment Manager client and select File > New > Administered Server Connection... to create an administered server connection for your repository (if you do not have one already).
2. Log on to the administered server connection and expand the Configuration folder.
3. Right-click Security Providers, choose New > Security provider definition..., and enter the appropriate values. Click Help in the dialog for more information.
4. Expand the Single Sign-On Providers folder, right-click Kerberos SSO Provider, and select Open.
5. Click Enable, select your security provider, and then click Save. You do not have to fill in any other details here unless you want to use SSO (simply having the provider enabled is sufficient to allow the group lookup).

Important: For group lookup to work properly, the Kerberos provider you configure here must be the same as the provider you configured for SPSS Modeler Server. In particular, they must be working within the same Kerberos realm. So if a user logs on to SPSS Modeler Server using SSO

and it identifies him as `jdoe@SPSS.COM` (where `SPSS.COM` is the realm), it will expect the security provider in IBM SPSS Collaboration and Deployment Services to recognize that user principal name and return the corresponding group membership from the LDAP directory.

Single sign-on for data sources

You can connect to databases from IBM® SPSS® Modeler using single sign-on. If you want to create a database connection using single sign-on, you must first use your ODBC management software to properly configure a data source and single sign-on token. Then when connecting to a database in IBM SPSS Modeler, IBM SPSS Modeler will use that same single sign-on token and the user will not be prompted to log on to the data source.

However, if the data source was not configured properly for single sign-on, IBM SPSS Modeler will prompt the user to log on to the data source. The user will still be able to access the data source after providing valid credentials.

For complete details about configuring ODBC data sources on your system with single sign-on enabled, see your database vendor documentation. Following is an example of the general steps that may be involved:

1. Configure your database so it can support Kerberos single sign-on.
 2. On the IBM SPSS Modeler Server machine, create an ODBC data source and test it. The DSN connection should not require a user ID and password.
 3. Connect to IBM SPSS Modeler Server using single sign-on and begin using the ODBC data source created and validate in step 2.
-

Adding and Editing the IBM SPSS Modeler Server Connection

You can manually edit or add a server connection in the Server Login dialog box. By clicking Add, you can access an empty Add/Edit Server dialog box in which you can enter server connection details. By selecting an existing connection and clicking Edit in the Server Login dialog box, the Add/Edit Server dialog box opens with the details for that connection so that you can make any changes.

Note: You cannot edit a server connection that was added from IBM® SPSS® Collaboration and Deployment Services, since the name, port, and other details are defined in IBM SPSS Collaboration and Deployment Services. Best practice dictates that the same ports should be used to communicate with both IBM SPSS Collaboration and Deployment Services and SPSS Modeler Client. These can be set as `max_server_port` and `min_server_port` in the options.cfg file.

To Add Server Connections

1. On the Tools menu, click Server Login. The Server Login dialog box opens.
 2. In this dialog box, click Add. The Server Login Add/Edit Server dialog box opens.
 3. Enter the server connection details and click OK to save the connection and return to the Server Login dialog box.
- **Server.** Specify an available server or select one from the list. The server computer can be identified by an alphanumeric name (for example, `myserver`) or an IP address assigned to the server computer (for example, `202.123.456.78`).
 - **Port.** Give the port number on which the server is listening. If the default does not work, ask your system administrator for the correct port number.
 - **Description.** Enter an optional description for this server connection.
 - **Ensure secure connection (use SSL).** Specifies whether an SSL (**Secure Sockets Layer**) connection should be used. SSL is a commonly used protocol for securing data sent over a network. To use this feature, SSL must be enabled on the server hosting IBM SPSS Modeler Server. If necessary, contact your local administrator for details.

To Edit Server Connections

1. On the Tools menu, click Server Login. The Server Login dialog box opens.
2. In this dialog box, select the connection you want to edit and then click Edit. The Server Login Add/Edit Server dialog box opens.
3. Change the server connection details and click OK to save the changes and return to the Server Login dialog box.

Related information

- [Starting IBM SPSS Modeler](#)

Searching for Servers in IBM SPSS Collaboration and Deployment Services

Instead of entering a server connection manually, you can select a server or server cluster available on the network through the Coordinator of Processes, available in IBM® SPSS® Collaboration and Deployment Services. A server cluster is a group of servers from which the Coordinator of Processes determines the server best suited to respond to a processing request.

Although you can manually add servers in the Server Login dialog box, searching for available servers lets you connect to servers without requiring that you know the correct server name and port number. This information is automatically provided. However, you still need the correct logon information, such as username, domain, and password.

Note: If you do not have access to the Coordinator of Processes capability, you can still manually enter the server name to which you want to connect or select a name that you have previously defined. See the topic [Adding and Editing the IBM SPSS Modeler Server Connection](#) for more information.

To search for servers and clusters

1. On the Tools menu, click Server Login. The Server Login dialog box opens.
2. In this dialog box, click Search to open the Search for Servers dialog box. If you are not logged on to IBM SPSS Collaboration and Deployment Services when you attempt to browse the Coordinator of Processes, you will be prompted to do so.
3. Select the server or server cluster from the list.
4. Click OK to close the dialog box and add this connection to the table in the Server Login dialog box.

Related information

- [Starting IBM SPSS Modeler](#)

Data and File Systems

Users working with IBM® SPSS® Modeler Server will probably need to access data files and other data sources on the network, as well as save files on the network. They may need the following information, as applicable:

- **ODBC data source information.** If users need access to ODBC data sources defined on the server computer, they will need the names, descriptions, and login information (including database login IDs and passwords) for the data sources.
- **Data file access.** If users need to access data files on the server computer or elsewhere on the network, they will need the names and locations of the data files.
- **Location for saved files.** When users save data while connected to IBM SPSS Modeler Server, they may attempt to save files on the server computer. However, this is often a write-protected location. If so, let users know where they should save data files. (Typically, the location is the user's home directory.)

User Authentication

IBM® SPSS® Modeler Server uses the operating system on the server machine to authenticate users who connect to the server. When a user connects to SPSS Modeler Server, all operations that are performed on behalf of the user are performed in the user's security context. Access to database tables is subject to user and/or password privileges in the database itself.

Windows. On Windows, any user with a valid account on the host network can log on. With the default authentication, users must have modify access rights to the `<modeler_server_install>|Tmp` directory. Without these rights, users cannot log on to SPSS Modeler Server from the client using the default authentication on Windows.

UNIX. By default, SPSS Modeler Server is assumed to run as root on UNIX. This allows any user with a valid account on the host network to log on and limits users' file access to their own files and directories. However, you can configure SPSS Modeler Server to run without root privilege. In this case, you must create a private password database to be used for authentication, and all SPSS Modeler users must share a single UNIX user account (and, consequently, share access to data files). For more information, see [Configuring as non-root using a private password database](#).

Configuring PAM

On the Linux platform, SPSS Modeler Server uses the Pluggable Authentication Module (PAM) for authentication.

To use PAM authentication the appropriate PAM modules must be correctly configured on the host system; for example, for PAM to interface with LDAP, a PAM LDAP module must exist on the host OS and be correctly configured. Refer to the operating system documentation for further

information. This is a prerequisite for SPSS Modeler Server to be able to use PAM.

To configure SPSS Modeler Server to use PAM, edit the SPSS Modeler Server "options.cfg" file and add (or edit) the line **authentication_methods, pam**.

You can use the service name **modelerserver** to provide a specific PAM configuration for SPSS Modeler Server if required. For example, the following steps explain how to configure for Red Hat Linux:

1. Change to the PAM configuration directory. For example: **/etc/pam.d**.
2. Using a text editor, create a new file called "modelerserver".
3. Add the PAM configuration information that you want to use. For example:

```
auth    include    system-auth
account    include    system-auth
password    required    pam_deny.so
session    required    pam_deny.so
```

Note: These lines might vary depending on your particular configuration. For more information, see the Linux documentation.

4. Save the file and restart the Modeler service.

- [Permissions](#)
- [File Creation](#)

Permissions

Windows. A user connecting to server software that is installed on an *NTFS* drive must login with an account that has the following permissions.

- Read and execute permissions to the server's installation directory and its subdirectories
- Read, execute, and write permissions to the directory location for temporary files.

In Windows Server 2008 and later, you cannot assume that users have these permission. Be sure to explicitly set permissions as needed.

If the server software is installed on a *FAT* drive, you do not need to set permissions because all files allow users to have full control.

UNIX. If you are not using internal authentication, a user connecting to the server software must login with an account that has the following permissions:

- Read and execute permissions to the server's installation directory and its subdirectories
- Read, execute, and write permissions to the directory location for temporary files.

File Creation

When IBM® SPSS® Modeler Server accesses and processes data, it often has to keep a temporary copy of that data on disk. The amount of disk space that will be used for temporary files depends on the size of the data file that the end user is analyzing and the type of analysis that he or she is performing. See the topic [Temporary Disk Space and RAM Requirements](#) for more information.

UNIX. The UNIX versions of IBM SPSS Modeler Server use the UNIX **umask** command to set file permissions for the temporary files. You can override the server's default permissions. See the topic [Controlling Permissions on File Creation](#) for more information.

Differences in Results

Users who run analyses in both modes may see slight differences in the results between IBM® SPSS® Modeler and IBM SPSS Modeler Server. The discrepancy usually occurs because of record ordering or rounding differences.

Record ordering. Unless a stream explicitly orders records by sorting them, the order in which records are presented may vary between streams executed locally and those executed on the server. There may also be differences in order between operations run within a database and those run in IBM SPSS Modeler Server. These differences are due to the different algorithms used by each system to implement functions that may reorder records, such as aggregation. Also, note that SQL does not specify the order in which records are returned from a database in cases where there is no explicit ordering operation.

Rounding differences. IBM SPSS Modeler running in local mode uses a different internal format for storing floating point values than does IBM SPSS Modeler Server. Due to rounding differences, results might vary slightly between each version.

IBM® SPSS® Modeler Administration

- [Starting and Stopping IBM SPSS Modeler Server](#)
 - [Handling Unresponsive Server Processes \(UNIX Systems\)](#)
 - [Configuring server profiles](#)
 - [Administration](#)
 - [IBM SPSS Modeler Server Administration](#)
 - [Using SSL to secure data transfer](#)
 - [Configuring groups](#)

-

Starting and Stopping IBM SPSS Modeler Server

IBM® SPSS® Modeler Server runs as a service on Windows or as a daemon process on UNIX.

Scheduling note: Stopping IBM SPSS Modeler Server disconnects end users and terminates their sessions, so try to schedule server restarts during periods of low usage. If this is not possible, be sure to notify users before stopping the server.

- [To Start, Stop, and Check Status on Windows](#)
 - [To Start, Stop, and Check Status on UNIX](#)
-

To Start, Stop, and Check Status on Windows

On Windows, you control IBM® SPSS® Modeler Server with the Services dialog box in the Windows Control Panel.

1. **Windows XP.** Open the Windows Start menu. Choose Settings and then Control Panel. Double-click Administrative Tools and then Services.
2. **Windows 2003 or 2008.** Open the Windows Start menu. Choose Control Panel, then Administrative Tools, then Services.
3. Select the IBM SPSS Modeler Server <nn.n> service. You can now check its status, start or stop it, and edit startup parameters, as appropriate.

By default, the service is configured for automatic startup, which means that if you stop it, it will restart automatically when the computer is rebooted. When started this way, the service runs unattended, and the server computer can be logged off without affecting it.

To Start, Stop, and Check Status on UNIX

On UNIX, you start or stop IBM® SPSS® Modeler Server by running the *modelersrv.sh* script in the IBM SPSS Modeler Server installation directory.

1. Change to the IBM SPSS Modeler Server installation directory. For example, at a UNIX command prompt, type

```
cd /usr/modelersrv
```

where *modelersrv* is the IBM SPSS Modeler Server installation directory.

2. To start the server, at the command prompt, type

```
./modelersrv.sh start
```

3. To stop the server, at the command prompt, type

```
./modelersrv.sh stop
```

4. To check the status of IBM SPSS Modeler Server, at a UNIX command prompt, type

```
./modelersrv.sh list
```

and look at the output, which is similar to what the UNIX *ps* command produces. The first process in the list is the IBM SPSS Modeler Server daemon process, and remaining processes are IBM SPSS Modeler sessions.

The IBM SPSS Modeler Server installation program includes a script (*auto.sh*) that configures your system to start the server daemon automatically at boot time. If you have run that script and then stop the server, the server daemon will restart automatically when the computer is rebooted. See the topic [Automatically Starting and Stopping IBM SPSS Modeler Server](#) for more information.

UNIX kernel limits

You must ensure that kernel limits on the system are sufficient for the operation of IBM SPSS Modeler Server. The data, memory, file, and processes ulimits are particularly important and should be set to unlimited within the IBM SPSS Modeler Server environment. To do this:

1. Add the following commands to modelersrv.sh:

```
ulimit -d unlimited  
ulimit -m unlimited  
ulimit -f unlimited  
ulimit -u unlimited
```

In addition, set the stack limit to the maximum allowed by your system (`ulimit -s xxxx`), for example:

```
ulimit -s 64000
```

2. Restart IBM SPSS Modeler Server.

Handling Unresponsive Server Processes (UNIX Systems)

IBM® SPSS® Modeler Server processes may become unresponsive for several reasons, including situations where they make a system call or ODBC driver call that becomes blocked (call never returns, or takes a very long time to return). When UNIX processes enter this state, they can be cleaned up using the UNIX `kill` command (interrupts initiated by IBM SPSS Modeler client, or the closing of IBM SPSS Modeler client, will have no effect). A `kill` command is provided as an alternative to the normal `stop` command, and enables an administrator to use `modelersrv.sh` to easily issue the appropriate `kill` command.

On systems which are susceptible to the accumulation of unusable (“zombie”) server processes, we recommend that IBM SPSS Modeler Server is stopped and restarted at regular intervals, using the following sequence of commands:

```
cd modeler_server_install_directory  
. ./modelersrv.sh stop  
. ./modelersrv.sh kill
```

Those IBM SPSS Modeler processes that are ended using the `modelersrv.sh kill` command will leave behind temporary files (from the temporary directory) that will need to be removed manually. Temporary files may be left behind in some other situations too, including application crashes due to resource exhaustion, user interrupts, system crashes, or other reasons. Therefore we recommend that, as part of the process of restarting IBM SPSS Modeler Server at regular intervals, all remaining files are removed from the IBM SPSS Modeler temporary directory.

Once all server processes have been closed and temporary files have been removed, IBM SPSS Modeler Server can be safely restarted.

Configuring server profiles

Server profiles allow you to run multiple, independent instances of SPSS® Modeler Server from a single installation. To a client, they will appear to be separate servers located on the same host but listening on different port numbers. Having multiple instances sharing one installation benefits administrators because it simplifies maintenance. Subsequent instances after the first can be created and deleted more quickly than would be required for a full installation and uninstallation, and Fix Packs only need be applied once.

The reason for running multiple server instances on the same host is to be able to configure each instance separately. If all the instances are identical, there is nothing to be gained. In particular, if the instances run *non-root* (so that all sessions share the same user account), each instance can use a different user account to provide data isolation between user groups. For example, a user logging in to an instance **A** will be allocated a session owned by some particular **User-A** and will have access only to that user's files and folders, whereas a user logging in to instance **B** will see a different set of files and folders accessible to **User-B**. This can be used in conjunction with group configuration so that logging on to a particular instance is restricted to specific groups, meaning that end users can only log on to the instance (or instances) appropriate to their role. See [Configuring groups](#).

In a standard SPSS Modeler Server installation, the folders config, data, and tmp are specific to a server instance. The purpose of the config folder is for the instance to have a private configuration, and the data and tmp folders support data isolation. Each instance has a private copy of these folders, and everything else is shared.

Note that much of the server configuration can remain common (database settings, for example), so a profile configuration will override the common configuration. The server will look first in the profile configuration and then fall back to the default. The files that are most likely to be changed for a profile are options, groups, and passwords.

See [Profile structure](#) for more information.

For information on how to configure a profile to use SSO, see [Configuring single sign-on](#). This requires you to register a Service Principal Name (SPN), perform some configuration if the Windows Service account is not local, and in some cases enable group lookup.

Working with server profiles

Following are some common use cases for server profiles. Some of these uses are supported via the use of scripts (see [Profile scripts](#)) and may require administrative/root privileges.

Creating a server profile

An SPSS® Modeler Server administrator named Jane uses a script to create a new profile:

- Jane must specify a unique name for the profile (it cannot be an existing profile name). If the profiles directory does not already exist, it is created for Jane. Then a new sub-directory is created in the profiles directory with name Jane specified, containing the directories config, data, log, and tmp.
- If Jane chooses, she can also specify the name of an existing profile to use as a template, in which case the content of the config folder within the existing profile is copied to the new profile. If she does not specify a template, or if the existing profile does not include an options file even though it should, then an empty options file is created in the new profile.
- Jane may also choose to specify a port number for the profile, in which case the port number is written as the value of the `port_number` property in the profile's options file. If she does not specify a port number, a value is chosen for her and written to the options file.
- Jane can also choose to specify the name of an operating system group that will have exclusive access to the profile in which case group configuration is enabled in the options file. In this case, a groups file is created that denies login to all but the specified group.

Configuring a server profile

Server administrator Jane configures a profile either by manually editing the profile configuration files, or by using the IBM® SPSS Modeler Administration Console in IBM SPSS Deployment Manager to connect to the profile service.

Creating a Windows service for a serverprofile

On Windows, the administrator uses a script to create a service for a specified profile:

- Jane must specify the name of an existing profile, and then a service instance is created for that profile. The command line for the service will include the `profile` argument. The name of the service will follow a standard pattern including the profile name.
- Jane might need to use the service administration console later and edit the service properties if she needs to change the user name and password for the service (when running non-root).

On UNIX, there are also ways to create "services" that start automatically when the system boots. The administrator may want to create profile services using these mechanisms, but note they are not officially supported by IBM SPSS Modeler.

Managing Windows services for server profiles

Administrators can use a script to perform the following tasks:

- See which server profile services are running
- Start a particular service
- Start all services
- Stop a particular service
- Stop all services

When starting or stopping all services, the list of profiles is obtained by searching the sub-directories of the profiles directory.

Deleting a server profile's Windows service

On Windows, administrators can use a script to delete a service for a specified profile (if a service exists for the profile). The name of the profile must be specified.

Removing a server profile

After stopping the profile's service, administrators can remove a profile by deleting its folder from inside the profiles directory.

Updating SPSS Modeler Server

When applying a Fix Pack to SPSS Modeler Server, the Fix Pack is applied to all server profiles. On Windows, all profile services are stopped and restarted automatically. On UNIX, you must manually stop and restart them.

Uninstalling SPSS Modeler Server

When SPSS Modeler Server is uninstalled, all server profiles are uninstalled. Note that the profiles directory and any profiles it contains are not removed automatically. They must be deleted manually. On Windows, all profile services are uninstalled automatically. On UNIX, you must manually remove them.

Installing a new version of SPSS Modeler Server

When installing a new version of SPSS Modeler Server, any existing server profiles are not migrated automatically. An administrator must manually copy profiles from one installation to the next (and edit the configurations where necessary) to recreate the services.

Profile structure

The profiles directory

Server profiles are stored in a directory location chosen by the server administrator. The default location is a directory named profiles in the [server install path]\config\ directory on the SPSS® Modeler Server, but we recommend using a different directory for profile storage for the following reasons:

- Profiles can be shared between nodes in a cluster
- Profiles can be preserved across upgrades
- Administrators and other users who configure profiles do not need to be granted write authority to the SPSS Modeler Server installation directory

The profiles directory does not exist after a fresh SPSS Modeler Server installation. It is created when the first profile is created.

The profiles directory contains one sub-directory for each profile, and the sub-directory name matches the profile name. Because the directory name and the profile name are the same, the profile name cannot include characters that are not valid in file names. Nor should profile names contain spaces, because they are likely to cause problems in scripts. Also keep in mind that profile names must be unique within a single installation.

The only way to identify all the profiles for an installation is to identify the sub-directories of the profiles directory. There is no separate list of profiles maintained anywhere. There is also no limit on the number of profiles that can be created for an installation, aside from what can be tolerated by the host system.

In the profiles directory, the sub-directory for any given profile must contain at least one directory called config, and within that directory there must be at least one file called options.cfg that defines the profile configuration. This file contains a subset of the settings in the standard SPSS Modeler Server options.cfg file (located in [server install path]\config), as many as are needed for the profile. Settings not present in the profile configuration must be set from the common options file in the installation config directory. The profile configuration must contain at least a setting for port_number because every profile service must listen on a different port number.

The profile configuration may include other *.cfg files normally found in the installation config directory, in which case these are read instead of the standard files (only the options file is cumulative). Additional files most likely to be included in a profile configuration are groups and passwords. Files that are ignored in a profile configuration include the JVM and SSO configuration files which are shared across all profiles.

A profile directory may also contain data and tmp directories that override the common data and tmp file locations, unless alternative locations are specified in the profile configuration.

If you use profiles to achieve data isolation, be sure permissions are set appropriately on the relevant directories.

The profiles configuration file

The location of the profiles directory is specified in a new configuration file called [server install path]\config\profiles.cfg. This shares a common format with other configuration files in the same directory, and the key for setting the profiles directory is **profiles_directory**. For example:

```
profiles_directory, "C:\\SPSS\\Modeler\\profiles"
```

A separate file is used for profile configuration (rather than adding settings to the standard options file) for two reasons:

- The profile configuration determines how the options files are read, so there is an intrinsic difficulty in defining one in the other
- The profiles configuration file is designed to be managed automatically, using scripts, so in simple cases users need not be concerned with it at all (but it can still be safely hand-edited to support more complex scenarios)

Aside from the location of the profiles directory, the only other entry in profiles.cfg is a port number. For example:

```
profile_port, 28501
```

This is the default port number for the next profile to be created, and it is incremented automatically each time a profile is created using a script. The profiles.cfg file is created only as needed, so it does not exist in a fresh installation.

Starting a profile

The service executable (modelerserver.exe) accepts an additional argument, **profile**, that identifies the profile for the service:

```
modelerserver -server profile=<profile-name>
```

Multiple services can run from the same installation if each service uses a different profile. If the profile argument is omitted, the service uses the common installation defaults without any profile overrides.

When invoked with the **profile** argument, the service:

- Reads [server install path]\config\profiles.cfg to obtain the location of the profiles directory
- Reads [profiles directory]\[profile name]\config\options.cfg to obtain the profile configuration (in particular, the port number)

If either step fails for any reason, the service prints an error message to the log and stops. If the service is invoked with a profile and it cannot load the profile, then it will not run.

Environment variables

The service defines some additional environment variables so that path names, etc., can be expressed without knowledge of the current profile:

Table 1. Environment variables

Variable	Value
PROFILE_NAME	The name of the current profile, or the empty string if no profile has been specified.
MODELERPROFILE	The full path to the directory for the current profile (for example, \$MODELERSERVER\profiles\\$PROFILE_NAME). If no profile has been specified, the value is the same as the \$MODELERSERVER.
MODELERDATA	The full path to the data directory for the current profile (for example, \$MODELERPROFILE\data). If no profile has been specified, the value will point to the standard data directory \$MODELERSERVER\data

These environment variables are set by the service process, so they are only visible within that process and any child processes it creates. If you set these variables outside the service process, they will be ignored and redefined within the process as described.

Logging

Each profile service expects to have a separate, private folder in which to place its log files. There is one copy of server_logging.log, etc., for each profile.

The default **log4cxx.properties** configuration in the installation's config directory uses the PROFILE_NAME environment variable to identify the log directory for the service:

```
log4j.appenders.LoggingAppender.File=${ALLUSERSPROFILE}/IBM/SPSS/ModelerServer/17/log/${PROFILE_NAME}/server_logging.log
```

You can change the log location for all profiles by changing the line above and including one of the two profile-specific environment variables, either PROFILE_NAME or MODELERPROFILE. For example, to relocate the log directory within the profile directory:

```
log4j.appenders.LoggingAppender.File=${MODELERPROFILE}/log  
/server_logging.log
```

Alternatively, you can change the log location for a particular profile by creating and editing a copy of the log4cxx.properties file in the profile configuration.

Profile scripts

The scripts described in this section are provided to assist with the creation and management of SPSS® Modeler Server profiles. All of the scripts are included in the scripts/profiles directory of the SPSS Modeler Server installation directory (for example, C:\Program Files\IBM\SPSS\ModelerServer\18\scripts\profiles).

- [Common script \(for all platforms\)](#)
- [Windows scripts](#)
- [UNIX script](#)

Related information

- [Working in the enterprise](#)
 - [Working with server profiles](#)
 - [Profile structure](#)
 - [Common script \(for all platforms\)](#)
 - [Windows scripts](#)
 - [UNIX script](#)
-

Common script (for all platforms)

The following script helps create and manage profiles. Variants of this script are provided with different extensions for different platforms (.bat for Windows and .sh for UNIX). The operation is the same in each case.

Creating a profile

```
create_profile [options] <profile-name>
```

Creates a new profile with the specified name. The profile name must be appropriate for use as a directory name on the server host (because the script will create a directory with that name) and should not contain spaces. The name must be distinct from any existing profile name.

Options:

```
-d, --profiles-directory<profiles-directory>
```

Specifies the profiles directory in which this and all subsequent profiles should be created. You must specify this only for the first profile, but a good practice is to specify it every time. If you omit it the first time, a default location will be chosen. If you change the profiles directory on a subsequent call, the new profile will be created in the new location, but any existing profiles will be ignored unless they are moved separately to the new location.

```
-t, --template <profile-name>
```

Specifies the name of an existing profile to use as a template. The profile configuration is copied from the existing profile to the new profile, and only the port number is changed.

```
-p, --port-number <port-number>
```

Specifies the port number for the profile service. The port number must be unique to this profile. If you omit the port number, a default will be chosen.

```
-g, --group-name <group-name>
```

Specifies the name of an operating system group that will have exclusive access to this profile. The profile is configured to allow login access only to members of this group.

File system permissions are not changed, so you must perform that action separately.

Examples:

```
scripts\profiles\create_profile.bat -d C:\Modeler\Profiles comet
```

Creates a new profile called **comet** in the directory C:\Modeler\Profiles. The profile will listen on a default port number. To determine the port number, open the options.cfg file that is generated for the profile (in this example, C:\Modeler\Profiles\comet\config\options.cfg).

```
scripts\profiles\create_profile.bat --template comet --group-name "Meteor Users"  
--port-number 28510 meteor
```

Creates a new profile called **meteor** in the directory C:\Modeler\Profiles (remembered from the previous command). The profile will listen on port 28510 and login access will be allowed only to members of the group **Meteor Users**. All other configuration options will be copied from the existing profile **comet**.

Related information

- [Working in the enterprise](#)
 - [Profile scripts](#)
 - [Common script \(for all platforms\)](#)
 - [Windows scripts](#)
 - [UNIX script](#)
-

Windows scripts

These scripts assist with the creation and management of Windows services for SPSS® Modeler Server profiles. They use the Windows Service Control program (SC.EXE) to perform the requested operations, and the script output comes from SC.EXE unless otherwise noted. You must have administrator privileges on the local machine to perform most of these tasks.

See [Microsoft's TechNet documentation](#) about SC.EXE for more information.

Creating a Windows service for a profile

```
create_windows_service [options] <profile-name>
```

Creates the Windows service for a specified profile. You must have administrator privileges to create a service. Use the Services Management Console to set additional properties for the service after it is created (for example, to set the account details for the service log on).

Options:

```
-u, --service-user <account-name>
```

Specifies the account used for the service log on (passim). This can be a local user account, a domain user account, or the local computer name (standing for the local system account). The default is the local system account. If you specify an account other than the local system account, you must go to the Services Management Console and set the password for the account before the service will start.

```
-s, --register-spn
```

Registers a Service Principal Name (SPN) for the service so that clients can connect using Kerberos SSO. You must specify the service login account in this case (-u) so that the SPN can be registered to that account. You must have domain administrator privileges to use this option (or have been delegated the authority to register an SPN).

```
-H, --service-host <host-name>
```

Specifies the host name to use in construction of the SPN. This must be the host name clients will connect through, and it must be qualified with a domain name that maps to the Kerberos realm (in a simple active directory configuration, the domain name and the Kerberos realm are one and the same).

Examples:

```
scripts\profiles\create_windows_service.bat comet
```

Creates a Windows service for the **comet** profile. The service is owned by the local system account, and clients are expected to log in with a user name and password.

```
scripts\profiles\create_windows_service.bat -s -H modelerserver.mycompany.com -u  
MYCOMPANY\ProjectMeteor meteor
```

Creates a Windows service for the **meteor** profile. The service is owned by the **ProjectMeteor** domain account, and clients can log in using SSO. The service will not start until you go to the Services Management Console and set the password for the **ProjectMeteor** account. The account will automatically be granted the right to log in as a service.

Deleting a Windows service for a profile

```
delete_windows_service [options] <profile-names...>
```

Deletes the Windows services for the specified profiles. You must have administrator privileges to delete a service.

Options:

```
-s, --summary
```

Lists the names of the services that were deleted. Services that do not exist or cannot be deleted will not be listed. Without this option, the deletion status of all the specified services will be listed.

```
-a, --all
```

Deletes the services for all profiles.

Examples:

```
scripts\profiles\delete_windows_service.bat comet  
Deletes the Windows services for the comet profile.  
scripts\profiles\delete_windows_service.bat --all  
Deletes the Windows services for all profiles.
```

Starting a Windows service for a profile

```
start_windows_service [options] <profile-names...>
```

Starts the Windows services for the specified profiles. You must have administrator privileges to start a service.

Options:

```
-s, --summary  
Lists the names of the services that were started. Services that are already running or cannot be started will not be listed. Without this option, the status of all the listed services is listed.  
-a, --all  
Starts the services for all profiles.
```

Examples:

```
scripts\profiles\start_windows_service.bat -s comet meteor  
Attempts to start the Windows services for the comet and meteor profiles, and lists the names of the services that were successfully started.
```

Stopping a Windows service for a profile

```
stop_windows_service [options] <profile-names...>
```

Stops the Windows services for the specified profiles. You must have administrator privileges to stop a service.

Options:

```
-s, --summary  
Lists the names of the services that were stopped. Services that are already stopped or cannot be stopped will not be listed. Without this option, the status of all the listed services is listed.  
-a, --all  
Stops the services for all profiles.
```

Examples:

```
scripts\profiles\stop_windows_service.bat -a -s  
Attempts to stop the Windows services for all profiles, and prints the names of those that were successfully stopped. The set of all profiles is obtained from the profiles directory.
```

Querying the state of a Windows service for a profile

```
query_windows_service [options] <profile-names...>
```

Shows the status of the Windows services for the specified profiles. You do not need administrator privileges to query a service.

Options:

```
-s, --summary  
Lists just the names of the services and their current state (RUNNING, STOPPED, etc.). If a service cannot be queried for any reason (for example, if it does not exist), the status is reported as UNKNOWN. Without this option, the full status of all the listed services is listed.  
-a, --all  
Queries the service status for all profiles.
```

Examples:

```
scripts\profiles\query_windows_service.bat -a  
Reports the full service status for all profiles.
```

- [Configuring groups](#)

UNIX script

The existing UNIX script that manages the SPSS® Modeler Server service now accepts an additional `profile` argument so that SPSS Modeler Server profile services can be managed independently.

`modelersrv.sh [options] {start|stop|kill|list}`

Manages the main SPSS Modeler Server service. See [IBM SPSS Modeler Administration](#) for more information.

Options:

`-p, --profile <profile-name>`

Manages the service instance for the specified profile. When this argument is used, the specified command applies only to the instance for the specified profile. When this argument is absent, the `start` command starts just the default instance (a service with no profile), but the `stop`, `kill`, and `list` commands apply to all active instances.

Examples:

```
./modelersrv.sh --profile comet start  
Starts the service for the comet profile.  
./modelersrv.sh --profile meteor start  
Starts the service for the meteor profile.  
./modelersrv.sh list  
Lists the processes for all active services.  
./modelersrv.sh --profile comet stop  
Stops the service for the comet profile.  
./modelersrv.sh stop  
Stops all active services
```

There is currently no supported method for starting SPSS Modeler Server profile services automatically on UNIX. The standard auto.sh script is available for configuring the system to start and stop the main SPSS Modeler Server service with the operating system, but this only applies to the default service -- not for any profile service.

Administration

IBM® SPSS® Modeler Server has a number of configurable options that control its behavior. You can set these options in two ways:

- Use the IBM SPSS Modeler Administration Console, which is available free of charge to current IBM SPSS Modeler customers. See the topic [IBM SPSS Modeler Server Administration](#) for more information.
- Use the options.cfg text file, located in the [server install path]/config directory. See the topic [Using the options.cfg file](#) for more information.

We recommend that you install IBM SPSS Deployment Manager and use its IBM SPSS Modeler Administration Console as your administration tool, rather than editing the options.cfg file. Editing the file requires access to the IBM SPSS Modeler Server file system, but IBM SPSS Modeler Administration Console allows you to authorize anyone with a user account to adjust these options. Also, IBM SPSS Modeler Administration Console provides additional information about the server processes, allowing you to monitor usage and performance. Unlike when editing the configuration file, most configuration options can be changed without restarting IBM SPSS Modeler Server.

More information about using IBM SPSS Modeler Administration Console and the options.cfg file is provided in the following topics.

Related information

- [IBM SPSS Modeler Server Administration](#)
- [Using the options.cfg file](#)

IBM SPSS Modeler Server Administration

The Modeler Administration Console in IBM® SPSS® Deployment Manager provides a console user interface to monitor and configure your SPSS Modeler Server installations, and is available free-of-charge to current SPSS Modeler Server customers. The application can be installed only on Windows computers; however, it can administer a server installed on any supported platform.

Many of the options available through the Modeler Administration Console can also be specified in the options.cfg file, which is located in the SPSS Modeler Server installation directory under /config. However, the Modeler Administration Console provides a shared graphical interface that allows you to connect, configure, and monitor multiple servers.

- [Starting Modeler Administration Console](#)
 - [Restarting the web service](#)
 - [Configuring Access with Modeler Administration Console](#)
 - [SPSS Modeler Server connections](#)
 - [SPSS Modeler Server Configuration](#)
 - [SPSS Modeler Server Monitoring](#)
 - [Using the options.cfg file](#)
 - [Closing unused database connections](#)
-

Starting Modeler Administration Console

From the Windows Start menu, choose [All] Programs, then IBM SPSS Collaboration and Deployment Services, then Deployment Manager.

When you first run the application, you see empty Server Administration and Properties panes (unless you already have Deployment Manager installed with an IBM® SPSS® Collaboration and Deployment Services server connection already set up). After you configure Modeler Administration Console, the Server Administrator pane on the left displays a node for each SPSS Modeler Server that you want to administer. The right-hand pane shows the configuration options for the selected server. You must first [set up a connection](#) for each server that you want to administer.

Restarting the web service

Whenever you make changes to an IBM® SPSS® Modeler Server in the Administration Console, you must restart the web service.

To restart the web service on Microsoft Windows:

1. On the computer where you installed IBM SPSS Modeler, select Services from Administrative Tools on the Control Panel.
2. Locate the server in the list and restart it.
3. Click OK to close the dialog box.

To restart the web service on UNIX:

On UNIX, you must restart the IBM SPSS Modeler Server by running the modelersrv.sh script in the IBM SPSS Modeler Server installation directory.

1. Change to the IBM SPSS Modeler Server installation directory. For example, at a UNIX command prompt, type:
cd /usr/<modelersrv>, where **modelersrv** is the IBM SPSS Modeler Server installation directory.
 2. To stop the server, at the command prompt, type
. ./modelersrv.sh stop
 3. To restart the server, at the command prompt, type
. ./modelersrv.sh start
-

Configuring Access with Modeler Administration Console

Administrator access to SPSS® Modeler Server through the Modeler Administration Console included with IBM® SPSS Deployment Manager is controlled with the **administrators** line in the options.cfg file, located in the SPSS Modeler Server installation directory under /config. This line is commented out by default, so you must edit this line to allow access to specific people, or use * to allow access to all users, as shown in the following examples:

```
administrators, "*"
administrators, "jsmith,mjones,achavez"
```

- The line must begin with **administrators**, and the entries must be contained in quotation marks. Entries are case sensitive.
- Separate multiple user IDs with commas.
- For Windows accounts, do not use domain names.
- Use the asterisk with care. It allows anyone with a valid user account for IBM SPSS Modeler Server (which, in most cases, is anyone on the network) to log in and change the configuration options.
- [Configuring Access with User Access Control](#)

Configuring Access with User Access Control

To use the Modeler Administration Console to make updates to a SPSS® Modeler Server configuration installed on a Windows machine that has User Access Control (UAC) enabled, you must have read, write, and execute permissions defined on the *config* directory and on the *options.cfg* file. These (NTFS) permissions must be defined at the specific user level and not at group level, this is due to the way that UAC and NTFS permissions interact.

The Modeler Administration Console is included in IBM® SPSS Deployment Manager.

Related information

SPSS Modeler Server connections

You must specify a connection to each SPSS® Modeler Server on your network that you want to administer. You must then log in to each server. Although the server connection is remembered across Modeler Administration Console sessions in IBM® SPSS Deployment Manager, the login credentials are not. You must log in every time you start IBM SPSS Deployment Manager.

To set up a server connection

1. Ensure that the IBM SPSS Modeler Server service is started.
2. From the File menu, choose New and then Administered Server Connection.
3. On the first page of the wizard, enter a name for your server connection. The name is for your own use and should be something descriptive; for example, *Production Server*. Ensure that Type is set to Administered **IBM SPSS Modeler Server**, then click Next.
4. On the second page, enter the hostname or IP address of the server. If you have changed the port from the default, enter the port number. Click Finish. The new server connection is shown in the Server Administrator pane.

To perform administration tasks, you must now log in.

To log in to the server

1. In the Server Administrator pane, double-click to select the server to which you want to log in.
2. In the Login dialog box, enter your credentials. (Use your user account for the server host.) Click OK.

If the login fails with the message Unable to obtain administrator rights on server, the most likely cause is that administrator access has not been configured correctly. See the topic [Configuring Access with Modeler Administration Console](#) for more information.

If the login fails with the message Failed to connect to server '<server>', make sure that the user ID and password are correct, then make sure that the IBM SPSS Modeler Server service is running. For example, under Windows, go to Control Panel > Administrative Tools > Services and check the entry for IBM SPSS Modeler Server. If the Status column does not show Started, select this line on the screen and click Start, then retry the login.

Once you log in to your IBM SPSS Modeler Server, two options are shown below the server name, [Configuration](#) and [Monitoring](#). Double-click one of these options.

-

Connections/Sessions

Modeler port number. (`port_number`) The port number for SPSS® Modeler Server to listen on. Change if another application already uses the default. End users must know the port number in order to use SPSS Modeler Server.

Embedded DataView service port number. (`data_view_port_number`) The port number for the DataView service embedded in SPSS Modeler Server to listen on. Change if another application already uses the default.

Maximum number of connections. (`max_sessions`) Maximum number of server sessions at one time. A value of -1 indicates no limit.

Analytic Server connection

Enable Analytic Server SSL (`as_ssl_enabled`). Specify Y to encrypt communications between Analytic Server, and SPSS® Modeler otherwise, N.

Host (`as_host`). The IP address of the Analytic Server.

Port Number (**as_port**). The Analytic Server port number.

Context Root (**as_context_root**). The context root of the Analytic Server.

Tenant (**as_tenant**). The tenant that the SPSS Modeler Server installation is a member of.

Realm (**as_realm**). The realm used for this Analytic Server.

Prompt for Password (**as_prompt_for_password**). Specify N if the SPSS Modeler Server is configured with the same authentication system for users and passwords as the system that is used on Analytic Server; for example, when you use Kerberos authentication, otherwise, Y.

Note: If you intend to use Kerberos SSO, you must set extra options in the options.cfg file. For more information, see [Options visible in options.cfg](#).

Note: To connect SSL enabled Analytic Server, extra steps are required as follows:

1. Use the following command to extract the certificate file trust.cer from the JKS file (i.e. trust.jks):

```
/bin/keytool -export -alias server-alias -storepass pass4jks -file /home/sslkeys/trust.cer -keystore /home/sslkeys/trust.jks
```

2. Import the trust.cer file into cacerts in the JRE used by your application server.
3. Import the trust.cer file into caserts in the JRE used by the SPSS Modeler Server.
4. Restart the SPSS Modeler Server and the IBM® SPSS Collaboration and Deployment Services Repository Server.

Data file access

Python executable path for Extension nodes and Custom Dialog Builder. (**eas_pyspark_python_path**) Full path to the Python executable file, including the name of the file. [**program_files_restricted**] may need to be set to No depending on your Python installation location.

Restrict access to only data file path. (**data_files_restricted**) When set to yes, this option restricts data files to the standard data directory and those listed in the Data File Path below.

Data file path. (**data_file_path**) A list of additional directories to which clients are allowed to read and write data files. This option is ignored unless the Restrict Access to Only Data File Path option is turned on. Note that you should use forward slashes in all path names. On Windows, specify multiple directories using semicolons (for example, [server install path]/data;c:/data;c:/temp). On Linux and UNIX, use colons (:) instead of semicolons. The data file path must include any path(s) specified by the **temp_directory** parameter described below.

Restrict access to only program files path. (**program_files_restricted**) When set to yes, this option restricts program file access to the standard bin directory and those listed in the Program files path below. As of release 17, the only program file to which access is restricted is the Python executable (see the Python executable path below).

Program files path. (**program_file_path**) A list of additional directories from which clients are allowed to execute programs. This option is ignored unless the Restrict Access to Only Program Files Path option is turned on. Note that you should use forward slashes in all pathnames. Specify multiple directories using semicolons.

Maximum file size. (**max_file_size**) Maximum size (in bytes) of temporary and exported data files created during stream execution (does not apply to SAS and SPSS® Statistics data files). A value of -1 indicates no limit.

Temporary directory. (**temp_directory**) The directory used to store temporary data files (cache files). Ideally, this directory should be on a separate high-speed drive or controller because speed of access to this directory may have a significant impact on performance. You may specify multiple temporary directories, separating each with a comma (for example: **temp_directory**, "D:/Modeler_temp, C:/Program Files/IBM/SPSS/ModelerServer/<version>/Tmp"). These should be located on different disks; the first directory is used most often, and additional directories are used to store temporary work files when certain data preparation operations (such as sort) use parallelism during execution. Allowing each execution thread to use separate disks for temporary storage can improve performance. Use forward slashes in all path specifications.

Note:

- Temporary files are generated in this directory during startup of SPSS Modeler Server. Ensure that you have the necessary access rights to this directory (for example, if the temporary directory is a shared network folder), otherwise SPSS Modeler Server startup will fail.
- The **temp_directory** setting does not apply when running Evaluation streams via IBM® SPSS Collaboration and Deployment Services jobs. When you run such a job, a temporary file is created. By default, the file is saved to the IBM SPSS Modeler Server installation directory. You can change the default data folder that the temp files are saved to when you create the IBM SPSS Modeler Server connection in IBM SPSS Modeler.

Python executable path for bulk loading. (**python_exe_path**) Full path to the Python executable including the executable name. If access to program files is restricted, then you must add the directory containing the Python executable to the program files path (see Restrict access to only program files path above).

Path to OPL library of full version of CPLEX. (**cplex_opl_lib_path**) Path to the OPL library for the full version of CPLEX.

Performance/Optimization

Stream rewriting. (`stream_rewriting_enabled`) Allows the server to optimize streams by rewriting them. For example, the server might push data reduction operations closer to the source node to minimize the size of the dataset as early as possible. Disabling this option is normally recommended only if the optimization causes an error or other unexpected results. This setting overrides the corresponding client optimization setting. If this setting is disabled in the server, then the client cannot enable it. But if it is enabled in the server, the client can choose to disable it.

Parallelism. (`max_parallelism`) Describes the number of parallel worker threads that SPSS® Modeler is allowed to use when running a stream. Setting this to 0 or any negative number causes IBM® SPSS Modeler to match the number of threads to the number of available processors on the computer; the default value for this option is -1. To turn off parallel processing (for machines with multiple processors), set this option to 1. To allow limited parallel processing, set it to a number smaller than the number of processors on your machine. Note that a hyperthreaded or dual-core processor is treated as two processors.

Buffer size (bytes). (`io_buffer_size`) Data files transferred from the server to the client are passed through a buffer of this number of bytes.

Cache compression. (`cache_compression`) An integer value in the range 0 to 9 that controls the compression of cache and other files in the server's temporary directory. Compression reduces the amount of disk space used, which can be important when space is limited. Compression increases processor time, but this is almost always made up by the reduction in disk access time. Note that only certain caches, those accessed sequentially, can be compressed. This option does not apply to random-access caches, such as those used by the network training algorithms. A value of 0 disables compression entirely. Values from 1 upward provide increasing degrees of compression but with a corresponding cost in access time. The default value is 1; higher values may be needed where disk space is at a premium.

Memory usage multiplier. (`memory_usage`) Controls the proportion of physical memory allocated for sorting and other in-memory caches. The default is 100, which corresponds to approximately 10% of physical memory. Increase this value to improve sort performance where free memory is available, but be careful of increasing it so high as to cause excessive paging.

Modeling memory limit percentage. (`modelling_memory_limit_percentage`) Controls the proportion of physical memory allocated for training Kohonen and *k*-means models. The default is 25%. Increase this value to improve training performance where free memory is available, but be careful of increasing it so high as to cause excessive paging when data spills onto the disk.

Allow modeling memory override. (`allow_modelling_memory_override`) Enables or disables the Optimize for Speed option in certain modeling nodes. The default is enabled. This option allows the modeling algorithm to claim all available memory, bypassing the percentage limit option. You may want to disable this if you need to share memory resources on the server machine.

Maximum and minimum server port. (`max_server_port` and `min_server_port`) Specifies the range of port numbers that can be used for the additional socket connections between client and server that are required for interactive models and stream execution. These require the server to listen on another port; not restricting the range could cause problems for users on systems with firewalls. Default value for both is -1, meaning "no restriction." Thus, for example, to set the server to listen on port 8000 or above, you would set `min_server_port` to 8000 and `max_server_port` to -1.

Note that you must open additional ports over the main server port to open or execute a stream, and correspondingly more ports if you want to open or execute concurrent streams. This is required in order to capture feedback from the stream execution.

By default, IBM SPSS Modeler will use any open port that is available; if it does not find one (for example, if they are all closed by a firewall), an error is displayed when you execute the stream. To configure the range of ports, IBM SPSS Modeler will need two open ports (in addition to the main server port) available per concurrent stream, plus 3 additional ports for each ODBC connection from within any connected client (2 ports for the ODBC connection for the duration of that ODBC connection, and an additional temporary port for authentication).

Note: An ODBC connection is an entry in the database connections list, and can be shared between multiple database nodes specified with the same database connection.

Note: It is possible that the authentication ports can be shared if the connections are made at different times.

Note: Best practice dictates that the same ports should be used to communicate with both IBM SPSS Collaboration and Deployment Services and SPSS Modeler Client. These can be set as `max_server_port` and `min_server_port`.

Note: If you change these parameters, you need to restart SPSS Modeler Server for the change to take effect.

Array fetch optimization. (`sql_row_array_size`) Controls the way that SPSS Modeler Server fetches data from the ODBC datasource. The default value is 1, which fetches a single row at a time. Increasing this value causes the server to read the information in larger chunks, fetching the specified number of rows into an array. With some operating system/database combinations, this can result in improvements to the performance of `SELECT` statements.

-

SQL

Maximum SQL string length. (**max_sql_string_length**) For a string imported from the database with SQL, the maximum number of characters that are guaranteed to be passed successfully. Depending on the operating system, string values longer than this may be truncated on the right without warning. The valid range is between 1 and 65,535 characters. This property also applies to the Database export node.

Note: The default value for this parameter is 2048. If the text you are analyzing is longer than 2048 characters (for example, this may occur if using the SPSS® Modeler Text Analytics Web Feed node) we recommend increasing this value if working in native mode otherwise your results may be truncated. If you are using a database and user-defined functions (UDF), this restriction does not occur; this can account for differences in results between native and UDF modes.

Automatic SQL generation. (**sql_generation_enabled**) Allows automatic SQL generation for streams, which may substantially improve performance. The default is enabled. Disabling this option is recommended only if the database is not able to support queries submitted by SPSS Modeler Server. Note that this setting overrides the corresponding client optimization setting; also note that for purposes of scoring, SQL generation must be enabled separately for each modeling node regardless of this setting. If this setting is disabled in the server, then the client cannot enable it. But if it is enabled in the server, the client can choose to disable it.

Default SQL string length. (**default_sql_string_length**). Specifies the default width of string columns that will be created within database cache tables. String fields in database cache tables will be created with a default width of 255 if there is no upstream type information. If you have wider values than this in your data, either instantiate an upstream Type node with those values, or set this parameter to a value that is large enough to accommodate those string values.

Enable Database UDF. (**db_udf_enabled**). If set to **y** (default), causes the SQL generation option to generate user-defined function (UDF) SQL instead of pure SPSS Modeler SQL. UDF SQL usually outperforms pure SQL.

SSL

Enable SSL. (**ssl_enabled**) Enables SSL encryption for connections between SPSS® Modeler and SPSS Modeler Server.

SSL keystore file. (**ssl_keystore**) The SSL key database file to be loaded when the server starts (either a full path or a relative path to the SPSS Modeler installation directory).

SSL keystore stash file. (**ssl_keystore_stash_file**) The name of the key database password stash file to be loaded when the server starts up (either a full path or a relative path to the SPSS Modeler installation directory). On Linux, if you want to leave this setting blank and be prompted for the password when starting the SPSS Modeler Server, see the following instructions:

- On Linux/UNIX:
 1. Make sure the **ssl_keystore_stash_file** setting in options.cfg does not have a value.
 2. Locate the following line in the modelersrv.sh file:

```
if "$INSTALLEDPATH/$SCLEMNAME" -server $ARGS; then
```
 3. Add the **-request_ssl_password** switch as follows:

```
if "$INSTALLEDPATH/$SCLEMNAME" -request_ssl_password -server $ARGS;
then
```
 4. Restart the SPSS Modeler Server. You will be prompted for a password. Enter the correct password, click OK, and the server will start.

Keystore certificate label. (**ssl_keystore_label**) Label for the specified certificate.

Note: To use the Administration Console with a server setup for SSL, you must import any certificates required by SPSS Modeler Server into the Deployment Manager trust store (under/jre/lib/security).

Note: If you change these parameters, you need to restart SPSS Modeler Server for the change to take effect.

Coordinator of Processes configuration

Host. (**cop_host**) The hostname or IP address of the Coordinator of Processes service. The default "spsscop" is a vanity name which administrators can choose to add as an alias for the IBM® SPSS® Collaboration and Deployment Services host in DNS.

Port number. (**`cop_port_number`**) The port number of the Coordinator of Processes service. The default, 8080, is the IBM SPSS Collaboration and Deployment Services default.

Context root. (**`cop_context_root`**) The URL of the Coordinator of Processes service.

Login name. (**`cop_user_name`**) The user name for authentication to the Coordinator of Processes service. This is an IBM SPSS Collaboration and Deployment Services login name so may include a security-provider prefix (for example: ad/jsmith).

Password. (**`cop_password`**) The password for authentication to the Coordinator of Processes service.

Note: If you update the options.cfg file manually instead of using the Modeler Administration Console in IBM SPSS Deployment Manager, you must manually encode the **`cop_password`** value that you specify in the file. Plain text passwords are invalid and cause registration with the Coordinator of Processes to fail.

Follow these steps to manually encode the password:

1. Open a Command Prompt, navigate to the SPSS Modeler .**/bin** directory, and run the command **pwutil.bat/sh**.
2. When requested, type the user name (the **`cop_user_name`** you are specifying in options.cfg) and press Enter.
3. When requested, type the password for that user.

The encoded password is displayed between double quotes on the command line as part of the returned string. For example:

```
C:\Program Files\IBM\SPSS\Modeler\18\bin>pwutil
User name: copuser
Password: Pass1234
copuser, "0Tqb4n.ob0wrs"
```

4. Copy the encoded password, without the double quotes, and paste it between the double quotes that already exist for the **`cop_password`** value in the options.cfg file.

Enabled. (**`cop_enabled`**) Determines whether the server should attempt to register with the Coordinator of Processes. The default is *not* to register because the administrator should choose which services are advertised through the Coordinator of Processes.

SSL Enabled. (**`cop_ssl_enabled`**) Determines whether SSL is used to connect to the Coordinator of Processes server. If this option is used, you must import the SSL certificate file into the SPSS Modeler Server JRE. To do this, you must obtain the SSL certificate file and its alias name and password. Then run the following command on the SPSS Modeler Server:

```
$JAVA_HOME/bin/keytool -import -trustcacerts -alias $ALIAS_NAME -file
$CERTIFICATE_FILE_PATH -keystore $ModelerServer_Install_Path/jre/lib/security/cacerts
```

Server name. (**`cop_service_name`**) The name of this SPSS Modeler Server instance; the default is the host name.

Description. (**`cop_service_description`**) A description of this instance.

Update interval (min). (**`cop_update_interval`**) The number of minutes between keep-alive messages; the default is 2.

Weight. (**`cop_service_weight`**) The weight of this instance, specified as an integer between 1 and 10. A higher weight attracts more connections. The default is 1.

Service host. (**`cop_service_host`**) The fully-qualified host name of the IBM SPSS Modeler Server host. The default of the host name is derived automatically; the administrator can override the default for multi-homed hosts.

Default data path. (**`cop_service_default_data_path`**) The default data path for a Coordinator of Processes registered IBM SPSS Modeler Server installation.

Options visible in options.cfg

Most configuration options can be changed using the IBM® SPSS® Modeler Administration Console included with IBM SPSS Deployment Manager. But there are some exceptions, such as those described in this section. The options in this section must be changed by editing the options.cfg file. See [IBM SPSS Modeler Server Administration](#) and [Using the options.cfg file](#) for more information. Note that there may be additional settings in options.cfg that are not listed here.

Note: This information only applies to a remote server (IBM SPSS Modeler Server, for example).

administrators. Specify the user names of those users to whom you want to grant administrator access. See the topic [Configuring Access with Modeler Administration Console](#) for more information.

allow_config_custom_overrides. Do not modify unless instructed to do so by a technical-support representative.

data_view_port_number. You can right-click a data node and select View Data to examine and refine your data in interesting ways with advanced data visualizations. This feature uses the port number 28900 by default. Modify the value for this **data_view_port_number** configuration option if you need to use a different port number. We recommend using the default, if possible.

fips_encryption. Enables FIPS compliant encryption. The default is **N**.

group_configuration. When enabled, IBM SPSS Modeler Server checks the groups.cfg file which controls who can log on to the server.

max_transfer_size. For internal system use only. **Do not modify.**

shell. (UNIX servers only) Overrides the default setting for the UNIX shell, for example **shell**, "/usr/bin/ksh". By default, IBM SPSS Modeler uses the shell defined in the user profile of the user who is connecting to IBM SPSS Modeler Server.

start_process_as_login_user. Set this to **y** if you are running SPSS Modeler Server with a private password database, starting the server service from a non-root account.

use_bigint_for_count. When the number of the records to be counted is larger than a normal integer ($2^{31}-1$) can hold, set this option to **y**. When this option is set to **y**, and a stream is connected to Db2; SQL Server; or a Teradata, Oracle, or Netezza database, a function is used where a record count is needed (for example, the Record_Count field generated by the Aggregate node).

When this option is enabled, and if working with either Db2 or SQL Server, SPSS Modeler uses COUNT_BIG() for record counting. If working with Teradata, Oracle, or Netezza, SPSS Modeler will use COUNT(). For all other databases, there is no SQL pushback for the function. The difference is that when **use_bigint_for_count** is enabled, all record counts are saved as BIG INT (or LONG) type (a 64-bit signed integer, $2^{63}-1$ to the maximum), as compared to normal integer (a 32-bit signed integer, $2^{31}-1$ to the maximum) when the options is disabled.

cop_ssl_enabled. Set this option to **y** if you are using SSL to connect to the Coordinator of Processes Service. If this option is used, you must import the SSL certificate file into the SPSS Modeler Server JRE. To do this, you must obtain the SSL certificate file and its alias name and password. Then run the following command on the SPSS Modeler Server:

```
$JAVA_HOME/bin/keytool -import -trustcacerts -alias $ALIAS_NAME -file  
$CERTIFICATE_FILE_PATH -keystore $ModelerServer_Install_Path/jre/lib/security/cacerts
```

cop_service_default_data_path. You can use this option to set the default data path for a Coordinator of Processes registered IBM SPSS Modeler Server installation.

Users can create their own Analytic Server connections in SPSS Modeler via Tools > Analytic Server Connections. Administrators can also define a default Analytic Server connection using the following properties:

as_ssl_enabled. **Y** or **N**.

as_host. Specify the Analytic Server host name or IP address.

as_port. Specify the Analytic Server port number.

as_context_root. Specify the Analytic Server context root.

as_tenant. Specify the name of the tenant that the IBM SPSS Modeler Server is a member of

as_prompt_for_password. **Y** or **N**.

By default, Analytic Server authentication using the Kerberos method is not enabled. To enable Kerberos authentication, use the three following properties:

as_kerberos_auth_mode. To enable Kerberos authentication, set this option to **y**.

as_kerberos_krb5_conf. Specify the path to the Kerberos configuration file that Analytic Server should use; for example, c:\windows\krb5.conf.

as_kerberos_krb5_spn. Specify the Analytic Server Kerberos SPN; for example, HTTP/ashost.mydomain.com@MYDOMAIN.COM.

SPSS Modeler Server Monitoring

The monitoring pane of Modeler Administration Console in IBM® SPSS® Deployment Manager shows a snapshot of all processes running on the SPSS Modeler Server computer, similar to the Windows Task Manager. To activate the monitoring pane, double-click the Monitoring node beneath the desired server in the Server Administrator pane. This populates the pane with a current snapshot of data from the server. The data refreshes at the rate shown (one minute by default). To refresh the data manually, click the Refresh button. To show only SPSS Modeler Server processes in this list, click the Filter out non-**SPSS Modeler** processes button.

Using the options.cfg file

The options.cfg file is located in the [server install path]/config directory. Each setting is represented by a comma-separated name-value pair, where the **name** is the name of the option and the **value** is the value for the option. Pound (hash) signs (#) indicate comments.

Note: Most configuration options can be changed using IBM® SPSS® Modeler Administration Console in IBM SPSS Deployment Manager, rather than this configuration file, but there are a few exceptions. See the topic [Options visible in options.cfg](#) for more information.

By using IBM SPSS Modeler Administration Console, you can avoid server restarts for all options except the server port. See the topic [IBM SPSS Modeler Server Administration](#) for more information.

Note: This information only applies to a remote server (IBM SPSS Modeler Server, for example).

Configuration options that can be added to the default file

By default, in-database caching is enabled with IBM SPSS Modeler Server. You can disable this feature by adding the following line to the options.cfg file:

```
enable_database_caching, N
```

Doing so causes temporary files to be created on the server and not in the database.

To view or change the IBM SPSS Modeler Server configuration options:

1. Open the options.cfg file with a text editor.
 2. Locate the options of interest. For a full list of options, see [SPSS Modeler Server Configuration](#).
 3. Edit the values, as appropriate. Note that all pathname values must use a forward slash (/) rather than a backslash as the pathname separator.
 4. Save the file.
 5. Stop and restart IBM SPSS Modeler Server so that the changes will take effect.
-

Closing unused database connections

By default, IBM® SPSS® Modeler caches at least one connection to a database once that connection has been accessed. The database session is held open even when streams requiring database access are not being executed.

Caching database connections can improve execution times by removing the need for IBM SPSS Modeler to reconnect to the database each time a stream is executed. However, in some environments, it is important for applications to release database resources as quickly as possible. If too many IBM SPSS Modeler sessions maintain connections to the database that are no longer used, database resources may become exhausted.

You can avoid this possibility by turning off the IBM SPSS Modeler option **cache_connection** in a custom database configuration file. Doing so can also make IBM SPSS Modeler more resilient to faults in the database connection (such as timeouts) that can occur when connections are used over a long period of time by an IBM SPSS Modeler session.

To cause unused database connections to be closed:

1. Locate the `[server install path]/config` directory.
2. Add the following file (or open it, if it already exists):
`odbc-custom-properties.cfg`
3. Add the following line to the file:
`cache_connection, N`
4. Save and close the file.
5. Restart IBM SPSS Modeler Server.

Note:

In-database caches are saved in database as either a regular table or a temporary table, depending on each database's implementation. For example, temporary tables are used for Db2, Oracle, Amazon Redshift, Sybase, and Teradata. For these databases, setting `cache_connection` to `N` does not work as expected because the temporary table is only valid within a session (it will be cleaned automatically by the database when the database connection is closed).

So when running an SPSS Modeler stream against one of these databases with `cache_connection` set to `N`, an error such as Failed to create table for in-database caching. Using file cache instead. may result. This indicates that SPSS Modeler failed to created the in-database cache. Also, in some cases for an SPSS Modeler-generated SQL query, a temporary table is used but the table is empty.

To work around this issue, you can choose to use a regular database table for in-database caches. To do this, create a custom database property configuration file that contains the following line:

```
table_create_temp_sql, 'CREATE TABLE <table-name> <(table-columns)>'
```

This forces a regular database table to be used for the in-database cache, and the table will be dropped when all connections to the database are closed or when the working stream is closed.

Using SSL to secure data transfer

Secure Sockets Layer (SSL) is a protocol for encrypting data transferred between two computers. SSL ensures that communication between the computers is secure. SSL can encrypt the authentication of a username/password and the contents of an exchange between a server and client.

- [How SSL works](#)
SSL relies on the server's public and private keys, in addition to a public key certificate that binds the server's identity to its public key.
- [Securing client/server and server-server communications with SSL](#)
Securing communications with SSL requires a number of configuration steps on the client and server systems.
- [Cognos SSL connection](#)
To enable SSL access between SPSS Modeler and Cognos Analytics, you must create and import the relevant certificate.
- [Cognos TM1 SSL connection](#)
To enable SSL access between SPSS Modeler and Cognos TM1, you must create and import the relevant certificate.
- [Configuring the URL prefix](#)
You must configure SPSS Collaboration and Deployment Services Repository URL prefix to enable SSL access to the repository.
- [Securing LDAP with SSL](#)
The following example illustrates how to enable SSL for LDAP with Microsoft Active Directory as a security provider.

How SSL works

SSL relies on the server's public and private keys, in addition to a public key certificate that binds the server's identity to its public key.

1. When a client connects to a server, the client authenticates the server with the public key certificate.
2. The client then generates a random number, encrypts the number with the server's public key, and sends the encrypted message back to the server.
3. The server decrypts the random number with its private key.
4. From the random number, both the server and client create the session keys used for encrypting and decrypting subsequent information.

The public key certificate is typically signed by a certificate authority. Certificate authorities, such as VeriSign and Thawte, are organizations that issue, authenticate, and manage security credentials contained in the public key certificates. Essentially, the certificate authority confirms the identity of the server. The certificate authority usually charges a monetary fee for a certificate, but self-signed certificates can also be generated.

Securing client/server and server-server communications with SSL

The main steps in securing client/server and server-server communications with SSL are:

1. Obtain and install the SSL certificate and keys.
2. Enable and configure SSL in the server administration application (IBM® SPSS® Deployment Manager).
3. If using encryption certificates with a strength greater than 2048 bits, install unlimited strength encryption on the client computers.
4. If using a self-signed certificate, copy the certificate on the client computer.
5. Instruct users to enable SSL when connecting to the server.

Notes:

- Occasionally a server product acts as a client. An example is IBM SPSS Statistics Server connecting to the IBM SPSS Collaboration and Deployment Services Repository. In this case, IBM SPSS Statistics Server is the *client*.
- On Linux/UNIX systems where both a non-root and SSL configuration are enabled, SSL security will be reduced. Because all user sessions run under the same credential as each other and as the Modeler Server daemon, the SSL certificate data that should be kept secret will instead be exposed to all users. This allows users to easily bypass the normal protections SSL provides to all other users. See [Introduction](#).
- **[Obtaining and installing SSL certificate and keys](#)**
For IBM SPSS Modeler; obtain or generate the certificate and key files and install them on the server.
- **[Enable and configure SSL in IBM SPSS Deployment Manager](#)**
Perform the steps to enable SSL for server administration in SPSS Deployment Manager.
- **[Installing unlimited strength encryption](#)**
The Java Runtime Environment shipped with the product has US export-strength encryption enabled. For enhanced security of your data, upgrading to unlimited-strength encryption is recommended. This procedure must be repeated for both client and server installations.
- **[Instructing users to enable SSL](#)**
When you connect to the server through a client product, enable SSL in the server login dialog box.

Obtaining and installing SSL certificate and keys

The first steps you must follow to configure SSL support are:

1. Obtain an SSL certificate and key file. There are three ways you can do this:
 - Purchase them from a public certificate authority (such as VeriSign, Thawte, or Entrust). The public certificate authority (CA) signs the certificate to verify the server that uses it.
 - Generate the key and certificate files with a third-party certificate authority. If this approach is taken then the third-party CA's root certificate must be imported into the client and server keystore files. See the topic [Importing a third-party root CA certificate](#) for more information.
 - Generate the key and certificate files with an internal self-signed certificate authority. The steps to do this are:
 - Prepare a key database. See the topic [Creating an SSL key database](#) for more information.
 - Create the self-signed certificate. See the topic [Creating a self-signed SSL certificate](#) for more information.
2. Copy the .kdb and .sth files created in step 1 into a directory to which the IBM SPSS Modeler Server has access and specify the path to that directory in the options.cfg file..
Note: Use forward slashes as separators in the directory path.
3. Set the following parameters in the options.cfg file:
 - ssl_enabled, Y
 - ssl_keystore, "<filename>.kdb" where <filename> is the name of your key database.
 - ssl_keystore_stash_file, "<filename>.sth" where <filename> is the name of the key database password stash file.
 - ssl_keystore_label, <label> where <label> is the label of your certificate.
4. For self-signed or third-party certificates install the certificate on client systems. For purchased public CA certificates, this step is not required. Ensure that access permissions deny casual browsing of the directory that contains the certificate. See the topic [Installing a self-signed SSL certificate](#) for more information.
 - [Configuring the environment to run GSKit](#)
 - [Creating an SSL key database](#)
 - [Creating a self-signed SSL certificate](#)
 - [Installing a self-signed SSL certificate](#)
 - [Importing a third-party root CA certificate](#)

Configuring the environment to run GSKit

The GSKCapiCmd is a non-Java-based command-line tool, and Java™ does not need to be installed on your system to use this tool; it is located in the <Modeler installation directory>/bin folder. The process to configure your environment to run IBM Global Security Kit (GSKit) varies depending on the platform in use.

To configure for Linux/Unix, add the shared libraries directory <Modeler installation directory>/lib to your environment:

```
$export <Shared library path environment variable>=<modeler_server_install_path>/bin  
$export PATH=$PATH:<modeler_server_install_path>/bin
```

The shared library path variable name depends on your platform:

- HP-UX uses the variable name: **SHLIB_PATH**
- Linux uses the variable name: **LD_LIBRARY_PATH**

For example, to set the environment on Linux, use:

```
$export LD_LIBRARY_PATH=/path/to/gskit/bin  
$export PATH=$PATH:/path/to/gskit/bin
```

Account access to files

Ensure that you grant the correct permissions for the accounts that will access the SSL files:

1. For all accounts that are used by SPSS® Modeler for connection, grant read access to the SSL files.
Note: This also applies to the *Log on as* user that is defined in the SPSS Modeler Server service. On UNIX or Linux, it applies to the user you are starting the server as.
2. For Windows, it is not enough that the accounts are in the Administrators group and that permission is given to that Administrators group when User Access Control (UAC) is enabled. In addition you must take one of the following actions:
 - Give the accounts permission separately.
 - Create a new group, add the accounts into the new group, and give the group permission to access the SSL files.
 - Disable UAC.

Creating an SSL key database

Use the GSKCapiCmd tool to create your key database. Before using the tool, you must configure your environment; see the topic [Configuring the environment to run GSKit](#) for more information

To create the key database, run GSKit and enter the following command:

```
gsk<ver>capi cmd[_64] -keydb -create -populate -db <filename>.kdb -pw <password> -stash
```

where **<ver>** is the GSKit version number, **<filename>** is the name you want to use for the key database file, and **<password>** is the password for the key database.

The **-stash** option creates a stash file at the same path as the key database, with a file extension of .sth. GSKit uses the stash file to obtain the password to the key database so that it doesn't have to be entered on the command line each time.

Note: You should use strong file system protection on the .sth file.

Creating a self-signed SSL certificate

To generate a self-signed certificate and store it in the key database, use the following command:

```
gsk<ver>capi cmd[_64] -cert -create -db <filename>.kdb -stashed -dn "CN=myserver,OU=mynetwork,O=mycompany,C=mycountry" -label <label> -expire <Number of days certificate is valid> -default_cert yes
```

where **<ver>** is the GSKit version number, **<filename>** is the name of the key database file, **<Number of days certificate is valid>** is the physical number of days that the certificate is valid, and **<label>** is a descriptive label to help you identify the file (for example, you could use a label such as: **myselfsigned**).

Installing a self-signed SSL certificate

For the client machines that connect to your server using SSL, you must distribute the public part of the certificate to the clients so that it can be stored in their key databases. To do this, perform the following steps:

1. Extract the public part to a file using the following command:

```
gsk<ver>capi cmd[_64] -cert -extract -db <filename>.kdb -stashed -label <label> -format ascii -target mycert.arm
```

2. Distribute mycert.arm to the clients. It should be copied to their jre/bin directory.
3. Add the new certificate to the clients' key database using the following command:

```
keytool -import -alias <label> -keystore ..\lib\security\cacerts -file mycert.arm
```

If prompted for a password, use: `changeit`. The keytool is located in the <Modeler installation directory>\jre\bin directory (or in the <Modeler installation directory>/SPSSModeler.app/Contents/PlugIns/jre/Contents/Home/bin directory on Mac).

Importing a third-party root CA certificate

Instead of purchasing a certificate from a well known certificate authority (CA) or creating a self-signed certificate, you can use a third-party certificate authority to sign your server certificates. The client and server must have access to the third-party CA's root certificate to verify the server certificates that are signed by the third-party CA. To do this:

1. Obtain the third-party CA root certificate. The process for this varies depending on the third-party CA's procedures. Third-party CAs often make their root certificates available for download.
2. Add the certificate to the servers' key database using the following command:

```
gsk<ver>capicmd[ _64} -cert -add -db <filename>.kdb -stashed -label <label> -file <ca_certificate>.crt  
-format binary -trust enable
```

3. Add the certificate to the clients' key database using the following command:

On Windows:

```
C:> cd <Modeler Client installation path>\jre\bin  
C:> keytool -import -keystore ..\lib\security\cacerts -file <ca_certificate>.crt -alias <label>
```

On Mac:

```
C:> cd <Modeler Client installation path>/SPSSModeler.app/Contents/PlugIns/jre/Contents/Home/bin  
C:> keytool -import -keystore ..\lib\security\cacerts -file <ca_certificate>.crt -alias <label>
```

If prompted for a password, use: `changeit`. The keytool is located in the <Modeler installation directory>\jre\bin directory (or in the <Modeler installation directory>/SPSSModeler.app/Contents/PlugIns/jre/Contents/Home/bin directory on Mac).

4. Validate the server's key database with the root CA certificate using the following command:

```
gsk<ver>capicmd[ _64} -cert -validate -db <filename>.kdb -stashed -label <label>
```

A successful validation is indicated by the returned message: OK.

Note: The commands explained above use a third-party CA root certificate that is in a binary format. If the certificate is in an ASCII format, use the `-format ascii` option.

The `-db` parameter specifies the name of the key database into which you import the third-party CA root certificate.

The `-label` parameter specifies the label to use for the third-party CA root certificate inside the key database file. The label you use here can be anything because it does not have any relation to the labels used in the IBM® SPSS® Modeler options.cfg file.

The `-file` parameter specifies the file that contains the third-party CA root certificate

Enable and configure SSL in IBM SPSS Deployment Manager

1. If installing a self-signed SSL certificate, copy the cacerts file that you created to the <Deployment Manager installation directory>\jre\lib\security directory. See the topic [Installing a self-signed SSL certificate](#) for more information.
2. Start the server administration application (IBM® SPSS® Deployment Manager) and connect to the server.
3. On the configuration page, set Secure Sockets Layer to `Yes`.
4. In SSL Public Key File, specify the full path to the public key file.
5. In SSL Private Key File, specify the full path to the private key file.
Note: If the public and private keys are stored in one file, specify the same file in SSL Public Key File and SSL Private Key File.
6. From the menus choose:
`File > Save`
7. Restart the server service or daemon. When you restart, you will be prompted for the SSL password. On Windows, you can select Remember this password to store the password securely. This option eliminates the need to enter the password every time the server is started.

Installing unlimited strength encryption

The Java Runtime Environment shipped with the product has US export-strength encryption enabled. For enhanced security of your data, upgrading to unlimited-strength encryption is recommended. This procedure must be repeated for both client and server installations.

To install unlimited strength encryption

1. Download the [Unrestricted SDK JCE policy files](#) from IBM.com (select the files applicable to Java 8).
Note: You will need to login with your IBMid credentials in order to download the files.
 2. Extract the unlimited jurisdiction policy files that are packaged in the compressed file. The compressed file contains a *US_export_policy.jar* file and a *local_policy.jar* file.
 3. Back up the existing copies of *US_export_policy.jar* and *local_policy.jar* from the directory *jre/lib/security*.
 4. Replace the existing copies of *US_export_policy.jar* and *local_policy.jar* files with the two files that you downloaded and extracted.
 5. Restart IBM® SPSS® Modeler Client or Server as appropriate.
-

Instructing users to enable SSL

When users connect to the server through a client product, they need to enable SSL in the dialog box for connecting to the server.

Cognos SSL connection

To connect to a Cognos Analytics server with HTTPS and an SSL secured port, you must first change some of the Cognos internal and external dispatcher settings. For details on how to make the required changes, see the Cognos Server Configuration and Administration guide.

After you change the dispatcher settings, import the SSL certification that you created in Cognos into the SPSS® Modeler JRE by following these steps:

1. In Cognos configuration, define a password for the IBM Cognos key store:
 - a. In the Explorer window, click *Cryptography* > *Cognos*.
 - b. In the Properties window, under *Encryption Key Settings*, set the *Encryption key store password*.
 - c. From the *File* menu, select *Save*.
 - d. From the *Actions* menu, select *Restart*.
2. From the command line, go to the *c10_location\bin* directory.
3. Set the *JAVA_HOME* environment variable to the Java™ Runtime Environment location used by the application server that is running Cognos. For example:

```
set JAVA_HOME=c11_location\bin\jre\<version>
```

4. From the command line, run the certificate tool. For example:

```
ThirdPartyCertificateTool.bat -E -T -r ca.cer -k ..\configuration\encryptkeypair\jEncKeystore  
-p <password>
```

5. Copy the *ca.cer* file to the SPSS Modeler Server location.
6. Open a command line and switch to the *<ModelerInstallationLocation>\jre\bin* folder.
7. Run the command to import the certificate. For example:

```
.\keytool -import -alias ca -file <Directory where ca.cer is located>\ca.cer  
-keystore "<ModelerInstallationLocation>\jre\lib\security\cacerts"
```

You can then use HTTPS and the SSL secured dispatcher to connect to Cognos. For example:

```
https://9.119.83.37:9343/p2pd/servlet/dispatch
```

Cognos TM1 SSL connection

To connect to Cognos TM1 with HTTPS and an SSL secured port, follow these steps:

1. Enable SSL on IBM Cognos TM1 Application Server. See the TM1 documentation at <https://www.ibm.com/docs/en/cognos-tm1/10.2.2?topic=configuration-usingssl-data-transmission-security>.
2. Download the *tm1server.pem* certification file. For example, if using Firefox:
 - a. Open a browser window and enter your TM1 Server datasource URL such as *https://9.30.204.176:8010/api/v1/*. Then click *View Certificate* to open the server certification.
 - b. In the new Firefox browser window, click *PEM (cert)* to download the *tm1server.pem* file.

- From the command line, go to the SPSS Modeler jre\bin directory and then run the following command to import the tm1server.pem file to the SPSS Modeler Server (modify the paths to match your environment, as needed):

```
C:\Program Files\IBM\SPSS\Modeler\18.3\jre\bin>
keytool.exe -import -alias tm1server -file C:
\Users\Administrator\Downloads\tm1server.pem -keystore ..\lib\security\cacerts
```

- Enter the default keystore password **changeit** if prompted.
- When prompted whether to trust this certificate, enter **yes**.

- Restart SPSS Modeler Client and SPSS Modeler Server.

You can now use HTTPS and the SSL secured port number to connect to Cognos TM1.

Configuring the URL prefix

If IBM® SPSS® Collaboration and Deployment Services Repository is set up for SSL access, the value of the URL Prefix configuration setting must be modified as follows:

- Log in to the repository using browser-based console.

- Open *URL Prefix* configuration option.

Configuration > Setup > URL Prefix

- Set the value of the prefix to **https** instead of **http** and set the port value to the SSL port number. For example:

```
[default]
http://<hostname>:<port>
[SSL-enabled]
https://<hostname>:<SSLport>
```

Securing LDAP with SSL

Lightweight Directory Access Protocol (LDAP) is an Internet Engineering Task Force (IETF) standard for exchanging information between network directories and databases containing any level of information. For systems requiring additional security, LDAP providers, such as Microsoft's Active Directory, can operate over Secure Socket Layer (SSL), provided that the Web or application server supports LDAP over SSL. Using SSL in conjunction with LDAP can ensure that login passwords, application information, and other sensitive data are not hijacked, compromised, or stolen.

The following example illustrates how to enable LDAPS using Microsoft's Active Directory as a security provider. For more specific information on any of the steps or to find details that address a particular release of the security provider, see the original vendor documentation.

- Verify that Active Directory and the Enterprise Certificate Authority are installed and functioning.
- Use the certificate authority to generate a certificate, and import the certificate into the certificate store of the IBM® SPSS® Deployment Manager installation. This allows the LDAPS connection to be established between the IBM SPSS Collaboration and Deployment Services Repository and an Active Directory server.

To configure IBM SPSS Deployment Manager for secure Active Directory connections, verify that a connection exists to the repository.

- Launch the IBM SPSS Deployment Manager.
- From the Tools menu, choose Server Administration.
- Log in to a previously defined administered server.
- Double-click the Configuration icon for the server to expand the hierarchy.
- Double-click the Security Providers icon to expand the hierarchy.
- Double-click the Active Directory security provider.
- Enter configuration values for the instance of Active Directory with security certificates installed.
- Select the Use SSL check box.
- Note the name in the Domain User field. Subsequent logins using Active Directory are authenticated using SSL.

For additional information about installing, configuring, and implementing LDAPS on a particular application server, see the original vendor's documentation.

Configuring groups

An authenticated user typically belongs to one or more security groups, and when group-based configuration is enabled for SPSS® Modeler Server, these groups can be used to permit or deny login to the server, or to customize the option settings for the user session.

Group configuration is supported in the following scenarios:

- In a *default* installation where the SPSS Modeler Server service runs under the Local System or root account and the user logs in with explicit credentials or using Single Sign-On (SSO): in this case the groups are the user's operating system security groups used to control file access, etc.
- In a *non-root* installation where the SPSS Modeler Server service runs under a non-privileged account and the user logs in using SSO: in this case the groups are the LDAP groups associated with the SSO principal. These groups are obtained from the LDAP security provider in IBM® SPSS Collaboration and Deployment Services, so some additional configuration is required to enable this scenario. See [Getting the SSO user's group membership](#) for more information.

If neither of these two scenarios apply, then the user's groups are not available and group configuration is not supported. In particular, in a *non-root* installation where the SPSS Modeler Server service runs under a non-privileged account and the user logs in using a user name and password, then the operating system groups are not available to the server and group configuration is not supported.

The principle of group-based configuration is that the option settings applied to a user's session can differ according to the user's group membership. These are the server-side settings normally read from the SPSS Modeler Server options.cfg file set identically for all sessions. The options.cfg file provides the defaults for all sessions, but there can be group-specific configuration files that override a subset of settings for particular sessions.

Group configuration allows for control of various settings, such as:

- Controlling file and DSN access
- Controlling resource usage

When the **group_configuration** option is enabled in options.cfg, IBM SPSS Modeler Server checks the groups.cfg file which controls who can log on to the server. The default is **N**. Following is a groups.cfg example that denies the **Test** group access to the server and allows the **Fraud** group access with a specified configuration. The asterisk allows all other groups access with the default configuration.

```
Test, DENY
Fraud, "groups/fraud.cfg"
*,
```

A specific group configuration, such as that for Fraud above, might restrict access to particular data sources or change resource settings (relating to SQL push back, memory usage, multi-threading, etc.) to enhance performance for members of that group.

The group configuration mechanism is designed to answer two questions:

1. Is the user allowed to use this instance of IBM SPSS Modeler Server?
2. If they are so allowed, then what configuration options do they get?

Regarding #2, the configuration options are those defined by options.cfg, and the default configuration refers to the settings in that file. The group mechanism allows you to override some of the default settings by specifying alternative configuration files for certain groups, where the settings in the group files take precedence over the defaults. The following parameters are supported in group configuration files. Note that there may be other parameters not listed here that can also be used in group configuration files.

```
sql_generation_enabled
db_udf_enabled
stream_rewriting_enabled
io_buffer_size
max_file_size
max_transfer_size
max_sql_string_length
default_sql_string_length
data_files_restricted
data_file_path
program_files_restricted
program_file_path
allow_modelling_memory_override
modelling_memory_limit_percentage
max_parallelism
enable_database_caching
sql_row_array_size
sql_data_sources_restricted
sql_data_source_path
memory_usage
sql_generation
sql_logging
sql_generation_logging
sql_log_native
```

```
sql_log_prettyprint
stream_rewriting
stream_rewriting_maximise_sql
date_baseline
date_2digit_baseline
time_rollover
date_format
time_format
decimal_separator
angles_in_radians
record_count_feedback_interval
record_count_suppress_input
decimal_places
column_width
cache_compression
enable_parallelism
database_caching
shell
use_bigint_for_count
trace_extension
```

Regarding #1, when group configuration is disabled, then everyone is allowed to use the server. When group configuration is enabled, then nobody is allowed to use it unless they are explicitly granted access in groups.cfg. So an empty groups.cfg file makes the server unusable by all. Typically, you add to groups.cfg the groups who should have access. For example:

```
A,
B,
C,
```

Optionally, for any group that you allow access, you can also specify a configuration file that overrides the default settings from options.cfg:

```
A, "a.cfg"
B, "b.cfg"
C, "c.cfg"
```

Any group for which you don't specify a configuration uses the default configuration, which comprises the settings from options.cfg.

The **DENY** option is allowed for more complex cases where a simple enumeration would grant more access than you really want. For example, you allocate a service for Fraud, but there are some developers who are also in the Fraud group who shouldn't have access. So you write:

```
devops, DENY
fraud,
```

You don't need to specify a default **DENY** because everyone else is excluded by virtue of not being included.

Note that this mechanism is subsidiary to the O/S logon mechanism (LDAP, etc). The user must always log on first, and if the O/S denies them access then they never get this far. If they can log on, then their O/S group membership is used to determine the group configuration, and they may be denied access at that point.

Controlling DSN access by group

Multi-factor authentication (MFA) requires that users can be restricted in the set of ODBC data source names (DSNs) that they are allowed to access according to their group membership.

The scheme for accomplishing this is similar to the existing scheme for file access. Two configuration settings are available in options.cfg:

```
sql_data_sources_restricted, N
sql_data_source_path, ""
```

If **sql_data_sources_restricted** is set to **Y**, then the user is limited to the DSNs listed in the associated path. DSNs are separated by the standard path separator character ; (semi-colon) on Windows and : (colon) on UNIX. For example, on Windows:

```
sql_data_sources_restricted, Y
sql_data_source_path, "Fraud - Analytic;Fraud - Operational"
```

When this restriction is enabled, it has the following results:

- When a user browses for data sources (for example, from the ODBC connection dialog, or when using the PSAPI Session `getServerDataSourceNames` API), instead of being presented with all the DSNs defined on the server system, the user will only see the subset of DSNs that is defined in the options.cfg path. Note that the path may contain DSNs that are not defined on the server, and these are ignored -- the user will not see those names.
- If a user constructs an ODBC node (or any node using an ODBC connection) that uses a script or PSAPI and the user specifies a DSN that is not included in the options.cfg path, the node will not run and the user will be presented with an error similar to Access denied to data source: <X>.

The data source path can include the **PATH**, **GROUP** and **USER** insertions described elsewhere for file paths. The **PATH** insertion allows the path to be constructed incrementally according to the user's group membership when group-based configuration is used. There might also be

circumstances where it makes sense to name a DSN after the group which owns it.

Building on the previous example, if access to the **Fraud** data sources is allowed only for members of the Fraud Analysts group, then the site can enable group configuration and create a configuration specific to the Fraud Analysts containing at least this line:

```
sql_data_source_path, "${PATH};Fraud - Analytic;Fraud - Operational"
```

The addition of the **PATH** prefix in this example ensures that the fraud analysts are still able to access other data sources allowed to everyone, or to other groups of which they are members.

Log files

IBM® SPSS® Modeler Server keeps a record of its important actions in a log file called `server_logging.log`. On UNIX, this file is in the `log` folder in the installation directory. On Windows, this file is in: `%ALLUSERSPROFILE%/IBM/SPSS/Modeler Server/<version>/log`.

The settings that control how logging is carried out in your installation are contained in the `log4cxx.properties` file.

Change the location of the log file

The default location of the log file is set, in the `log4cxx.properties` file, as:

```
log4j.appenders.MainLog.File=${app_log_location}/${PROFILE_NAME}/${app_type}logging.log
```

To change the log file location, edit this entry.

Enable tracing

There may be occasions when you require finer detail than just a basic list of information that shows the main actions; for example, this detail might be asked for by your support staff to help identify an issue. In these situations, you can amend the log to provide more detailed trace information.

To enable tracing, in the `log4cxx.properties` file, disable the line `log4j.rootLogger=INFO, MainLog, ConsoleLog` and enable the following line in its place: `log4j.rootLogger=TRACE, MainLog, TraceLog`

To change the location of the trace log, edit the entry:

```
log4j.appenders.TraceLog.File=${app_log_location}/${PROFILE_NAME}/${app_type}tracing_${PROCESS_ID}.log
```

Amend logging options

The `log4cxx.properties` file contains the controls that define how various events are logged. These controls are normally set to either **INFO** to record actions in the log file, or **WARN** to notify the user of a potential problem. If you are using the log file to identify potential errors, you can also set some of the controls to **TRACE**.

Control the size of the log file

By default, the log file continues to grow in size every time you use SPSS Modeler Server. To prevent the log becoming too large, you can either set it to be started from scratch every day, or define a size limit for it.

To set the log to be started as a new log every day, in the `log4cxx.properties` file, use the following entries:

```
log4j.appenders.MainLog=org.apache.log4j.DailyRollingFileAppender  
log4j.appenders.MainLog.DatePattern=''.yyyy-MM-dd
```

Alternatively, to define a size limit for the log (for example 8 Mb), in the `log4cxx.properties` file, use the following entries:

```
log4j.appenders.MainLog=org.apache.log4j.RollingFileAppender  
log4j.appenders.MainLog.MaxFileSize=8MB
```

Client log file

Note that you can also enable logging for IBM SPSS Modeler client. To do so, open the file `log4j2.xml` in a text editor and change `level="info"` to `level="debug"` in this line:

```
<Logger name="com.spss" additivity="false" level="info">
```

On Mac, the default client log file location is /Applications/IBM/SPSS/Modeler/18.4/Resources/log/. On Windows, the default location is \${env.USERPROFILE}/BM/SPSS/Modeler/18.4/log, where env.USERPROFILE is usually C:\Users%username% with %username% being the proper folder name.

Performance Overview

Real performance in analyzing data is affected by a number of factors, from server and database configuration to the ordering of individual nodes within a stream. In general, you can obtain the best performance by doing the following:

- Store your data in a DBMS, and use SQL generation and optimization whenever possible.
- Use hardware that meets or exceeds the recommendations given in [Architecture and Hardware Recommendations](#).
- Ensure that the client and server performance and optimization settings are properly configured. Note that when SPSS® Modeler is connected to an SPSS Modeler Server installation, the server performance and optimization settings override the client equivalents.
- Design streams for maximum performance.

More information about each of these performance factors is available in the following sections.

- [Server performance and optimization settings](#)
- [Client Performance and Optimization Settings](#)
- [Database Usage and Optimization](#)
- [Stream performance](#)

Many factors can impact how your SPSS Modeler streams perform.

Server performance and optimization settings

Certain IBM® SPSS® Modeler Server settings can be configured to optimize performance. You can adjust these settings using the IBM SPSS Modeler Administration Console interface included in IBM SPSS Deployment Manager. See the topic [IBM SPSS Modeler Server Administration](#) for more information.

The settings are grouped under the heading Performance and Optimization in the IBM SPSS Modeler Administration Console configuration window. The settings are preconfigured for optimal performance for most installations. However, you may need to adjust them depending on your particular hardware, the size of your data sets, and the contents of your streams. See the topic [Performance/Optimization](#) for more information.

Related information

- [IBM SPSS Modeler Server Administration](#)
- [Performance/Optimization](#)

Client Performance and Optimization Settings

The client performance and optimization settings are available from the Options tab of the Stream Properties dialog box. To display these options, choose the following from the client menu.

Tools > Stream Properties > Options > Optimization

You can use the Optimization settings to optimize stream performance. Note that the performance and optimization settings on IBM® SPSS® Modeler Server (if used) override any equivalent settings in the client. If these settings are disabled in the server, then the client cannot enable them. But if they are enabled in the server, the client can choose to disable them.

Note: Database modeling and SQL optimization require that IBM SPSS Modeler Server connectivity be enabled on the IBM SPSS Modeler computer. With this setting enabled, you can access database algorithms, push back SQL directly from IBM SPSS Modeler, and access IBM SPSS Modeler Server. To verify the current license status, choose the following from the IBM SPSS Modeler menu.

Help > About > Additional Details

If connectivity is enabled, you see the option Server Enablement in the License Status tab.

See [Connecting to IBM SPSS Modeler Server](#) for more information.

Note: Whether SQL pushback and optimization are supported depends on the type of database in use. For the latest information on which databases and ODBC drivers are supported and tested for use with IBM SPSS Modeler, see the corporate Support site at <http://www.ibm.com/support>.

Enable stream rewriting. Select this option to enable stream rewriting in IBM SPSS Modeler. Four types of rewriting are available, and you can select one or more of them. Stream rewriting reorders the nodes in a stream behind the scenes for more efficient operation, without altering stream semantics.

- Optimize SQL generation. This option enables nodes to be reordered within the stream so that more operations can be pushed back using SQL generation for execution in the database. When it finds a node that cannot be rendered into SQL, the optimizer will look ahead to see if there are any downstream nodes that can be rendered into SQL and safely moved in front of the problem node without affecting the stream semantics. Not only can the database perform operations more efficiently than IBM SPSS Modeler, but such pushbacks act to reduce the size of the data set that is returned to IBM SPSS Modeler for processing. This, in turn, can reduce network traffic and speed stream operations. Note that the Generate SQL check box must be selected for SQL optimization to have any effect.
- Optimize CLEM expression. This option enables the optimizer to search for CLEM expressions that can be preprocessed before the stream is run, in order to increase the processing speed. As a simple example, if you have an expression such as $\log(\text{salary})$, the optimizer would calculate the actual salary value and pass that on for processing. This can be used both to improve SQL pushback and IBM SPSS Modeler Server performance.
- Optimize syntax execution. This method of stream rewriting increases the efficiency of operations that incorporate more than one node containing IBM SPSS Statistics syntax. Optimization is achieved by combining the syntax commands into a single operation, instead of running each as a separate operation.
- Optimize other execution. This method of stream rewriting increases the efficiency of operations that cannot be delegated to the database. Optimization is achieved by reducing the amount of data in the stream as early as possible. While maintaining data integrity, the stream is rewritten to push operations closer to the data source, thus reducing data downstream for costly operations, such as joins.

Enable parallel processing. When running on a computer with multiple processors, this option allows the system to balance the load across those processors, which may result in faster performance. Use of multiple nodes or use of the following individual nodes may benefit from parallel processing: C5.0, Merge (by key), Sort, Bin (rank and tile methods), and Aggregate (using one or more key fields).

Generate SQL. Select this option to enable SQL generation, allowing stream operations to be pushed back to the database by using SQL code to generate execution processes, which may improve performance. To further improve performance, Optimize SQL generation can also be selected to maximize the number of operations pushed back to the database. When operations for a node have been pushed back to the database, the node will be highlighted in purple when the stream is run.

- Database caching. For streams that generate SQL to be executed in the database, data can be cached midstream to a temporary table in the database rather than to the file system. When combined with SQL optimization, this may result in significant gains in performance. For example, the output from a stream that merges multiple tables to create a data mining view may be cached and reused as needed. With database caching enabled, simply right-click any nonterminal node to cache data at that point, and the cache is automatically created directly in the database the next time the stream is run. This allows SQL to be generated for downstream nodes, further improving performance. Alternatively, this option can be disabled if needed, such as when policies or permissions preclude data being written to the database. If database caching or SQL optimization is not enabled, the cache will be written to the file system instead. See the topic [Caching options for nodes](#) for more information.
- Use relaxed conversion. This option enables the conversion of data from either strings to numbers, or numbers to strings, if stored in a suitable format. For example, if the data is kept in the database as a string, but actually contains a meaningful number, the data can be converted for use when the pushback occurs.

Note: Due to minor differences in SQL implementation, streams run in a database may return slightly different results from those returned when run in IBM SPSS Modeler. For similar reasons, these differences may also vary depending on the database vendor.

Database Usage and Optimization

Database server. If possible, create a dedicated database instance for data mining so that the production server is not impacted by IBM® SPSS® Modeler queries. SQL statements generated by IBM SPSS Modeler can be demanding—multiple tasks on the IBM SPSS Modeler Server machine can be executing SQL in the same database.

In-database mining. Many database vendors provide data mining extensions for their products. These extensions allow data mining activities (such as model-building or scoring) to run within the database server, or within a separate dedicated server. IBM SPSS Modeler's in-database mining features complement and extend its SQL generation capability, providing a way to drive the vendor-specific database extensions. In some cases, taking this approach avoids the potentially expensive overhead of data transfer between IBM SPSS Modeler and the database. Database caching can further increase the benefits. For more information, see the file *DatabaseMiningGuide.pdf*, which is available as a part of your downloaded eImage.

- [SQL Optimization](#)

SQL Optimization

For best performance, you should always try to maximize the amount of SQL generated to exploit the performance and scalability of the database. Only the parts of the stream that cannot be compiled to SQL should be executed within IBM® SPSS® Modeler Server. For more information, see [SQL optimization](#).

Uploading File-Based Data

Data that is not stored in a database cannot benefit from SQL optimization. If the data you want to analyze is not already in a database, you can upload it using a Database Output node. You can also use this node to store intermediate data sets from data preparation and the results of deployment.

IBM SPSS Modeler can interface with the external loaders for many common database systems. Several scripts are included with the software and are available (with documentation) in the `/scripts` subdirectory under your IBM SPSS Modeler installation folder.

The following table shows the potential performance benefit of bulk-loading. The figures show the elapsed time to export 250,000 records and 21 fields to an Oracle database. The external loader was Oracle's `sqlldr` utility.

Table 1. Performance benefit of bulk-loading

Export option	Time (in seconds)
Default (ODBC)	409
Bulk-load via ODBC	52
Bulk-load via external loader	33

Stream performance

Many factors can impact how your SPSS® Modeler streams perform.

Keep these general tips in mind:

- Where possible, consider minimizing the size of your data by limiting processing to only those fields that are needed by using Filter nodes and the Filter tab in source nodes.
- Leverage in-database processing capability whenever possible to reduce the amount of data pulled in to SPSS Modeler.
- Minimize the network distance between your IBM® SPSS Modeler Server and the source data.
- Certain data sources require more overhead than others. For example, the Excel source node takes longer to access the same data than a CSV file. XML data is inherently wasteful and shouldn't be used for storing large amounts of data.
- If using Python-based nodes or R-based nodes, note that there are internal data transfers that must take place. This can sometimes slow processing.
- Accomplishing your tasks with the fewest number of nodes is usually preferable to more nodes.
- Use Type nodes only when necessary. This is especially true when Hadoop is the data source because each Type node processes the entire data flow. See [What is instantiation?](#).
- Certain statistical modeling nodes might be slow, especially with data sets that have many categorical fields.
- Changing the order of nodes can influence processing speed, so experiment with node order. For example, if you have a stream with nodes that reduce data by subsetting or reducing the number of fields, move them as early in the stream as possible.
- If a modeling node you're using has a corresponding -AS version, use the -AS node instead because it's multi-threaded and can improve processing.

SQL optimization

One of the most powerful capabilities of IBM® SPSS® Modeler is the ability to perform many data preparation and mining operations directly in the database. By generating SQL code that can be pushed back to the database for execution, many operations, such as sampling, sorting, deriving new fields, and certain types of graphing, can be performed in the database rather than on the IBM SPSS Modeler or IBM SPSS Modeler Server computer. When you are working with large data sets, these *pushbacks* can dramatically enhance performance in several ways:

- By reducing the size of the result set to be transferred from the DBMS to IBM SPSS Modeler. When large result sets are read through an ODBC driver, network I/O or driver inefficiencies can result. For this reason, the operations that benefit most from SQL optimization are row and column selection and aggregation (Select, Sample, Aggregate nodes). These operations typically reduce the size of the data set to be transferred. Data can also be cached to a temporary table in the database at critical points in the stream (after a Merge or Select node, for example) to further improve performance.
- By using the performance and scalability of the database. Efficiency is increased because a DBMS can often take advantage of parallel processing, more powerful hardware, more sophisticated management of disk storage, and the presence of indexes.

Given these advantages, IBM SPSS Modeler is designed to maximize the amount of SQL generated by each stream so that only those operations that can't be compiled to SQL will be run by IBM SPSS Modeler Server. Because of limitations in what can be expressed in standard SQL (SQL-92), however, certain operations may not be supported. For more information, see [Tips for maximizing SQL generation](#).

Note: Keep the following information in mind when working with SQL:

- Because of minor differences in SQL implementation, streams that run in a database can return slightly different results when they run in IBM SPSS Modeler. These differences may also vary depending on the database vendor, for similar reasons. For example, depending on the database configuration for case sensitivity in string comparison and string collation, IBM SPSS Modeler streams that run by using SQL pushback might produce different results from those that run without SQL pushback. Contact your database administrator for advice on configuring your database. To maximize compatibility with IBM SPSS Modeler, we recommend making sure database string comparisons are case-sensitive.
- Database modeling and SQL optimization require that IBM SPSS Modeler Server connectivity is enabled on the IBM SPSS Modeler computer. With this setting enabled, you can access database algorithms, push back SQL directly from IBM SPSS Modeler, and access IBM SPSS Modeler Server. To verify the current license status, from the IBM SPSS Modeler menu, go to:
 - Help > About > Additional Details

If connectivity is enabled, you see the option Server Enablement in the License Status tab.

See [Connecting to IBM SPSS Modeler Server](#) for more information.

- When using IBM SPSS Modeler to generate SQL, the result that uses SQL push back might not be consistent with IBM SPSS Modeler native on some platforms (Linux/zLinux, for example). The reason is that floating point is handled differently on different platforms.

Note: When you run streams in a Netezza database, date and time details are taken from that database. This behavior might differ from your local or IBM SPSS Modeler Server date and time if, for example, the database is on a machine that is located in a different country or time zone.

Database requirements

For more information about which databases and ODBC drivers are supported and tested for use with IBM SPSS Modeler, see the product compatibility matrices on the corporate Support site at <http://www.ibm.com/support>.

You might gain more performance improvements by using database modeling.

ODBC driver setup

To ensure that time details (such as HH:MM:SS) are processed correctly when using SQL 2012 on Windows 32bit systems, when setting up your ODBC SQL Server Wire Protocol Driver, select both the Enable Quoted Identifiers and Fetch TWFS as Time options.

How SQL generation works

The initial fragments of a stream leading from the database source nodes are the main targets for SQL generation. When a node is encountered that cannot be compiled to SQL, the data are extracted from the database and subsequent processing is performed by IBM® SPSS® Modeler Server.

During stream preparation and prior to execution, the SQL generation process happens as follows:

- The server reorders streams to move downstream nodes into the “SQL zone” where it can be proven safe to do so. (This feature can be disabled on the server.)
- Working from the source nodes toward the terminal nodes, SQL expressions are constructed incrementally. This phase stops when a node is encountered that cannot be converted to SQL or when the terminal node (for example, Table node or Graph node) is converted to SQL. At the end of this phase, each node is labeled with an SQL statement if the node and its predecessors have an SQL equivalent.
- Working from the nodes with the most complicated SQL equivalents back toward the source nodes, the SQL is checked for validity. The SQL that was successfully validated is chosen for execution.
- Nodes for which all operations have generated SQL are highlighted in purple on the stream canvas. Based on the results, you may want to further reorganize your stream where appropriate to take full advantage of database execution. See the topic [Tips for maximizing SQL generation](#) for more information.

Where Improvements Occur

SQL optimization improves performance in a number of data operations:

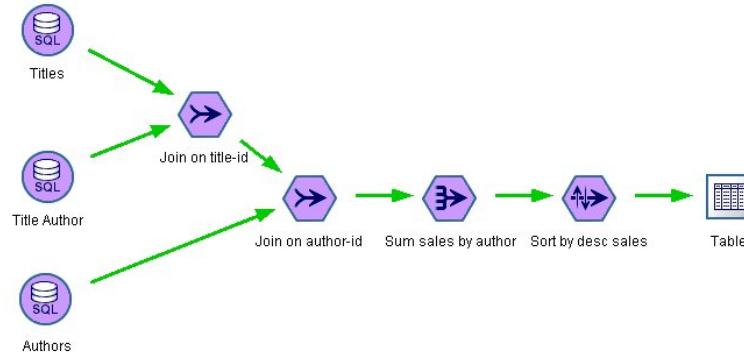

- Joins (merge by key). Join operations can increase optimization within databases.
- Aggregation. The Aggregate, Distribution, and Web nodes all use aggregation to produce their results. Summarized data uses considerably less bandwidth than the original data.
- Selection. Choosing records based on certain criteria reduces the quantity of records.
- Sorting. Sorting records is a resource-intensive activity that is performed more efficiently in a database.
- Field derivation. New fields are generated more efficiently in a database.
- Field projection. IBM SPSS Modeler Server extracts only fields that are required for subsequent processing from the database, which minimizes bandwidth and memory requirements. The same is also true for superfluous fields in flat files: although the server must read the superfluous fields, it does not allocate any storage for them.
- Scoring. SQL can be generated from decision trees, rulesets, linear regression, and factor-generated models.

• [SQL Generation Example](#)

SQL Generation Example

The following stream joins three database tables by key operations and then performs an aggregation and sort.

Figure 1. Optimized stream with purple nodes indicating SQL pushbacks (operations performed in database)

Generated SQL

The generated SQL for this stream is as follows:

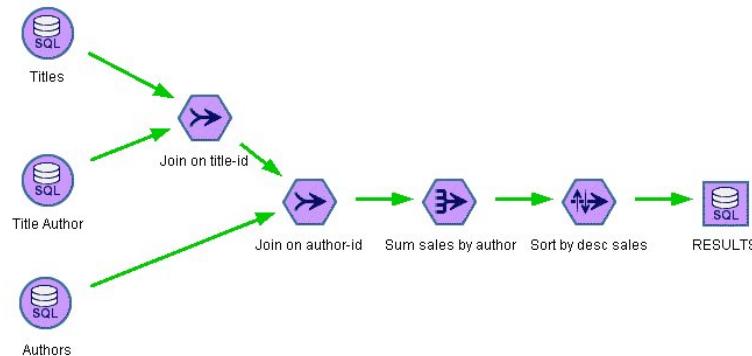

```

SELECT
    T2. au_lname AS C0,
    T2. au_fname AS C1,
    SUM({fn CONVERT(T0. ytd_sales ,SQL_BIGINT)}) AS C2
FROM
    dbo . titles T0,
    dbo . titleauthor T1,
    dbo . authors T2
WHERE
    (T0. title_id = T1. title_id )
    AND (T1. au_id = T2. au_id )
GROUP BY T2. au_lname ,T2. au_fname
ORDER BY 3 DESC
  
```

Executing the Stream

When the stream is terminated with a database export node, it is possible for the whole stream to be executed in the database.

Figure 2. Entire stream executed in database

-

Configuring SQL Optimization

1. Install an ODBC driver and configure a data source for the database you want to use. See the topic [Data Access](#) for more information.
2. Create a stream that uses a source node to pull data from that database.
3. Check to be sure that SQL generation is enabled on the client and server, if applicable. It is enabled by default for both.

To Enable SQL Optimization on the Client

1. From the Tools menu, choose Stream Properties...> Options.
2. Click the Optimization tab. Select Generate SQL to enable SQL optimization. Optionally, you can select other settings to improve performance. See the topic [Client Performance and Optimization Settings](#) for more information.

To Enable SQL Optimization on the Server

Because server settings override any specifications made on the client, the server configuration settings Stream Rewriting and Automatic SQL Generation must both be turned on. For more information about how to change IBM® SPSS® Modeler Server settings, see the section [Performance/Optimization](#). Note that if these settings are disabled in the server, then the client cannot enable them. But if they are enabled in the server, the client can choose to disable them.

To Enable Optimization When Scoring Models

For purposes of scoring, SQL generation must be enabled separately for each modeling node, regardless of any server or client-level settings. This is done because some models generate extremely complex SQL expressions that may not be evaluated effectively within the database. The database may report errors when trying to execute the generated SQL, due to the size or complexity of the SQL.

A certain amount of trial-and-error may be needed to determine whether SQL generation improves performance for a given model. This is done on the Settings tab after adding a generated model to a stream.

Previewing Generated SQL

You can preview generated SQL in the message log before executing it in the database. This may be useful for debugging purposes, and it allows you to export the generated SQL to edit or run in the database at a future date. It also indicates which nodes will be pushed back to the database, which may help you determine whether the stream can be reordered to improve performance.

1. Make sure that Display SQL in the messages log during stream execution and Display SQL generation details in the messages log during stream preparation are selected in the User Options dialog box. See the topic [Client Performance and Optimization Settings](#) for more information.
2. On the stream canvas, select the node or stream that you want to preview.
3. Click the Preview SQL button on the toolbar.
All nodes for which SQL is generated (and that will be pushed back to the database when the stream is executed) are colored purple on the stream canvas.
4. To preview the generated SQL, from the menus choose:
Tools...>Stream Properties...>Messages...

Viewing SQL for Model Nuggets

For some models, SQL for the model nugget can be generated, pushing back the model scoring stage to the database. The main use of this feature is not to improve performance, but to allow streams containing these nuggets to have their full SQL pushed back. See the topic [Nodes supporting SQL generation](#) for more information.

To view the SQL for a model nugget that supports SQL generation:

1. Select the Settings tab on the model nugget.
 2. Choose one of the options Generate with (no) missing value support or Generate SQL for this model, as appropriate.
 3. In the model nugget menu, choose:
File > Export SQL
 4. Save the file.
 5. Open the file to view the SQL.
-

Tips for maximizing SQL generation

To get the best performance boost from SQL optimization, pay attention to the following items.

Stream order. SQL generation may be halted when the function of the node has no semantic equivalent in SQL because IBM® SPSS® Modeler's data-mining functionality is richer than the traditional data-processing operations supported by standard SQL. When this happens, SQL generation is also suppressed for any downstream nodes. Therefore, you may be able to significantly improve performance by reordering nodes to put operations that halt SQL as far downstream as possible. The SQL optimizer can do a certain amount of reordering automatically (just make sure stream rewriting is enabled), but further improvements may be possible. A good candidate for this is the Select node, which can often be brought forward. See the topic [Nodes supporting SQL generation](#) for more information.

CLEM expressions. If a stream cannot be reordered, you may be able to change node options or CLEM expressions or otherwise recast the way the operation is performed, so that it no longer inhibits SQL generation. Derive, Select, and similar nodes can commonly be rendered into SQL, provided that all of the CLEM expression operators have SQL equivalents. Most operators can be rendered, but there are a number of operators that inhibit SQL generation (in particular, the sequence functions ["@ functions"]). Sometimes generation is halted because the generated query has become too complex for the database to handle. See the topic [CLEM Expressions and Operators Supporting SQL Generation](#) for more information.

Multiple source nodes. Where a stream has multiple database source nodes, SQL generation is applied to each input branch independently. If generation is halted on one branch, it can continue on another. Where two branches merge (and both branches can be expressed in SQL up to the merge), the merge itself can often be replaced with a database join, and generation can be continued downstream.

Database algorithms. Model estimation is always performed on IBM SPSS Modeler Server rather than the database, except when using database-native algorithms from Microsoft, IBM, or Oracle.

Scoring models. In-database scoring is supported for some models by rendering the generated model into SQL. However, some models generate extremely complex SQL expressions that aren't always evaluated effectively within the database. For this reason, SQL generation must be enabled separately for each model node. If you find that a model node is inhibiting SQL generation, go to the Settings tab on the node dialog box and select Generate SQL for this model (with some models, you may have additional options controlling generation). Run tests to confirm that the option is beneficial for your application. See the topic [Nodes supporting SQL generation](#) for more information.

When testing modeling nodes to see if SQL generation for models works effectively, we recommend first saving all streams from IBM SPSS Modeler. Some database systems may hang while trying to process the (potentially complex) generated SQL, requiring IBM SPSS Modeler to be closed from the Windows task manager.

Database caching. If you are using a node cache to save data at critical points in the stream (for example, following a Merge or Aggregate node), make sure that database caching is enabled along with SQL optimization. This will allow data to be cached to a temporary table in the database (rather than the file system) in most cases. See the topic [Configuring SQL Optimization](#) for more information.

Vendor-specific SQL. Most of the generated SQL is standards-conforming (SQL-92), but some nonstandard, vendor-specific features are exploited where practical. The degree of SQL optimization can vary, depending on the database source.

SQL configuration option. By default, SPSS Modeler considers SQL queries written in an ODBC source node to be non-replayable, meaning that the query is considered to return different results when being executed multiple times. However, in some cases, this may prevent SPSS Modeler

from generating SQL for downstream nodes. You can override this behavior by changing the following value to `Y` in the `odbc-db2-custom-properties.cfg`. The file is located in the SPSS Modeler config directory.

```
assume_custom_sql_replayable, Y
```

Nodes supporting SQL generation

The following tables show nodes representing data-mining operations that support SQL generation. With the exception of the database modeling nodes, if a node does not appear in these tables, it does not support SQL generation.

You can preview the SQL that is generated before executing it. See the topic [Previewing Generated SQL](#) for more information.

Table 1. Sources

Node supporting SQL generation	Notes
Database	This node is used to specify tables and views to be used for further analysis. This node enables entry of SQL queries. Avoid results sets with duplicate column names. See the topic Writing SQL Queries for more information.

Table 2. Record operations

Node supporting SQL generation	Notes
Select	Supports generation only if SQL generation for the select expression itself is supported (see expressions below). If any fields have nulls, SQL generation does not give the same results for discard as are given in native IBM® SPSS® Modeler.
Sample	Simple sampling supports SQL generation to varying degrees depending on the database. See Table 3 .
Aggregate	SQL generation support for aggregation depends on the data storage type. See Table 4 .
RFM Aggregate	Supports generation except if saving the date of the second or third most recent transactions, or if only including recent transactions. However, including recent transactions does work if the <code>datetime_date(YEAR,MONTH,DAY)</code> function is pushed back.
Sort	
Merge	No SQL generated for merge by order. Merge by key with full or partial outer join is only supported if the database/driver supports it. Non-matching input fields can be renamed by means of a Filter node, or the Filter tab of a source node. Supports SQL generation for merge by condition. For all types of merge, <code>SQL_SP_EXISTS</code> is not supported if inputs originate in different databases.
Append	Supports generation if inputs are unsorted. Note: SQL optimization is only possible when your inputs have the same number of columns.
Distinct	A Distinct node with the (default) mode Create a composite record for each group selected does not support SQL optimization.

Table 3. SQL generation support in the Sample node for simple sampling

Mode	Sample	Max size	Seed	Db2 for z/OS	Db2 for OS/400	Db2 for Win/UNIX	Netezza	Oracle	SQL Server	Teradata
Include	First	n/a		Y	Y	Y	Y	Y	Y	Y
	1-in-n	off		Y	Y	Y	Y	Y		Y
		max		Y	Y	Y	Y	Y		Y
	Random %	off	off	Y		Y	Y	Y		Y
		on	Y			Y		Y		
		max	off	Y		Y	Y	Y		Y
			on	Y		Y		Y		
Discard	First	off					Y	Y		
		max					Y	Y		
	1-in-n	off		Y	Y	Y	Y	Y		Y
		max		Y	Y	Y	Y	Y		Y
	Random %	off	off	Y		Y	Y	Y		Y
		on	Y			Y		Y		
		max	off	Y		Y	Y	Y		Y
			on	Y		Y		Y		

Table 4. SQL generation support in the Aggregate node

Storage	Sum	Mean	Min	Max	SDev	Median	Count	Variance	Percentile
Integer	Y	Y	Y	Y	Y	Y*	Y	Y	Y*

Storage	Sum	Mean	Min	Max	SDev	Median	Count	Variance	Percentile
Real	Y	Y	Y	Y	Y	Y*	Y	Y	Y*
Date			Y	Y		Y*	Y		Y*
Time			Y	Y		Y*	Y		Y*
Timestamp			Y	Y		Y*	Y		Y*
String			Y	Y		Y*	Y		Y*

* Median and Percentile are supported on Oracle.

Table 5. Field operations

Node supporting SQL generation	Notes
Type	Supports SQL generation if the Type node is instantiated and no ABORT or WARN type checking is specified.
Filter	
Derive	Supports SQL generation if SQL generated for the derive expression is supported (see expressions below).
Ensemble	Supports SQL generation for Continuous targets. For other targets, supports generation only if the "Highest confidence wins" ensemble method is used.
Filler	Supports SQL generation if the SQL generated for the derive expression is supported (see expressions below).
Anonymize	Supports SQL generation for Continuous targets, and partial SQL generation for Nominal and Flag targets.
Reclassify	
Binning	Supports SQL generation if the "Tiles (equal count)" binning method is used and the "Read from Bin Values tab if available" option is selected. Note: Due to differences in the way that bin boundaries are calculated (this is caused by the nature of the distribution of data in bin fields), you might see differences in the binning output when comparing normal stream execution results and SQL pushback results. To avoid this, use the Record count tiling method, and either Add to next or Keep in current tiles to obtain the closest match between the two methods of stream execution.
RFM Analysis	Supports SQL generation if the "Read from Bin Values tab if available" option is selected, but downstream nodes will not support it.
Partition	Supports SQL generation to assign records to partitions.
SetToFlag	
Restructure	

Table 6. Graphs

Node supporting SQL generation	Notes
Graphboard	SQL generation is supported for the following graph types: Area, 3-D Area, Bar, 3-D Bar, Bar of Counts, Heat map, Pie, 3-D Pie, Pie of Counts. For Histograms, SQL generation is supported for categorical data only. SQL generation is not supported for Animation in Graphboard.
Distribution	
Web	
Evaluation	

For some models, SQL for the model nugget can be generated, pushing back the model scoring stage to the database. The main use of this feature is not to improve performance, but to allow streams containing these nuggets to have their full SQL pushed back. See the topic [Viewing SQL for Model Nuggets](#) for more information.

Table 7. Model nuggets

Model nugget supporting SQL generation	Notes
C&R Tree	Supports SQL generation for the single tree option, but not for the boosting, bagging or large dataset options.
QUEST	
CHAID	
C5.0	
Decision List	
Linear	Supports SQL generation for the standard model option, but not for the boosting, bagging or large dataset options.
Neural Net	Supports SQL generation for the standard model option (Multilayer Perceptron only), but not for the boosting, bagging or large dataset options.
PCA/Factor	
Logistic	Supports SQL generation for Multinomial procedure but not Binomial. For Multinomial, generation is not supported when confidences are selected, unless the target type is Flag.
Generated Rulesets	

Model nugget supporting SQL generation	Notes
Auto Classifier	If a User Defined Function (UDF) scoring adapter is enabled, these nuggets support SQL pushback. In addition, If either SQL generation for Continuous targets, or the "Highest confidence wins" ensemble method are used, these nuggets support further pushback downstream.
Auto Numeric	

Table 8. Output

Node supporting SQL generation	Notes
Table	Supports generation if SQL generation is supported for highlight expression (see expressions below).
Matrix	Supports generation except if "All numerics" is selected for the Fields option.
Analysis	Supports generation, depending on the options selected.
Transform	
Graphs	SQL Pushback is not supported if animation is enabled in a Graphboard node.
Statistics	Supports generation if the Correlate option is not used.
Report	
Set Globals	

Table 9. Export

Node supporting SQL generation	Notes
Database	
Publisher	The published stream will contain generated SQL.

CLEM Expressions and Operators Supporting SQL Generation

The following tables show the mathematical operations and expressions that support SQL generation and are often used during data mining. Operations absent from these tables do not support SQL generation in the current release.

Table 1. Operators

Operation supporting SQL generation	Notes
+	
-	
/	
*	
><	Used to concatenate strings.

Table 2. Relational operators

Operation supporting SQL generation	Notes

Using SQL Functions in CLEM Expressions

The `@SQLFN` function can be used to add named SQL functions within CLEM expressions, for purposes of database execution only. This can be useful in special cases where proprietary SQL or other vendor-specific customizations are required.

Use of this function is not covered by the standard IBM® SPSS® Modeler support agreement, since execution relies on external database components beyond the control of IBM Corp., but may be deployed in special cases, typically as part of a Services engagement. Contact <http://www.ibm.com/software/analytics/spss/services/> for more information if necessary.

Writing SQL Queries

When using the Database node, you should pay special attention to any SQL queries that result in a dataset with duplicate column names. These duplicate names often prevent SQL optimization for any downstream nodes.

IBM® SPSS® Modeler uses nested **SELECT** statements to push back SQL for streams that use an SQL query in the Database source node. In other words, the stream nests the query specified in the Database source node inside of one or more **SELECT** statements generated during the optimization of downstream nodes. Therefore, if the result set of a query contains duplicate column names, the statement cannot be nested by the RDBMS. Nesting difficulties occur most often during a table join where a column with the same name is selected in more than one of the joined tables. For example, consider this query in the source node:

```
SELECT e.ID, e.LAST_NAME, d.*  
FROM EMP e RIGHT OUTER JOIN  
DEPT d ON e.ID = d.ID;
```

The query will prevent subsequent SQL optimization, since this **SELECT** statement would result in a dataset with two columns called **ID**.

In order to allow full SQL optimization, you should be more explicit when writing SQL queries and specify column aliases when a situation with duplicate column names arises. The statement below illustrates a more explicit query:

```
SELECT e.ID AS ID1, e.LAST_NAME, d.*  
FROM EMP e RIGHT OUTER JOIN  
DEPT d ON e.ID = d.ID;
```

-

Scoring adapter for Teradata - duplicate rows

The IBM® SPSS® Modeler Server Scoring Adapter for Teradata expects no identical rows in its input data. Teradata does not allow the existence of two identical rows in a table. However, duplicate rows can happen when joining tables, or when the user uses only part of the fields of a table as input. These duplicate rows will lead to an incorrect number of records after a cartesian join.

Configuring Oracle for UNIX Platforms

- [Configuring Oracle for SQL Optimization](#)

Configuring Oracle for SQL Optimization

When running IBM® SPSS® Modeler Server on UNIX platforms and reading from an Oracle database, consider the following tips to ensure that generated SQL is being fully optimized within the database.

Proper Locale Specification

When running IBM SPSS Modeler Server in a locale other than that shipped with the Connect ODBC drivers, you should reconfigure the machine to enhance SQL optimization. Connect ODBC drivers ship only with the *en_US* locale files. Consequently, if the IBM SPSS Modeler Server machine is running in a different locale or if the shell in which IBM SPSS Modeler Server was started did not have the locale fully defined, generated SQL may not be fully optimized within Oracle. The reasons are as follows:

- IBM SPSS Modeler Server uses the ODBC locale files corresponding to the locale in which it is running to translate the codes returned from the database into text strings. It then uses these text strings to determine which database it is actually connecting to.
- If the locale (as returned to IBM SPSS Modeler Server by the system `$LANG` query) is not *en_US*, IBM SPSS Modeler cannot translate the codes it receives from the ODBC driver into text. In other words, an untranslated code, rather than the string *Oracle*, is returned to IBM SPSS Modeler Server at the start of a database connection. This means that IBM SPSS Modeler is unable to optimize streams for Oracle.

To check and reset locale specifications:

1. In a UNIX shell, run:

```
#locale
```

This will return the locale information for the shell. For example:

```
$ locale
LANG=en_US.ISO8859-15
LC_CTYPE="en_US.ISO8859-15"
LC_NUMERIC="en_US.ISO8859-15"
LC_TIME="en_US.ISO8859-15"
LC_COLLATE="en_US.ISO8859-15"
LC_MONETARY="en_US.ISO8859-15"
LC_MESSAGES="en_US.ISO8859-15"
LC_ALL=en_US.ISO8859-15
```

2. Change to your Connect ODBC/locale directory. (Here you will see a single directory, *en_US*.)

3. Create a soft link to this *en_US* directory, specifying the name of the locale setup in the shell. An example is as follows:

```
#ln -s en_US en_US.ISO8859-15
```

For a non-English locale, such as *fr_FR.ISO8859-1*, you should create the soft link as follows:

```
#ln -s en_US fr_FR.ISO8859-1
```

4. Once you have created the link, restart IBM SPSS Modeler Server from this same shell. (IBM SPSS Modeler Server receives its locale information from the shell from which it is started.)

Notes

When optimizing a UNIX machine for SQL pushbacks to Oracle, consider the following tips:

- The full locale must be specified. In the above example, you must create the link in the form `language_territory.code-page`. The existing *en_US* locale directory is not sufficient.
- To fully optimize in-database mining, both `LANG` and `LC_ALL` must be defined in the shell used to start IBM SPSS Modeler Server. `LANG` may be defined in the shell as you would any other environment variable before restarting IBM SPSS Modeler Server. For example, see the following definition:

```
#LANG=en_US.ISO8859-15; export LANG
```

- Each time you start IBM SPSS Modeler Server you will need to check that the shell locale information is fully specified and that the appropriate soft link exists in the ODBC/locale directory.

Configuring UNIX Startup Scripts

- [Introduction](#)
 - [Scripts](#)
 - [Automatically Starting and Stopping IBM SPSS Modeler Server](#)
 - [Manually Starting and Stopping IBM SPSS Modeler Server](#)
 - [Editing Scripts](#)
 - [Controlling Permissions on File Creation](#)
 - [IBM SPSS Modeler Server and the data access pack](#)
-

Introduction

This appendix describes some of the scripts that ship with the UNIX versions of IBM® SPSS® Modeler Server, and it explains how to configure the scripts. Scripts are used to:

- Configure IBM SPSS Modeler Server to start automatically when the server computer is restarted.
 - Manually stop and restart IBM SPSS Modeler Server.
 - Change permissions on files created by IBM SPSS Modeler Server.
 - Configure IBM SPSS Modeler Server to work with the ODBC Connect drivers provided with IBM SPSS Modeler Server. See the topic [IBM SPSS Modeler Server and the data access pack](#) for more information.
-

Scripts

IBM® SPSS® Modeler Server uses several scripts, including:

- modelersrv.sh. The manual startup script for IBM SPSS Modeler Server is located in the IBM SPSS Modeler Server installation directory. It configures the environment for the server when the server daemon process is *manually* started. Run it when you want to manually start and stop the server. Edit it when you need to change the configuration for manual startup.
 - auto.sh. This is a script that configures your system to start the server daemon process automatically at boot time. Run it once to configure your system for automatic startup. You do not need to edit it. The script is located in the IBM SPSS Modeler Server installation directory.
 - rc.modeler. When you run auto.sh, this script is created in a location that depends on your server's operating system. It configures the environment for the server when it is *automatically* started. Edit it when you need to change the configuration for automatic startup.
-

Automatically Starting and Stopping IBM SPSS Modeler Server

IBM® SPSS® Modeler Server must be started as a daemon process. The installation program includes a script (*auto.sh*) that you can run to configure your system to automatically stop and restart IBM SPSS Modeler Server.

To configure the system for automatic startup and shutdown

1. Log on as root.
2. Change to the IBM SPSS Modeler Server installation directory.
3. Run the script. At the UNIX prompt, type:

```
./auto.sh
```

An automatic startup script, *rc.modeler*, is created in the location shown in the table above. The operating system will use *rc.modeler* to start the IBM SPSS Modeler Server daemon process whenever the server computer is rebooted. The operating system will also use *rc.modeler* to stop the daemon whenever the system is shut down.

Manually Starting and Stopping IBM SPSS Modeler Server

You can manually start and stop IBM® SPSS® Modeler Server by running the *modelersrv.sh* script.

To manually start and stop IBM SPSS Modeler Server

1. Change to the IBM SPSS Modeler Server installation directory.
2. To start the server, at the UNIX command prompt, type:

```
./modelersrv.sh start
```

3. To stop the server, at the UNIX command prompt type:

```
./modelersrv.sh stop
```

Editing Scripts

If you use both manual and automatic startup, make parallel changes in both *modelersrv.sh* and *rc.modeler*. If you use only manual startup, make changes in *modelersrv.sh*. If you use only automatic startup, make changes in *rc.modeler*.

To edit the scripts

1. Stop IBM® SPSS® Modeler Server. (See the topic [Manually Starting and Stopping IBM SPSS Modeler Server](#) for more information.)
2. Locate the appropriate script. (See the topic [Scripts](#) for more information.)
3. Open the script in a text editor, make changes, and save the file.
4. Start IBM SPSS Modeler Server, either automatically (by restarting the server computer) or manually.

Controlling Permissions on File Creation

IBM® SPSS® Modeler Server creates temporary files with read, write, and execute permissions for everyone. You can override this default by editing the **UMASK** setting in the startup script, either in *modelersrv.sh*, *rc.modeler*, or in both. (For more information, see [Editing Scripts](#) above.) We recommend 077 as the most restrictive **UMASK** setting to use. Settings that are more restrictive could cause permissions problems for IBM SPSS Modeler Server.

IBM SPSS Modeler Server and the data access pack

If you want to use the ODBC drivers with IBM® SPSS® Modeler Server, the ODBC environment must be configured by *odbc.sh* when the IBM SPSS Modeler Server process starts. You do this by editing the appropriate IBM SPSS Modeler start up script, either in *modelersrv.sh*, *rc.modeler*, or in both. (See [Editing Scripts](#) for more information.)

For more information, see the Technical Support web site at <http://www.ibm.com/support>. If you have questions about creating or setting permissions for ODBC data sources, contact your database administrator.

To configure ODBC to start with IBM SPSS Modeler Server

1. Stop the IBM SPSS Modeler Server host if it is running.
2. Download the relevant compressed TAR archive for the platform on which you have IBM SPSS Modeler Server installed. Make sure that you download the correct drivers for your installed version of IBM SPSS Modeler Server. Copy the file to the location where you want to install the ODBC drivers (for example, /usr/spss/odbc).
3. Extract the TAR archive file using **tar -xvof**.
4. Run the *setodbcpath.sh* script that is extracted from the archive.
5. Edit the script *odbc.sh* to add the definition of ODBCINI to the bottom of this script and export it, for example:

```
ODBCINI=/usr/spss/odbc/odbc.ini; export ODBCINI
```

ODBCINI must point to the full pathname of the *odbc.ini* file that you want IBM SPSS Modeler to read to get a list of the ODBC datasources that you define (a default *odbc.ini* is installed with the drivers).

6. Save *odbc.sh*.
7. (64-bit IBM SPSS Modeler Server installations only; for other installations, continue from the next step) Define and export **LD_LIBRARY_PATH_64** in *odbc.sh*:

```

if [ "$LD_LIBRARY_PATH_64" = "" ]; then
    LD_LIBRARY_PATH_64=<library_path>
else
    LD_LIBRARY_PATH_64=<library_path>:$LD_LIBRARY_PATH_64
fi
export LD_LIBRARY_PATH_64

```

where library_path is the same as for the LD_LIBRARY_PATH definition already in the script that has been initialized with your installation path (for example, /usr/spss/odbc/lib). The easiest way to do this is to copy the `if` and `export` statements for LD_LIBRARY_PATH in your odbc.sh file, append them to the end of the file, and then replace the "LD_LIBRARY_PATH" strings in the newly appended `if` and `export` statements with "LD_LIBRARY_PATH_64".

As an example, your final odbc.sh file on a 64-bit IBM SPSS Modeler Server installation might look like this:

```

if [ "$LD_LIBRARY_PATH" = "" ]; then
    LD_LIBRARY_PATH=/usr/spss/odbc/lib
else
    LD_LIBRARY_PATH=/usr/spss/odbc/lib:$LD_LIBRARY_PATH
fi
export LD_LIBRARY_PATH
if [ "$LD_LIBRARY_PATH_64" = "" ]; then
    LD_LIBRARY_PATH_64=/usr/spss/odbc/lib
else
    LD_LIBRARY_PATH_64=/usr/spss/odbc/lib:$LD_LIBRARY_PATH_64
fi
export LD_LIBRARY_PATH_64
ODBCINI=/usr/spss/odbc/odbc.ini; export ODBCINI

```

Remember to export LD_LIBRARY_PATH_64, as well as defining it with the `if` loop.

8. Edit the odbc.ini file that you defined earlier using \$ODBCINI. Define the data source names that you require (these depend on the database that you are accessing).
9. Save the odbc.ini file.
10. Configure IBM SPSS Modeler Server to use these drivers. To do so, edit modelersrv.sh and add the following line immediately below the line that defines SCLEMNAME:

```
. <odbc.sh_path>
```

where odbc.sh_path is the full path to the odbc.sh file that you edited near the beginning of this procedure, for example:

```
. /usr/spss/odbc/odbc.sh
```

Note: The syntax is important here; be sure to leave a space between the first period and the path to the file.

11. Save modelersrv.sh.

Important: For the SDAP driver to work on Db2 on z/OS, you must grant access to SYSIBM.SYSPACKSTMT.

To test the connection

1. Restart IBM SPSS Modeler Server.
2. Connect to IBM SPSS Modeler Server from a client.
3. On the client, add a Database source node to the canvas.
4. Open the node and verify that you can see the data source names that you defined in the odbc.ini file earlier in the configuration procedure.

If you do not see what you expect here, or you get errors when you try to connect to a data source that you have defined, follow the Troubleshooting procedure. See the topic [Troubleshooting ODBC configuration](#) for more information.

To configure ODBC to start with IBM SPSS Modeler Solution Publisher Runtime

When you can successfully connect to the database from IBM SPSS Modeler Server, you can configure an IBM SPSS Modeler Solution Publisher Runtime installation on the same server by referencing the same odbc.sh script from the startup script of IBM SPSS Modeler Solution Publisher Runtime.

1. Edit the modelerrun script in IBM SPSS Modeler Solution Publisher Runtime to add the following line immediately above the last line of the script:

```
. <odbc.sh_path>
```

where odbc.sh_path is the full path to the odbc.sh file that you edited near the beginning of this procedure, for example:

```
. /usr/spss/odbc/odbc.sh
```

Note: The syntax is important here. Be sure to leave a space between the first period and the path to the file.

2. Save the modelerrun script file.

3. By default, the DataDirect Driver Manager is not configured for IBM SPSS Modeler Solution Publisher Runtime to use ODBC on UNIX systems. To configure UNIX to load the DataDirect Driver Manager, enter the following commands (where sp_install_dir is the installation directory of Solution Publisher Runtime):

```
cd sp_install_dir  
rm -f libspssodbc.so  
ln -s libspssodbc_datadirect.so libspssodbc.so
```

To configure ODBC to start with IBM SPSS Modeler Batch

No configuration of the IBM SPSS Modeler Batch script is necessary for ODBC. This is because you connect to IBM SPSS Modeler Server from IBM SPSS Modeler Batch in order to run streams. Ensure that the IBM SPSS Modeler Server ODBC configuration has been made and is working correctly, as described earlier in this section.

To add or edit a data source name

1. Edit the odbc.ini file to include the new or changed name.
2. Test the connection as described earlier in this section.

When the connection with IBM SPSS Modeler Server is working correctly, the new or changed data source should also work correctly with IBM SPSS Modeler Solution Publisher Runtime and IBM SPSS Modeler Batch.

SQL Server support with the Data Access Pack driver

The ODBC configuration for SQL Server must have the **Enable_QuotedIdentifiers** ODBC connection attribute set to **Yes** (the default for this driver is **No**). On UNIX this attribute is configured in the system information file (odbc.ini) using the **QuotedID** option.

- [Troubleshooting ODBC configuration](#)
- [Library paths](#)

Troubleshooting ODBC configuration

No data sources listed, or random text displayed

If you open a Database source node and the list of available data sources is empty or contains unexpected entries, it may be due to a problem with the startup script.

1. Check that \$ODBCINI is defined within *modelersrv.sh*, either explicitly in the script itself, or in the *odbc.sh* script that is referenced in *modelersrv.sh*.
2. In the latter case, ensure that ODBCINI points to the full path to the *odbc.ini* file that you have used to define your ODBC data sources.
3. If the path specification in ODBCINI is correct, check the value of \$ODBCINI that is being used in the IBM® SPSS® Modeler Server environment by echoing the variable from within *modelersrv.sh*. To do so, add the following line to *modelersrv.sh* after the point where you define ODBCINI:

```
echo $ODBCINI
```

4. Save and then execute *modelersrv.sh*. The value of \$ODBCINI that is being set in the IBM SPSS Modeler Server environment is written to *stdout* for verification.
5. If no value at all is returned to *stdout*, and you are defining \$ODBCINI in the *odbc.sh* script that you are referencing from *modelersrv.sh*, check that the referencing syntax is correct. It should be:

```
. <odbc.sh_path>
```

where *odbc.sh_path* is the full path to the *odbc.sh* file that you edited near the beginning of this procedure, for example:

```
. /usr/spss/odbc/odbc.sh
```

Note: The syntax is important here; be sure to leave a space between the first period and the path to the file.

When the correct value is echoed to *stdout* on running *modelersrv.sh*, you should be able to see the data source names in the Database source node when you restart IBM SPSS Modeler Server and connect to it from the client.

IBM SPSS Modeler client hangs on clicking Connect in Database Connections dialog box

This behavior can be caused by your library path not being correctly set to include the path to the ODBC libraries. The library path is defined by \$LD_LIBRARY_PATH (and \$LD_LIBRARY_PATH_64 on 64-bit versions).

To see the value of the library path in the IBM SPSS Modeler Server daemon environment, echo the value of the appropriate environment variable from within *modelersrv.sh*, after the line where you are appending the ODBC library path to the library path, and execute the script. The library path value will be echoed to the terminal when you next execute the script.

If you are referencing *odbc.sh* from *modelersrv.sh* to set up your IBM SPSS Modeler Server ODBC environment, echo your library path value from the line after the one where you reference the *odbc.sh* script. To echo the value, add the following line to the script, then save and execute the script file:

```
echo $<library_path_variable>
```

where *<library_path_variable>* is the appropriate library path variable for your server operating system.

The returned value of your library path must include the path to the *lib* subdirectory of your ODBC installation. If it does not, append this location to the file.

If you are running the 64-bit version of IBM SPSS Modeler Server, *\$LD_LIBRARY_PATH_64* will override *\$LD_LIBRARY_PATH* if it is set. If you are having this problem on one of these 64-bit platforms, echo *LD_LIBRARY_PATH_64* as well as *\$LD_LIBRARY_PATH* from *modelersrv.sh* and, if required, set *\$LD_LIBRARY_PATH_64* so that it includes the *lib* subdirectory of your ODBC installation, and export the definition.

Data source name not found and no default driver specified

If you see this error on clicking Connect in the Database Connections dialog box, it usually indicates that your *odbc.ini* file is incorrectly defined. Check that the data source name (DSN) as defined within the **[ODBC Data Sources]** section at the top of the file matches the string specified between the square brackets further down in *odbc.ini* to define the DSN. If these are different in any way, you will see this error when you try to connect using the DSN from within IBM SPSS Modeler. Following is an example of an *incorrect* specification:

```
[ODBC Data Sources]
Oracle=Oracle Wire Protocol

...
[Oracle Driver]
Driver=/usr/ODBC/lib/XEora22.so
Description=SPSS 5.2 Oracle Wire Protocol
AlternateServers=
...
```

You need to change one of the two strings in bold so that they match exactly. Doing so should resolve the error.

Specified driver could not be loaded

This error also indicates that the *odbc.ini* file is incorrectly defined. One possibility is that the Driver parameter within the driver stanza is incorrectly set, for example:

```
[ODBC Data Sources]
Oracle=Oracle Wire Protocol

...
[Oracle]
Driver=/nosuchpath/ODBC/lib/XEora22.so
Description=SPSS 5.2 Oracle Wire Protocol
AlternateServers=
```

1. Check that the shared object specified by the Driver parameter exists.
2. Correct the path to the shared object if it is incorrect.
3. If the Driver parameter is specified in this format:

```
Driver=ODBCHOME/lib/XEora22.so
```

this indicates that you have not initialized your ODBC-related scripts. Run the *setodbcpath.sh* script that is installed with the drivers. See the topic [IBM SPSS Modeler Server and the data access pack](#) for more information. When you have run this script, you should see that the string "ODBCHOME" has been substituted with the path to your ODBC installation. This should resolve the issue.

Another cause may be a problem with the driver's library. Use the **ivtestlib** tool provided with ODBC to confirm that the driver can't be loaded. For Connect64, use the **ddtestlib** tool. Correct the problem by setting the library path variable in the startup script.

For example, if the Oracle driver cannot be loaded for a 32-bit installation, follow these steps:

1. Use **ivtestlib** to confirm that the driver cannot be loaded. For example, at the UNIX prompt, type:

```
sh
cd ODBCDIR
./odbc.sh
./bin/ivtestlib MFor815
```

where **ODBCDIR** is replaced by the path to your ODBC installation directory.

2. Read the message to see if there is an error. For example, the message: Load of MFor815.so failed: ld.so.1: bin/ivtestlib: fatal: libclntsh.so: open failed: No such file or directory indicates that the Oracle client library, *libclntsh.so*, is missing or that it is not on the library path.
3. Confirm that the library exists. If it doesn't, reinstall the Oracle client. If the library is there, type the following sequence of commands from the UNIX command prompt:

```
LD_LIBRARY_PATH=$LD_LIBRARY_PATH:/bigdisk/oracle/product/8.1.6/lib  
export LD_LIBRARY_PATH  
.bin/ivtestlib Mfor815
```

where */bigdisk/oracle/product/8.1.6/lib* is replaced by the path to *libclntsh.so* and **LD_LIBRARY_PATH** is the library path variable for your operating system.

Note that if you are running IBM SPSS Modeler 64-bit on Linux, the library path variable contains the suffix *_64*. Therefore, the first two lines in the previous example would become:

```
LD_LIBRARY_PATH_64=$LD_LIBRARY_PATH_64:/bigdisk/oracle/product/8.1.6/lib  
export LD_LIBRARY_PATH_64
```

4. Read the message to confirm that the driver can now be loaded. For example, the message: Load of MFor815.so successful, qehandle is 0xFF3A1BE4 indicates that the Oracle client library can be loaded.
5. Correct the library path in the IBM SPSS Modeler startup script.
6. Restart the IBM SPSS Modeler Server with the startup script that you edited (*modelersrv.sh* or *rc.modeler*).

Library paths

The name of the library path variable on Linux 64-bit operating system is **LD_LIBRARY_PATH_64**. Use this value to make appropriate substitutions when you're configuring or troubleshooting on your system.

Configuring and Running SPSS® Modeler Server as a Non-Root Process on UNIX

- [Introduction](#)
- [Configuring as non-root without a private password database](#)
- [Configuring as non-root using a private password database](#)
- [Running SPSS Modeler Server as a non-root user](#)
- [Troubleshooting user authentication failures](#)

Introduction

These instructions provide information on running IBM® SPSS® Modeler Server as a non-root process on UNIX systems.

Running as root. The default installation of IBM SPSS Modeler Server assumes that the server daemon process will run as root. Running as root allows IBM SPSS Modeler to authenticate reliably each user login and start each user session on the corresponding UNIX user account. This ensures that users have access only to their own files and directories.

Running as non-root. Running IBM SPSS Modeler Server as a non-root process means having the real and effective user IDs of the server daemon process set to an account of your choice. All user sessions started by SPSS Modeler Server will use the same UNIX account and this means that any file data read or written by SPSS Modeler is shared by all SPSS Modeler users. Access to database data is not affected because users have to authenticate themselves independently to each of the database data sources they use. Without root privilege, IBM SPSS Modeler operates in one of two ways:

- **Without a private password database.** With this method, SPSS Modeler uses the existing UNIX password database, NIS, or LDAP server that is normally used for user authentication on the UNIX system. See the topic [Configuring as non-root without a private password database](#) for more information.
- **With a private password database.** With this method, SPSS Modeler authenticates users against a private password database, distinct from the UNIX password database, NIS, or LDAP server that is normally used for authentication on UNIX. See the topic [Configuring as non-root using a private password database](#) for more information.

Note: On Linux/UNIX systems where both a non-root and SSL configuration are enabled, SSL security will be reduced. Because all user sessions run under the same credential as each other and as the Modeler Server daemon, the SSL certificate data that should be kept secret will instead be exposed to all users. This allows users to easily bypass the normal protections SSL provides to all other users. See [Securing client/server and server-server communications with SSL](#).

Configuring as non-root without a private password database

To configure IBM® SPSS® Modeler Server to run on a non-root account without the need for a private password database, follow these steps:

1. Open the SPSS Modeler Server *options.cfg* file for editing.
2. Set the option **start_process_as_login_user** to **Y**.
3. Save and close the *options.cfg* file.

By default, SPSS Modeler Server tries each authentication method until it finds one that works. However, if desired you can use the **authentication_methods** option in *options.cfg* to configure the server to try only one specific authentication method. Possible values for the option are **pasw_modeler, gss, pam, sspi, unix, or windows**.

Note that running as non-root is likely to require configuration updates. See the topic [Troubleshooting user authentication failures](#) for more information.

CAUTION:

Do not enable the **start_process_as_login_user** setting and then start the IBM SPSS Modeler Server as **root**. Doing so would mean that, for all users that are connected to the server, their server processes would run as **root**; this is a security risk. Note that the server may stop automatically if you attempt this.

Configuring as non-root using a private password database

If you choose to authenticate users by means of a private password database, all user sessions are started on the same non-root user account.

To configure IBM® SPSS® Modeler Server to run on a non-root account in this way, follow these steps:

1. Create a group to contain all of your users. You can name this group whatever you'd like, but for this example, let's call it *modelerusers*.
2. Create the user account on which to run IBM SPSS Modeler Server. This account is for the sole use of the IBM SPSS Modeler Server daemon process. For this example, let's call it *modelerserv*.

When creating the account, note that:

- The primary group should be the *<modelerusers>* group created previously.
 - The home directory can be the IBM SPSS Modeler installation directory or any other convenient default (consider using something other than the installation directory if you need the account to survive upgrades).
3. Next, configure the startup scripts to start IBM SPSS Modeler Server using the newly created account. Locate the appropriate startup script and open it in a text editor. See the topic [Scripts](#) for more information.
 - a. Change the **umask** setting to allow at least group read access on created files:

```
umask 027
```

4. Edit the server options file, *config/options.cfg*, to specify authentication against the private password database by appending the line:

```
authentication_methods, "pasw_modeler"
```

5. Edit the server options file, *config/options.cfg*, to set the option **start_process_as_login_user** to **Y**.
6. Next, you'll need to create a private password database stored in the file *config/passwords.cfg*. The password file defines the user name/password combinations that are allowed to login to IBM SPSS Modeler. *Note:* These are private to IBM SPSS Modeler and have no connection with the user names and passwords used to login to UNIX. You can use the same user names for convenience, but you cannot use the same passwords.

To create the password file, you will need to use the password utility program, *pwutil*, located in the *bin* directory of the IBM SPSS Modeler Server installation. The synopsis of this program is:

```
pwutil [ username [ password ] ]
```

The program takes a user name and plain-text password and writes the user name and encrypted password to the standard output in a format suitable for inclusion in the password file. For example, to define a user *modeler* with the password “data mining” you would type:

```
bin/pwutil modeler "data mining" > config/passwords.cfg
```

Defining a single user name is sufficient in most cases, where all users log in with the same name and password. However additional users can be created by using the **>>** operator to append each to the file, for example:

```
bin/pwutil modeler "data miner2" >> config/passwords.cfg
```

Note: If a single **>** is used, the contents of *passwords.cfg* will be overwritten each time, replacing any users set previously. Remember that all users share the same UNIX user account regardless.

Note: If you add new users to the private passwords database while SPSS Modeler Server is running, you will need to restart SPSS Modeler Server so that it can recognize the newly defined users. Until you do so, logins will fail for any new users added via `pwutl` since the last restart of SPSS Modeler Server.

7. Recursively change the ownership of the IBM SPSS Modeler installation directory and its contents to be user `<modelerserv>` and group `<modelerusers>` where the names referenced are those you created earlier. For example:

```
chown -R -h modelerserv:modelerusers .
```

8. Consider creating subdirectories in the data directory for your IBM SPSS Modeler users so that they have somewhere to store working data without interference. These directories should be group-owned by the `<modelerusers>` group and have group read, write, and search permissions. For example, to create a working directory for user `bob`:

```
mkdir data/bob
chown bob:modelerusers data/bob
chmod ug=rwx,o= data/bob
```

Additionally, you can set the set-group-ID bit on the directory so that any data files copied into the directory will be automatically group-owned by `<modelerusers>`:

```
chmod g+s data/bob
```

Running SPSS Modeler Server as a non-root user

To run SPSS® Modeler Server as a non-root user, follow these steps:

1. Log in using the non-root user account created earlier.
2. If you are running with the configuration file option `start_process_as_login_user` enabled, you can start, stop, and check the status of SPSS Modeler Server. See the topic [To Start, Stop, and Check Status on UNIX](#) for more information.

End users connect to SPSS Modeler Server by logging in from the client software. You must give end users the information that they need to connect, including the IP address or host name of the server machine.

Troubleshooting user authentication failures

Depending on how the operating system is configured to perform authentication, you may experience failures to log on to SPSS® Modeler Server when running in a non-root configuration. For example, this may occur if your operating system is configured (using the `/etc/nsswitch.conf` file or similar) to check the local shadow password file, rather than use NIS or LDAP. This occurs because SPSS Modeler Server requires read access to the files used to perform authentication, including the `/etc/shadow` file or its equivalent, which stores secure user account information. However, the operating system file permissions are generally set so that `/etc/shadow` is accessible only by the root user. Under these circumstances a non-root process cannot read `/etc/shadow` to validate user passwords, resulting in an authentication error.

There are several ways to resolve this issue:

- Ask your system administrator to configure the operating system to use NIS or LDAP for authentication.
- Change the file permissions on the protected files, for example by granting read access to the `/etc/shadow` file so that the local user account used to run SPSS Modeler Server can access the file. While this workaround might be deemed unsuitable in production environments, it could be temporarily applied to a test environment to verify whether the authorization failure is linked to the operating system configuration.
- Specify an access control list (ACL) for the `/etc/shadow` file.
- Run SPSS Modeler Server as root, to enable the server processes to read the `/etc/shadow` file.

CAUTION:

In this case, ensure that the options.cfg file for SPSS Modeler Server contains the option `start_process_as_login_user, N` to avoid the security issue explained earlier.

Configuring and Running SPSS® Modeler Server with a private password file on Windows

- [Introduction](#)
- [Configuring a private password database](#)

Introduction

These instructions provide information on running IBM® SPSS® Modeler Server using a private password file on Windows systems. With this method, IBM SPSS Modeler authenticates users against a private password database, distinct from the system authentication on Windows.

Configuring a private password database

If you choose to authenticate users by using a private password database, all user sessions are started on the same user account.

To configure SPSS® Modeler Server in this way, follow these steps:

1. Create the user account on which to run SPSS Modeler Server. This account is for the sole use of the SPSS Modeler Server daemon process. You must start the daemon process as that user account in the Log On tab of the SPSS Modeler Server 18.4.0 Service. For this example, let's call it *modelerserv*.
2. Edit the server options file (config/options.cfg) to set the option `start_process_as_login_user` to **Y**
3. Edit the server options file (config/options.cfg) to specify authentication against the private password database by appending the line:

```
authentication_methods, "pasw_modeler"
```

4. Next, you need to create a private password database that is stored in the file config/passwords.cfg. The password file defines the user name/password combinations that are allowed to log in to SPSS Modeler. Note that these combinations are private to SPSS Modeler and have no connection with the user names and passwords that are used to log in to Windows. You can use the same user names for convenience, but you cannot use the same passwords.

To create the password file, you need to use the password utility program, pwutil, in the bin directory of the SPSS Modeler Server installation. The synopsis of this program is:

```
pwutil [ username [ password ] ]
```

The program takes a user name and plain-text password and writes the user name and encrypted password to the standard output in a format suitable for inclusion in the password file. For example, to define a user that is called **modeler** with the password **data mining**, you would use a DOS prompt to navigate to the SPSS Modeler Server installation directory and then type:

```
bin\pwutil modeler "data mining" > config\passwords.cfg
```

Note: Make sure that you have only 1 instance of each user in the file; duplicates prevent SPSS Modeler Server from starting. Defining a single user name is sufficient in most cases, where all users log in with the same name and password. However, more users can be created by using the **>>** operator to append each to the file. For example:

```
bin\pwutil modeler "data miner2" >> config\passwords.cfg
```

Note:

If a single **>** is used, the contents of passwords.cfg are overwritten each time, replacing any users set previously. Remember that all users share the same UNIX user account regardless.

If you add new users to the private passwords database while SPSS Modeler Server is running, you will need to restart SPSS Modeler Server so that it can recognize the newly defined users. Until you do so, logins will fail for any new users added via **pwutil** since the last restart of SPSS Modeler Server.

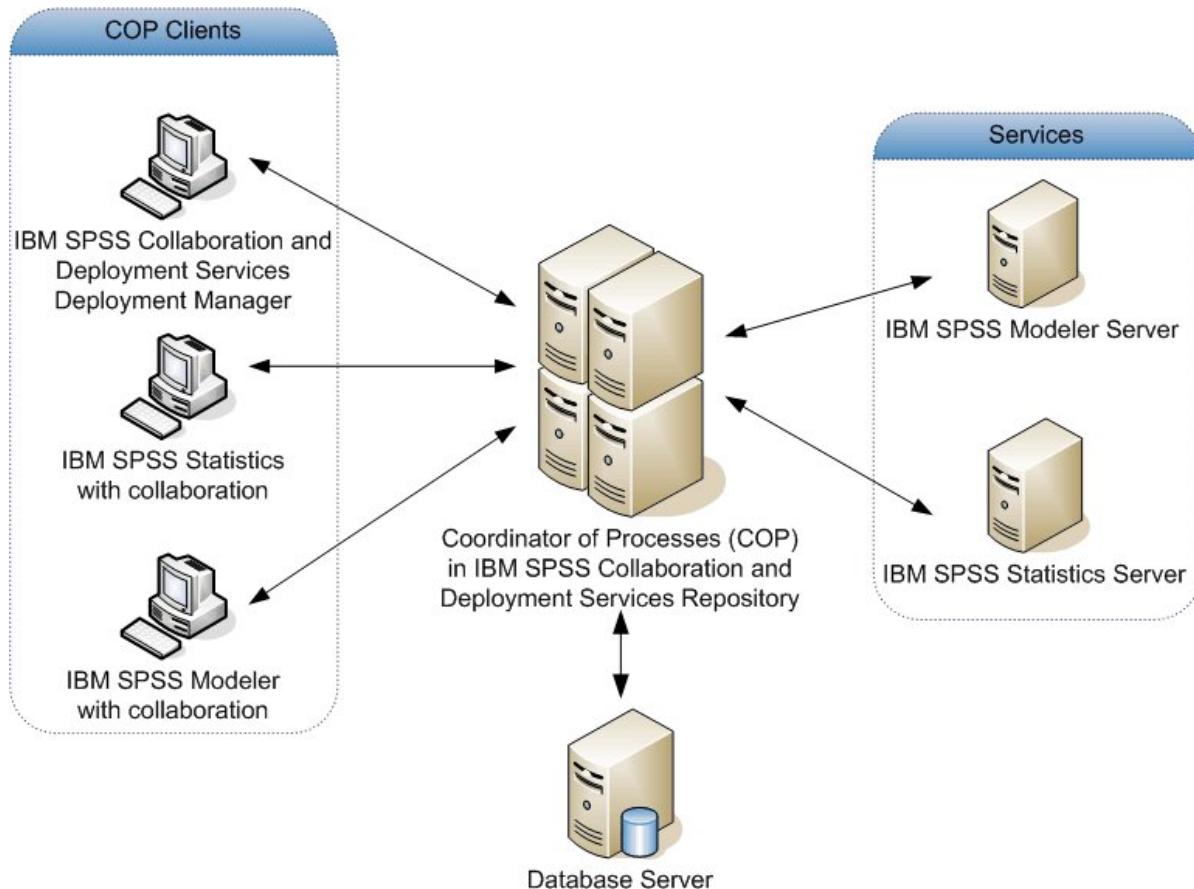

5. Give the user that was created in step 1 full control over the server options file config\options.cfg and the **%ALLUSERSPROFILE%\IBM\SPSS** directory.
6. In the system services, stop the IBM SPSS Modeler Server service and change the Log on from the Local System Account to the user account created in step 1. Then, restart the service.

Load Balancing with Server Clusters

With IBM® SPSS® Collaboration and Deployment Services, a plug-in called the Coordinator of Processes can be used to manage services on the network. The Coordinator of Processes provides server management capabilities designed to optimize client-server communication and processing.

Services to be managed, such as IBM SPSS Statistics Server or IBM SPSS Modeler Server, register with the Coordinator of Processes upon starting and periodically send updated status messages. Services can also store any necessary configuration files in the IBM SPSS Collaboration and Deployment Services Repository and retrieve them when initializing.

Figure 1. Coordinator of Processes Architecture

Executing your IBM SPSS Modeler streams on a server can increase performance. In some cases, you may have only the choice of one or two servers. In other cases, you might be offered a larger choice of servers because there is a substantive difference between each server, such as owner, access rights, server data, test versus production servers, and so on. In addition, if you have the Coordinator of Processes on your network, you might be offered a server cluster.

A server cluster is a group of servers that are interchangeable in terms of configuration and resources. The Coordinator of Processes determines which server is best suited to respond to a processing request, using an algorithm that will balance the load according to several criteria, including the server weights, user priorities, and current processing loads. For more information, see the *Coordinator of Processes Service Developer's Guide* available in the IBM SPSS Collaboration and Deployment Services documentation suite.

Whenever you connect to a server or server cluster in IBM SPSS Modeler, you can enter a server manually or search for a server or cluster using the Coordinator of Processes. See the topic [Connecting to IBM SPSS Modeler Server](#) for more information.

LDAP authentication

These instructions provide basic guidelines on how to configure SPSS® Modeler Server on UNIX to use LDAP authentication, where the identities of the users who will log in to the server are stored in an LDAP directory.

Note: As a prerequisite, the LDAP client software must be correctly configured on the host operating system. For more information, see the original vendor documentation.

Usually no additional configuration is required and the use of LDAP is not apparent to the server. Examples of where no additional changes are required include the following circumstances:

- The LDAP client and server software are configured according to RFC 2307.
- Access to the `passwd` (and, where applicable, `shadow`) database is redirected to LDAP, for example in `nsswitch.conf`.
- Each valid user of SPSS Modeler Server has a `passwd` (and `shadow`) entry that is stored in the LDAP directory.
- The SPSS Modeler Server service is started by using the root account.

There are two sets of circumstances when it might become necessary to configure SPSS Modeler Server specifically for LDAP:

- When the service is started by using an account other than root, the service might not have the authority to authenticate by using the default method. Typically this is because access to the shadow database is restricted.
- When users do not have `passwd` (or `shadow`) entries that are stored in the directory; that is, they do not have user identities that are valid for login to the host system.

The LDAP authentication procedure uses the PAM subsystem and requires that a PAM LDAP module exists and is correctly configured for the host operating system. For more information, see the original vendor documentation.

Complete the following steps to configure SPSS Modeler Server to use LDAP authentication exclusively.

Note: These steps provide the most basic configuration that can be expected to work. More options or alternative settings might be required depending on your operating system and local security policy. For more information, see the original operating documentation.

1. Edit the service configuration file (`options.cfg`) and add (or edit) the line: `authentication_methods, pam`. This line instructs the server to use PAM authentication in preference to the default authentication.
2. Provide a PAM configuration for the SPSS Modeler Server service; which often requires root privileges. The service is identified by the name `modelerserver`.
3. On a Linux type system, which uses `/etc/pam.d`, create a file in that directory with the name `modelerserver` and add content similar to the following example:

```
# IBM SPSS Modeler Server
auth required pam_ldap.so
account required pam_ldap.so
password required pam_deny.so
session required pam_deny.so
```

4. The names of the referenced PAM modules vary by operating system; confirm the modules that are required for your host operating system.

Note: The lines in steps 3 specify that SPSS Modeler Server must refer to the PAM LDAP module for authentication and account management. However, changing of passwords and session management are not supported so these actions are not allowed. If account management is not required or is inappropriate, change the relevant line to permit all requests, as in the following example:

```
# IBM SPSS Modeler Server
auth required pam_ldap.so
account required pam_permit.so
password required pam_deny.so
session required pam_deny.so
```

Overview

- [IBM SPSS Collaboration and Deployment Services](#)

IBM® SPSS® Collaboration and Deployment Services is an enterprise-level application that enables widespread use and deployment of predictive analytics.

- [System architecture](#)

In general, IBM SPSS Collaboration and Deployment Services consists of a single, centralized IBM SPSS Collaboration and Deployment Services Repository that serves a variety of clients, using execution servers to process analytical assets.

- [Working with files](#)

IBM SPSS Collaboration and Deployment Services

IBM® SPSS® Collaboration and Deployment Services is an enterprise-level application that enables widespread use and deployment of predictive analytics.

IBM SPSS Collaboration and Deployment Services provides centralized, secure, and auditable storage of analytical assets and advanced capabilities for management and control of predictive analytic processes, as well as sophisticated mechanisms for delivering the results of analytical processing to users. The benefits of IBM SPSS Collaboration and Deployment Services include:

- Safeguarding the value of analytical assets
- Ensuring compliance with regulatory requirements
- Improving the productivity of analysts
- Minimizing the IT costs of managing analytics

IBM SPSS Collaboration and Deployment Services allows you to securely manage diverse analytical assets and fosters greater collaboration among those developing and using them. Furthermore, the deployment facilities ensure that people get the information they need to take timely, appropriate action.

- [Collaboration](#)

Collaboration refers to the ability to share and reuse analytic assets efficiently, and is the key to developing and implementing analytics across an enterprise.

- [Deployment](#)

To realize the full benefit of predictive analytics, the analytic assets need to provide input for business decisions. Deployment bridges the

gap between analytics and action by delivering results to people and processes on a schedule or in real time.

Collaboration

Collaboration refers to the ability to share and reuse analytic assets efficiently, and is the key to developing and implementing analytics across an enterprise.

Analysts need a location in which to place files that should be made available to other analysts or business users. That location needs a version control implementation for the files to manage the evolution of the analysis. Security is required to control access to and modification of the files. Finally, a backup and restore mechanism is needed to protect the business from losing these crucial assets.

To address these needs, IBM® SPSS® Collaboration and Deployment Services provides a repository for storing assets using a folder hierarchy similar to most file systems. Files stored in the IBM SPSS Collaboration and Deployment Services Repository are available to users throughout the enterprise, provided those users have the appropriate permissions for access. To assist users in finding assets, the repository offers a search facility.

Analysts can work with files in the repository from client applications that leverage the service interface of IBM SPSS Collaboration and Deployment Services. Products such as IBM SPSS Statistics and IBM SPSS Modeler allow direct interaction with files in the repository. An analyst can store a version of a file in development, retrieve that version at a later time, and continue to modify it until it is finalized and ready to be moved into a production process. These files can include custom interfaces that run analytical processes allowing business users to take advantage of an analyst's work.

The use of the repository protects the business by providing a central location for analytical assets that can be easily backed-up and restored. In addition, permissions at the user, file, and version label levels control access to individual assets. Version control and object version labels ensure the correct versions of assets are being used in production processes. Finally, logging features provide the ability to track file and system modifications.

- [Deployment](#)
-

Deployment

To realize the full benefit of predictive analytics, the analytic assets need to provide input for business decisions. Deployment bridges the gap between analytics and action by delivering results to people and processes on a schedule or in real time.

In IBM® SPSS® Collaboration and Deployment Services, individual files stored in the repository can be included in processing **jobs**. Jobs define an execution sequence for analytical artifacts and can be created with IBM SPSS Deployment Manager. The execution results can be stored in the repository, on a file system, or delivered to specified recipients. Results stored in the repository can be accessed by any user with sufficient permissions using the IBM SPSS Collaboration and Deployment Services Deployment Portal interface. The jobs themselves can be triggered according to a defined schedule or in response to system events.

In addition, the scoring service of IBM SPSS Collaboration and Deployment Services allows analytical results from deployed models to be delivered in real time when interacting with a customer. An analytical model configured for scoring can combine data collected from a current customer interaction with historical data to produce a score that determines the course of the interaction. The service itself can be leveraged by any client application, allowing the creation of custom interfaces for defining the process.

The deployment facilities of IBM SPSS Collaboration and Deployment Services are designed to easily integrate with your enterprise infrastructure. Single sign-on reduces the need to manually provide credentials at various stages of the process. Moreover, the system can be configured to be compliant with Federal Information Processing Standard Publication 140-2.

Note: If a SPSS Modeler stream contains a node that uses a list type, the branch containing that node does not support the scoring service.

System architecture

In general, IBM® SPSS® Collaboration and Deployment Services consists of a single, centralized IBM SPSS Collaboration and Deployment Services Repository that serves a variety of clients, using execution servers to process analytical assets.

Figure 1. IBM SPSS Collaboration and Deployment Services Architecture

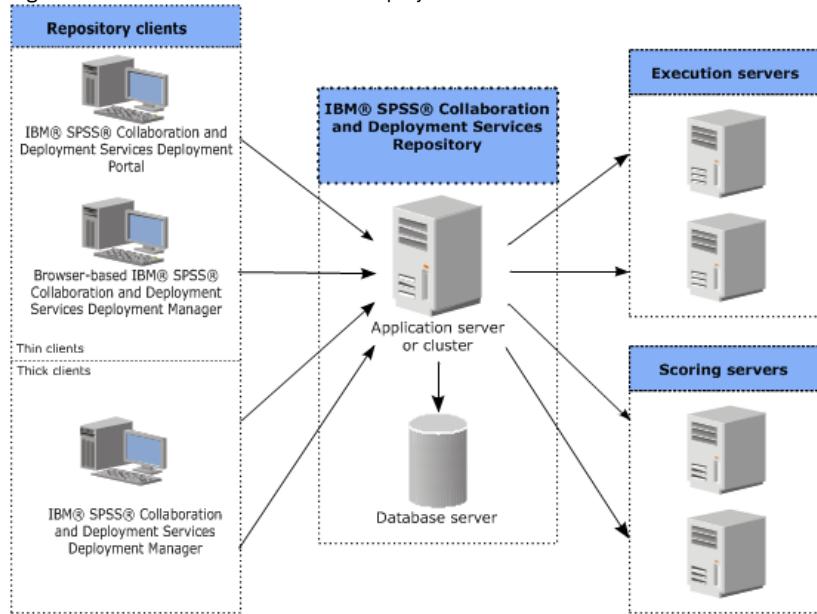

Figure 2. IBM SPSS Collaboration and Deployment Services Architecture

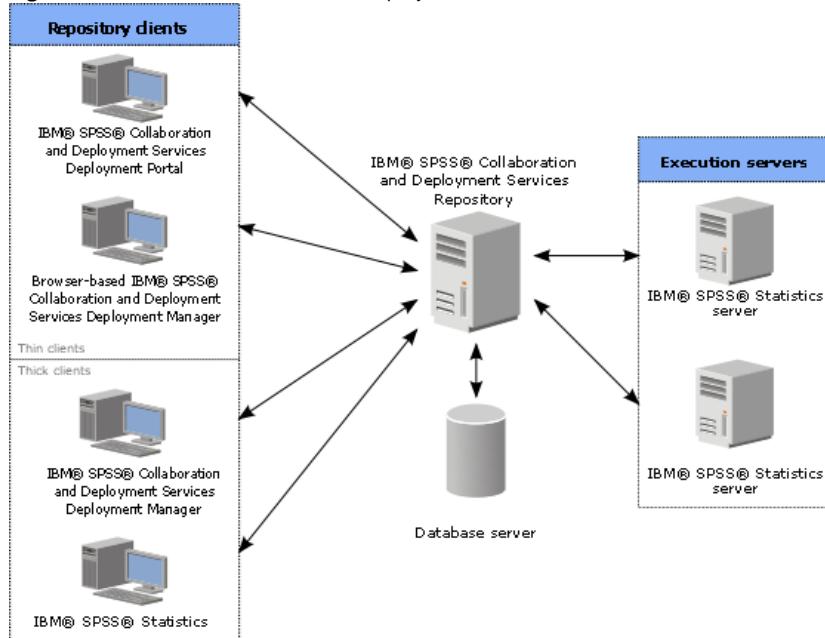

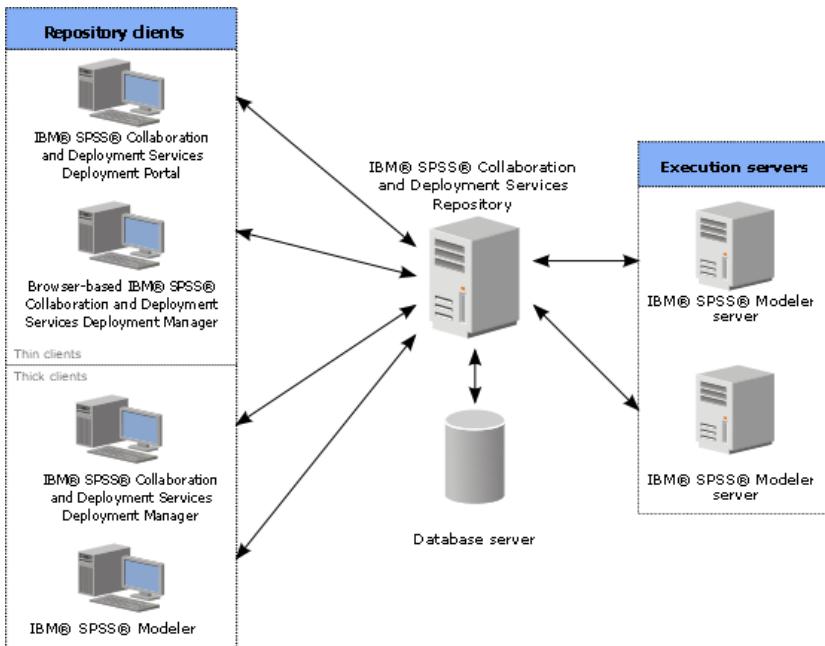

Figure 3. IBM SPSS Collaboration and Deployment Services Architecture

IBM SPSS Collaboration and Deployment Services consists of the following components:

- IBM SPSS Collaboration and Deployment Services Repository for analytical artifacts
- IBM SPSS Statistics
- IBM SPSS Modeler
- IBM SPSS Deployment Manager
- IBM SPSS Collaboration and Deployment Services Deployment Portal
- Browser-based IBM SPSS Deployment Manager

- **IBM SPSS Collaboration and Deployment Services Repository**

The repository provides a centralized location for storing analytical assets, such as models and data. The repository requires an installation of a relational database, such as IBM Db2, Microsoft SQL Server, or Oracle.

- **IBM SPSS Modeler with collaboration**

- **IBM SPSS Deployment Manager**

IBM SPSS Deployment Manager is a client application for IBM SPSS Collaboration and Deployment Services Repository that enables users to schedule, automate, and execute analytical tasks, such as updating models or generating scores.

- **IBM SPSS Collaboration and Deployment Services Deployment Portal**

IBM SPSS Collaboration and Deployment Services Deployment Portal is a thin-client interface for accessing the repository. Unlike the browser-based IBM SPSS Deployment Manager, which is intended for administrators, IBM SPSS Collaboration and Deployment Services Deployment Portal is a web portal serving a variety of users.

- **Browser-based IBM SPSS Deployment Manager**

- **Execution servers**

Execution servers provide the ability to execute resources stored within the repository. When a resource is included in a job for execution, the job step definition includes the specification of the execution server used for processing the step. The execution server type depends on the resource.

Related information

- [IBM SPSS Collaboration and Deployment Services](#)
-

IBM SPSS Collaboration and Deployment Services Repository

The repository provides a centralized location for storing analytical assets, such as models and data. The repository requires an installation of a relational database, such as IBM Db2, Microsoft SQL Server, or Oracle.

The repository includes facilities for:

- Security
- Version control
- Searching
- Auditing

Configuration options for the repository are defined using the IBM® SPSS® Deployment Manager or the browser-based IBM SPSS Deployment Manager. The contents of the repository are managed with the Deployment Manager and accessed with the IBM SPSS Collaboration and Deployment Services Deployment Portal.

IBM SPSS Modeler with collaboration

IBM® SPSS® Modeler with collaboration allows interaction with the IBM SPSS Collaboration and Deployment Services Repository from within the IBM SPSS Modeler interface. Files can be stored and retrieved directly from IBM SPSS Modeler.

In addition, IBM SPSS Modeler streams stored in the repository can be executed as steps within jobs. A job can contain any number of steps, with each step corresponding to a separate file. Relationships defined between the steps determine the processing flow. The job can be scheduled to execute at a specific time, according to a recurrence pattern, or in response to a defined event. Moreover, notifications can be sent to specified recipients to report on individual step and overall job execution status.

Collaboration between IBM SPSS Collaboration and Deployment Services and IBM SPSS Modeler is enabled through the use of adapters. These adapters are installed into the IBM SPSS Collaboration and Deployment Services environment to add the product-specific features. For more information, consult the IBM SPSS Modeler documentation.

Note: If you have a job containing an SPSS Modeler stream that uses an Analytic Server source node, you must allow a direct connection between the IBM SPSS Collaboration and Deployment Services Server and Analytic Server. Otherwise, the job will fail if the firewall blocks the connection between the two servers.

IBM SPSS Deployment Manager

IBM® SPSS® Deployment Manager is a client application for IBM SPSS Collaboration and Deployment Services Repository that enables users to schedule, automate, and execute analytical tasks, such as updating models or generating scores.

The client application allows a user to perform the following tasks:

- View any existing files within the system, including and data files
- Import files into the repository
- Schedule jobs to be executed repeatedly using a specified recurrence pattern, such as quarterly or hourly
- Modify existing job properties
- Determine the status of a job
- Specify email notification of job status

In addition, the client application allows users to perform administrative tasks for IBM SPSS Collaboration and Deployment Services, including:

- Manage users
- Configure security providers
- Assign roles and actions

Browser-based IBM SPSS Deployment Manager

The browser-based IBM SPSS Deployment Manager is a thin-client interface for performing setup and system management tasks, including:

- Setting system configuration options
- Configuring security providers
- Managing MIME types

Non-administrative users can perform any of these tasks provided they have the appropriate actions associated with their login credentials. The actions are assigned by an administrator.

You typically access the browser-based IBM SPSS Deployment Manager at the following URL:

`http://<host IP address>:<port>/security/login`

Note: An IPv6 address must be enclosed in square brackets, such as `[3ffe:2a00:100:7031::1]`.

If your environment is configured to use a custom context path for server connections, include that path in the URL.

`http://<host IP address>:<port>/<context path>/security/login`

IBM SPSS Collaboration and Deployment Services Deployment Portal

IBM® SPSS® Collaboration and Deployment Services Deployment Portal is a thin-client interface for accessing the repository. Unlike the browser-based IBM SPSS Deployment Manager, which is intended for administrators, IBM SPSS Collaboration and Deployment Services Deployment Portal is a web portal serving a variety of users.

The web portal includes the following functionality:

- Browsing the repository content by folder
- Opening published content
- Running jobs
- Generating scores using models stored in the repository
- Searching repository content
- Viewing content properties
- Accessing individual user preferences, such as email address and password, general options, subscriptions, and options for output file formats

You typically access the home page at the following URL:

`http://<host IP address>:<port>/peb`

Note: An IPv6 address must be enclosed in square brackets, such as `[3ffe:2a00:100:7031::1]`.

If your environment is configured to use a custom context path for server connections, include that path in the URL.

`http://<host IP address>:<port>/<context path>/peb`

Browser-based IBM SPSS Deployment Manager

The browser-based IBM® SPSS® Deployment Manager is a thin-client interface for performing setup and system management tasks, including:

- Configuring the system.
- Configuring security providers.
- Managing MIME types.

Non-administrative users can perform any of these tasks provided they have the appropriate actions associated with their login credentials. The actions are assigned by an administrator.

- [Working with files](#)

Execution servers

Execution servers provide the ability to execute resources stored within the repository. When a resource is included in a job for execution, the job step definition includes the specification of the execution server used for processing the step. The execution server type depends on the resource.

Execution servers currently supported by IBM® SPSS® Collaboration and Deployment Services include:

- **SAS**. The SAS execution server is the SAS executable file `sas.exe`, included with Base SAS® Software. Use this execution server to process SAS syntax files.
- **Remote Process**. A remote process execution server allows processes to be initiated and monitored on remote servers. When the process completes, it returns a success or failure message. Any machine acting as a remote process server must have the necessary infrastructure installed for communicating with the repository.

Note: The IBM SPSS Collaboration and Deployment Services Remote Process Server has a default thread pool core size of 16, which allows a maximum of 16 concurrent jobs to be executed on a single remote process server. Any concurrent jobs in excess of 16 must wait in the queue until the available thread pool has free resources. To manually configure the IBM SPSS Collaboration and Deployment Services Remote Process Server thread pool core size, add the following JVM option (with a user defined value) to the remote process server's startup script: `prms.thread.pool.coreSize=<user defined value>`

For more information regarding the start-up script, see the "Starting and stopping the remote process server" section in the IBM SPSS Collaboration and Deployment Services Remote Process Server guide.

Execution servers that process other specific types of resources can be added to the system by installing the appropriate adapters. For information, consult the documentation for those resource types.

The IBM SPSS Modeler execution server is IBM SPSS Modeler Server, which permits distributed analysis for data mining and model building. This execution server requires the specification of user credentials under which the processing occurs.

Two types of execution servers are available for processing IBM SPSS Statistics syntax files. The first is a remote execution server that corresponds to the IBM SPSS Statistics server product. This execution server requires the specification of user credentials under which the syntax processing occurs. The other type of execution server is local to the repository and corresponds to the batch facility included with the IBM SPSS Statistics server product. However, unlike the IBM SPSS Statistics server product, the batch facility can be run from the command line and requires no user credentials for execution.

To allow load balancing, two or more execution servers can be grouped together in a server cluster. When a job step uses a cluster for execution, IBM SPSS Collaboration and Deployment Services determines which managed server in the cluster is best suited to handle processing requests at that time. For more information, consult the IBM SPSS Deployment Manager documentation.

During job creation, assign an execution server or server cluster to each step included in the job. When the job executes, the repository uses the specified execution servers to perform the corresponding analyses.

Working with files

In IBM® SPSS® Deployment Manager, the general process for working with files involves:

1. Define an execution server for processing the if an appropriate definition does not already exist.
 2. Add the to a job as a job step.
 3. Specify the job properties, including any schedules for execution.
-

Server definitions

Executing an IBM® SPSS® Collaboration and Deployment Services Repository resource as a job step requires the specification of an appropriate corresponding server to process the instructions contained in the job step. The connection information for such a server is specified within a server definition.

Server definitions can be classified as either execution servers or repository servers.

- Execution servers process the contents of an IBM SPSS Collaboration and Deployment Services Repository resource. The execution server type must correspond to the resource type being processed. A SAS An IBM SPSS Modeler An IBM SPSS Statistics job step, for example, requires a SAS an IBM SPSS Modeler an IBM SPSS Statistics server definition.
- A repository server corresponds to an IBM SPSS Collaboration and Deployment Services repository installation. A server of this type is typically used by job steps that need to return result artifacts to a repository.

Server definitions are contained in the *Resource Definitions* folder of the Content Explorer. Specifically, they are defined in the *Servers* subfolder.

- [Adding new server definitions](#)
When you create a server definition, specify the name, type, location, and parameters for the server.
 - [Modifying server definitions](#)
To modify a server definition, double-click the server in the Content Explorer.
-

Adding new server definitions

To add a new server:

1. In the Content Explorer, open the *Resource Definitions* folder.
2. Click the *Servers* folder.
3. From the File menu, choose:

New > Server Definition

The Add New Server Definition wizard opens. Alternatively, the new server definition dialog box can be accessed by clicking New next to a server field on the General tab for some steps. The process for defining new servers consists of:

1. Naming the server definition and specifying its type. Note that the server types available depend on which product adapters are installed to the repository.
2. Selecting a location in the *Servers* folder for the definition.
3. Specifying parameters for the server that define connection or execution information. The parameter set depends on the server type.

- **[IBM SPSS Modeler server parameters](#)**

An IBM SPSS Modeler Server Definition specifies the connection parameters for IBM SPSS Modeler servers used to process job steps. IBM SPSS Modeler streams are executed on the IBM SPSS Modeler server.

IBM SPSS Modeler server parameters

An IBM® SPSS® Modeler Server Definition specifies the connection parameters for IBM SPSS Modeler servers used to process job steps. IBM SPSS Modeler streams are executed on the IBM SPSS Modeler server.

1. In the Host field, enter the hostname where the server resides. For example, if you are creating an IBM SPSS Modeler server definition, the host would be the machine that contains your IBM SPSS Modeler server.
2. In the Port field, enter the port number to be used to connect to the host.
3. In the Default Data Path field, enter the path on which you want to place data files.
4. If Secure Socket Layer (SSL) is to be used for the server connection, select This is a secure port.
5. Click Finish. The new definition appears in the *Servers* folder.

Note: When you run a IBM SPSS Collaboration and Deployment Services job in an Evaluation stream, a temporary file is created. By default, the file is saved to the IBM SPSS Modeler Server installation directory. You can change the default data folder that the temp files are saved to when you create the IBM SPSS Modeler Server connection in IBM SPSS Modeler.

Modifying server definitions

To modify a server definition:

1. In the Content Explorer, open the *Resource Definitions* folder.
2. Open the *Servers* folder.
3. Double-click the server to be modified. The Edit Server Definition dialog opens.
4. Modify the server definition parameters as necessary.
5. Click Finish to save your changes.

IBM® SPSS® Modeler Job Steps

Working with IBM SPSS Modeler streams

This section describes IBM® SPSS® Modeler streams within the context of IBM SPSS Deployment Manager. IBM SPSS Modeler streams are brought into Deployment Manager fully formed. For more detailed information on how to create and work with streams, refer to the IBM SPSS Modeler documentation.

You can work with IBM SPSS Modeler streams in Deployment Manager. Like any other step, an IBM SPSS Modeler stream must be added to a job before you can execute it using Deployment Manager. Specifically, you can perform the following tasks:

- Importing streams
- Modifying stream parameters
- Executing streams

Note: If you have a job containing an SPSS Modeler stream that uses an Analytic Server source node, you must allow a direct connection between the IBM SPSS Collaboration and Deployment Services Server and Analytic Server. Otherwise, the job will fail if the firewall blocks the connection

between the two servers.

- [IBM SPSS Modeler Server configuration](#)
-

IBM SPSS Modeler Server configuration

Before you begin working with IBM® SPSS® Modeler streams in the Deployment Manager, you need to perform the following configuration tasks:

- Create an IBM SPSS Modeler server definition. See the topic [IBM SPSS Modeler server parameters](#) for more information.
- Define server credentials.

IBM SPSS Modeler Job Properties - General

By default, the General properties tab appears when you click an IBM® SPSS® Modeler stream in the job canvas.

The General properties tab contains the following information:

Job step name. The name of the job step. Typically, the name of the job step is the name of the IBM SPSS Modeler stream, appended with the suffix **_step**. However, you can modify the job step name.

To modify the name of the job step, type the revised name in the Job step name field. Your changes are reflected in the job canvas.

IBM SPSS Modeler Stream. The name and path of the original IBM SPSS Modeler stream. The source stream is not modifiable.

Override Type Use this option to specify whether the settings in either a job step or the node in a stream take priority during execution.

- Job overrides stream If you select this option, when you execute the job, the node properties use the values that you set in the job step.
- Stream overrides job Selecting this option disables the node property controls in the job step; the only exceptions are some of the credential controls. If you change the node properties in the stream, when you execute the job step, the changed node properties are used.

The Override Type options affect the credential settings in the following ways:

- If you choose Job overrides stream, you can edit the credential selection controls, and your selected credentials take effect at run-time.
- If you choose Stream overrides job, there are two possible cases:
 - When you create nodes in SPSS Modeler Client that use credentials, and if the authentication mode is Stored credential, and the credential name exists in IBM SPSS Collaboration and Deployment Services, the credential selection control is unavailable. However, if the credential name does not exist in IBM SPSS Collaboration and Deployment Services, you can use the credential selection control; your selected credentials take effect at run-time.
 - When you create nodes in SPSS Modeler Client that use credentials, if the authentication mode is Username and password, you can use the credential selection control; your selected credentials take effect at run-time.

Object version. The labeled version of the IBM SPSS Modeler stream to use. From the Object version drop-down list, select the labeled version that you want to use.

Iterative Variable List. If the step acts as an iterative consumer, identify the variable from the iterative producer providing the values for the step. An iterative producer step must appear immediately before the step in the job for the step to act as an iterative consumer.

IBM SPSS Modeler server. The IBM SPSS Modeler server or server cluster on which the stream will be executed. The list contains all servers and server clusters currently configured to execute IBM SPSS Modeler steps. To change the server, select from the IBM SPSS Modeler Server drop-down list. To create a new server definition, click New to launch the server definition wizard.

IBM SPSS Modeler login. The credential information used to access the IBM SPSS Modeler server or server cluster. To change the credentials, select a credential definition from the IBM SPSS Modeler Login drop-down list. To define new credentials, click New to launch the credentials definition wizard.

Content Repository Server. The content repository server allows a job to save files to an IBM SPSS Collaboration and Deployment Services Repository. Typically, the content repository server is specified when refreshing models using IBM SPSS Modeler. To specify a content repository server, select a server from the Content Repository Server drop-down list. To create a new server definition, click New to launch the server definition wizard. To generate a content repository server definition based on the current server information, click Generate. A server definition is created and automatically populated in the *Content Repository Server* field.

Content Repository Login. The login information for the content repository server. To specify a content repository login, select a credential from the Content Repository Login drop-down list. To create a new login, click New to launch the content repository login wizard. If single sign-on is not used to connect to the IBM SPSS Collaboration and Deployment Services Repository, click Generate to generate a content repository server login based on existing security settings. A content repository login is created and automatically populated in the *Content Repository Login* field. Login generation is not available when using single sign-on.

Warning expression. Define warnings for job steps connected by a Conditional connector. The warning expression (e.g., `completion_code`, `warning`, or `success`) must be lowercase.

To use warning expressions:

1. Connect two job steps with a Conditional connector. In the Expression field for the conditional connector, type `warning==true`.
2. Navigate to the General tab of the parent job step.
3. In the Warning expression field, specify a warning code--for example, `completion_code==18`. This expression overrides the default warning code, if any.

When the job is run, the system will execute the parent job step. Then the system will evaluate the condition for `warning==true`. If true, the system will look at the warning expression specified and determine if the condition was met. If the condition specified in the warning expression was met, the system proceeds to the next job step.

Type. The way you want to run the stream.

- Run Stream. With this option, you can run the complete stream or, if the stream contains branches, choose one or more branches to run. In the latter case, the Run Options list is displayed. All branches are checked by default, meaning that all branches will execute when the stream runs. Uncheck any branches that you do not want to execute; doing so can improve performance.
Note: If the stream contains a script and is configured to "Run Script" on execution, no execution branches will be displayed in the list in the IBM SPSS Collaboration and Deployment Services job editor.

- Model Management. Choose this option if you want the stream to make use of model management features, such as evaluation, refresh and score. Choose the feature from the Types list that is displayed. **Evaluation Options**

Performance. Specify the threshold percentages for the following categories: Bad or Good. A percentage for Better is not user-defined. The system subtracts the Good percentage from 100 to arrive at the Better threshold. Threshold values are mandatory for evaluation streams.

Metrics. The measurement criteria by which the stream's effectiveness is assessed. Valid values include Accreditation, Accuracy, and Gains. If Gains is selected, then a percentile needs to be specified as well. If Accreditation is selected, then the accreditation step needs to be specified. Valid values include "Collect Statistics" and "Run Evaluation".

Refresh Options

Lists all model-nugget relationships in the stream that can be refreshed using the node names defined in the stream. Select a specific relationship to be refreshed by checking the box before the relationship. Uncheck a relationship to prevent it from being refreshed when the step executes. To select all relationships for refresh, click the Check All button. To unselect all relationships, click the Uncheck All button.

Score Options

Choose the branch or branches you want to designate as scoring branches.

Guidelines for Providing IBM SPSS Modeler and Content Repository Information

For all IBM SPSS Modeler job steps, both IBM SPSS Modeler server and IBM SPSS Modeler login information are required.

IBM® SPSS® Modeler Job Properties - Data Files

The Data Files table contains the following information:

Node Name. The name of the input node that contains the data used by the stream. The name is prefixed by the names of any supernodes containing the node separated by slashes. For example, if the node *MyNode* is within a supernode named *Supernode1*, the name appears as */Supernode1/MyNode*. The node name is not modifiable.

Node Type. The node type as defined in the stream. The node type is not modifiable.

File Name. The name of the input data file. To change the name, click the File Name cell and change the name.

Format. The format of the output file--for example, a comma delimited file. To modify the file format type, click the Format cell. A drop-down arrow appears. Select the format type.

Location. The location of the input data files. To modify location, click in the column and then click the resulting ellipsis button. The Input File Location dialog box opens. Change the location as necessary.

Nodes within locked supernodes are not accessible. They cannot be viewed or modified.

- [Specifying the input file location](#)

For some job steps, you can specify the location of input files used by the step.

-

Specifying the input file location

For some job steps, you can specify the location of input files used by the step.

To define the location of an input file:

1. Type the new path for the data file in the Folder field.
 2. Click OK.
-

IBM® SPSS® Modeler Job Properties - Data View

If the stream contains a Geo Spatial node, the connection details are displayed here.

Node Name. The name of the Data View node.

Analytic Data View. The analytic data view used.

Label. The label used.

Table Name. The name of the database table used.

Data Access Plan. Select a data access plan from the analytic data view. A data access plan associates the data model tables in an analytic data view with physical data sources. An analytic data view typically contains multiple data access plans. When you change the data access plan in use, you change the data used by your stream. For example, if the analytic data view contains a data access plan for training a model and a data access plan for testing a model, you can switch from training data to testing data by changing the data access plan in use.

- [Data Access Plan](#)
-

IBM® SPSS® Modeler Job Properties - ODBC data sources

The *ODBC Data Sources* table contains the following information.

Node Name. The name of the input node that contains the data used by the stream. The name is prefixed by the names of any supernodes containing the node separated by slashes. For example, if the node *MyNode* is within a supernode named *Supernode1*, the name appears as */Supernode1/MyNode*.

Node Type. The node type as defined in the stream.

ODBC Data Sources. The current ODBC data source name (DSN). To change to a different ODBC data source, click the cell containing current data source name, then click the "..." button that is displayed. Doing so displays a dialog box from where you can choose an existing DSN or create a new one. Note that the job step settings always override the stream; therefore, if you modify the stream to use a different data source you must also edit the job to use the same source, otherwise the job may fail to run.

Credentials. To change the database username and password when changing the ODBC data source, click the cell containing the current credentials, then click the "..." button that is displayed. Doing so displays a dialog box from where you can choose an existing credential definition or create a new one.

Database Table. The database table that corresponds to the node.

Nodes within locked supernodes are not accessible. They cannot be viewed or modified.

Changing the ODBC connection

You can change the ODBC connection either to one that is already defined, or to one that you create here.

Use Existing ODBC DSN. Click Browse to display a list of existing ODBC DSNs from which you can choose.

Create New ODBC DSN. Select this option and click New to define a new ODBC connection for use with stream job steps.

Browsing for an ODBC connection

This is a list of all the ODBC connections that have been defined on this host and to which you have access.

Choose one from the list and click OK.

Changing the database credentials

When changing the connection, you can switch to use the corresponding database username and password here. You can use an existing credential definition from the repository, or you can create a new definition.

Generate Repository credentials from existing Username and Password. (displayed only if importing a job from Release 4.2.1 of IBM® SPSS® Collaboration and Deployment Services) Click the Generate button to generate repository credentials from an existing username and password if these have been set in the imported job. For example, if the username **sa** already exists, repeatedly clicking Generate will create the usernames **sa1**, **sa2**, and so on.

Use Existing Credential. Click the Browse button to display a list of existing credential definitions from which you can choose.

Create New Credential. Select this option and click New to create a new credential definition for use with the current connection.

Browsing for a credential definition

This is a list of all the credential definitions that have been created on this host and to which you have access.

Choose one from the list and click OK.

IBM® SPSS® Modeler Job Properties - Geo Spatial

If the stream contains a Geo Spatial node, the connection details are displayed here.

Source Type. The datasource type.

File Name. If using a Shape file, specify the file name.

Map Service URL. If using a Map service, specify the URL to the service.

Map ID. Specify the map ID.

IBM SPSS Modeler Job Properties - Parameters

You can modify parameters for IBM® SPSS® Modeler streams using the IBM SPSS Deployment Manager. The Parameters table contains the following information:

Name. The parameter name.

Storage. Describes how the parameter is stored--for example, as a string.

Value. The value of the parameter.

Type. The parameter type.

Parameters within locked supernodes are not accessible. They cannot be viewed or modified.

IBM SPSS Modeler Job Properties - Results

To display output settings for an IBM® SPSS® Modeler job step, click the Results tab.

Node Name. The name of the node that contains the output of the stream processing. The name is prefixed by the names of any supernodes containing the node separated by slashes. For example, if the node *MyNode* is within a supernode named *Supernode1*, the name appears as */Supernode1/MyNode*. The node name is not modifiable.

Node Type. The node type as defined in the stream. The node type is not modifiable.

File Name. The name of the corresponding file. To modify the name, click in the File Name column and type the new name.

Note: The file extension is determined by the selected file format, which is automatically appended to the file name.

Format. The format of the output file. To modify the file format type, click in the Format column. A drop-down arrow appears. Select the format type.

Location. The location of the file. To modify location, open the Results Location dialog box by clicking in the column and then clicking the resulting ellipsis button.

Permissions. Access permissions for the file if saved to the repository. To modify permissions, open the Output Permissions dialog box by clicking in the Permissions column and then clicking the resulting ellipsis button.

Properties. The properties (metadata) of the file. To define properties, open the Output Properties dialog box by clicking in the Properties column and then clicking the resulting ellipsis button.

Nodes within locked supernodes are not accessible. They cannot be viewed or modified.

IBM® SPSS® Modeler Job properties - Cognos Import

If the stream contains an IBM Cognos source node, the Cognos connection details are displayed here.

Node Name. The name of the Cognos source node.

Connection URL. The URL of the Cognos server to which the connection is made.

Package Name. The name of the Cognos package from which the metadata is imported.

Anonymous. Contains Anonymous if anonymous login is used for the Cognos server connection, or Credential if a specific Cognos username and password are used.

Credentials. The username and password (if required) on the Cognos server.

Note: Cognos credentials must be created in a domain, which represents the Cognos namespace ID.

IBM® SPSS® Modeler Job properties - Cognos Export

If the stream contains an IBM Cognos Export node, the Cognos and ODBC connection details are displayed here.

Node Name. The name of the Cognos export node.

Connection URL. The URL of the Cognos server to which the connection is made.

Package Name. The name of the Cognos package used to export the metadata.

Datasource. The name of the Cognos database used to export the data.

Folder. The path and name of the folder on the Cognos server where the export package is created.

Anonymous. Contains Anonymous if anonymous login is used for the Cognos server connection, or Credential if a specific Cognos username and password are used.

Credentials. The username and password (if required) on the Cognos server.

DSN. The database source name (DSN) of the Cognos database.

Table Name. The name of the database table used for the export.

Credentials. The username and password used for connection to the database used for the export.

Note: Cognos credentials must be created in a domain, which represents the Cognos namespace ID.

IBM® SPSS® Modeler Job Properties - Legacy TM1 Import

If the stream contains a Legacy TM1 Import node, the connection details are displayed here.

Node Name. The name of the Legacy TM1 Import node.

TM1 Server. The Cognos TM1 Server name.

Cube. The TM1 cube from which the data will be imported.

View. The view to import from the TM1 cube.

Credential. Credential for the Cognos TM1 Server.

IBM® SPSS® Modeler Job Properties - Legacy TM1 Export

If the stream contains a Legacy TM1 Export node, the connection details are displayed here.

Node Name. The name of the Legacy TM1 Export node.

TM1 Server. The Cognos TM1 Server name.

Cube. The TM1 cube into which the data will be exported.

Credential. Credential for the Cognos TM1 Server.

IBM® SPSS® Modeler Job Properties - TM1 Import

If the stream contains a TM1 Import node, the connection details are displayed here.

Node Name. The name of the TM1 Import node.

Admin Host. The Cognos TM1 administration host.

TM1 Server. The Cognos TM1 Server name.

Cube. The TM1 cube from which the data will be imported.

View. The view to import from the TM1 cube. You can import a public or a private view.

Rows. The rows to import from the TM1 cube.

Columns. The columns to import from the TM1 cube.

Credential. Credential for the Cognos TM1 Server.

IBM® SPSS® Modeler Job Properties - TM1 Export

If the stream contains a TM1 Export node, the connection details are displayed here.

Node Name. The name of the TM1 Export node.

Admin Host. The Cognos TM1 administration host.

TM1 Server. The Cognos TM1 Server name.

Cube. The TM1 cube into which the data will be exported.

Measure. The measure that will be exported.

Credential. Credential for the Cognos TM1 Server.

IBM® SPSS Modeler Job Properties - Analytic Server Import

If the stream contains an Analytic Server Source node, the connection details are displayed here.

Use Default Analytic Server. True or False specifies whether the default Analytic Server connection defined by an administrator in options.cfg is used (True), or if a different Analytic Server is used – the one specified in the stream/job (False).

URL. The URL for the Analytic Server in the format `https://hostname:port/contextroot`, where `hostname` is the IP address or host name of the Analytic Server, `port` is its port number, and `contextroot` is the context root of the Analytic Server.

Tenant. The name of the tenant that the SPSS® Modeler Server is a member of.

Credential. The credential for logging on to Analytic Server.

Service Principal Name. The Kerberos service principal name.

Config File Path. The Kerberos service config file path.

Data Source. The data source name on Analytic Server.

IBM® SPSS Modeler Job Properties - Analytic Server Export

If the stream contains an Analytic Server Export node, the connection details are displayed here.

Use Default Analytic Server. True or False specifies whether the default Analytic Server connection defined by an administrator in options.cfg is used (True), or if a different Analytic Server is used – the one specified in the stream/job (False).

URL. The URL for the Analytic Server in the format `https://hostname:port/contextroot`, where `hostname` is the IP address or host name of the Analytic Server, `port` is its port number, and `contextroot` is the context root of the Analytic Server.

Tenant. The name of the tenant that the SPSS® Modeler Server is a member of.

Credential. The credential for logging on to Analytic Server.

Service Principal Name. The Kerberos service principal name.

Config File Path. The Kerberos service config file path.

Data Source. The data source name on Analytic Server.

IBM® SPSS® Modeler Job Properties - Notifications

Allows you to specify email notifications for job step failure and success.

Click the Update button in each case to add or delete notification recipients.

Viewing Streams in IBM SPSS Modeler

You can launch the IBM® SPSS® Modeler application directly from IBM SPSS Deployment Manager.

To view the stream in the IBM SPSS Modeler application, double-click on the stream in the Content Explorer. The system launches the IBM SPSS Modeler application and displays the stream in IBM SPSS Modeler.

It is important to note that if any changes are made to the files in a job--for example, an IBM SPSS Modeler stream (.str)--any job that contains the file is affected. When changes are made to the file, a new version of the file is saved to the repository. However, the job that contains the file is not automatically updated with the modified file. To incorporate the file updates into the affected job:

1. Reopen the job. When the job is reopened, an asterisk appears with the job name in the job canvas, indicating that the job contains unsaved changes.
2. Resave the job.

IBM SPSS Modeler Completion Codes

The completion codes for IBM® SPSS® Modeler jobs are described in the following table. Use these completion codes for any conditional relationships that involve IBM SPSS Modeler streams.

Table 1. Completion codes for IBM SPSS Modeler jobs

Code	Description
0	success
1	stream execution error
2	publishing error
8	unknown error

-

IBM SPSS Modeler Stream Limitations

When you work with streams in the IBM® SPSS® Deployment Manager, the system has the following constraints:

- Naming. If the node name, label, and type are the same, you cannot schedule a job for execution because a conflict arises.
- Scripting. If a stream script contains overrides for a specific node—for example, the script sets the output location for a graph—the script supersedes any conflicting user-specified values defined in Deployment Manager.
- Supernodes. Execution of an IBM SPSS Modeler job step corresponds to the processing and execution of all top-level terminal nodes in the stream. If any terminal node is a terminal supernode, the terminal nodes within that supernode execute recursively. In contrast, if source or process supernodes, which are by definition non-terminal, contain terminal nodes, those nodes do not execute. The terminal nodes in the non-terminal supernodes do appear in Deployment Manager but are not processed during execution of the step.
- Parameters. Parameters defined for supernodes cannot have the same name as parameters defined for a stream. The names must be unique.

- Text Analytics node restrictions. You cannot use the SPSS Modeler Text Analytics File List or Web Feed nodes for scoring within an IBM SPSS Collaboration and Deployment Services - Scoring configuration.

In addition to the items listed above, there are the following specific constraints.

- No unlock checkbox is available when you store a stream in the IBM SPSS Collaboration and Deployment Services repository. Unlock is the default when storing streams. To lock or unlock an object, choose Tools > Repository > Explore, navigate to the object, and right-click on its name to display the context menu.
- In Deployment Manager, when you run a job that contains a stream with an Evaluation node set to produce a Gains graph, the graph output may be incomplete if the system is running under Oracle Weblogic 11g using the Oracle JRockit JRE. To avoid this problem, use the IBM JRE.

Node Types

When you open an IBM® SPSS® Modeler stream from IBM SPSS Deployment Manager, you see that the stream nodes are represented by different shaped icons. Circle icons represent source data nodes, while hexagonal nodes represent processing operations on data records and fields. Triangles indicate graphical output, while pentagons represent modeling nodes. Output (other than graphical) and export operations are indicated by rectangular nodes.

The various nodes are fully described in the *IBM SPSS Modeler Source, Process and Output Nodes* and the *IBM SPSS Modeler Modeling Nodes* guides.

Scoring Service

The Scoring Service allows client applications to employ real-time scores derived from predictive models developed in IBM® SPSS® Modeler. The service fetches the specified model, loads it, invokes the correct scoring implementation, and returns the result to the client.

Scoring is the process of generating real-time values by supplying predictive models with input data. A scoring model is any artifact that can be used to produce output values given input data. In general, to use a model for generating scores:

1. Select a model to use for scoring from the IBM SPSS Collaboration and Deployment Services Repository.
2. Define a scoring configuration for the model.
3. Supply the configured model with data and generate scores.

For more information about scoring and the Scoring Service, see the IBM SPSS Collaboration and Deployment Services documentation.

- [IBM SPSS Modeler stream limitations](#)

IBM SPSS Modeler stream limitations

When you work with streams in IBM® SPSS® Deployment Manager, the system has the following constraints for the Scoring Service:

- Supernodes. Source nodes inside supernodes are not supported, and terminal nodes inside supernodes are not supported.
- Geospatial nodes. Geospatial nodes are not supported.
- Model builder nodes. Model builder node as the terminal node is not supported.
- In-database mining. Streams containing in-database mining nuggets are not supported.
- UDF, UDA, and WUDA. Streams using database functions (UDF), database aggregations (UDA), or database window aggregates (WUDA) are not supported.
- Source nodes. Source nodes with an output data model containing a list type are not supported.
- Terminal nodes. Terminal nodes with an input data model containing a list type are not supported.
- Text Analytics node restrictions. You cannot use the SPSS Modeler Text Analytics File List or Web Feed nodes for scoring within an IBM SPSS Collaboration and Deployment Services - Scoring configuration.
- Analytic Server source nodes. If you have a job containing an SPSS Modeler stream that uses an Analytic Server source node, you must allow a direct connection between the IBM SPSS Collaboration and Deployment Services Server and Analytic Server. Otherwise, the job will fail if the firewall blocks the connection between the two servers.

Supported languages

IBM® SPSS® Modeler supports R and Apache Spark (via Python). See the following sections for more information.

- [R](#)
 - [Python for Spark](#)
 - [Extension nodes](#)
-

R

IBM® SPSS® Modeler supports R.

Allowable R syntax

- In the syntax field on the Syntax tab of the various Extension nodes, only statements and functions that are recognized by R are allowed.
- For the Extension Transform node and the Extension model nugget, data passes through the R script (in batch). For this reason, R scripts for model scoring and process nodes shouldn't include operations that span or combine rows in the data, such as sorting or aggregation. This limitation is imposed to ensure that data can be split up in a Hadoop environment, and during in-database mining. Extension Output and Extension model building nodes do not have this limitation.
- The addition of a non-batch data transfer mode, in both the Extension Transform node and the Extension model nugget, means that you can either span or combine rows in the data in SPSS Modeler Server.
- All R nodes can be seen as independent global R environments. Therefore, using `library` functions within the two separate R nodes requires the loading of the R library in both R scripts.
- To display the value of an R object that is defined in your R script, you must include a call to a printing function. For example, to display the value of an R object that is called `data`, include the following line in your R script:

```
print(data)
```

- You cannot include a call to the R `setwd` function in your R script because this function is used by IBM SPSS Modeler to control the file path of the R scripts output file.
 - Stream parameters that are defined for use in CLEM expressions and scripting are not recognized if used in R scripts.
 - IBM SPSS Modeler doesn't support the interactive plot in R
 - Some R objects are automatically populated when Extension nodes are used in a flow (for example, `modelerData` and `modelerDataModel` data frames). For more information, see [Model building syntax](#).
-

Python for Spark

IBM® SPSS® Modeler supports Python scripts for Apache Spark.

Note:

- Python nodes depend on the Spark environment.
 - Python scripts must use the Spark API because data will be presented in the form of a Spark DataFrame.
 - Old nodes created in version 17.1 will still only run against IBM SPSS Analytic Server (the data originates from an IBM SPSS Analytic Server source node and has not been extracted to IBM SPSS Modeler Server). New Python and Custom Dialog Builder nodes created in version 18.0 or later can run against IBM SPSS Modeler Server.
 - When installing Python, make sure all users have permission to access the Python installation.
 - If you want to use the Machine Learning Library (MLlib), you must install a version of Python that includes NumPy. Then you must configure the IBM SPSS Modeler Server (or the local server in IBM SPSS Modeler Client) to use your Python installation. For details, see [Scripting with Python for Spark](#).
 - [Scripting with Python for Spark](#)
 - [Switching to a different Python environment](#)
-

Scripting with Python for Spark

IBM® SPSS® Modeler can execute Python scripts using the Apache Spark framework to process data. This documentation provides the Python API description for the interfaces provided.

The IBM SPSS Modeler installation includes a Spark distribution (for example, IBM SPSS Modeler 18.4 includes Spark 3.2.1).

Prerequisites

- If you plan to execute Python/Spark scripts against IBM SPSS Analytic Server, you must have a connection to Analytic Server, and Analytic Server must have access to a compatible installation of Apache Spark. Refer to your IBM SPSS Analytic Server documentation for details

about using Apache Spark as the execution engine.

- If you plan to execute Python/Spark scripts against IBM SPSS Modeler Server (or the local server included with IBM SPSS Modeler Client, which requires Windows 64 or Mac64), you no longer need to install Python and edit options.cfg to use your Python installation. Starting with version 18.1, IBM SPSS Modeler now includes a Python distribution. However, if you require a certain module that is not included with the default IBM SPSS Modeler Python distribution, you can go to <Modeler_installation_directory>/python and install additional packages. Even though a Python distribution is now included with IBM SPSS Modeler, you can still point to your own Python installation as in previous releases if desired by adding the following option to options.cfg:

```
# Set to the full path to the python executable  
(including the executable name) to enable use of PySpark.  
eas_pyspark_python_path, ""
```

Windows example:

```
eas_pyspark_python_path, "C:\\Your_Python_Install\\python.exe"
```

Linux example:

```
eas_pyspark_python_path, "/Your_Python_Install/bin/python"
```

Note: If you point to your own Python installation, it must be version 3.8.x. IBM SPSS Modeler was tested with Anaconda for Python 3.8 and Python 3.8.6.

- If you plan to determine the PySpark version that is used by the IBM SPSS Modeler, you can run the following script.

```
import pkg_resources  
    print("pandas version")  
    print(pkg_resources.get_distribution("pandas").version)  
    print("pyspark version")  
    print(pkg_resources.get_distribution("pyspark").version)
```

Based on your OS, run the following commands in the corresponding paths before you run the script to determine the PySpark version.

For Windows

Path: <Modeler-InstallationDirectory>\18.4\spark\python
Command:

```
"<Modeler-InstallationDirectory>\18.4\python\python.exe" setup.py sdist
```

For Mac

Path: <Modeler-InstallationDirectory>/18.4/IBM SPSS Modeler.app/Contents/spark/python
Command:

```
"<Modeler-InstallationDirectory>/18.4/IBM SPSS Modeler.app/Contents/python/bin/python3" setup.py  
sdist
```

For Linux

Path: <Modeler-InstallationDirectory>/18.4/spark/python
Command:

```
<Modeler-InstallationDirectory>/18.4/python/bin/python3 setup.py sdist
```

Note: <Modeler-InstallationDirectory> corresponds to the IBM SPSS Modeler Thick Client installation for local server, whereas it corresponds to the IBM SPSS Modeler Server installation for remote server.

The IBM SPSS Analytic Server context object

The execution context for a Python/Spark script is defined by an Analytic Server context object. When running against IBM SPSS Modeler Server, the context object is for the embedded version of Analytic Server that is included with the IBM SPSS Modeler Server installation. To obtain the context object, the script must include the following:

```
import spss.pyspark.runtime  
asContext = spss.pyspark.runtime.getContext()
```

From the Analytic Server context, you can obtain the Spark context and the SQL context:

```
sparkContext = asc.getSparkContext()  
sqlContext = asc.getSparkSQLContext()
```

Refer to your Apache Spark documentation for information about the Spark context and the SQL context.

Accessing data

Data is transferred between a Python/Spark script and the execution context in the form of a Spark SQL DataFrame. A script that consumes data (that is, any node except a source node) must retrieve the data frame from the context:

```
inputData = asContext.getSparkInputData()
```

A script that produces data (that is, any node except a terminal node) must return a data frame to the context:

```
asContext.setSparkOutputData(outputData)
```

You can use the SQL context to create an output data frame from an RDD where required:

```
outputData = sqlContext.createDataFrame(rdd)
```

Defining the data model

A node that produces data must also define a data model that describes the fields visible downstream of the node. In Spark SQL terminology, the data model is the schema.

A Python/Spark script defines its output data model in the form of a `pyspark.sql.types.StructType` object. A `StructType` describes a row in the output data frame and is constructed from a list of `StructField` objects. Each `StructField` describes a single field in the output data model.

You can obtain the data model for the input data using the `:schema` attribute of the input data frame:

```
inputSchema = inputData.schema
```

Fields that are passed through unchanged can be copied from the input data model to the output data model. Fields that are new or modified in the output data model can be created using the `StructField` constructor:

```
field = StructField(name, dataType, nullable=True, metadata=None)
```

Refer to your Spark documentation for information about the constructor.

You must provide at least the field name and its data type. Optionally, you can specify metadata to provide a measure, role, and description for the field (see [Data metadata](#)).

DataModelOnly mode

IBM SPSS Modeler needs to know the output data model for a node, before the node is executed, in order to enable downstream editing. To obtain the output data model for a Python/Spark node, IBM SPSS Modeler executes the script in a special "data model only" mode where there is no data available. The script can identify this mode using the `isComputeDataModelOnly` method on the Analytic Server context object.

The script for a transformation node can follow this general pattern:

```
if asContext.isComputeDataModelOnly():
    inputSchema = asContext.getSparkInputSchema()
    outputSchema = ... # construct the output data model
    asContext.setSparkOutputSchema(outputSchema)
else:
    inputData = asContext.getSparkInputData()
    outputData = ... # construct the output data frame
    asContext.setSparkOutputData(outputData)
```

Building a model

A node that builds a model must return to the execution context some content that describes the model sufficiently that the node which applies the model can recreate it exactly at a later time.

Model content is defined in terms of key/value pairs where the meaning of the keys and the values is known only to the build and score nodes and is not interpreted by Modeler in any way. Optionally the node may assign a MIME type to a value with the intent that Modeler might display those values which have known types to the user in the model nugget.

A value in this context may be PMML, HTML, an image, etc. To add a value to the model content (in the build script):

```
asContext.setModelContentFromString(key, value, mimeType=None)
```

To retrieve a value from the model content (in the score script):

```
value = asContext.getModelContentToString(key)
```

As a shortcut, where a model or part of a model is stored to a file or folder in the file system you can bundle all the content stored to that location in one call (in the build script):

```
asContext.setModelContentFromPath(key, path)
```

Note that in this case there is no option to specify a MIME type because the bundle may contain various content types.

If you need a temporary location to store the content while building the model you can obtain an appropriate location from the context:

```
path = asContext.createTemporaryFolder()
```

To retrieve existing content to a temporary location in the file system (in the score script):

```
path = asContext.getModelContentToPath(key)
```

Error handling

To raise errors, throw an exception from the script and display it to the IBM SPSS Modeler user. Some exceptions are predefined in the module `spss.pyspark.exceptions`. For example:

```
from spss.pyspark.exceptions import ASContextException
if ... some error condition ...
    raise ASContextException("message to display to user")
```

Analytic Server Context

The Context provides support for the Analytic Server context interface for interaction with IBM® SPSS® Analytic Server.

AnalyticServerContext Objects

`AnalyticServerContext` Objects set up the context environment which provides several interfaces for interacting with IBM SPSS Analytic Server. An application that wants to construct this context instance must do so using the `spss.pyspark.runtime.getContext()` interface rather than implementing the interface directly.

Returns the Pyspark python `SparkContext` instance:

```
ctx.getSparkContext() : SparkContext
```

Returns the Pyspark python `SQLContext` instance:

```
ctx.getSparkSQLContext() : SQLContext
```

Returns `True` to describe whether the execution is made only to compute the output data model. Otherwise returns `False`:

```
ctx.isComputeDataModelOnly() : Boolean
```

Returns `True` if the script is running in the Spark environment. Currently, it always returns `True`:

```
ctx.isSparkExecution() : Boolean
```

Loads input data from the upstream temporary file and generates the `pyspark.sql.DataFrame` instance:

```
ctx.getSparkInputData() : DataFrame
```

Returns a `pyspark.sql.StructType` instance generated from the input data model. Returns `None` if the input data model does not exist:

```
ctx.getSparkInputSchema() : StructType
```

Serializes the output data frame into Analytic Server context and returns the context:

```
ctx.setSparkOutputData( outDF ) : AnalyticServerContext
```

Parameter:

- `outDF (DataFrame) : The output data frame value`

Exceptions:

- `DataOutputNotSupported` : If this interface is invoked in the function `pyspark:buildmodel`
- `ASContextException` : If the output data frame is `None`
- `InconsistentOutputDataModel` : The field names and storage type information common to both objects is inconsistent

Converts the `outSchema StructType` instance into a data model, serializes it into the Analytic Server context, and returns the context:

```
ctx.setSparkOutputSchema(outSchema) : AnalyticServerContext
```

Parameter:

- `outSchema(StructType)` : The output `StructType` object

Exceptions:

- `ASContextException` : If the output schema instance is `None`
- `InconsistentOutputDataModel` : The field names and storage type information common to both objects is inconsistent

Stores the location of model building output to the Analytic Server context and returns the context:

```
ctx.setModelContentFromPath(key, path, mimetype=None) : AnalyticServerContext
```

The path can be a directory path which should use the `ctx.createTemporaryFolder()` API to generate , when everything under the directory is packaged up as model content.

Parameters:

- `key (string)` : key string value
- `path (string)` : location of model building output string path
- `mimetype (string, optional)` : the MIME type of the content

Exceptions:

- `ModelErrorNotSupported` : When not invoking this API from the `pyspark:buildmodel` function
- `KeyError` : If the key attribute is `None` or the string is empty

Stores the model building content, metadata, or other attributes to the Analytic Server context and returns the context:

```
ctx.setModelContentFromString(key, value, mimetype=None) : AnalyticServerContext
```

Parameters:

- `key (string)` : key string value
- `value (string)` : the model metadata string value
- `mimetype (string, optional)` : the MIME type of the content

Exceptions:

- `ModelErrorNotSupported` : When not invoking this API from the `pyspark:buildmodel` function
- `KeyError` : If the key attribute is `None` or the string is empty

Returns the temporary folder location that is managed by Analytic Server; this can be used to store the model content:

```
ctx.createTemporaryFolder() : string
```

Exception:

- `ModelErrorNotSupported` : When not invoking this API from the `pyspark:buildmodel` function

Returns the location of the model which matches the input key:

```
ctx.getModelContentToPath(key) : string
```

Parameter:

- `key (string)` : key string value

Exceptions:

- `ModelErrorNotSupported` : When not invoking this API from the `pyspark:applymodel` function
- `KeyError` : If the key attribute is `None` or the string is empty
- `IncompatibleModelContentType` : If the model content type is not a container

Returns the model content, metadata of the model, or other model attributes which match the input key:

```
ctx.getModelContentToString(key) : string
```

Parameter:

- `key (string)` : key string value

Exceptions:

- `ModelErrorNotSupported` : When not invoking this API from the `pyspark:applymodel` function
- `KeyError` : If the key attribute is `None`, or the string is empty, or the key does not exist
- `IncompatibleModelContentType` : If the model content type is not consistent

Returns the mime-type assigned to the input key. It returns `None` if the specified content has no mime type:

```
ctx.getModelContentMimeType(key) : string
```

Parameter:

- `key (string)` : key string value

Exceptions:

- `ModelErrorNotSupported` : When not invoking this API from the `pyspark:applymodel` function
- `KeyError` : If the key attribute is `None`, or the string is empty, or the key does not exist

Data metadata

This section describes how to set up the data model attributes based on `pyspark.sql.StructField`.

`spss.datamodel.Role Objects`

This class enumerates valid roles for each field in a data model.

`BOTH`: Indicates that this field can be either an antecedent or a consequent.

`FREQWEIGHT`: Indicates that this field is used to be as frequency weight; this is not displayed to the user.

`INPUT`: Indicates that this field is a predictor or an antecedent.

`NONE`: Indicates that this field is not used directly during modeling.

`TARGET`: Indicates that this field is predicted or a consequent.

`PARTITION`: Indicates that this field is used to identify the data partition.

`RECORDID`: Indicates that this field is used to identify the record id.

`SPLIT`: Indicates that this field is used to split the data.

`spss.datamodel.Measure Objects`

This class enumerates measurement levels for fields in a data model.

`UNKNOWN`: Indicates that the measure type is unknown.

`CONTINUOUS`: Indicates that the measure type is continuous.

`NOMINAL`: Indicates that the measure type is nominal.

`FLAG`: Indicates that the field value is one of two values.

`DISCRETE`: Indicates that the field value should be interpreted as a collection of values.

`ORDINAL`: Indicates that the measure type is ordinal.

`TYPELESS`: Indicates that the field can have any value compatible with its storage.

`pyspark.sql.StructField Objects`

Represents a field in a `StructType`. A `StructField` object comprises four fields:

- `name (string)`: name of a `StructField`
- `dataType (pyspark.sql.DataType)`: specific data type
- `nullable (bool)`: if the values of a `StructField` can contain `None` values
- `metadata (dictionary)`: a python dictionary used to store the option attributes

You can use the metadata dictionary instance to store the measure, role, or label attribute for the specific field. The key words for these attributes are:

- `measure`: the key word for `measure` attribute
- `role`: the key word for `role` attribute
- `displayLabel`: the key word for `label` attribute

Example:

```
from spss.datamodel.Role import Role
from spss.datamodel.Measure import Measure
_metadata = {}
_metadata['measure'] = Measure.TYPELESS
_metadata['role'] = Role.NONE
_metadata['displayLabel'] = "field label description"
StructField("userName", StringType(), nullable=False,
metadata=_metadata)
```

Date, time, timestamp

For operations that use date, time, or timestamp type data, the value is converted to the real value based on the value **1970-01-01:00:00:00** (using Coordinated Universal Time).

For the date, the value represents the number of days, based on the value **1970-01-01** (using Coordinated Universal Time).

For the time, the value represents the number of seconds at 24 hours.

For the timestamp, the value represents the number of seconds based on the value **1970-01-01:00:00:00** (using Coordinated Universal Time).

Exceptions

This section describes possible exception instances.

MetadataException Objects

A subclass of python Exception.

This exception is thrown if an error occurs during operate the metadata object.

UnsupportedOperationException Objects

A subclass of python Exception.

This exception is thrown if the specific operation does not allow execution.

InconsistentOutputDataModel Objects

A subclass of python Exception.

This Exception is thrown if both `setSparkOutputSchema` and `setSparkOutputData` are invoked but the field names and storage type information common to both objects are inconsistent.

IncompatibleModelContentType Objects

A subclass of python Exception.

This Exception is thrown during the following scenarios:

- Using `setModelContentFormString` to set model but using `getModelContentToPath` to get value
- Using `setModelContentFormPath` to set model but using `getModelContentToString` to get value

DataOutputNotSupportedException Objects

A subclass of python Exception.

This exception is raised in `setSparkOutputData` in an execution handled by function `pyspark:buildmodel`.

ModelErrorNotSupportedException Objects

A subclass of python Exception.

This exception is only raised if the script does not invoke the `getModelContentPathByKey` and `getModelContentToString` API in the `pyspark:applymodel` function.

ModelOutputNotSupportedException Objects

A subclass of python Exception.

This exception is only raised if the script does not invoke the `setModelContentFromPath` and `setModelContentFromString` APIs in the `pyspark:buildmodel` function.

ASContextException Objects

A subclass of python Exception.

This exception is thrown if an unexpected runtime exception occurs.

Examples

This section contains Python for Spark scripting examples.

Basic scripting example for processing data

```
import spss.pyspark.runtime
from pyspark.sql.types import *

ctx = spss.pyspark.runtime.getContext()

if ctx.isComputeDataModelOnly():
    _schema = ctx.getSparkInputSchema()
    ctx.setSparkOutputSchema(_schema)
else:
    _structType = ctx.getSparkInputSchema()
    df = ctx.getSparkInputData()
    _newDF = df.sample(False, 0.01, 1)
    ctx.setSparkOutputData(_newDF)
```

Example model building script, using the LinearRegressionWithSGD algorithm

```
from pyspark.context import SparkContext
from pyspark.sql.context import SQLContext
from pyspark.sql import Row
from pyspark.mllib.regression import
LabeledPoint,LinearRegressionWithSGD, LinearRegressionModel
from pyspark.mllib.linalg import DenseVector
import numpy
import json

import spss.pyspark.runtime
from spss.pyspark.exceptions import ASContextException

ascontext = spss.pyspark.runtime.getContext()
sc = ascontext.getSparkContext()
df = ascontext.getSparkInputData()

# field settings amd algorithm parameters

target = '%%target_field%%'
predictors = [%%predictor_fields%%]
num_iterations=%%num_iterations%%
prediction_field = "$LR-" + target

# save linear regression model to a filesystem path

def save(model, sc, path):
    data =
    sc.parallelize([json.dumps({"intercept":model.intercept,"weights":model.weights.tolist()})])
    data.saveAsTextFile(path)

# print model details to stdout
```

```

def dump(model,predictors):
    print(prediction_field+" = " + str(model.intercept))
    weights = model.weights.tolist()
    for i in range(0,len(predictors)):
        print("\t"+predictors[i]+"*"+ str(weights[i]))

# check that required fields exist in the input data

input_field_names = [ty[0] for ty in df.dtypes[:]]
if target not in input_field_names:
    raise ASContextException("target field "+target+" not found") for predictor in predictors:
    if predictor not in input_field_names:
        raise ASContextException("predictor field "+predictor+" not found")

# define map function to convert from dataframe Row objects to mllib LabeledPoint

def row2LabeledPoint(target,predictors,row):
    pvals = []
    for predictor in predictors:
        pval = getattr(row,predictor)
        pvals.append(float(pval))
    tval = getattr(row,target)
    return LabeledPoint(float(tval),DenseVector(pvals))

# convert dataframe to an RDD containing LabeledPoint

training_points = df.rdd.map(lambda row:
row2LabeledPoint(target,predictors,row))

# build the model

model = LinearRegressionWithSGD.train(training_points,num_iterations,intercept=True)

# write a text description of the model to stdout

dump(model,predictors)

# save the model to the filesystem and store into the output model content

modelpath = ascontext.createTemporaryFolder()
save(model,sc,modelpath)
ascontext.setModelContentFromPath("model",modelpath)

```

Example model scoring script, using the LinearRegressionWithSGD algorithm

```

import json
import spss.pyspark.runtime
from pyspark.sql import Row
from pyspark.mllib.regression import
LabeledPoint,LinearRegressionWithSGD, LinearRegressionModel
from pyspark.mllib.linalg import DenseVector
from pyspark.sql.context import SQLContext
import numpy
from pyspark.sql.types import DoubleType, StructField

ascontext = spss.pyspark.runtime.getContext()
sc = ascontext.getSparkContext()

prediction_field = "$LR-" + '%%target_field%%'
predictors = [%%predictor_fields%%]

# compute the output schema by adding the prediction field
outputSchema = ascontext.getSparkInputSchema()
outputSchema.fields.append(StructField(prediction_field,
DoubleType(), nullable=True))

# make a prediction based on a regression model and Dataframe Row object
# return a list containing the input row values and the predicted value
def predict(row,model,predictors,infields,prediction_field_name):
    pvals = []
    rdict = row.asDict()
    for predictor in predictors:
        pvals.append(float(rdict[predictor]))
    estimate = float(model.predict(pvals))
    result = []
    for field in infields:
        result.append(rdict[field])
    result.append(estimate)
    return result

```

```

# load a serialized model from the filesystem

def load(sc, path):
    js = sc.textFile(path).take(1)[0]
    obj = json.loads(js)
    weights = numpy.array(obj["weights"])
    intercept = obj["intercept"]
    return LinearRegressionModel(weights, intercept)

ascontext.setSparkOutputSchema(outputSchema)

if not ascontext.isComputeDataModelOnly():
    # score the data in the input data frame
    indf = ascontext.getSparkInputData()

    model_path = ascontext.getModelContentToPath("model")
    model = load(sc, model_path)

    # compute the scores
    infield_names = [ty[0] for ty in indf.dtypes[:]]
    scores_rdd = indf.rdd.map(lambda row:predict(row,model,predictors,infield_names,prediction_field))

    # create an output DataFrame containing the scores
    sqlCtx = SQLContext(sc)
    outdf = sqlCtx.createDataFrame(scores_rdd,schema=outputSchema)

    # return the output DataFrame as the result
    ascontext.setSparkOutputData(outdf)

```

Switching to a different Python environment

You can change the Python environment used by the Extension nodes and Custom Dialog Builder in IBM® SPSS® Modeler:

1. Grant edit permissions for options.cfg:
 - a. From the IBM SPSS Modeler Server installation directory, open config/options.cfg in a text editor.
 - b. Modify the following line to grant users edit permissions:

```
administrators, "*"
```

 - c. Save the file and then restart the IBM SPSS Modeler Server.
2. Open IBM SPSS Modeler and connect to the IBM SPSS Modeler Server.
3. Go to Tools>Manage Modeler Server Configuration.
4. Under Data File Access, modify the Python executable path and then click OK.
5. Restart the IBM SPSS Modeler Server and then reconnect to it in IBM SPSS Modeler.
6. Go to Tools>Manage Modeler Server Configuration and verify that your new Python path was saved.

Extension nodes

To complement IBM® SPSS® Modeler and its data mining abilities, the Extension nodes enable expert users to input their own R scripts or Python for Spark scripts to carry out data processing, model building, and model scoring.

- [Extension Output node](#)
- [Extension Model node](#)
- [Extension model nugget](#)
- [Extension Transform node](#)
- [Extension Import node](#)

Extension Export node

With the Extension Export node, you can run R or Python for Spark scripts to export data.

- [Extension Export node - Syntax tab](#)
- [Extension Export node - Console Output tab](#)
- [Publishing streams](#)

Extension Export node - Syntax tab

Select your type of syntax – R or Python for Spark. See the following sections for more information. When your syntax is ready, you can click Run to execute the Extension Export node.

R Syntax

R Syntax. You can enter, or paste, custom R scripting syntax for data analysis into this field.

Convert flag fields. Specifies how flag fields are treated. There are two options: Strings to factor, Integers and Reals to double, and Logical values (True, False). If you select Logical values (True, False) the original values of the flag fields are lost. For example, if a field has values Male and Female, these are changed to True and False.

Convert missing values to the R 'not available' value (NA). When selected, any missing values are converted to the R NA value. The value NA is used by R to identify missing values. Some R functions that you use might have an argument that can be used to control how the function behaves when the data contain NA. For example, the function might allow you to choose to automatically exclude records that contain NA. If this option is not selected, any missing values are passed to R unchanged, and might cause errors when your R script is executed.

Convert date/time fields to R classes with special control for time zones. When selected, variables with date or datetime formats are converted to R date/time objects. You must select one of the following options:

- **R POSIXct.** Variables with date or datetime formats are converted to R POSIXct objects.
- **R POSIXlt (list).** Variables with date or datetime formats are converted to R POSIXlt objects.

Note: The POSIX formats are advanced options. Use these options only if your R script specifies that datetime fields are treated in ways that require these formats. The POSIX formats do not apply to variables with time formats.

Python Syntax

Python Syntax. You can enter, or paste, custom Python scripting syntax for data analysis into this field. For more information about Python for Spark, see [Python for Spark](#) and [Scripting with Python for Spark](#).

Extension Export node - Console Output tab

The Console Output tab contains any output that is received when the R script or Python for Spark script on the Syntax tab runs (for example, if using an R script, it shows output received from the R console when the R script in the R Syntax field on the Syntax tab is executed). This output might include R or Python error messages or warnings that are produced when the R or Python script is executed. The output can be used, primarily, to debug the script. The Console Output tab also contains the script from the R Syntax or Python Syntax field.

Every time the Extension Export script is executed, the content of the Console Output tab is overwritten with the output received from the R console or Python for Spark. The output cannot be edited.

Publishing streams

Publishing streams is done directly from IBM® SPSS® Modeler using any of the standard export nodes: Database, Flat File, Statistics Export, Extension Export, Data Collection Export, SAS Export, Excel, and XML Export nodes. The type of export node determines the format of the results to be written each time the published stream is executed using the IBM SPSS Modeler Solution Publisher Runtime or external application. For example, if you want to write your results to a database each time the published stream is run, use a Database export node.

To publish a stream

1. Open or build a stream in the normal manner and attach an export node at the end.
2. On the Publish tab in the export node, specify a root name for the published files (that is, the file name to which the .pim, .par, and .xml extensions will be appended).
3. Click Publish to publish the stream, or select Publish the stream to automatically publish the stream each time the node is executed.

Published name. Specify the root name for the published image and parameter files.

- The image file (*.pim) provides all of the information needed for the Runtime to execute the published stream exactly as it was at the time of export. If you are confident that you will not need to change any of the settings for the stream (such as the input data source or the output data file), you can deploy the image file only.

- The parameter file (*.par) contains configurable information about data sources, output files, and execution options. If you want to be able to control the input or output of the stream without republishing the stream, you will need the parameter file as well as the image file.
 - The metadata file (*.xml) describes the inputs and outputs of the image and their data models. It is designed for use by applications which embed the runtime library and which need to know the structure of the input and output data.
- Note: This file is only produced if you select the Publish metadata option.

Publish parameters. If required, you can include stream parameters in the *.par file. You can change these stream parameter values when you execute the image either by editing the *.par file or through the runtime API.

This option enables the Parameters button. The Publish Parameters dialog box is displayed when you click the button.

Choose the parameters you want to include in the published image by selecting the relevant option in the Publish column.

On stream execution. Specifies whether the stream is automatically published when the node is executed.

- Export data. Executes the export node in the standard manner, without publishing the stream. (Basically, the node executes in IBM SPSS Modeler the same way it would if IBM SPSS Modeler Solution Publisher were not available.) If you select this option, the stream will not be published unless you do so explicitly by clicking Publish in the export node dialog box. Alternatively, you can publish the current stream using the Publish tool on the toolbar or by using a script.
- Publish the stream. Publishes the stream for deployment using IBM SPSS Modeler Solution Publisher. Select this option if you want to automatically publish the stream every time it is executed.

Note:

- If you plan to run the published stream with new or updated data, it is important to note that the order of fields in the input file must be the same as the order of fields in the source node input file specified in the published stream.
- When publishing to external applications, consider filtering extraneous fields or renaming fields to conform with input requirements. Both can be accomplished using a Filter node prior to the export node.

Extension Output node

If Output to screen is selected on the Output tab of the Extension Output node dialog, on-screen output is displayed in an output browser window. The output is also added to the Output manager. The output browser window has its own set of menus that allow you to print or save the output, or export it to another format. The Edit menu only contains the Copy option. The Extension Output node's output browser has two tabs; the Text Output tab that displays text output, and the Graph Output tab that displays graphs and charts.

If Output to file is selected on the Output tab of the Extension Output node dialog, the output browser window is not displayed upon successful execution of the Extension Output node.

- [Extension Output node - Syntax tab](#)
- [Extension Output node - Console Output tab](#)
- [Extension Output node - Output tab](#)
- [Extension Output Browser](#)

Extension Output node - Syntax tab

Select your type of syntax – R or Python for Spark. See the following sections for more information. When your syntax is ready, you can click Run to execute the Extension Output node. The output objects are added to the Output manager, or optionally to the file specified in the Filename field on the Output tab.

R Syntax

R Syntax. You can enter, or paste, custom R scripting syntax for data analysis into this field.

Convert flag fields. Specifies how flag fields are treated. There are two options: Strings to factor, Integers and Reals to double, and Logical values (True, False). If you select Logical values (True, False) the original values of the flag fields are lost. For example, if a field has values Male and Female, these are changed to True and False.

Convert missing values to the R 'not available' value (NA). When selected, any missing values are converted to the R NA value. The value NA is used by R to identify missing values. Some R functions that you use might have an argument that can be used to control how the function behaves when the data contain NA. For example, the function might allow you to choose to automatically exclude records that contain NA. If this option is not selected, any missing values are passed to R unchanged, and might cause errors when your R script is executed.

Convert date/time fields to R classes with special control for time zones. When selected, variables with date or datetime formats are converted to R date/time objects. You must select one of the following options:

- **R POSIXct**. Variables with date or datetime formats are converted to R `POSIXct` objects.
- **R POSIXlt (list)**. Variables with date or datetime formats are converted to R `POSIXlt` objects.

Note: The POSIX formats are advanced options. Use these options only if your R script specifies that datetime fields are treated in ways that require these formats. The POSIX formats do not apply to variables with time formats.

Python Syntax

Python Syntax. You can enter, or paste, custom Python scripting syntax for data analysis into this field. For more information about Python for Spark, see [Python for Spark](#) and [Scripting with Python for Spark](#).

Extension Output node - Console Output tab

The Console Output tab contains any output that is received when the R script or Python for Spark script on the Syntax tab runs (for example, if using an R script, it shows output received from the R console when the R script in the R Syntax field on the Syntax tab is executed). This output might include R or Python error messages or warnings that are produced when the R or Python script is executed. The output can be used, primarily, to debug the script. The Console Output tab also contains the script from the R Syntax or Python Syntax field.

Every time the Extension Output script is executed, the content of the Console Output tab is overwritten with the output received from the R console or Python for Spark. The output cannot be edited.

Extension Output node - Output tab

Output name. Specifies the name of the output that is produced when the node is executed. When Auto is selected, the name of the output is automatically set to "R Output" or "Python Output" depending on the script type. Optionally, you can select Custom to specify a different name.

Output to screen. Select this option to generate and display the output in a new window. The output is also added to the Output manager.

Output to file. Select this option to save the output to a file. Doing so enables the Output Graph and Output File radio buttons.

Output Graph. Only enabled if Output to file is selected. Select this option to save any graphs that result from executing the Extension Output node to a file. Specify a filename to use for the generated output in the Filename field. Click the ellipses button (...) to choose a specific file and location. Specify the file type in the File type drop-down list. The following file types are available:

- Output object (.cou)
- HTML (.html)

Output Text. Only enabled if Output to file is selected. Select this option to save any text output that results from executing the Extension Output node to a file. Specify a filename to use for the generated output in the Filename field. Click the ellipses button (...) to specify a specific file and location. Specify the file type in the File type drop-down list. The following file types are available:

- HTML (.html)
- Output object (.cou)
- Text document (.txt)

Extension Output Browser

If Output to screen is selected on the Output tab of the Extension Output node dialog box, on-screen output is displayed in an output browser window. The output is also added to the Output manager. The output browser window has its own set of menus that allow you to print or save the output, or export it to another format. The Edit menu only contains the Copy option. The output browser of the Extension Output node has two tabs:

- The Text Output tab displays text output
- The Graph Output tab displays graphs and charts

If Output to file is selected on the Output tab of the Extension Output node dialog box instead of Output to screen, the output browser window is not displayed upon successful execution of the Extension Output node.

- [Extension Output Browser - Text Output tab](#)
- [Extension Output Browser - Graph Output tab](#)

Extension Output Browser - Text Output tab

The Text Output tab displays any text output that is generated when the R script or Python for Spark script on the Syntax tab of the Extension Output node is executed.

Note: R or Python for Spark error messages or warnings that result from executing your Extension Output script are always displayed on the Console Output tab of the Extension Output node.

Extension Output Browser - Graph Output tab

The Graph Output tab displays any graphs or charts that are generated when the R script or Python for Spark script on the Syntax tab of the Extension Output node is executed. For example, if your R script contains a call to the R `plot` function, the resulting graph is displayed on this tab.

Extension Model node

With the Extension Model node, you can run R or Python for Spark scripts to build and score models.

- [Extension Model node - Syntax tab](#)
- [Extension Model node - Model Options tab](#)
- [Extension Model node - Console Output tab](#)
- [Extension Model node - Text Output tab](#)

Extension Model node - Syntax tab

Select your type of syntax – R or Python for Spark. Then enter or paste your custom scripting syntax into one of the following fields. When your syntax is ready, you can click Run to execute the Extension Model node.

R syntax

R model building syntax. You can enter, or paste, custom R scripting syntax for model building into this field.

R model scoring syntax. You can enter, or paste, custom R scripting syntax for model scoring into this field.

Python for Spark syntax

Python model building syntax. You can enter, or paste, custom Python scripting syntax for model building into this field.

Python model scoring syntax. You can enter, or paste, custom Python scripting syntax for model scoring into this field.

For more information about Python for Spark, see [Python for Spark](#) and [Scripting with Python for Spark](#).

Extension Model node - Model Options tab

Model name. You can generate the model name automatically based on the target or ID field (or model type in cases where no such field is specified), or specify a custom name.

Extension Model node - Console Output tab

The Console Output tab contains any output that is received when the R script or Python for Spark script on the Syntax tab runs (for example, if using an R script, it shows output received from the R console when the R script in the R Syntax field on the Syntax tab is executed). This output might include R or Python error messages or warnings that are produced when the R or Python script is executed. The output can be used, primarily, to debug the script. The Console Output tab also contains the script from the R Syntax or Python Syntax field.

Every time the Extension Model script is executed, the content of the Console Output tab is overwritten with the output received from the R console or Python for Spark. The output cannot be edited.

Extension Model node - Text Output tab

The Text Output tab is present in the Extension Model node if requested by selecting the Display R text output check box on the Model Options tab of the Extension Model node dialog box. This tab can display only text output. Any text output that is produced by executing your R model building script is displayed on this tab. If you execute the model building script again, without having first specified a different name for the model, the content of the Text Output tab from the previous execution will be overwritten. The text output cannot be edited.

If you include a call to the R `sink` function in your script, any output that is produced after this function is saved to the specified file and is not displayed on the Text Output tab.

Note: R or Python for Spark error messages or warnings that result from executing your model building script are always displayed on the Console Output tab of the Extension Model node.

Extension model nugget

The Extension model nugget is generated and placed on the Models palette after executing the Extension Model node, which contains the R or Python for Spark script that defines the model building and model scoring. By default, the Extension model nugget contains the script that is used for model scoring, options for reading the data, and any output from the R console or Python for Spark. Optionally, the Extension model nugget can also contain various other forms of model output, such as graphs and text output. After the Extension model nugget is generated and added to the stream canvas, an output node can be connected to it. The output node is then used in the usual way within IBM® SPSS® Modeler streams for obtaining information about the data and models, and for exporting data in various formats.

To use this node with R, you must install IBM SPSS Modeler - Essentials for R. See the *IBM SPSS Modeler - Essentials for R: Installation Instructions* for installation instructions and compatibility information. You must also have a compatible version of R installed on your computer.

- [Extension model nugget - Syntax tab](#)
- [Extension model nugget - Model Options tab](#)
- [Extension model nugget - Graph Output tab](#)
- [Extension model nugget - Text Output tab](#)
- [Extension model nugget - Console Output tab](#)

Extension model nugget - Syntax tab

The Syntax tab is always present in the Extension model nugget.

R model scoring syntax. If using R, the R script that is used for model scoring is displayed in this field. By default, this field is enabled but not editable. To edit the R model scoring script, click Edit.

Python model scoring syntax. If using Python for Spark, the Python script that is used for model scoring is displayed in this field. By default, this field is enabled but not editable. To edit the Python model scoring script, click Edit.

Edit. Click Edit to make the scoring syntax field editable. You can then edit your model scoring script by typing in the scoring syntax field. For example, you might want to edit your model scoring script if you identify an error in your model scoring script after you have executed the Extension model nugget. Any changes that you make to the model scoring script in the Extension model nugget will be lost if you regenerate the model by executing the Extension Model node.

Extension model nugget - Model Options tab

The Model Options tab is always present in the Extension model nugget.

Read Data Options. These options only apply to R, not Python for Spark. With these options, you can specify how missing values, flag fields, and variables with date or datetime formats are handled.

- Read data in batches. If you are processing a large amount of data (that is too big to fit into the R engine's memory, for example), use this option to break the data down into batches that can be sent and processed individually. Specify the maximum number of data records to be included in each batch.

For both the Extension Transform node and the Extension Scoring nugget, data passes through the R script (in batch). For this reason, scripts for model scoring and process nodes that are run in either a Hadoop or Database environment should not include operations that span or combine rows in the data, such as sorting or aggregation. This limitation is imposed to ensure that data can be split up in a Hadoop environment, and during in-database mining. This limitation does not apply if the scripts for model scoring are run in SPSS® Modeler Server. Extension Output and Extension Model nodes do not have this limitation.

- Convert flag fields. Specifies how flag fields are treated. There are two options: Strings to factor, Integers and Reals to double, and Logical values (True, False). If you select Logical values (True, False) the original values of the flag fields are lost. For example, if a field has values Male and Female, these are changed to True and False.
- Convert missing values to the R 'not available' value (NA). When selected, any missing values are converted to the R NA value. The value NA is used by R to identify missing values. Some R functions that you use might have an argument that can be used to control how the function behaves when the data contain NA. For example, the function might allow you to choose to automatically exclude records that contain NA. If this option is not selected, any missing values are passed to R unchanged, and might cause errors when your R script is executed.
- Convert date/time fields to R classes with special control for time zones When selected, variables with date or datetime formats are converted to R date/time objects. You must select one of the following options:
 - **R POSIXct**. Variables with date or datetime formats are converted to R POSIXct objects.
 - **R POSIXlt (list)**. Variables with date or datetime formats are converted to R POSIXlt objects.

Note: The POSIX formats are advanced options. Use these options only if your R script specifies that datetime fields are treated in ways that require these formats. The POSIX formats do not apply to variables with time formats.

The options that are selected for the Convert flag fields, Convert missing values to the R 'not available' value (NA), and Convert date/time fields to R classes with special control for time zones controls are not recognized when the Extension model nugget is run against a database. When the node is run against a database, the default values for these controls are used instead:

- Convert flag fields is set to Strings to factor, Integers and Reals to double.
- Convert missing values to the R 'not available' value (NA) is selected.
- Convert date/time fields to R classes with special control for time zones is not selected.

Extension model nugget - Graph Output tab

The Graph Output tab is present in the Extension model nugget if requested by selecting the Display R graphs as HTML check box on the Model Options tab of the Extension Model node dialog box. Graphs that result from executing the model building R script can be displayed on this tab. For example, if your R script contains a call to the R `plot` function, the resulting graph is displayed on this tab. If you execute the model building script again, without having first specified a different name for the model, the content of the Graph Output tab from the previous execution will be overwritten.

Extension model nugget - Text Output tab

The Text Output tab is present in the Extension model nugget if requested by selecting the Display R text output check box on the Model Options tab of the Extension Model node dialog box. This tab can display only text output. Any text output that is produced by executing your Extension Model script is displayed on this tab. If you execute the Extension Model script again, without having first specified a different name for the model, the content of the Text Output tab from the previous execution will be overwritten. The text output cannot be edited.

Note:

- If you include a call to the R `sink` function in your script, any output that is produced after this function is saved to the specified file and is not displayed on the Text Output tab.
- Error messages or warnings that result from executing your Extension Model script are always displayed on the Console Output tab of the Extension Model node.

Extension model nugget - Console Output tab

The Console Output tab is always present in the Extension model nugget. It contains any output that is received when the R script or Python for Spark script on the Syntax tab runs (for example, if using an R script, it shows output received from the R console when the R script in the R model scoring syntax field on the Syntax tab of the Extension model nugget is executed). This output includes any R or Python error messages or warnings that are produced when the R or Python script is executed, and any text output from the R console. The output can be used, primarily, to debug the script.

Every time the model scoring script is executed, the content of the Console Output tab is overwritten with the output received from the R console or Python for Spark. The console output cannot be edited.

Extension Transform node

With the Extension Transform node, you can take data from an IBM® SPSS® Modeler stream and apply transformations to the data using R scripting or Python for Spark scripting. When the data has been modified, it is returned to the stream for further processing, model building and model scoring. The Extension Transform node makes it possible to transform data using algorithms that are written in R or Python for Spark, and enables the user to develop data transformation methods that are tailored to a particular problem.

To use this node with R, you must install IBM SPSS Modeler - Essentials for R. See the *IBM SPSS Modeler - Essentials for R: Installation Instructions* for installation instructions and compatibility information. You must also have a compatible version of R installed on your computer.

- [Extension Transform node - Syntax tab](#)
- [Extension Transform node - Console Output tab](#)

Extension Transform node - Syntax tab

Select your type of syntax – R or Python for Spark. See the following sections for more information. When your syntax is ready, you can click Run to execute the Extension Transform node.

R Syntax

R Syntax. You can enter, or paste, custom R scripting syntax for data analysis into this field.

Convert flag fields. Specifies how flag fields are treated. There are two options: Strings to factor, Integers and Reals to double, and Logical values (True, False). If you select Logical values (True, False) the original values of the flag fields are lost. For example, if a field has values Male and Female, these are changed to True and False.

Convert missing values to the R 'not available' value (NA). When selected, any missing values are converted to the R NA value. The value NA is used by R to identify missing values. Some R functions that you use might have an argument that can be used to control how the function behaves when the data contain NA. For example, the function might allow you to choose to automatically exclude records that contain NA. If this option is not selected, any missing values are passed to R unchanged, and might cause errors when your R script is executed.

Convert date/time fields to R classes with special control for time zones. When selected, variables with date or datetime formats are converted to R date/time objects. You must select one of the following options:

- **R POSIXct.** Variables with date or datetime formats are converted to R POSIXct objects.
- **R POSIXlt (list).** Variables with date or datetime formats are converted to R POSIXlt objects.

Note: The POSIX formats are advanced options. Use these options only if your R script specifies that datetime fields are treated in ways that require these formats. The POSIX formats do not apply to variables with time formats.

Python Syntax

Python Syntax. You can enter, or paste, custom Python scripting syntax for data analysis into this field. For more information about Python for Spark, see [Python for Spark](#) and [Scripting with Python for Spark](#).

Extension Transform node - Console Output tab

The Console Output tab contains any output that is received when the R script or Python for Spark script on the Syntax tab runs (for example, if using an R script, it shows output received from the R console when the R script in the R Syntax field on the Syntax tab is executed). This output might include R or Python error messages or warnings that are produced when the R or Python script is executed. The output can be used, primarily, to debug the script. The Console Output tab also contains the script from the R Syntax or Python Syntax field.

Every time the Extension Transform script is executed, the content of the Console Output tab is overwritten with the output received from the R console or Python for Spark. The output cannot be edited.

Extension Import node

With the Extension Import node, you can run R or Python for Spark scripts to import data.

- [Extension Import node - Syntax tab](#)
- [Extension Import node - Console Output tab](#)
- [Filtering or renaming fields](#)
- [Viewing and setting information about types](#)

Extension Import node - Syntax tab

Select your type of syntax – R or Python for Spark. Then enter or paste your custom script for importing data. When your syntax is ready, you can click Run to execute the Extension Import node.

R example

```
# import R demo data cars to modeler
modelerData <- cars

# write the data model that matches the data
var1<-c(fieldName="speed",fieldLabel="",fieldStorage="integer",fieldMeasure="",fieldFormat="", fieldRole="")
var2<-c(fieldName="dist",fieldLabel="",fieldStorage="integer",fieldMeasure="",fieldFormat="", fieldRole="")
modelerDataModel<-data.frame(var1, var2)
```

Python for Spark example

```
import spss.pyspark.runtime
from pyspark.sql import SQLContext
from pyspark.sql.types import *

ctx = spss.pyspark.runtime.getContext()
if ctx.isComputeDataModelOnly():
    _schema = StructType([StructField("Age", LongType(), nullable=True), \
                          StructField("Sex", StringType(), nullable=True), \
                          StructField("BP", StringType(), nullable=True), \
                          StructField("Cholesterol", StringType(), nullable=True), \
                          StructField("Na", DoubleType(), nullable=True), \
                          StructField("K", DoubleType(), nullable=True), \
                          StructField("Drug", StringType(), nullable=True)])
    ctx.setSparkOutputSchema(_schema)
else:
    sqlContext = ctx.getSparkSQLContext()
    # the demo data is in modeler installation path
    df = sqlContext.read.option("inferSchema", "true").option("header", "true").csv("/opt/IBM/SPSS/ModelerServer/Cloud/demos/DRUG1n")
    ctx.setSparkOutputData(df)
    df.show()
    # print (df.dtypes[:])
```

Extension Import node - Console Output tab

The Console Output tab contains any output that is received when the R script or Python for Spark script on the Syntax tab runs (for example, if using an R script, it shows output received from the R console when the R script in the R Syntax field on the Syntax tab is executed). This output might include R or Python error messages or warnings that are produced when the R or Python script is executed. The output can be used, primarily, to debug the script. The Console Output tab also contains the script from the R Syntax or Python Syntax field.

Every time the Extension Import script is executed, the content of the Console Output tab is overwritten with the output received from the R console or Python for Spark. The output cannot be edited.

Filtering or renaming fields

You can rename or exclude fields at any point in a stream. For example, as a medical researcher, you may not be concerned about the potassium level (field-level data) of patients (record-level data); therefore, you can filter out the `K` (potassium) field. This can be done using a separate Filter node or using the Filter tab on a source or output node. The functionality is the same regardless of which node it is accessed from.

- From source nodes, such as Variable File, Fixed File, Statistics File, XML, or Extension Import, you can rename or filter fields as the data are read into IBM® SPSS® Modeler.
- Using a Filter node, you can rename or filter fields at any point in the stream.

- From Statistics Export, Statistics Transform, Statistics Model, and Statistics Output nodes, you can filter or rename fields to conform to IBM SPSS Statistics naming standards. See the topic [Renaming or Filtering Fields for](#) more information.
 - You can use the Filter tab in any of the above nodes to define or edit multiple response sets. See the topic [Editing Multiple Response Sets](#) for more information.
 - Finally, you can use a Filter node to map fields from one source node to another.
-

Viewing and setting information about types

From various source nodes as well as the Type node, you can specify field metadata and properties that are invaluable to modeling and other work in IBM® SPSS® Modeler. These properties include:

- Specifying a usage type, such as range, set, ordered set, or flag, for each field in your dataset.
- Setting options for handling missing values and system nulls.
- Setting the role of a field for modeling purposes.
- Specifying values for a field as well as options used to automatically read values from the dataset.
- Specifying field and value labels.

Select help specific to your situation from the list below.

Extensions

Extensions are custom components that extend the capabilities of IBM® SPSS® Modeler. Extensions are packaged in extension bundles (.mpe files) and are installed to IBM SPSS Modeler. Extensions can be created by any user and shared with other users by sharing the associated extension bundle.

The following utilities are provided for working with extensions:

- The [Extension Hub](#), which is accessed from Extensions > Extension Hub, is an interface for searching for, downloading, and installing extensions from the IBM SPSS Predictive Analytics collection on GitHub. From the Extension Hub dialog, you can also view details of the extensions that are installed on your computer, get updates for installed extensions, and remove extensions.
 - You can install an extension bundle that is stored on your local computer from Extensions > Install Local Extension Bundle.
 - You can use the [Custom Dialog Builder for Extensions](#) to create an extension that includes a user interface, which is referred to as a custom node dialog. Custom node dialogs generate R script or Python for Spark script that carries out the tasks that are associated with the extension. You design the generated script as part of designing the custom dialog.
- [Extension Hub](#)**
• [Installing local extension bundles](#)
• [Creating and managing custom nodes](#)
-

Extension Hub

From the Extension Hub dialog, you can do the following tasks:

- Explore extensions that are available from the IBM® SPSS® Predictive Analytics collection on GitHub. You can select extensions to install now or you can download selected extensions and install them later.
- Get updated versions of extensions that are already installed on your computer.
- View details about the extensions that are already installed on your computer.
- Remove extensions that are installed on your computer.

To download or remove extensions:

1. From the menus, choose: Extensions > Extension Hub
2. Select the extensions that you want to download or remove and click OK. All selections that are made on the Explore and Installed tabs are processed when you click OK.

By default, the extensions that are selected for download are downloaded and installed on your computer. From the Settings tab, you can choose to download the selected extensions to a specified location without installing them. You can then install them later by choosing Extensions > Install Local Extension Bundle. For Windows, you can install an extension by double-clicking the extension bundle file.

Important:

- For Windows 7 and later, installing an updated version of an existing extension bundle might require running IBM SPSS Modeler with administrator privileges. You can start IBM SPSS Modeler with administrator privileges by right-clicking the icon for IBM SPSS Modeler and

choosing Run as administrator. In particular, if you receive an error message that states that one or more extension bundles could not be installed, then try running with administrator privileges.

- If connecting to the Internet via a proxy, you may receive an error like "Some features are not available because no Internet connection was detected" when you try to open the Extension Hub via the Extensions > Extension Hub menu option. To resolve this, you add the following parameters to the #
JVM options in the jvm.cfg file (located in the config directory of your SPSS Modeler installation). Save the file and restart SPSS Modeler.

```
options, "-DproxyHost=proxyIP"  
options, " -DproxyPort=proxyPort"
```

Note: The license that you agree to when you install an extension can be viewed at any later time by clicking More info... for the extension on the Installed tab.

- [Explore tab \(Extension Hub\)](#)
- [Installed tab \(Extension Hub\)](#)
- [Settings \(Extension Hub\)](#)
- [Extension Details](#)

Explore tab (Extension Hub)

The Explore tab displays all of the extensions that are available from the IBM® SPSS® Predictive Analytics collection on GitHub (<https://ibmpredictiveanalytics.github.io/>). From the Explore tab, you can select new extensions to download and install, and you can select updates for extensions that are already installed on your computer. The Explore tab requires an internet connection.

- For each extension, the number of the latest version and the associated date of that version are displayed. A brief summary of the extension is also provided. For extensions that are already installed on your computer, the installed version number is also displayed.
- You can view detailed information about an extension by clicking More info. When an update is available, More info displays information about the update.
- You can view the prerequisites for running an extension, such as whether the IBM SPSS Modeler - Integration Plug-in for R is required, by clicking Prerequisites. When an update is available, Prerequisites displays information about the update.

Refine by

You can refine the set of extensions that are displayed. You can refine by general categories of extensions, the language in which the extension is implemented, the type of organization that provided the extension, or the state of the extension. For each group, such as Category, you can select multiple items by which to refine the displayed list of extensions. You can also refine by search terms. Searches are not case-sensitive, and the asterisk (*) is treated as any other character and does not indicate a wildcard search.

- To refine the displayed list of extensions, click Apply. Pressing the enter key when the cursor is in the Search box has the same effect as clicking Apply.
- To reset the list to display all available extensions, delete any text in the Search box, deselect all items, and click Apply.
- [How to get integration plug-ins](#)

How to get integration plug-ins

To get the IBM® SPSS® Modeler - Integration Plug-in for R:

Install IBM SPSS Modeler - Essentials for R, available from https://github.com/IBMPredictiveAnalytics/R_Essentials_Modeler/releases/ or the IBM SPSS Statistics community at <https://www.ibm.com/products/spss-statistics/support>. IBM SPSS Modeler - Essentials for R includes the IBM SPSS Modeler - Integration Plug-in for R. Essentials for R does not include the R programming language. Before installing IBM SPSS Modeler - Essentials for R you will need to install R version 4.0 if it is not already installed. It is available from <https://cran.r-project.org/>. It is recommended to download and install R 4.0.x.

Note: If you are installing Essentials for R on a computer that does not have internet access and you plan to use the R scripts that are included with Essentials for R, then you must obtain any R packages that are required by those scripts and manually install them in R. To determine which R packages are required for a specific R script, open the Extension Hub dialog (Extensions > Extension Hub), click the Installed tab, and then click More info for the desired extension. The required R packages are listed on the Extension Details dialog. R packages can be obtained from any of the R CRAN mirror sites, which are accessed from <http://www.r-project.org/>. Be sure to obtain the versions of the packages that match your R version. The version-specific packages are available from links on the "Contributed Packages" page of the CRAN mirror site.

Installed tab (Extension Hub)

The Installed tab displays all of the extensions that are installed on your computer. From the Installed tab, you can select updates for installed extensions that are available from the IBM® SPSS® Predictive Analytics collection on GitHub and you can remove extensions. To get updates for installed extensions, you must have an internet connection.

- For each extension, the installed version number is displayed. When an internet connection is available, the number of the latest version and the associated date of that version are displayed. A brief summary of the extension is also provided.
- You can view detailed information about an extension by clicking More info. When an update is available, More info displays information about the update.
- You can view the prerequisites for running an extension, such as whether the IBM SPSS Modeler - Integration Plug-in for R is required, by clicking Prerequisites. When an update is available, Prerequisites displays information about the update.

Refine by

You can refine the set of extensions that are displayed. You can refine by general categories of extensions, the language in which the extension is implemented, the type of organization that provided the extension, or the state of the extension. For each group, such as Category, you can select multiple items by which to refine the displayed list of extensions. You can also refine by search terms. Searches are not case-sensitive, and the asterisk (*) is treated as any other character and does not indicate a wildcard search.

- To refine the displayed list of extensions, click Apply. Pressing the enter key when the cursor is in the Search box has the same effect as clicking Apply.
- To reset the list to display all available extensions, delete any text in the Search box, deselect all items, and click Apply.

Private extensions

Private extensions are extensions that are installed on your computer but are not available from the IBM SPSS Predictive Analytics collection on GitHub. The features for refining the set of displayed extensions and for viewing the prerequisites to run an extension are not available for private extensions.

Note: When using the Extension Hub without an internet connection, some of the features of the Installed tab might not be available.

Related information

- [Extension Details](#)

Settings (Extension Hub)

The Settings tab specifies whether extensions that are selected for download are downloaded and then installed or downloaded but not installed. This setting applies to new extensions and updates to existing extensions. You might choose to download extensions without installing them if you are downloading extensions to distribute to other users within your organization. You might also choose to download, but not install, extensions if you don't have the prerequisites for running the extensions but plan to get the prerequisites.

If you choose to download extensions without installing them, you can install them later by choosing Extensions...>Install Local Extension Bundle. For Windows, you can install an extension by double-clicking the extension bundle file.

Extension Details

The Extension Details dialog box displays the information that was provided by the author of the extension. In addition to required information, such as Summary, and Version, the author might have included URLs to locations of relevance, such as the author's home page. If the extension was downloaded from the Extension Hub, then it includes a license that can be viewed by clicking View license.

Custom Nodes. The Custom Nodes table lists the custom node dialogs that are included in the extension.

Note: Installing an extension that contains a custom node dialog might require a restart of IBM® SPSS® Modeler to see the entry for the node dialog in the Custom Nodes table.

Dependencies. The Dependencies group lists add-ons that are required to run the components included in the extension.

- Integration Plug-In for R. The components for an extension may require the Integration Plug-in for R.
- R packages. Lists any R packages that are required by the extension. See the topic [Required R packages](#) for more information.

How To Access the Details for an Installed Extension

1. From the menus, choose:
Extensions...>Extension Hub

2. Click the Installed tab on the Extension Hub dialog.
3. Click More info for the desired extension.

Related information

- [Creating and editing extension bundles](#)
 - [Installing local extension bundles](#)
-

Installing local extension bundles

To install an extension bundle that is stored on your local computer:

1. From the menus choose:
Extensions > Install Local Extension Bundle...
2. Select the extension bundle. Extension bundles have a file type of mpe.

Important: For users of Windows 7 and later versions of Windows, installing an updated version of an existing extension bundle might require running IBM® SPSS® Modeler with administrator privileges. You can start IBM SPSS Modeler with administrator privileges by right-clicking the icon for IBM SPSS Modeler and choosing Run as administrator. In particular, if you receive an error message that states that one or more extension bundles could not be installed, then try running with administrator privileges.

- [Installation locations for extensions](#)
- [Required R packages](#)

Related information

- [Extension Details](#)
-

Installation locations for extensions

By default, extensions are installed to a general user-writable location for your operating system.

You can override the default location by defining a path with the IBM_SPSS_MODELER_EXTENSION_PATH environment variable. The specified location must exist on the target computer. After you set IBM_SPSS_MODELER_EXTENSION_PATH, you must restart IBM® SPSS® Modeler for the changes to take effect.

To create an environment variable on Windows, from the Control Panel:

Windows 7

1. Select User Accounts.
2. Select Change my environment variables.
3. Click New, enter the name of the environment variable (for instance, IBM_SPSS_MODELER_EXTENSION_PATH) in the Variable name field and enter the path or paths in the Variable value field.

Windows 8 or Later

1. Select System.
2. Select the Advanced tab and click Environment Variables. The Advanced tab is accessed from Advanced system settings.
3. In the User variables section, click New, enter the name of the environment variable (for instance, IBM_SPSS_MODELER_EXTENSION_PATH) in the Variable name field and enter the path or paths in the Variable value field.

Important: For users of Windows 7 and later versions of Windows, installing an updated version of an existing extension bundle might require running IBM SPSS Modeler with administrator privileges. You can start IBM SPSS Modeler with administrator privileges by right-clicking the icon for IBM SPSS Modeler and choosing Run as administrator. In particular, if you receive an error message that states that one or more extension bundles could not be installed, then try running with administrator privileges.

Running streams in batch mode that contain extensions

To use Custom Dialog Builder extensions with Modeler Batch:

1. In Modeler Client, use Custom Dialog Builder to create and install your custom node. The extension node files will be in the following directory, by default:
 - Windows: C:\ProgramData\IBM\SPSS\Modeler\<version>\CDB\
 - Mac: /Users/yourname/Library/Application Support/IBM/SPSS\Modeler/<version>/CDB/
2. Copy the CDB directory to the Modeler Batch machine.
3. Export the environment variable **IBM_SPSS_MODELER_EXTENSION_PATH** to the new directory. You can now run the stream in batch mode.

Required R packages

If you do not have internet access, you will need to obtain any required R packages for a particular extension, that are not found on your computer, from someone who does. You can view the list of required R packages from the Extension Details dialog box, once the extension is installed. See the topic [Extension Details](#) for more information. Packages can be downloaded from <http://www.r-project.org/> and then installed from within R. For details, see the *R Installation and Administration* guide, distributed with R.

Note: For UNIX (including Linux) users, packages are downloaded in source form and then compiled. This requires that you have the appropriate tools installed on your machine. See the *R Installation and Administration* guide for details. In particular, Debian users should install the `r-base-dev` package from `apt-get install r-base-dev`.

Creating and managing custom nodes

The Custom Dialog Builder for Extensions creates nodes to use inside SPSS® Modeler streams.

Using the Custom Dialog Builder for Extensions you can:

- Create a custom node dialog for executing a node that is implemented in R, or in Apache Spark (via Python). See [Building the script template](#) for more information.
- Open a file containing the specification for a custom node dialog--perhaps created by another user--and add the dialog to your installation of IBM® SPSS Modeler, optionally making your own modifications.
- Save the specification for a custom node dialog so that other users can add it to their installations of IBM SPSS Modeler.
- Create custom nodes and write Python for Spark scripts to read data from wherever your data source is, and write data out to any data format supported by Apache Spark. See [Importing and exporting data using Python for Spark](#) for more information.
- Create custom nodes and write R scripts to read data from wherever your data source is, and write data out to any data format supported by R. See [Importing and exporting data using R](#) for more information.

In the Custom Dialog Builder for Extensions, you create or modify custom node dialogs within extensions. When you open the Custom Dialog Builder for Extensions, a new extension that contains an empty custom node dialog is created. When you save or install custom node dialogs from the Custom Dialog Builder for Extensions, they are saved or installed as part of an extension.

Note:

- You cannot create your own version of a node dialog for a standard IBM SPSS Modeler node.
- Scripting is not supported for nodes that are created with Custom Dialog Builder, including Custom Dialog Builder R nodes and Custom Dialog Builder Python nodes.

How to start the Custom Dialog Builder for Extensions

From the menus, choose **Extensions > Custom Node Dialog Builder**

Note:

- Python nodes depend on the Spark environment.
- Python scripts must use the Spark API because data will be presented in the form of a Spark DataFrame.
- Old nodes created in version 17.1 will still only run against IBM SPSS Analytic Server (the data originates from an IBM SPSS Analytic Server source node and has not been extracted to IBM SPSS Modeler Server). New Python and Custom Dialog Builder nodes created in version 18.0 or later can run against IBM SPSS Modeler Server.
- When installing Python, make sure all users have permission to access the Python installation.
- If you want to use the Machine Learning Library (MLlib), you must install a version of Python that includes NumPy. Then you must configure the IBM SPSS Modeler Server (or the local server in IBM SPSS Modeler Client) to use your Python installation. For details, see [Scripting with Python for Spark](#).

Custom Dialog Builder layout

Dialog Canvas

The dialog canvas is the area of the Custom Dialog Builder where you design the layout of your node dialog.

Properties Pane

The properties pane is the area of the Custom Dialog Builder where you specify properties of the controls that make up the node dialog as well as properties of the dialog itself, such as the node type.

Tools Palette

The tools palette provides the set of controls that can be included in a custom node dialog. You can show or hide the Tools Palette by choosing Tools Palette from the View menu.

Script Template

The Script Template specifies the R script or Python for Spark script that is generated by the custom node dialog. You can move the Script Template pane to a separate window by clicking Move to New Window. To move a separate Script Template window back into the Custom Dialog Builder, click Restore to Main Window.

Building a custom node dialog

The basic steps involved in building a custom node dialog are:

1. Specify the properties of the node dialog itself, such as the title that appears when the node dialog is launched and the location of the new node within the IBM® SPSS® Modeler palettes. See the topic [Dialog Properties](#) for more information.
2. Specify the controls, such as field choosers and check boxes, that make up the node dialog and any sub-dialogs. See the topic [Control types](#) for more information.
3. Create the script template that specifies the R code or Python for Spark code that is generated by the node dialog. See the topic [Building the script template](#) for more information.
4. Specify properties of the extension that contains your node dialog. See the topic [Extension Properties](#) for more information.
5. Install the extension that contains the node dialog to IBM SPSS Modeler and/or save the extension to an extension bundle (.mpe) file. See the topic [Managing custom node dialogs](#) for more information.

You can preview your node dialog as you're building it. See the topic [Previewing a custom node dialog](#) for more information.

Dialog Properties

The Custom Dialog Builder window shows the properties for the node dialog and for the selected user interface control. To view and set Dialog Properties, click on the canvas in an area outside of any controls. With no controls on the canvas, Dialog Properties are always visible.

Dialog Name. The Dialog Name property is required and specifies a unique name to associate with the node dialog. To minimize the possibility of name conflicts, you may want to prefix the name with an identifier for your organization, such as a URL.

Title. The Title property specifies the text to be displayed in the title bar of the node dialog box.

Help File. The Help File property is optional and specifies the path to a help file for the node dialog. This is the file that will be launched when the user clicks the Help button on the dialog. Help files must be in HTML format. A copy of the specified help file is included with the specifications for the node dialog when the node dialog is installed or saved. The Help button on the run-time dialog is hidden if there is no associated help file.

- Localized versions of the help file that exist in the same directory as the help file are automatically added to the node dialog when you add the help file. Localized versions of the help file are named <Help File>_<language identifier>.htm. For more information, see the topic [Creating Localized Versions of Custom Node Dialogs](#).
- Supporting files, such as image files and style sheets, can be added to the node dialog by first saving the node dialog. You then manually add the supporting files to the node dialog file (.cfe). For information about accessing and manually modifying custom node dialog files, see the section that is titled "To localize dialog strings" in the topic [Creating Localized Versions of Custom Node Dialogs](#).

Script Type. Specifies the type of script that can be used to build the Script Template. In IBM® SPSS® Modeler, R scripting or Python for Spark scripting can be used.

Score from the Model. Specifies whether the model that is built using the model building script is to be used for scoring.

Node Type. Specifies the type of node that will be created when you install your node dialog.

Palette. Specifies the palette to which the newly created node will be added when you install your node dialog.

Node Icon. Click the ellipsis (...) button to select an image to be used as the node icon for the newly created node. The image that you choose must be a .gif file.

Laying out controls on the dialog canvas

You add controls to a custom node dialog by dragging them from the tools palette onto the dialog canvas. To ensure consistency with built-in node dialogs, the dialog canvas is divided into four functional columns in which you can place controls.

- The first (leftmost) column is primarily intended for a Field Chooser control.
- Sub-dialog buttons must be in the rightmost column (for example, the third column if only three columns are used) and no other controls can be in the same column as Sub-dialog buttons. In that regard, the fourth column can contain only Sub-dialog buttons.

Although not shown on the dialog canvas, when the node dialog is installed into IBM® SPSS® Modeler, the appropriate buttons are added to the dialog (for example: OK, Cancel, Apply, Reset and, if appropriate, Help and Run). The presence and locations of these buttons is automatic. However, the Help button is hidden if there is no help file associated with the node dialog (as specified by the Help File property in Dialog Properties).

You can change the vertical order of the controls within a column by dragging them up or down, but the exact position of the controls is determined automatically for you. At run-time, controls resize in appropriate ways when the dialog itself is resized. Controls such as field choosers automatically expand to fill the available space below them.

Building the script template

The script template specifies the R script or Python for Spark script that the custom node dialog will generate. A single custom node dialog can be used to specify one or more operations which will run in sequence.

The script template might consist of *static text*. Static text is different to the static text control; it is R code or Python for Spark code that is always generated when the node runs. For example, command names and subcommand specifications that don't depend on user input are static text. The script template might also consist of control identifiers that are replaced at run-time with the values of the associated custom node dialog controls. For example, the set of fields specified in a field chooser is represented with the control identifier for the field chooser control.

To build the Script Template

1. For static text that does not depend on user-specified values, enter the R script or Python for Spark script as you would in, for example, the R model building syntax field of the R Build node.
2. Add control identifiers of the form `%%Identifier%%` at the locations where you want to insert R script or Python for Spark script generated by controls, where `Identifier` is the value of the Identifier property for the control.
 - You can insert a control identifier by selecting a row in the table of identifiers, right-clicking and selecting Add to script template.
 - You can also insert a control identifier by right-clicking a control on the canvas and selecting Add to script template.
 - You can also select from a list of available control identifiers by pressing **Ctrl+Spacebar**. The list contains the control identifiers followed by the items available with the script auto-completion feature.

If you manually enter identifiers, retain any spaces, since all spaces in identifiers are significant.

At run-time, and for all controls other than check boxes, check box groups, and the static text control, each identifier is replaced with the current value of the Script property of the associated control. If the control is empty at run-time, it does not generate any script. For check boxes and check box groups, the identifier is replaced by the current value of the Checked R Script or Unchecked R Script property of the associated control, depending on the current state of the control--checked or unchecked. See the topic [Control types](#) for more information.

Example: Including run-time values in an R script template

In this example, the custom node dialog will generate and run R script to build and score a linear regression model, using a call to the R `lm` function with the signature shown here.

```
lm(formula, data)
```

- `formula` specifies an expression, such as `Na~Age`, where `Na` is the target field of the model, and the input field of the model is `Age`.
- `data` is a data frame containing the values of the fields that are specified in the formula.

Consider a custom node dialog with a single field chooser control that allows the user to choose the input field of the linear model. The script template to generate and run the R script that builds the model is entered on the Script tab, and might look like this:

```
modelerModel <- lm(Na~%%input%%, data=modelerData)
```

- `%%input%%` is the value of the Identifier property for the field chooser control. At run-time it will be replaced by the current value of the Script property of the control.

- Defining the Script property of the field chooser control to be `%%ThisValue%%` specifies that at run-time the current value of the property will be the value of the control, which is the field that is chosen from the field chooser.

Suppose the user of the custom node dialog selects the Age field as the input field of the model. The following R script is then generated by the node dialog:

```
modelerModel <- lm(Na~Age,data=modelerData)
```

The script template to generate and run the R script that scores the model is entered on the Score Script tab, and might look like this:

```
result <- predict(modelerModel,newdata=modelerData)
var1 <-c(fieldName="predicted", fieldLabel="",fieldStorage="real",fieldMeasure="",fieldFormat="",
fieldRole="")
modelerDataModel<-data.frame(modelerDataModel,var1)
```

This R script does not depend on any user-specified values, only on the model that is built using the model building R script. Therefore, the model scoring R script is entered as it would be in the R model scoring syntax field of the R Build node.

Previewing a custom node dialog

You can preview the node dialog that is currently open in the Custom Dialog Builder. The dialog appears and functions as it would when run from a node within IBM® SPSS® Modeler.

- Field choosers are populated with dummy fields.
- The OK button closes the preview.
- If a help file is specified, the Help button is enabled and will open the specified file. If no help file is specified, the help button is disabled when previewing, and hidden when the actual dialog is run.

To preview a custom node dialog, from the menus in the Custom Dialog Builder, choose File> Preview Dialog.

Control types

The tools palette provides all of the standard controls that might be needed in a custom node dialog.

- Field Chooser: A list of all the fields from the active dataset. See the topic [Field Chooser](#) for more information.
- Check Box: A single check box. See the topic [Check Box](#) for more information.
- Combo Box: A combo box for creating drop-down lists. See the topic [Combo Box](#) for more information.
- List Box: A list box for creating single selection or multiple selection lists. See the topic [Combo Box](#) for more information.
- Text control: A text box that accepts arbitrary text as input. See the topic [Text control](#) for more information.

- Number control: A text box that is restricted to numeric values as input. See the topic [Number Control](#) for more information.
 - Date control: A spinner control for specifying date/time values, which include dates, times, and datetimes. See the topic [Date control](#) for more information.
 - Secured Text: A text box that masks user entry with asterisks. See the topic [Secured Text](#) for more information.
 - Static Text control: A control for displaying static text. See the topic [Static Text Control](#) for more information.
 - Color Picker: A control for specifying a color and generating the associated RGB value. See the topic [Color Picker](#) for more information.
 - Table control: A table with a fixed number of columns and a variable number of rows that are added at run time. See the topic [Table Control](#) for more information.
 - Item Group: A container for grouping a set of controls, such as a set of check boxes. See the topic [Item Group](#) for more information.
 - Radio Group: A group of radio buttons. See the topic [Radio Group](#) for more information.
 - Check Box Group: A container for a set of controls that are enabled or disabled as a group, by a single check box. See the topic [Check Box Group](#) for more information.
 - File Browser: A control for browsing the file system to open or save a file. See the topic [File Browser](#) for more information.
 - Tab: A single tab. See the topic [Tab](#) for more information.
 - Sub-dialog Button: A button for launching a sub-dialog. See the topic [Sub-dialog button](#) for more information.

Field Chooser

The Field Chooser control displays the list of fields that are available to the end user of the node dialog. You can display all fields from the active dataset (the default) or you can filter the list based on type and measurement level--for instance, numeric fields that have a measurement level of scale. You can also specify any other Field Chooser as the source of fields for the current Field Chooser. The Field Chooser control has the following properties:

Identifier. The unique identifier for the control.

Title. An optional title that appears above the control. For multi-line titles, use \n to specify line breaks.

Title Position. Specifies the position of the title relative to the control. Values are Top and Left where Top is the default. This property only applies when the chooser type is set to select a single field.

ToolTip. Optional ToolTip text that appears when the user hovers over the control. The specified text only appears when hovering over the title area of the control. Hovering over one of the listed fields displays the field name and label.

Mnemonic Key. An optional character in the title to use as a keyboard shortcut to the control. The character appears underlined in the title. The shortcut is activated by pressing Alt+[mnemonic key].

Chooser Type. Specifies whether the Field Chooser in the custom node dialog can be used to select a single field or multiple fields from the field list.

Separator Type. Specifies the delimiter between the selected fields in the generated script. The allowed separators are a blank, a comma, and a plus sign (+). You can also enter an arbitrary single character to be used as the separator.

Minimum Fields. The minimum number of fields that must be specified for the control, if any.

Maximum Fields. The maximum number of fields that can be specified for the control, if any.

Required for Execution. Specifies whether a value is required in this control in order for execution to proceed. If True is specified, the user of the node dialog must specify a value for the control otherwise clicking the OK button will generate an error. If False is specified, the absence of a

value in this control has no effect on the state of the OK button.

Variable Filter. Allows you to filter the set of fields that are displayed in the control. You can filter on field type and measurement level, and you can specify that multiple response sets are included in the field list. Click the ellipsis (...) button to open the Filter dialog. You can also open the Filter dialog by double-clicking the Field Chooser control on the canvas. See the topic [Filtering Field Lists](#) for more information.

Field Source. Specifies that another Field Chooser is the source of fields for the current Field Chooser. When the Field Source property is not set, the source of fields is the active dataset. Click the ellipsis (...) button to open the [Field Source](#) dialog box and specify the field source.

Script. Specifies the script that is generated and run by this control at run-time and can be inserted in the script template.

- You can specify any valid R script or Python for Spark script. For multi-line scripts or long scripts, click the ellipsis (...) button and enter your script in the Script Property dialog.
- The value `%%ThisValue%%` specifies the run-time value of the control, which is the list of fields. This is the default.

Enabling Rule. Specifies a rule that determines when the current control is enabled. Click the ellipsis (...) button to open the [Enabling Rule](#) dialog box and specify the rule. The Enabling Rule property is visible only when other controls that can be used to specify an enabling rule exist on the canvas.

Specifying the Field Source for a Field Chooser

The Field Source dialog box specifies the source of the fields that are displayed in the Field Chooser. The source can be any other Field Chooser. You can choose to display the fields that are in the selected control or the fields, from the active dataset, that are not in the selected control.

Filtering Field Lists

The Filter dialog box, associated with field chooser controls, allows you to filter the types of fields from the active dataset that can appear in the lists. You can also specify whether multiple response sets associated with the active dataset are included. Numeric fields include all numeric formats except date and time formats.

Check Box

The Check Box control is a simple check box that can generate and run different R scripts or Python for Spark scripts for the checked versus the unchecked state. The Check Box control has the following properties:

Identifier. The unique identifier for the control.

Title. An optional title that appears above the control. For multi-line titles, use \n to specify line breaks.

ToolTip. Optional ToolTip text that appears when the user hovers over the control.

Mnemonic Key. An optional character in the title to use as a keyboard shortcut to the control. The character appears underlined in the title. The shortcut is activated by pressing Alt+[mnemonic key].

Default Value. The default state of the check box--checked or unchecked.

Checked/Unchecked Script. Specifies the R script or Python for Spark script that is generated and run when the control is checked and when it is unchecked. To include the script in the script template, use the value of the Identifier property. The generated script, whether from the Checked Script or Unchecked Script property, will be inserted at the specified positions of the identifier. For example, if the identifier is *checkbox1*, then at run time, instances of %%checkbox1%% in the script template will be replaced by the value of the Checked Script property when the box is checked and the Unchecked Script property when the box is unchecked.

- You can specify any valid R script or Python for Spark script. For multi-line scripts or long scripts, click the ellipsis (...) button and enter your script in the Script Property dialog.

Enabling Rule. Specifies a rule that determines when the current control is enabled. Click the ellipsis (...) button to open the [Enabling Rule](#) dialog box and specify the rule. The Enabling Rule property is visible only when other controls that can be used to specify an enabling rule exist on the canvas.

-

Combo Box

The Combo Box control allows you to create a drop-down list that can generate and run R script or Python for Spark script specific to the selected list item. It is limited to single selection. The Combo Box control has the following properties:

Identifier. The unique identifier for the control. This is the identifier to use when referencing the control in the script template.

Title. An optional title that appears above the control. For multi-line titles, use \n to specify line breaks.

Title Position. Specifies the position of the title relative to the control. Values are Top and Left where Top is the default.

ToolTip. Optional ToolTip text that appears when the user hovers over the control.

List Items. Click the ellipsis (...) button to open the [List Item Properties](#) dialog box, which allows you to specify the list items of the control. You can also open the List Item Properties dialog by double-clicking the Combo Box control on the canvas.

Mnemonic Key. An optional character in the title to use as a keyboard shortcut to the control. The character appears underlined in the title. The shortcut is activated by pressing Alt+[mnemonic key].

Editable. Specifies whether the Combo Box control is editable. When the control is editable, a custom value can be entered at run time.

Script. Specifies the R script or Python for Spark script that is generated by this control at run time and can be inserted in the script template.

- The value %%**ThisValue**%% specifies the run time value of the control and is the default. If the list items are manually defined, the run time value is the value of the Script property for the selected list item. If the list items are based on a target list control, the run time value is the value of the selected list item. For multiple selection list box controls, the run time value is a blank-separated list of the selected items. See the topic [Specifying list items for combo boxes and list boxes](#) for more information.
- You can specify any valid R script or Python for Spark script. For multi-line scripts or long scripts, click the ellipsis (...) button and enter your script in the Script Property dialog.

Quote Handling. Specifies handling of quotation marks in the run time value of %%**ThisValue**%% when the Script property contains %%**ThisValue**%% as part of a quoted string. In this context, a quoted string is a string that is enclosed in single quotation marks or double quotation marks. Quote handling applies only to quotation marks that are the same type as the quotation marks that enclose %%**ThisValue**%%. The following types of quote handling are available.

Python

Quotation marks in the run time value of %%ThisValue%% that match the enclosing quotation marks are escaped with the backslash character (\). For example, if the Script property is '%%%ThisValue%%%' and the run time value of the combo box is **Combo box's value**, then the generated script is '**Combo box\'s value**'. Note that quote handling is not done when %%ThisValue%% is enclosed in triple quotation marks.

R

Quotation marks in the run time value of %%ThisValue%% that match the enclosing quotation marks are escaped with the backslash character (\). For example, if the Script property is '%%%ThisValue%%%' and the run time value of the combo box is **Combo box's value**, then the generated script is '**Combo box\'s value**'.

None

Quotation marks in the run time value of %%ThisValue%% that match the enclosing quotation marks are retained with no modification.

Enabling Rule. Specifies a rule that determines when the current control is enabled. Click the ellipsis (...) button to open the [Enabling Rule](#) dialog box and specify the rule. The Enabling Rule property is visible only when other controls that can be used to specify an enabling rule exist on the canvas.

Specifying list items for combo boxes and list boxes

The List Item Properties dialog box allows you to specify the list items of a combo box or list box control.

Manually defined values. Allows you to explicitly specify each of the list items.

- Identifier. A unique identifier for the list item.
- Name. The name that appears in the list for this item. The name is a required field.
- Default. For a combo box, specifies whether the list item is the default item displayed in the combo box. For a list box, specifies whether the list item is selected by default.
- Script. Specifies the R script or Python for Spark script that is generated when the list item is selected.
- You can specify any valid R script or Python for Spark script. For multi-line scripts or long scripts, click the ellipsis (...) button and enter your script in the Script Property dialog.

Note: You can add a new list item in the blank line at the bottom of the existing list. Entering any of the properties other than the identifier will generate a unique identifier, which you can keep or modify. You can delete a list item by clicking on the *Identifier* cell for the item and pressing delete.

List Box

The List Box control allows you to display a list of items that support single or multiple selection and generate R script or Python for Spark script specific to the selected items. The List Box control has the following properties:

Identifier. The unique identifier for the control. This is the identifier to use when referencing the control in the script template.

Title. An optional title that appears above the control. For multi-line titles, use \n to specify line breaks.

ToolTip. Optional ToolTip text that appears when the user hovers over the control.

List Items. Click the ellipsis (...) button to open the [List Item Properties](#) dialog box, which allows you to specify the list items of the control. You can also open the List Item Properties dialog by double-clicking the List Box control on the canvas.

Mnemonic Key. An optional character in the title to use as a keyboard shortcut to the control. The character appears underlined in the title. The shortcut is activated by pressing Alt+[mnemonic key].

List Box Type. Specifies whether the list box supports single selection only or multiple selection. You can also specify that items are displayed as a list of check boxes.

Separator Type. Specifies the delimiter between the selected list items in the generated script. The allowed separators are a blank, a comma, and a plus sign (+). You can also enter an arbitrary single character to be used as the separator.

Minimum Selected. The minimum number of items that must be selected in the control, if any.

Maximum Selected. The maximum number of items that can be selected in the control, if any.

Script. Specifies the R script or Python for Spark script that is generated by this control at run time and can be inserted in the script template.

- The value `%%ThisValue%%` specifies the run time value of the control and is the default. If the list items are manually defined, the run time value is the value of the Script property for the selected list item. If the list items are based on a target list control, the run time value is the value of the selected list item. For multiple selection list box controls, the run time value is a list of the selected items, delimited by

the specified Separator Type (default is blank separated). See the topic [Specifying list items for combo boxes and list boxes](#) for more information.

- You can specify any valid R script or Python for Spark script. For multi-line scripts or long scripts, click the ellipsis (...) button and enter your script in the Script Property dialog.

Quote Handling. Specifies handling of quotation marks in the run time value of `%%ThisValue%%` when the Script property contains `%%ThisValue%%` as part of a quoted string. In this context, a quoted string is a string that is enclosed in single quotation marks or double quotation marks. Quote handling applies only to quotation marks that are the same type as the quotation marks that enclose `%%ThisValue%%`. The following types of quote handling are available.

Python

Quotation marks in the run time value of `%%ThisValue%%` that match the enclosing quotation marks are escaped with the backslash character (\). For example, if the Script property is '`%%ThisValue%%`' and the selected list item is `List item's value`, then the generated script is '`List item\'s value`'. Note that quote handling is not done when `%%ThisValue%%` is enclosed in triple quotation marks.

R

Quotation marks in the run time value of `%%ThisValue%%` that match the enclosing quotation marks are escaped with the backslash character (\). For example, if the Script property is '`%%ThisValue%%`' and the selected list item is `List item's value`, then the generated script is '`List item\'s value`'.

None

Quotation marks in the run time value of `%%ThisValue%%` that match the enclosing quotation marks are retained with no modification.

Enabling Rule. Specifies a rule that determines when the current control is enabled. Click the ellipsis (...) button to open the [Enabling Rule](#) dialog box and specify the rule. The Enabling Rule property is visible only when other controls that can be used to specify an enabling rule exist on the canvas.

Text control

The Text control is a simple text box that can accept arbitrary input, and has the following properties:

Identifier. The unique identifier for the control. This is the identifier to use when referencing the control in the script template.

Title. An optional title that appears above the control. For multi-line titles, use `\n` to specify line breaks.

Title Position. Specifies the position of the title relative to the control. Values are Top and Left where Top is the default.

ToolTip. Optional ToolTip text that appears when the user hovers over the control.

Mnemonic Key. An optional character in the title to use as a keyboard shortcut to the control. The character appears underlined in the title. The shortcut is activated by pressing Alt+[mnemonic key].

Text Content. Specifies whether the contents are arbitrary or whether the text box must contain a string that adheres to rules for IBM® SPSS® Modeler field names.

Default Value. The default contents of the text box.

Width. Specifies the width of the text area of the control in characters. The allowed values are positive integers. An empty value means that the width is automatically determined.

Required for execution. Specifies whether a value is required in this control in order for execution to proceed. If True is specified, the user of the node dialog must specify a value for the control otherwise clicking the OK button will generate an error. If False is specified, the absence of a value in this control has no effect on the state of the OK button. The default is False.

Script. Specifies the R script or Python for Spark script that is generated and run by this control at run time and can be inserted in the script template.

- You can specify any valid R script or Python for Spark script. For multi-line scripts or long scripts, click the ellipsis (...) button and enter your script in the Script Property dialog.
- The value `%%ThisValue%%` specifies the run time value of the control, which is the content of the text box. This is the default.
- If the Script property includes `%%ThisValue%%` and the run time value of the text box is empty, then the text box control does not generate any script.

Quote Handling. Specifies handling of quotation marks in the run time value of `%%ThisValue%%` when the Script property contains `%%ThisValue%%` as part of a quoted string. In this context, a quoted string is a string that is enclosed in single quotation marks or double quotation marks. Quote handling applies only to quotation marks that are the same type as the quotation marks that enclose `%%ThisValue%%`. The following types of quote handling are available.

Python

Quotation marks in the run time value of `%%ThisValue%%` that match the enclosing quotation marks are escaped with the backslash character (\). For example, if the Script property is '`%%ThisValue%%`' and the run time value of the text control is `Text box's value`, then the generated script is '`Text box\'s value`'. Quote handling is not done when `%%ThisValue%%` is enclosed in triple quotation marks.

R

Quotation marks in the run time value of `%%ThisValue%%` that match the enclosing quotation marks are escaped with the backslash character (\). For example, if the Script property is '`%%ThisValue%%`' and the run time value of the text control is `Text box's value`, then the generated script is '`Text box\'s value`'.

None

Quotation marks in the run time value of `%%ThisValue%%` that match the enclosing quotation marks are retained with no modification.

Enabling Rule. Specifies a rule that determines when the current control is enabled. Click the ellipsis (...) button to open the [Enabling Rule](#) dialog box and specify the rule. The Enabling Rule property is visible only when other controls that can be used to specify an enabling rule exist on the canvas.

Number Control

The Number control is a text box for entering a numeric value, and has the following properties:

Identifier. The unique identifier for the control. This is the identifier to use when referencing the control in the script template.

Title. An optional title that appears above the control. For multi-line titles, use \n to specify line breaks.

Title Position. Specifies the position of the title relative to the control. Values are Top and Left where Top is the default.

ToolTip. Optional ToolTip text that appears when the user hovers over the control.

Mnemonic Key. An optional character in the title to use as a keyboard shortcut to the control. The character appears underlined in the title. The shortcut is activated by pressing Alt+[mnemonic key].

Numeric Type. Specifies any limitations on what can be entered. A value of Real specifies that there are no restrictions on the entered value, other than it be numeric. A value of Integer specifies that the value must be an integer.

Spin Input. Specifies whether the control is displayed as a spinner. The default is False.

Increment. The increment when the control is displayed as a spinner.

Default Value. The default value, if any.

Minimum Value. The minimum allowed value, if any.

Maximum Value. The maximum allowed value, if any.

Width. Specifies the width of the text area of the control in characters. The allowed values are positive integers. An empty value means that the width is automatically determined.

Required for execution. Specifies whether a value is required in this control in order for execution to proceed. If True is specified, the user of the node dialog must specify a value for the control otherwise clicking the OK button will generate an error. If False is specified, the absence of a value in this control has no effect on the state of the OK button. The default is False.

Script. Specifies the R script or Python for Spark script that is generated and run by this control at run time and can be inserted in the script template.

- You can specify any valid R script or Python for Spark script. For multi-line scripts or long scripts, click the ellipsis (...) button and enter your script in the Script Property dialog.
- The value `%%ThisValue%%` specifies the run time value of the control, which is the numeric value. This is the default.
- If the Script property includes `%%ThisValue%%` and the run time value of the number control is empty, then the number control does not generate any script.

Enabling Rule. Specifies a rule that determines when the current control is enabled. Click the ellipsis (...) button to open the [Enabling Rule](#) dialog box and specify the rule. The Enabling Rule property is visible only when other controls that can be used to specify an enabling rule exist on the canvas.

Date control

The Date control is a spinner control for specifying date/time values, which include dates, times, and datetimes. The Date control has the following properties:

Identifier. The unique identifier for the control. This is the identifier to use when referencing the control in the script template.

Title. An optional title that appears above the control. For multi-line titles, use \n to specify line breaks.

Title Position. Specifies the position of the title relative to the control. Values are Top and Left where Top is the default.

ToolTip. Optional ToolTip text that appears when the user hovers over the control.

Mnemonic Key. An optional character in the title to use as a keyboard shortcut to the control. The character appears underlined in the title. The shortcut is activated by pressing Alt+[mnemonic key].

Type. Specifies whether the control is for dates, times, or datetime values.

Date

The control specifies a calendar date of the form yyyy-mm-dd. The default run time value is specified by the Default Value property.

Time

The control specifies the time of day in the form hh:mm:ss. The default run time value is the current time of day.

Datetime

The control specifies a date and time of the form yyyy-mm-dd hh:mm:ss. The default run time value is the current date and time of day.

Default Value. The default run time value of the control when the type is Date. You can specify to display the current date or a particular date.

Script. Specifies the R script or Python for Spark script that is generated and run by this control at run time and can be inserted in the script template.

- You can specify any valid R script or Python for Spark script. For multi-line scripts or long scripts, click the ellipsis (...) button and enter your script in the Script Property dialog.
- The value `%%ThisValue%%` specifies the run time value of the control. This is the default.

Enabling Rule. Specifies a rule that determines when the current control is enabled. Click the ellipsis (...) button to open the [Enabling Rule](#) dialog box and specify the rule. The Enabling Rule property is visible only when other controls that can be used to specify an enabling rule exist on the canvas.

Note: The Date control is not supported in releases of IBM® SPSS® Modeler before release 18.

Secured Text

The Secured Text control is a text box that masks user entry with asterisks.

Identifier. The unique identifier for the control. This is the identifier to use when referencing the control in the script template.

Title. An optional title that appears above the control. For multi-line titles, use \n to specify line breaks.

Title Position. Specifies the position of the title relative to the control. Values are Top and Left where Top is the default.

ToolTip. Optional ToolTip text that appears when the user hovers over the control.

Mnemonic Key. An optional character in the title to use as a keyboard shortcut to the control. The character appears underlined in the title. The shortcut is activated by pressing Alt+[mnemonic key].

Width. Specifies the width of the text area of the control in characters. The allowed values are positive integers. An empty value means that the width is automatically determined.

Required for execution. Specifies whether a value is required in this control in order for execution to proceed. If True is specified, the user of the node dialog must specify a value for the control otherwise clicking the OK button will generate an error. If False is specified, the absence of a value in this control has no effect on the state of the OK button. The default is False.

Script. Specifies the R script or Python for Spark script that is generated and run by this control at run time and can be inserted in the script template.

- You can specify any valid R script or Python for Spark script. For multi-line scripts or long scripts, click the ellipsis (...) button and enter your script in the Script Property dialog.
- The value `%%ThisValue%%` specifies the run time value of the control, which is the content of the text box. This is the default.
- If the Script property includes `%%ThisValue%%` and the run time value of the secured text control is empty, then the secured text control does not generate any R script or Python for Spark script.

Quote Handling. Specifies handling of quotation marks in the run time value of `%%ThisValue%%` when the Script property contains `%%ThisValue%%` as part of a quoted string. In this context, a quoted string is a string that is enclosed in single quotation marks or double quotation marks. Quote handling applies only to quotation marks that are the same type as the quotation marks that enclose `%%ThisValue%%` and only when `Encrypt passed value=False`. The following types of quote handling are available.

Python

Quotation marks in the run time value of `%%ThisValue%%` that match the enclosing quotation marks are escaped with the backslash character (\). For example, if the Script property is '`%%ThisValue%%`' and the run time value of the control is `Secured Text's value`, then the generated script is '`Secured Text\'s value`'. Quote handling is not done when `%%ThisValue%%` is enclosed in triple quotation marks.

R

Quotation marks in the run time value of `%%ThisValue%%` that match the enclosing quotation marks are escaped with the backslash character (\). For example, if the Script property is '`%%ThisValue%%`' and the run time value of the control is `Secured Text's value`, then the generated script is '`Secured Text\'s value`'.

None

Quotation marks in the run time value of `%%ThisValue%%` that match the enclosing quotation marks are retained with no modification.

Enabling Rule. Specifies a rule that determines when the current control is enabled. Click the ellipsis (...) button to open the [Enabling Rule](#) dialog box and specify the rule. The Enabling Rule property is visible only when other controls that can be used to specify an enabling rule exist on the canvas.

Note: The Secured Text control is not supported in releases of IBM® SPSS® Modeler before release 18.

Static Text Control

The Static Text control allows you to add a block of text to your node dialog, and has the following properties:

Identifier. The unique identifier for the control.

Title. The content of the text block. For multi-line content, use \n to specify line breaks.

Enabling Rule. Specifies a rule that determines when the current control is enabled. Click the ellipsis (...) button to open the [Enabling Rule](#) dialog box and specify the rule. The Enabling Rule property is visible only when other controls that can be used to specify an enabling rule exist on the canvas.

Color Picker

The Color Picker control is a user interface for specifying a color and generating the associated RGB value. The Color Picker control has the following properties:

Identifier. The unique identifier for the control. This is the identifier to use when referencing the control in the script template.

Title. An optional title that appears above the control. For multi-line titles, use \n to specify line breaks.

Title Position. Specifies the position of the title relative to the control. Values are Top and Left where Top is the default.

ToolTip. Optional ToolTip text that appears when the user hovers over the control.

Mnemonic Key. An optional character in the title to use as a keyboard shortcut to the control. The character appears underlined in the title. The shortcut is activated by pressing Alt+[mnemonic key].

Script. Specifies the R script or Python for Spark script that is generated and run by this control at run time and can be inserted in the script template.

- You can specify any valid R script or Python for Spark script. For multi-line scripts or long scripts, click the ellipsis (...) button and enter your script in the Script Property dialog.
- The value %%**ThisValue**%% specifies the run time value of the control, which is the RGB value of the selected color. The RGB value is represented as a blank separated list of integers in the following order: R value, G value, B value.

Enabling Rule. Specifies a rule that determines when the current control is enabled. Click the ellipsis (...) button to open the [Enabling Rule](#) dialog box and specify the rule. The Enabling Rule property is visible only when other controls that can be used to specify an enabling rule exist on the canvas.

Note: The Color Picker control is not supported in releases of IBM® SPSS® Modeler before release 18.

Table Control

The Table control creates a table with a fixed number of columns and a variable number of rows that are added at run time. The Table control has the following properties:

Identifier. The unique identifier for the control. This is the identifier to use when referencing the control in the script template.

Title. An optional title that appears above the control. For multi-line titles, use \n to specify line breaks.

ToolTip. Optional ToolTip text that appears when the user hovers over the control.

Mnemonic Key. An optional character in the title to use as a keyboard shortcut to the control. The character appears underlined in the title. The shortcut is activated by pressing Alt+[mnemonic key].

Reorder Buttons. Specifies whether move up and move down buttons are added to the table. These buttons are used at run time to reorder the rows of the table.

Table Columns. Click the ellipsis (...) button to open the [Table Columns](#) dialog box, where you specify the columns of the table.

Minimum Rows. The minimum number of rows that must be in the table.

Maximum Rows. The maximum number of rows that can be in the table.

Required for Execution. Specifies whether a value is required in this control in order for execution to proceed. If True is specified, the user of the node dialog must specify a value for the control otherwise clicking the OK button will generate an error. If False is specified, the absence of a value in this control has no effect on the state of the OK button.

Script. Specifies the R script or Python for Spark script that is generated by this control at run time and can be inserted in the script template.

- The value %%**ThisValue**%% specifies the run time value of the control and is the default. The run time value is a blank-separated list of the script that is generated by each column in the table, starting with the leftmost column. If the Script property includes %%**ThisValue**%% and none of the columns generate script, then the table as a whole does not generate any script.
- You can specify any valid R script or Python for Spark script. For multi-line scripts or long scripts, click the ellipsis (...) button and enter your script in the Script Property dialog.

Enabling Rule. Specifies a rule that determines when the current control is enabled. Click the ellipsis (...) button to open the [Enabling Rule](#) dialog box and specify the rule. The Enabling Rule property is visible only when other controls that can be used to specify an enabling rule exist on the canvas.

Note: The Table control is not supported in releases of IBM® SPSS® Modeler before release 18.

Specifying columns for table controls

The Table Columns dialog box specifies the properties of the columns of the Table control.

Identifier. A unique identifier for the column.

Column Name. The name of the column as it appears in the table.

Contents. Specifies the type of data for the column. The value Real specifies that there are no restrictions on the entered value, other than it is numeric. The value Integer specifies that the value must be an integer. The value Any specifies that there are no restrictions on the entered value. The value Variable Name specifies that the value must meet the requirements for a valid variable name in IBM® SPSS® Statistics.

Default Value. The default value for this column, if any, when new rows are added to the table at run time.

Separator Type. Specifies the delimiter between the values of the column, in the generated script. The allowed separators are a blank, a comma, and a plus sign (+). You can also enter an arbitrary single character to be used as the separator.

Quoted. Specifies whether each value in the column is enclosed in double quotation marks in the generated script.

Quote Handling. Specifies handling of quotation marks in cell entries for the column when the Quoted property is true. Quote handling applies only to double quotation marks in cell values. The following types of quote handling are available.

Python

Double quotation marks in cell values are escaped with the backslash character (\). For example, if the cell value is `This "quoted" value` then the generated script is `"This \\\"quoted\\\" value"`.

R

Double quotation marks in cell values are escaped with the backslash character (\). For example, if the cell value is `This "quoted" value` then the generated script is `"This \\\"quoted\\\" value"`.

None

Double quotation marks in cell values are retained with no modification.

Width(chars). Specifies the width of the column in characters. The allowed values are positive integers.

Script. Specifies the R script or Python for Spark script that is generated by this column at run time. The generated script for the table as a whole is a blank-separated list of the script that is generated by each column in the table, starting with the leftmost column.

- You can specify any valid R script or Python for Spark script. For multi-line scripts or long scripts, click the ellipsis (...) button and enter your script in the Script Property dialog.
- The value `%%ThisValue%%` specifies the run time value of the column, which is a list of the values in the column, delimited by the specified separator.
- If the Script property for the column includes `%%ThisValue%%` and the run time value of the column is empty, then the column does not generate any script.

Note: You can add a row for a new Table column in the blank line at the bottom of the existing list in the Table Columns dialog. Entering any of the properties other than the identifier generates a unique identifier, which you can keep or modify. You can delete a Table column by clicking the identifier cell for the Table column and pressing delete.

Link to Control

You can link a Table control to a Field Chooser control. When a Table control is linked to a Field Chooser, there is a row in the table for each field in the Field Chooser. Rows are added to the table by adding fields to the Field Chooser. Rows are deleted from the table by removing fields from the Field Chooser. A linked Table control can be used, for example, to specify properties of fields that are selected in a Field Chooser.

To enable linking, the table must have a column with Variable Name for the Contents property and there must be at least one Field Chooser control on the canvas.

To link a Table control to a Field Chooser, specify the Field Chooser from the list of Available controls in the Link to Control group on the Table Columns dialog box. Then, select the table column, referred to as the Linked column, that defines the link. When the table is rendered, the linked column displays the current fields in the Field Chooser. You can link only to multi-field Field Choosers.

Item Group

The Item Group control is a container for other controls, allowing you to group and control the script generated from multiple controls. For example, you have a set of check boxes that specify optional settings for a subcommand, but only want to generate the script for the subcommand if at least one box is checked. This is accomplished by using an Item Group control as a container for the check box controls. The following types of controls can be contained in an Item Group: field chooser, check box, combo box, list box, text control, number control, static text, radio group, and file browser. The Item Group control has the following properties:

Identifier. The unique identifier for the control. This is the identifier to use when referencing the control in the script template.

Title. An optional title for the group. For multi-line titles, use \n to specify line breaks.

Script. Specifies the R script or Python for Spark script that is generated and run by this control at run time and can be inserted in the script template.

- You can specify any valid R script or Python for Spark script. For multi-line scripts or long scripts, click the ellipsis (...) button and enter your script in the Script Property dialog.
- You can include identifiers for any controls contained in the item group. At run time the identifiers are replaced with the R script or Python script generated by the controls.
- The value %%**ThisValue**%% generates a blank-separated list of the R script or Python script generated by each control in the item group, in the order in which they appear in the group (top to bottom). This is the default. If the Script property includes %%**ThisValue**%% and no script is generated by any of the controls in the item group, then the item group as a whole does not generate any script.

Enabling Rule. Specifies a rule that determines when the current control is enabled. Click the ellipsis (...) button to open the [Enabling Rule](#) dialog box and specify the rule. The Enabling Rule property is visible only when other controls that can be used to specify an enabling rule exist on the canvas.

Radio Group

The Radio Group control is a container for a set of radio buttons, each of which can contain a set of nested controls. The Radio Group control has the following properties:

Identifier. The unique identifier for the control. This is the identifier to use when referencing the control in the script template.

Title. An optional title for the group. For multi-line titles, use `\n` to specify line breaks.

ToolTip. Optional ToolTip text that appears when the user hovers over the control.

Radio Buttons. Click the ellipsis (...) button to open the [Radio Group Properties](#) dialog box, which allows you to specify the properties of the radio buttons as well as to add or remove buttons from the group. The ability to nest controls under a given radio button is a property of the radio button and is set in the Radio Group Properties dialog box. Note that you can also open the Radio Group Properties dialog by double-clicking the Radio Group control on the canvas.

Script. Specifies the R script or Python for Spark script that is generated by this control at run time and can be inserted in the script template.

- You can specify any valid R script or Python for Spark script. For multi-line scripts or long scripts, click the ellipsis (...) button and enter your script in the Script Property dialog.
- The value `%%ThisValue%%` specifies the run time value of the radio button group, which is the value of the Script property for the selected radio button. This is the default. If the Script property includes `%%ThisValue%%` and no script is generated by the selected radio button, then the radio button group does not generate any script.

Enabling Rule. Specifies a rule that determines when the current control is enabled. Click the ellipsis (...) button to open the [Enabling Rule](#) dialog box and specify the rule. The Enabling Rule property is visible only when other controls that can be used to specify an enabling rule exist on the canvas.

Defining radio buttons

The Radio Button Group Properties dialog box allows you to specify a group of radio buttons.

Identifier. A unique identifier for the radio button.

Column Name. The name that appears next to the radio button. The name is a required field.

ToolTip. Optional ToolTip text that appears when the user hovers over the control.

Mnemonic Key. An optional character in the name to use as a mnemonic. The specified character must exist in the name.

Nested Group. Specifies whether other controls can be nested under this radio button. The default is false. When the nested group property is set to true, a rectangular drop zone is displayed, nested and indented, under the associated radio button. The following controls can be nested under a radio button: field chooser, check box, text control, static text, number control, combo box, list box, and file browser.

Default. Specifies whether the radio button is the default selection.

Enabling Rule. Specifies a rule that determines when the current control is enabled. Click the ellipsis (...) button to open the [Enabling Rule](#) dialog box and specify the rule. The Enabling Rule property is visible only when other controls that can be used to specify an enabling rule exist on the canvas.

Script. Specifies the R script or Python for Spark script that is generated when the radio button is selected.

- You can specify any valid R script or Python for Spark script. For multi-line scripts or long scripts, click the ellipsis (...) button and enter your script in the Script Property dialog.
- For radio buttons containing nested controls, the value `%%ThisValue%%` generates a blank-separated list of the R script or Python for Spark script generated by each nested control, in the order in which they appear under the radio button (top to bottom).

You can add a new radio button in the blank line at the bottom of the existing list. Entering any of the properties other than the identifier will generate a unique identifier, which you can keep or modify. You can delete a radio button by clicking on the *Identifier* cell for the button and pressing delete.

Check Box Group

The Check Box Group control is a container for a set of controls that are enabled or disabled as a group, by a single check box. The following types of controls can be contained in a Check Box Group: field chooser, check box, combo box, list box, text control, number control, static text, radio group, and file browser. The Check Box Group control has the following properties:

Identifier. The unique identifier for the control. This is the identifier to use when referencing the control in the script template.

Title. An optional title for the group. For multi-line titles, use `\n` to specify line breaks.

Checkbox Title. An optional label that is displayed with the controlling check box. Supports `\n` to specify line breaks.

ToolTip. Optional ToolTip text that appears when the user hovers over the control.

Mnemonic Key. An optional character in the title to use as a keyboard shortcut to the control. The character appears underlined in the title. The shortcut is activated by pressing Alt+[mnemonic key].

Default Value. The default state of the controlling check box--checked or unchecked.

Checked/Unchecked R Script. Specifies the R script that is generated when the control is checked and when it is unchecked. To include the R script in the script template, use the value of the Identifier property. The generated R script, whether from the Checked R Script or Unchecked R Script property, will be inserted at the specified positions of the identifier. For example, if the identifier is `checkboxgroup1`, then at run time, instances of `%%checkboxgroup1%%` in the script template will be replaced by the value of the Checked R Script property when the box is checked and the Unchecked R Script property when the box is unchecked.

- You can specify any valid R script or Python for Spark script. For multi-line scripts or long scripts, click the ellipsis (...) button and enter your script in the Script Property dialog.
- You can include identifiers for any controls contained in the check box group. At run time the identifiers are replaced with the R script generated by the controls.

- The value `%%ThisValue%%` can be used in either the Checked R Script or Unchecked R Script property. It generates a blank-separated list of the R script generated by each control in the check box group, in the order in which they appear in the group (top to bottom).
- By default, the Checked R Script property has a value of `%%ThisValue%%` and the Unchecked R Script property is blank.

Enabling Rule. Specifies a rule that determines when the current control is enabled. Click the ellipsis (...) button to open the [Enabling Rule](#) dialog box and specify the rule. The Enabling Rule property is visible only when other controls that can be used to specify an enabling rule exist on the canvas.

File Browser

The File Browser control consists of a text box for a file path and a browse button that opens a standard IBM® SPSS® Modeler dialog to open or save a file. The File Browser control has the following properties:

Identifier. The unique identifier for the control. This is the identifier to use when referencing the control in the script template.

Title. An optional title that appears above the control. For multi-line titles, use `\n` to specify line breaks.

Title Position. Specifies the position of the title relative to the control. Values are Top and Left where Top is the default.

ToolTip. Optional ToolTip text that appears when the user hovers over the control.

Mnemonic Key. An optional character in the title to use as a keyboard shortcut to the control. The character appears underlined in the title. The shortcut is activated by pressing Alt+[mnemonic key].

File System Operation. Specifies whether the dialog launched by the browse button is appropriate for opening files or for saving files. A value of Open indicates that the browse dialog validates the existence of the specified file. A value of Save indicates that the browse dialog does not validate the existence of the specified file.

Browser Type. Specifies whether the browse dialog is used to select a file (Locate File) or to select a folder (Locate Folder).

File Filter. Click the ellipsis (...) button to open the [File Filter](#) dialog box, which allows you to specify the available file types for the open or save dialog. By default, all file types are allowed. Note that you can also open the File Filter dialog by double-clicking the File Browser control on the canvas.

File System Type. In distributed analysis mode, this specifies whether the open or save dialog browses the file system on which IBM SPSS Modeler Server is running or the file system of your local computer. Select Server to browse the file system of the server or Client to browse the file system of your local computer. The property has no effect in local analysis mode.

Required for execution. Specifies whether a value is required in this control in order for execution to proceed. If True is specified, the user of the node dialog must specify a value for the control otherwise clicking the OK button will generate an error. If False is specified, the absence of a value in this control has no effect on the state of the OK button. The default is False.

Default. The default value of the control.

Script. Specifies the R script or Python for Spark script that is generated by this control at run time and can be inserted in the script template.

- You can specify any valid R script or Python for Spark script. For multi-line scripts or long scripts, click the ellipsis (...) button and enter your script in the Script Property dialog.

- The value `%%ThisValue%%` specifies the run time value of the text box, which is the file path enclosed by double quotation marks, specified manually or populated by the browse dialog. This is the default.
- If the Script property includes `%%ThisValue%%` and the run time value of the text box is empty, then the file browser control does not generate any script.

Enabling Rule. Specifies a rule that determines when the current control is enabled. Click the ellipsis (...) button to open the [Enabling Rule](#) dialog box and specify the rule. The Enabling Rule property is visible only when other controls that can be used to specify an enabling rule exist on the canvas.

File type filter

The File Filter dialog box allows you to specify the file types displayed in the Files of type and Save as type drop-down lists for open and save dialogs accessed from a File System Browser control. By default, all file types are allowed.

To specify file types not explicitly listed in the dialog box:

1. Select Other.
2. Enter a name for the file type.
3. Enter a file type using the form `* .suffix`--for example, `* .xls`. You can specify multiple file types, each separated by a semicolon.

Tab

The Tab control adds a tab to the node dialog. Any of the other controls can be added to the new tab. The Tab control has the following properties:

Identifier. The unique identifier for the control.

Title. The title of the tab.

Position. Specifies the position of the tab on the node dialog, relative to the other tabs on the node dialog.

Script. Specifies the R script or Python for Spark script that is generated and run by this control at run time and can be inserted in the script template.

- You can specify any valid R script or Python for Spark script and you can use `\n` for line breaks.
- The value `%%ThisValue%%` generates a blank-separated list of the R script or Python for Spark script generated by each control in the tab, in the order in which they appear on the tab (top to bottom and left to right). This is the default.
- If the Script property includes `%%ThisValue%%` and no R script or Python for Spark script is generated by any of the controls in the tab, then the tab as a whole does not generate any script.

Enabling Rule. Specifies a rule that determines when the current control is enabled. Click the ellipsis (...) button to open the [Enabling Rule](#) dialog box and specify the rule. The Enabling Rule property is visible only when other controls that can be used to specify an enabling rule exist on the canvas.

Sub-dialog button

The Sub-dialog Button control specifies a button for launching a sub-dialog and provides access to the Dialog Builder for the sub-dialog. The Sub-dialog Button has the following properties:

Identifier. The unique identifier for the control.

Title. The text that is displayed in the button.

ToolTip. Optional ToolTip text that appears when the user hovers over the control.

Sub-dialog. Click the ellipsis (...) button to open the Custom Dialog Builder for the sub-dialog. You can also open the builder by double-clicking on the Sub-dialog button.

Mnemonic Key. An optional character in the title to use as a keyboard shortcut to the control. The character appears underlined in the title. The shortcut is activated by pressing Alt+[mnemonic key].

Enabling Rule. Specifies a rule that determines when the current control is enabled. Click the ellipsis (...) button to open the [Enabling Rule](#) dialog box and specify the rule. The Enabling Rule property is visible only when other controls that can be used to specify an enabling rule exist on the canvas.

Note: The Sub-dialog Button control cannot be added to a sub-dialog.

-

Dialog properties for a sub-dialog

To view and set properties for a sub-dialog:

1. Open the sub-dialog by double-clicking on the button for the sub-dialog in the main dialog, or single-click the sub-dialog button and click the ellipsis (...) button for the Sub-dialog property.
2. In the sub-dialog, click on the canvas in an area outside of any controls. With no controls on the canvas, the properties for a sub-dialog are always visible.

Sub-dialog Name. The unique identifier for the sub-dialog. The Sub-dialog Name property is required.

Note: If you specify the Sub-dialog Name as an identifier in the Script Template--as in `%%My Sub-dialog`

`Name%%`--it will be replaced at run-time with a blank-separated list of the script generated by each control in the sub-dialog, in the order in which they appear (top to bottom and left to right).

Title. Specifies the text to be displayed in the title bar of the sub-dialog box. The Title property is optional but recommended.

Help File. Specifies the path to an optional help file for the sub-dialog. This is the file that will be launched when the user clicks the Help button on the sub-dialog, and may be the same help file specified for the main dialog. Help files must be in HTML format. See the description of the Help File property for [Dialog Properties](#) for more information.

Specifying an Enabling Rule for a Control

You can specify a rule that determines when a control is enabled. For example, you can specify that a radio group is enabled when a field chooser is populated. The available options for specifying the enabling rule depend on the type of control that defines the rule.

You can specify that the current control is enabled when a Field Chooser is populated with at least one field (Non-empty). You can alternately specify that the current control is enabled when a Field Chooser is not populated (Empty).

Check Box or Check Box Group

You can specify that the current control is enabled when a Check Box or Check Box Group is checked. You can alternately specify that the current control is enabled when a Check Box or Check Box Group is not checked.

Combo Box or Single-Select List Box

You can specify that the current control is enabled when a particular value is selected in a Combo Box or Single-Select List Box. You can alternately specify that the current control is enabled when a particular value is not selected in a Combo Box or Single-Select List Box.

Multi-Select List Box

You can specify that the current control is enabled when a particular value is among the selected values in a Multi-Select List Box. You can alternately specify that the current control is enabled when a particular value is not among the selected values in a Multi-Select List Box.

Radio Group

You can specify that the current control is enabled when a particular radio button is selected. You can alternately specify that the current control is enabled when a particular radio button is not selected.

Controls for which an enabling rule can be specified have an associated Enabling Rule property.

Note:

- Enabling rules apply whether the control that defines the rule is enabled or not. For example, consider a rule that specifies that a radio group is enabled when a field chooser is populated. The radio group is then enabled whenever the field chooser is populated, regardless of whether the field chooser is enabled.
- When a Tab control is disabled, all controls on the tab are disabled regardless of whether any of those controls have an enabling rule that is satisfied.
- When a Check Box Group is disabled, all controls in the group are disabled regardless of whether the controlling check box is checked.

Extension Properties

The Extension Properties dialog specifies information about the current extension within the Custom Dialog Builder for Extensions, such as the name of the extension and the files in the extension.

- All custom node dialogs that are created in the Custom Dialog Builder for Extensions are part of an extension.
- Fields on the Required tab of the Extension Properties dialog must be specified before you can install an extension and the custom node dialogs that are contained in it.

To specify the properties for an extension, from the menus in the Custom Dialog Builder for Extensions choose:

Extension > Properties

- [Required properties of extensions](#)
- [Optional properties of extensions](#)

Required properties of extensions

Name

A unique name to associate with the extension. It can consist of up to three words and is not case sensitive. Characters are restricted to seven-bit ASCII. To minimize the possibility of name conflicts, you may want to use a multi-word name, where the first word is an identifier for your organization, such as a URL. Note that name will also be used for the extension bundle (.mpe) file name by default when you save the extension. We recommend using the default name when you save. If you save with a different name, you will not be able to uninstall the extension in the future.

Summary

A short description of the extension that is intended to be displayed as a single line.

Version

A version identifier of the form x.x.x, where each component of the identifier must be an integer, as in 1.0.0. Zeros are implied if not provided. For example, a version identifier of 3.1 implies 3.1.0. The version identifier is independent of the IBM® SPSS® Modeler version.

Minimum SPSS Modeler Version

The minimum version of SPSS Modeler required to run the extension.

Files

The Files list displays the files that are currently included in the extension. Click Add to add files to the extension. You can also remove files from the extension and you can extract files to a specified folder.

- Custom node dialogs have a filetype of .cfe.
- Translation files for components of the extension are added from the Localization settings on the Optional tab.
- You can add a readme file to the extension. Specify the filename as ReadMe.txt. Users can access the readme file from the dialog that displays the details for the extension. You can include localized versions of the readme file, specified as ReadMe_<language>

Optional properties of extensions

General properties

Description

A more detailed description of the extension than that provided for the Summary field. For example, you might list the major features available with the extension.

Date

An optional date for the current version of the extension. No formatting is provided.

Author

The author of the extension. You might want to include an email address.

Links

A set of URLs to associate with the extension; for example, the author's home page. The format of this field is arbitrary so be sure to delimit multiple URLs with spaces, commas, or some other reasonable delimiter.

Keywords

A set of keywords with which to associate the extension.

Platform

Information about any restrictions that apply to using the extension on particular operating system platforms.

Dependencies

Maximum SPSS Modeler Version

The maximum version of IBM® SPSS® Modeler on which the extension can be run.

Integration Plug-in for R required

Specifies whether the Integration Plug-in for R is required.

If the extension requires any R packages from the CRAN package repository, then enter the names of those packages in the Required R Packages control. Names are case sensitive. To add the first package, click anywhere in the Required R Packages control to highlight the entry field. Pressing Enter, with the cursor in a given row, will create a new row. You delete a row by selecting it and pressing Delete.

Localization

Custom Nodes

You can add translated versions of the properties file (specifies all strings that appear in the node dialog) for a custom node dialog within the extension. To add translations for a particular node dialog, select the dialog, click Add Translations, and select the folder that contains the translated versions. All translated files for a particular node dialog must be in the same folder. For instructions on creating the translation files, see the topic [Creating Localized Versions of Custom Node Dialogs](#).

Translation Catalogues Folder

You can provide localized versions of the Summary and Description fields for the extension that are displayed when end users view the extension details from the Extension Hub. The set of all localized files for an extension must be in a folder named lang. Browse to the lang folder that contains the localized files and select that folder.

To provide localized versions of the Summary and Description fields, create a file named <extension name>_<language-identifier>.properties for each language for which a translation is being provided. At run time, if the .properties file for the current user interface language cannot be found, the values of the Summary and Description fields that are specified on the Required and Optional tabs are used.

- <extension name> is the value of the Name field for the extension, with any spaces replaced by underscore characters.
- <language-identifier> is the identifier for a particular language. Identifiers for the languages that are supported by IBM SPSS Modeler are shown in what follows.

For example, the French translations for an extension named MYORG MYSTAT are stored in the file MYORG_MYSTAT_fr.properties.

The .properties file must contain the following two lines, which specify the localized text for the two fields:

```
Summary=<localized text for Summary field>
Description=<localized text for Description field>
```

- The keywords Summary and Description must be in English and the localized text must be on the same line as the keyword, and with no line breaks.
- The file must be in ISO 8859-1 encoding. Characters that cannot be directly represented in this encoding must be written with Unicode escapes ("\\u").

The lang folder that contains the localized files must have a subfolder named <language-identifier> that contains the localized .properties file for a particular language. For example, the French .properties file must be in the lang/fr folder.

Language Identifiers

de. German

en. English

es. Spanish

fr. French

it. Italian

ja. Japanese

ko. Korean

pl. Polish

pt_BR. Brazilian Portuguese

ru. Russian

zh_CN. Simplified Chinese

zh_TW. Traditional Chinese

Managing custom node dialogs

The Custom Dialog Builder for Extensions allows you to manage custom node dialogs, within extensions that are created by you or by other users. Custom node dialogs must be installed to all instances of SPSS® Modeler Client or SPSS Modeler Batch where they are needed before they can be used. Note that there is nothing that needs to be installed to SPSS Modeler Server to use a custom dialog node in server mode.

Note: You can only modify custom node dialogs that are created in IBM® SPSS Modeler.

Opening an extension that contains custom node dialogs

You can open an extension bundle file (.mpe) that contains the specifications for one or more custom node dialogs or you can open an installed extension. You can modify any of the node dialogs in the extension and save or install the extension. Installing the extension installs the node dialogs that are contained in the extension. Saving the extension saves changes that were made to any of the node dialogs in the extension.

To open an extension bundle file, from the menus in the Custom Dialog Builder for Extensions choose:

File > Open

To open an installed extension, from the menus in the Custom Dialog Builder for Extensions choose:

File > Open Installed

Note: If you are opening an installed extension to modify it, choosing File > Install reinstalls it, replacing the existing version. Using Edit on the context menu of a node created using the Custom Dialog Builder will not open the node dialog in the Custom Dialog Builder.

Saving to an extension bundle file

Saving the extension that is open in the Custom Dialog Builder for Extensions also saves the custom node dialogs that are contained in the extension. Extensions are saved to an extension bundle file (.mpe). We recommend keeping the default file name, which matches the name you specified in Name field of the Extension Properties dialog.

From the menus in the Custom Dialog Builder for Extensions, choose:

File > Save

Installing an extension

Installing the extension that is open in the Custom Dialog Builder for Extensions also installs the custom node dialogs that are contained in the extension. Installing an existing extension replaces the existing version, which includes replacing all custom node dialogs in the extension that were already installed.

To install the currently open extension, from the menus in the Custom Dialog Builder for Extensions choose:

File > Install

By default, extensions are installed to a general user-writable location for your operating system. For more information, see the topic [Installation locations for extensions](#).

Note: In an open stream, the existing versions of the node dialogs that are contained in the extension will not be replaced. When you open a stream that contains a Custom Dialog Builder node that has been re-installed, you will receive a warning message.

Uninstalling an extension

From the menus in the Custom Dialog Builder for Extensions, choose:

File > Uninstall

Uninstalling an extension uninstalls all custom node dialogs that are contained in the extension. You can also uninstall extensions from the Extension Hub.

Note: To successfully uninstall an extension, the extension bundle .mpe file name must match the name specified in the Extension Properties dialog. This is the default file name. If you modified the file name, rename it to match the Name field and try uninstalling again.

Importing a custom dialog package file

You can import a custom dialog package (.cdf) file into the Custom Dialog Builder for Extensions. The .cdf file is converted into a .cfi file, which is added to a new extension.

From the menus in the Custom Dialog Builder for Extensions, choose:

File > Import

You can also add .cfi files to an extension from the Extension Properties dialog, which is accessed from Extension > Properties within the Custom Dialog Builder for Extensions.

Adding a custom node dialog to an extension

You can add a new custom node dialog to an extension.

From the menus in the Custom Dialog Builder for Extensions, choose:

Extension > New Dialog

Switching between multiple custom node dialogs in an extension

If the current extension contains multiple custom node dialogs, you can switch between them.

From the menus in the Custom Dialog Builder for Extensions, choose:

Extension > Edit Dialog and select the custom node dialog that you want to work with.

Creating a new extension

When you create a new extension in the Custom Dialog Builder for Extensions, a new empty custom node dialog is added to the extension.

To create a new extension, from the menus in the Custom Dialog Builder for Extensions choose:

File > New

Extensions in SPSS Modeler Batch or in IBM SPSS Collaboration and Deployment Services

To use extensions in an SPSS Modeler Batch or IBM SPSS Collaboration and Deployment Services installation, ensure that the environment variable *IBM_SPSS_MODELER_EXTENSION_PATH* is defined on the target environment, and that it points to the location that contains the extensions. If the streams that contain a custom node were stored to the IBM SPSS Collaboration and Deployment Services Repository before the *IBM_SPSS_MODELER_EXTENSION_PATH* environment variable was defined, you must re-store the streams to the repository before they will run successfully.

Note: Ensure that the version of the SPSS Modeler Batch or IBM SPSS Collaboration and Deployment Services adapter for SPSS Modeler matches the version of SPSS Modeler Client where the extension was created.

Creating Localized Versions of Custom Node Dialogs

You can create localized versions of custom node dialogs for any of the languages supported by IBM® SPSS® Modeler. You can localize any string that appears in a custom node dialog and you can localize the optional help file.

To localize dialog strings

You must create a copy of the properties file associated with the custom node dialog for each language that you plan to deploy. The properties file contains all of the localizable strings associated with the node dialog.

Extract the custom node dialog file (.cfe) from the extension by selecting the file in the Extension Properties dialog (within the Custom Dialog Builder for Extensions) and clicking Extract. Then, extract the contents of the .cfe file. A .cfe file is simply a .zip file. The extracted contents of a .cfe file includes a properties file for each supported language, where the name of the file for a particular language is given by <Dialog Name>_<language identifier>.properties (see language identifiers in the table that follows).

1. Open each properties file, that you plan to translate, with a text editor that supports UTF-8, such as Notepad on Windows. Modify the values associated with any properties that need to be localized, but do not modify the names of the properties. Properties associated with a specific control are prefixed with the identifier for the control. For example, the ToolTip property for a control with the identifier *options_button* is *options_button_tooltip_LABEL*. Title properties are simply named <*identifier*>_LABEL, as in *options_button_LABEL*.
2. Add the localized versions of the properties files back to the custom node dialog file (.cfe) from the Localization settings on the Optional tab of the Extension Properties dialog. For more information, see the topic [Optional properties of extensions](#).

When the node dialog is launched, IBM SPSS Modeler searches for a properties file whose language identifier matches the current language, as specified by the Language drop-down on the General tab in the Options dialog box. If no such properties file is found, the default file <Dialog Name>.properties is used.

To localize the help file

1. Make a copy of the help file associated with the custom node dialog and localize the text for the language you want.
2. Rename the copy to <Help File>_<language identifier>.htm, using the language identifiers in the table below. For example, if the help file is myhelp.htm and you want to create a German version of the file, then the localized help file should be named myhelp_de.htm.

Store all localized versions of the help file in the same directory as the non-localized version. When you add the non-localized help file from the Help File property of Dialog Properties, the localized versions are automatically added to the node dialog.

If there are supplementary files such as image files that also need to be localized, then you must manually modify the appropriate paths in the main help file to point to the localized versions. Supplementary files, including localized versions, must be manually added to the custom node dialog (.cfe) file. See the previous section titled "To localize dialog strings" for information about accessing and manually modifying custom node dialog files.

When the node dialog is launched, IBM SPSS Modeler searches for a help file whose language identifier matches the current language, as specified by the Language drop-down on the General tab in the Options dialog box. If no such help file is found, the help file specified for the node dialog (the file specified in the Help File property of Dialog Properties) is used.

Language Identifiers

de. German

en. English

es. Spanish

fr. French

it. Italian

ja. Japanese

ko. Korean

pl. Polish

pt_BR. Brazilian Portuguese

ru. Russian

zh_CN. Simplified Chinese

zh_TW. Traditional Chinese

Note: Text in custom node dialogs and associated help files is not limited to the languages supported by IBM SPSS Modeler. You are free to write the node dialog and help text in any language without creating language-specific properties and help files. All users of your node dialog will then see the text in that language.

Importing and exporting data using Python for Spark

Using the Custom Dialog Builder for Extensions, you can create custom nodes and write Python for Spark scripts to read data from wherever your data source is, and write data out to any data format supported by Apache Spark.

For example, a user wants to write his data to a database. He uses the Custom Dialog Builder for Extensions and Python for Spark to create a custom export JDBC node and then runs the model to write data into a database. To read data from the database, he can also create a custom import JDBC node. He could also use this same method to read data into SPSS® Modeler from a JSON file, for example. Then, after reading his data into SPSS Modeler, he can use all available SPSS Modeler nodes to work on his business problem.

Note: If you want to use JDBC with Python for Spark import and export functionality, you must copy your JDBC driver file to the as/lib directory inside your IBM® SPSS Modeler installation directory.

To import/export data using Python for Spark

1. Go to Extensions...>Custom Node Dialog Builder.
 2. Under Dialog Properties, select Python for Spark for the Script Type and select Import or Export for the Node Type.
 3. Enter other properties as desired, such as a Dialog Name.
 4. In the Script section, type or paste your Python for Spark script for importing or exporting data.
 5. Click Install to install the Python for Spark script. New custom import nodes will be added to the Sources palette, and new custom export nodes will be added to the Export palette.
-

Importing and exporting data using R

Using the Custom Dialog Builder for Extensions, you can create custom nodes and write R scripts to read data from wherever your data source is, and write data out to any data format supported by R.

For example, a user wants to write her data to a database. She uses the Custom Dialog Builder for Extensions and R scripting to create a custom export JDBC node and then runs the model to write data into a database. To read data from the database, she can also create a custom import JDBC node. She could also use this same method to read data into SPSS® Modeler from a JSON file, for example. Then, after reading his data into SPSS Modeler, he can use all available SPSS Modeler nodes to work on his business problem.

To import/export data using R

1. Go to Extensions...>Custom Node Dialog Builder.
 2. Under Dialog Properties, select R for the Script Type and select Import or Export for the Node Type.
 3. Enter other properties as desired, such as a Dialog Name.
 4. In the Script section, type or paste your R script for importing or exporting data.
 5. Click Install to install the R script. New custom import nodes will be added to the Sources palette, and new custom export nodes will be added to the Export palette.
-

Introduction to CRISP-DM

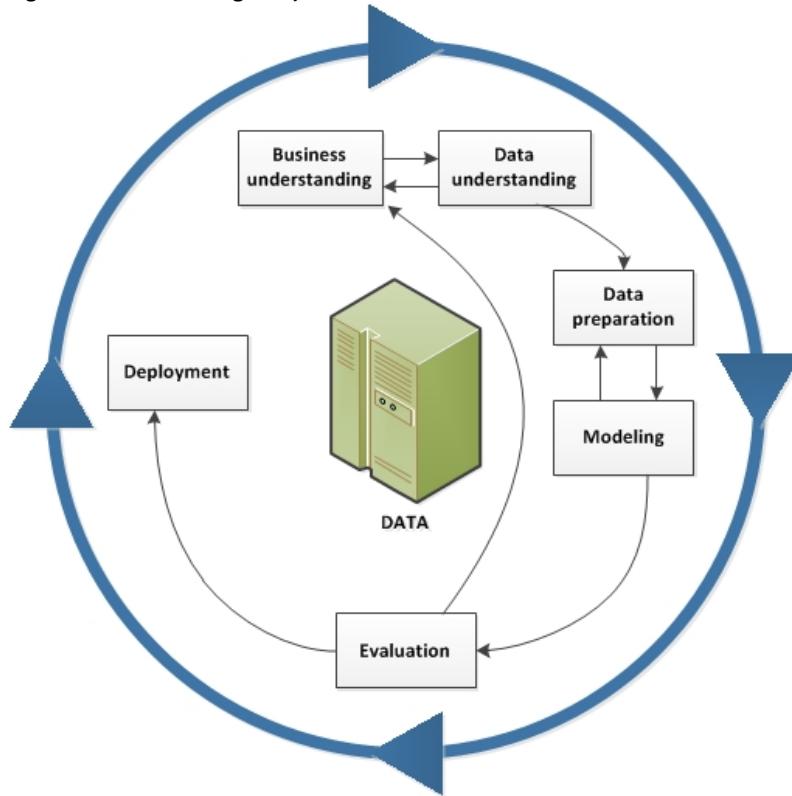

- [CRISP-DM Help Overview](#)

CRISP-DM Help Overview

CRISP-DM, which stands for Cross-Industry Standard Process for Data Mining, is an industry-proven way to guide your data mining efforts.

- As a **methodology**, it includes descriptions of the typical phases of a project, the tasks involved with each phase, and an explanation of the relationships between these tasks.
- As a **process model**, CRISP-DM provides an overview of the data mining life cycle.

Figure 1. The data mining life cycle

The life cycle model consists of six phases with arrows indicating the most important and frequent dependencies between phases. The sequence of the phases is not strict. In fact, most projects move back and forth between phases as necessary.

The CRISP-DM model is flexible and can be customized easily. For example, if your organization aims to detect money laundering, it is likely that you will sift through large amounts of data without a specific modeling goal. Instead of modeling, your work will focus on data exploration and visualization to uncover suspicious patterns in financial data. CRISP-DM allows you to create a data mining model that fits your particular needs.

In such a situation, the modeling, evaluation, and deployment phases might be less relevant than the data understanding and preparation phases. However, it is still important to consider some of the questions raised during these later phases for long-term planning and future data mining goals.

- [CRISP-DM in IBM SPSS Modeler](#)
- [Additional resources](#)

CRISP-DM in IBM SPSS Modeler

IBM® SPSS® Modeler incorporates the CRISP-DM methodology in two ways to provide unique support for effective data mining.

- The CRISP-DM project tool helps you organize project streams, output, and annotations according to the phases of a typical data mining project. You can produce reports at any time during the project based on the notes for streams and CRISP-DM phases.
- Help for CRISP-DM guides you through the process of conducting a data mining project. The help system includes tasks lists for each step as well as examples of how CRISP-DM works in the real world. You can access CRISP-DM Help by choosing CRISP-DM Help from the main window Help menu.

- [CRISP-DM Project Tool](#)
- [Help for CRISP-DM](#)

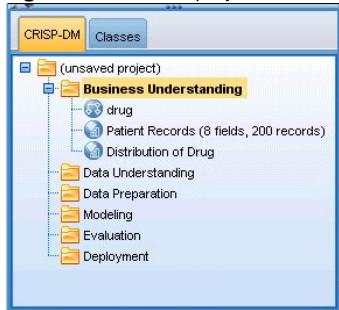

Related information

- [Additional resources](#)

CRISP-DM Project Tool

The CRISP-DM project tool provides a structured approach to data mining that can help ensure your project's success. It is essentially an extension of the standard IBM® SPSS® Modeler project tool. In fact, you can toggle between the CRISP-DM view and the standard Classes view to see your streams and output organized by type or by phases of CRISP-DM.

Figure 1. CRISP-DM project tool

Using the CRISP-DM view of the project tool, you can:

- Organize a project's streams and output according to data mining phases.
- Take notes on your organization's goals for each phase.
- Create custom tooltips for each phase.
- Take notes on the conclusions drawn from a particular graph or model.
- Generate an HTML report or update for distribution to the project team.

Related information

- [Additional resources](#)
- [Help for CRISP-DM](#)

Help for CRISP-DM

IBM® SPSS® Modeler offers an online guide for the non-proprietary CRISP-DM process model. The guide is organized by project phases and provides the following support:

- An overview and task list for each phase of CRISP-DM
- Help on producing reports for various milestones
- Real-world examples illustrating how a project team can use CRISP-DM to light the way for data mining
- Links to additional resources on CRISP-DM

You can access CRISP-DM Help by choosing CRISP-DM Help from the main window Help menu.

 - [Determining Business Objectives](#)
 - [Assessing the Situation](#)
 - [Determining Data Mining Goals](#)
 - [Producing a Project Plan](#)
 - [Ready for the next step?](#)
-

Business Understanding Overview

Even before working in IBM® SPSS® Modeler, you should take the time to explore what your organization expects to gain from data mining. Try to involve as many key people as possible in these discussions and document the results. The final step of this CRISP-DM phase discusses how to produce a project plan using the information gathered here.

Although this research may seem dispensable, it's not. Getting to know the business reasons for your data mining effort helps to ensure that everyone is on the same page before expending valuable resources.

-

Determining Business Objectives

Your first task is to try to gain as much insight as possible into the business goals for data mining. This may not be as easy as it seems, but you can minimize later risk by clarifying problems, goals, and resources.

The CRISP-DM methodology provides a structured way for you to accomplish this.

Task List

- Start gathering [background information](#) about the current business situation.
 - [Document specific business objectives](#) decided upon by key decision makers.
 - Agree upon criteria used to determine [data mining success from a business perspective](#).
 - [E-Retail Example--Finding Business Objectives](#)
 - [Compiling the Business Background](#)
 - [Defining Business Objectives](#)
 - [Business Success Criteria](#)
-

E-Retail Example--Finding Business Objectives

A Web-Mining Scenario Using CRISP-DM

As more companies make the transition to selling over the Web, an established computer/electronics e-retailer is facing increasing competition from newer sites. Faced with the reality that Web stores are cropping up as fast (or faster!) than customers are migrating to the Web, the

company must find ways to remain profitable despite the rising costs of customer acquisition. One proposed solution is to cultivate existing customer relationships in order to maximize the value of each of the company's current customers.

Thus, a study is commissioned with the following objectives:

- Improve cross-sales by making better recommendations.
- Increase customer loyalty with a more personalized service.

Tentatively, the study will be judged a success if:

- Cross-sales increase by 10%.
- Customers spend more time and see more pages on the site per visit.
- The study finishes on time and under budget.

Related information

- [E-Retail Example--Assessing the Situation](#)
 - [Compiling the Business Background](#)
 - [Defining Business Objectives](#)
 - [Business Success Criteria](#)
-

Compiling the Business Background

Understanding your organization's business situation helps you know what you're working with in terms of:

- Available resources (personnel and material)
- Problems
- Goals

You'll need to do a bit of research on the current business situation in order to find real answers to questions that can impact the outcome of the data mining project.

Task 1--Determine Organizational Structure

- Develop organizational charts to illustrate corporate divisions, departments, and project groups. Be sure to include managers' names and responsibilities.
- Identify key individuals in the organization.
- Identify an internal sponsor who will provide financial support and/or domain expertise.
- Determine whether there is a steering committee and procure a list of members.
- Identify business units that will be affected by the data mining project.

Task 2--Describe Problem Area

- Identify the problem area, such as marketing, customer care, or business development.
- Describe the problem in general terms.
- Clarify the prerequisites of the project. What are the motivations behind the project? Does the business already use data mining?
- Check on the status of the data mining project within the business group. Has the effort been approved, or does data mining need to be "advertised" as a key technology for the business group?
- If necessary, prepare informational presentations on data mining to your organization.

Task 3--Describe Current Solution

- Describe any solutions currently used to address the business problem.
- Describe the advantages and disadvantages of the current solution. Also, address the level of acceptance this solution has had within the organization.

Related information

- [E-Retail Example--Finding Business Objectives](#)
 - [Defining Business Objectives](#)
 - [Business Success Criteria](#)
-

Defining Business Objectives

This is where things get specific. As a result of your research and meetings, you should construct a concrete primary objective agreed upon by the project sponsors and other business units affected by the results. This goal will eventually be translated from something as nebulous as "reducing customer churn" to specific data mining objectives that will guide your analytics.

Task List

Be sure to take notes on the following points for later incorporation into the project plan. Remember to keep goals realistic.

- Describe the problem you want to solve using data mining.
- Specify all business questions as precisely as possible.
- Determine any other business requirements (such as not losing any existing customers while increasing cross-sell opportunities).
- Specify expected benefits in business terms (such as reducing churn among high-value customers by 10%).

Related information

- [E-Retail Example--Finding Business Objectives](#)
 - [Compiling the Business Background](#)
 - [Business Success Criteria](#)
-

Business Success Criteria

The goal ahead may be clear, but will you know once you're there? It's important to define the nature of business success for your data mining project before proceeding further. Success criteria fall into two categories:

- **Objective.** These criteria can be as simple as a specific increase in the accuracy of audits or an agreed-upon reduction in churn.
- **Subjective.** Subjective criteria such as "discover clusters of effective treatments" are more difficult to pin down, but you can agree upon who makes the final decision.

Task List

- As precisely as possible, document the success criteria for this project.
- Make sure each business objective has a correlative criterion for success.
- Align the arbiters of the subjective measurements of success. If possible, take notes on their expectations.

Related information

- [E-Retail Example--Finding Business Objectives](#)
 - [Compiling the Business Background](#)
 - [Defining Business Objectives](#)
-

Assessing the Situation

Now that you have a clearly defined goal, it's time to make an assessment of where you are right now. This step involves asking questions such as:

- What sort of data are available for analysis?
 - Do you have the personnel needed to complete the project?
 - What are the biggest risk factors involved?
 - Do you have a contingency plan for each risk?
- [E-Retail Example--Assessing the Situation](#)
 - [Resource Inventory](#)
 - [Requirements, Assumptions, and Constraints](#)
 - [Risks and Contingencies](#)
 - [Terminology](#)
 - [Cost/Benefit Analysis](#)
-

E-Retail Example--Assessing the Situation

A Web-Mining Scenario Using CRISP-DM

This is the electronics e-retailer's first attempt at Web mining, and the company has decided to consult a data mining specialist to help in getting started. One of the first tasks the consultant faces is to assess the company's resources for data mining.

Personnel. It's clear that there is in-house expertise with managing server logs and product and purchase databases, but little experience in data warehousing and data cleaning for analysis. Thus, a database specialist may also be consulted. Since the company hopes the results of the study will become part of a continuing Web-mining process, management must also consider whether any positions created during the current effort will be permanent ones.

Data. Since this is an established company, there is plenty of Web log and purchase data to draw from. In fact, for this initial study, the company will restrict the analysis to customers who have "registered" on the site. If successful, the program can be expanded.

Risks. Aside from the monetary outlays for the consultants and the time spent by employees on the study, there is not a great deal of immediate risk in this venture. However, time is always important, so this initial project is scheduled for a single financial quarter.

Also, there is not a lot of extra cash flow at the moment, so it is imperative that the study come in under budget. If either of these goals should be in danger, the business managers have suggested that the project's scope should be reduced.

Related information

- [Resource Inventory](#)
 - [Requirements, Assumptions, and Constraints](#)
 - [Risks and Contingencies](#)
 - [Terminology](#)
 - [Cost/Benefit Analysis](#)
 - [E-Retail Example--Data Mining Goals](#)
-

Resource Inventory

Taking an accurate inventory of your resources is indispensable. You can save a lot of time and headaches by taking a real look at hardware, data sources, and personnel issues.

Task 1--Research Hardware Resources

- What hardware do you need to support?

Task 2--Identify Data Sources and Knowledge Stores

- Which data sources are available for data mining? Take note of data types and formats.
- How are the data stored? Do you have live access to data warehouses or operational databases?
- Do you plan to purchase external data, such as demographic information?
- Are there any security issues preventing access to required data?

Task 3--Identify Personnel Resources

- Do you have access to business and data experts?
- Have you identified database administrators and other support staff that may be needed?

Once you have asked these questions, include a list of contacts and resources for the phase report.

Related information

- [E-Retail Example--Assessing the Situation](#)
 - [Requirements, Assumptions, and Constraints](#)
 - [Risks and Contingencies](#)
 - [Terminology](#)
 - [Cost/Benefit Analysis](#)
-

Requirements, Assumptions, and Constraints

Your efforts are more likely to pay off if you make an honest assessment of liabilities to the project. Making these concerns as explicit as possible will help to avert future problems.

Task 1--Determine Requirements

The fundamental requirement is the business goal discussed earlier, but consider the following:

- Are there security and legal restrictions on the data or project results?
- Is everyone aligned on the project scheduling requirements?
- Are there requirements on results deployment (for example, publishing to the Web or reading scores into a database)?

Task 2--Clarify Assumptions

- Are there economic factors that might affect the project (for example, consulting fees or competitive products)?
- Are there data quality assumptions?
- How does the project sponsor/management team expect to view the results? In other words, do they want to understand the model itself or simply view the results?

Task 3--Verify Constraints

- Do you have all passwords required for data access?
- Have you verified all legal constraints on data usage?
- Are all financial constraints covered in the project budget?

Related information

- [E-Retail Example--Assessing the Situation](#)
 - [Resource Inventory](#)
 - [Risks and Contingencies](#)
 - [Terminology](#)
 - [Cost/Benefit Analysis](#)
-

Risks and Contingencies

It is also wise to consider possible risks over the course of the project. Types of risks include:

- Scheduling (What if the project takes longer than anticipated?)
- Financial (What if the project sponsor encounters budgetary problems?)
- Data (What if the data are of poor quality or coverage?)
- Results (What if the initial results are less dramatic than expected?)

After you have considered the various risks, come up with a contingency plan to help avert disaster.

Task List

- Document each possible risk.
- Document a contingency plan for each risk.

Related information

- [E-Retail Example--Assessing the Situation](#)
 - [Resource Inventory](#)
 - [Requirements, Assumptions, and Constraints](#)
 - [Terminology](#)
 - [Cost/Benefit Analysis](#)
-

Terminology

To ensure that business and data mining teams are "speaking the same language," you should consider compiling a glossary of technical terms and buzzwords that need clarification. For example, if "churn" for your business has a particular and unique meaning, it is worth explicitly stating that for the benefit of the whole team. Likewise, the team may benefit from clarification of the usage of a gains chart.

Task List

- Keep a list of terms or jargon confusing to team members. Include both business and data mining terminology.
- Consider publishing the list on the intranet or in other project documentation.

Related information

- [E-Retail Example--Assessing the Situation](#)

- [Resource Inventory](#)
 - [Requirements, Assumptions, and Constraints](#)
 - [Risks and Contingencies](#)
 - [Cost/Benefit Analysis](#)
-

Cost/Benefit Analysis

This step answers the question, **What is your bottom line?** As part of the final assessment, it's critical to compare the costs of the project with the potential benefits of success.

Task List

Include in your analysis estimated costs for:

- Data collection and any external data used
- Results deployment
- Operating costs

Then, take into account the benefits of:

- The primary objective being met
- Additional insights generated from data exploration
- Possible benefits from better data understanding

Related information

- [E-Retail Example--Assessing the Situation](#)
 - [Resource Inventory](#)
 - [Requirements, Assumptions, and Constraints](#)
 - [Risks and Contingencies](#)
 - [Terminology](#)
-

Determining Data Mining Goals

Now that the business goal is clear, it's time to translate it into a data mining reality. For example, the business objective to "reduce churn" can be translated into a data mining goal that includes:

- Identifying high-value customers based on recent purchase data
- Building a model using available customer data to predict the likelihood of churn for each customer
- Assigning each customer a rank based on both churn propensity and customer value

These data mining goals, if met, can then be used by the business to reduce churn among the most valuable customers.

As you can see, business and technology must work hand-in-hand for effective data mining. Read on for specific tips on how to determine data mining goals.

- [Data Mining Goals](#)
 - [E-Retail Example--Data Mining Goals](#)
 - [Data Mining Success Criteria](#)
-

Data Mining Goals

As you work with business and data analysts to define a technical solution to the business problem, remember to keep things concrete.

Task List

- Describe the **type** of data mining problem, such as clustering, prediction, or classification.
- Document technical goals using specific units of time, such as predictions with a three-month validity.
- If possible, provide actual numbers for desired outcomes, such as producing churn scores for 80% of existing customers.

Related information

- [E-Retail Example--Data Mining Goals](#)
 - [Data Mining Success Criteria](#)
-

E-Retail Example--Data Mining Goals

A Web-Mining Scenario Using CRISP-DM

With the help of its data mining consultant, the e-retailer has been able to translate the company's business objectives into data mining terms. The goals for the initial study to be completed this quarter are:

- Use historical information about previous purchases to generate a model that links "related" items. When users look at an item description, provide links to other items in the related group (**market basket analysis**).
- Use Web logs to determine what different customers are trying to find, and then redesign the site to highlight these items. Each different customer "type" will see a different main page for the site (**profiling**).
- Use Web logs to try to predict where a person is going next, given where he or she came from and has been on your site (**sequence analysis**).

Related information

- [Data Mining Goals](#)
 - [Data Mining Success Criteria](#)
 - [Sample Project Plan](#)
-

Data Mining Success Criteria

Success must also be defined in technical terms to keep your data mining efforts on track. Use the data mining goal determined earlier to formulate benchmarks for success. IBM® SPSS® Modeler provides tools such as the Evaluation node and the Analysis node to help you analyze the accuracy and validity of your results.

Task List

- Describe the methods for model assessment (for example, accuracy, performance, etc.).
- Define benchmarks for evaluating success. Provide specific numbers.
- Define subjective measurements as best you can and determine the arbiter of success.
- Consider whether the successful deployment of model results is part of data mining success. Start planning now for deployment.

Related information

- [Data Mining Goals](#)
 - [E-Retail Example--Data Mining Goals](#)
-

Producing a Project Plan

At this point, you're ready to produce a plan for the data mining project. The questions you have asked so far and the business and data mining goals you have formulated will form the basis for this road map.

- [Writing the Project Plan](#)
 - [Sample Project Plan](#)
 - [Assessing Tools and Techniques](#)
-

Writing the Project Plan

The project plan is the master document for all of your data mining work. If done well, it can inform everyone associated with the project of the goals, resources, risks, and schedule for all phases of data mining. You may want to publish the plan, as well as documentation gathered throughout this phase, to your company's intranet.

Task List

When creating the plan, be sure you've answered the following questions:

- Have you discussed the project tasks and proposed plan with everyone involved?
- Are time estimates included for all phases or tasks?
- Have you included the effort and resources needed to deploy the results or business solution?
- Are decision points and review requests highlighted in the plan?
- Have you marked phases where multiple iterations typically occur, such as modeling?

Related information

- [Sample Project Plan](#)
 - [Assessing Tools and Techniques](#)
-

Sample Project Plan

The overview plan for the study is as shown in the table below.

Table 1. Sample project plan overview

Phase	Time	Resources	Risks
Business understanding	1 week	All analysts	Economic change
Data understanding	3 weeks	All analysts	Data problems, technology problems
Data preparation	5 weeks	Data mining consultant, some database analyst time	Data problems, technology problems
Modeling	2 weeks	Data mining consultant, some database analyst time	Technology problems, inability to find adequate model
Evaluation	1 week	All analysts	Economic change, inability to implement results
Deployment	1 week	Data mining consultant, some database analyst time	Economic change, inability to implement results

Related information

- [Writing the Project Plan](#)
 - [Assessing Tools and Techniques](#)
-

Assessing Tools and Techniques

Since you've already chosen to use IBM® SPSS® Modeler as your tool for data mining success, you can use this step to research which data mining techniques are most appropriate for your business needs. IBM SPSS Modeler offers a full range of tools for each phase of data mining. To decide when to use the various techniques, consult the modeling section of the online Help.

Related information

- [Writing the Project Plan](#)
 - [Sample Project Plan](#)
 - [Ready for the next step?](#)
-

Ready for the next step?

Before exploring data and beginning work in IBM® SPSS® Modeler, be sure you have answered the following questions.

From a business perspective:

- What does your business hope to gain from this project?
- How will you define the successful completion of our efforts?
- Do you have the budget and resources needed to reach our goals?
- Do you have access to all the data needed for this project?
- Have you and your team discussed the risks and contingencies associated with this project?

- Do the results of your cost/benefit analysis make this project worthwhile?

After you've answered the above questions, did you translate those answers into a data mining goal?

From a data mining perspective:

- How specifically can data mining help you meet your business goals?
- Do you have an idea about which data mining techniques might produce the best results?
- How will you know when your results are accurate or effective enough? (*Have we set a measurement of data mining success?*)
- How will the modeling results be deployed? Have you considered deployment in your project plan?
- Does the project plan include all phases of CRISP-DM?
- Are risks and dependencies called out in the plan?

If you can answer "yes" to the above questions, then you're ready to take a closer look at the data.

 - [Exploring Data](#)
 - [Verifying Data Quality](#)
 - [Ready for the next step?](#)
-

Data Understanding Overview

The data understanding phase of CRISP-DM involves taking a closer look at the data available for mining. This step is critical in avoiding unexpected problems during the next phase--data preparation--which is typically the longest part of a project.

Data understanding involves accessing the data and exploring it using tables and graphics that can be organized in IBM® SPSS® Modeler using the CRISP-DM project tool. This enables you to determine the quality of the data and describe the results of these steps in the project documentation.

Related information

- [CRISP-DM Help Overview](#)

 - [Modeling Overview](#)
 - [Evaluation Overview](#)
 - [Deployment Overview](#)
-

Collecting Initial Data

At this point in CRISP-DM, you're ready to access data and bring it into IBM® SPSS® Modeler. Data come from a variety of sources, such as:

- **Existing data.** This includes a wide variety of data, such as transactional data, survey data, Web logs, etc. Consider whether the existing data are enough to meet your needs.
- **Purchased data.** Does your organization use supplemental data, such as demographics? If not, consider whether it may be needed.
- **Additional data.** If the above sources don't meet your needs, you may need to conduct surveys or begin additional tracking to supplement the existing data stores.

Task List

Take a look at the data in IBM SPSS Modeler and consider the following questions. Be sure to take notes on your findings. See the topic [Writing a Data Collection Report](#) for more information.

- Which attributes (columns) from the database seem most promising?
 - Which attributes seem irrelevant and can be excluded?
 - Is there enough data to draw generalizable conclusions or make accurate predictions?
 - Are there too many attributes for your modeling method of choice?
 - Are you merging various data sources? If so, are there areas that might pose a problem when merging?
 - Have you considered how missing values are handled in each of your data sources?
- [E-Retail Example--Initial Data Collection](#)
• [Writing a Data Collection Report](#)
-

E-Retail Example--Initial Data Collection

A Web-Mining Scenario Using CRISP-DM

The e-retailer in this example uses several important data sources, including:

Web logs. The raw access logs contain all of the information on how customers navigate the Web site. References to image files and other non-informative entries in the Web logs will need to be removed as part of the data preparation process.

Purchase data. When a customer submits an order, all of the information pertinent to that order is saved. The orders in the purchase database need to be mapped to the corresponding sessions in the Web logs.

Product database. The product attributes may be useful when determining "related" products. The product information needs to be mapped to the corresponding orders.

Customer database. This database contains extra information collected from registered customers. The records are by no means complete, because many customers do not fill out questionnaires. The customer information needs to be mapped to the corresponding purchases and sessions in the Web logs.

At this moment, the company has no plans to purchase external databases or spend money conducting surveys because its analysts are busy managing the data they currently have. At some point, however, they may want to consider an extended deployment of data mining results, in which case purchasing additional demographic data for unregistered customers may be quite useful. It may also be useful to have demographic information to see how the e-retailer's customer base differs from the average Web shopper.

Related information

- [Writing a Data Collection Report](#)
-

Writing a Data Collection Report

Using the material gathered in the previous step, you can begin to write a data collection report. Once complete, the report can be added to the project Web site or distributed to the team. It can also be combined with the reports prepared in the next steps--data description, exploration, and quality verification. These reports will guide your work throughout the data preparation phase.

Related information

- [E-Retail Example--Initial Data Collection](#)
-

Describing Data

There are many ways to describe data, but most descriptions focus on the quantity and quality of the data--how much data is available and the condition of the data. Listed below are some key characteristics to address when describing data.

- **Amount of data.** For most modeling techniques, there are trade-offs associated with data size. Large data sets can produce more accurate models, but they can also lengthen the processing time. Consider whether using a subset of data is a possibility. When taking notes for the final report, be sure to include size statistics for all data sets, and remember to consider both the number of records as well as fields (attributes) when describing data.

- **Value types.** Data can take a variety of formats, such as **numeric**, **categorical** (string), or **Boolean** (true/false). Paying attention to value type can head off problems during later modeling.
- **Coding schemes.** Frequently, values in the database are representations of characteristics such as gender or product type. For example, one data set may use *M* and *F* to represent *male* and *female*, while another may use the numeric values 1 and 2. Note any conflicting schemes in the data report.

With this knowledge in hand, you are now ready to write the [data description report](#) and share your findings with a larger audience.

-

E-Retail Example--Describing Data

A Web-Mining Scenario Using CRISP-DM

There are many records and attributes to process in a Web-mining application. Even though the e-retailer conducting this data mining project has limited the initial study to the approximately 30,000 customers who have registered on the site, there are still millions of records in the Web logs.

Most of the value types in these data sources are symbolic, whether they are dates and times, Web pages accessed, or answers to multiple-choice questions from the registration questionnaire. Some of these variables will be used to create new variables that are numeric, such as number of Web pages visited and time spent at the Web site. The few existing numeric variables in the data sources include the number of each product ordered, the amount spent during a purchase, and product weight and dimension specifications from the product database.

There is little overlap in the coding schemes for the various data sources because the data sources contain very different attributes. The only variables that overlap are "keys," such as the customer IDs and product codes. These variables must have identical coding schemes from data source to data source; otherwise, it would be impossible to merge the data sources. Some additional data preparation will be necessary to recode these key fields for merging.

- [Writing a Data Description Report](#)
-

Writing a Data Description Report

To proceed effectively with your data mining project, consider the value of producing an accurate data description report using the following metrics:

Data Quantity

- What is the format of the data?
- Identify the method used to capture the data--for example, ODBC.
- How large is the database (in numbers of rows and columns)?

Data Quality

- Does the data include characteristics relevant to the business question?
- What data types are present (symbolic, numeric, etc.)?
- Did you compute basic statistics for the key attributes? What insight did this provide into the business question?
- Are you able to prioritize relevant attributes? If not, are business analysts available to provide further insight?

Exploring Data

Use this phase of CRISP-DM to explore the data with the tables, charts, and other visualization tools available in IBM® SPSS® Modeler. Such analyses can help to address the data mining goal constructed during the [business understanding](#) phase. They can also help to formulate hypotheses and shape the data transformation tasks that take place during data preparation.

- [E-Retail Example--Exploring Data](#)

- [Writing a Data Exploration Report](#)
-

E-Retail Example--Exploring Data

A Web-Mining Scenario Using CRISP-DM

Although CRISP-DM suggests conducting an initial exploration at this point, data exploration is difficult, if not impossible, on raw Web logs, as our e-retailer has found out. Typically, Web log data must be processed first in the data preparation phase to produce data that can be meaningfully explored. This departure from CRISP-DM underscores the fact that the process can and should be customized for your particular data mining needs. CRISP-DM is cyclical, and data miners typically move back and forth between phases.

Although Web logs must be processed before exploration, the other data sources available to the e-retailer are more amenable to exploration. Using the purchase database for exploration reveals interesting summaries about customers, such as how much they spend, how many items they buy per purchase, and where they come from. Summaries of the customer database will show the distribution of responses to the items on the registration questionnaire.

Exploration is also useful for looking for errors in the data. While most of the data sources are automatically generated, information in the product database was entered by hand. Some quick summaries of listed product dimensions will help to discover typos, such as "119-inch" (instead of "19-inch") monitor.

Related information

- [Writing a Data Exploration Report](#)
-

Writing a Data Exploration Report

As you create graphs and run statistics on the available data, start forming hypotheses about how the data can answer the technical and business goals.

Task List

Take notes on your findings for inclusion in the data exploration report. Be sure to answer the following questions:

- What sort of hypotheses have you formed about the data?
- Which attributes seem promising for further analysis?
- Have your explorations revealed new characteristics about the data?
- How have these explorations changed your initial hypothesis?
- Can you identify particular subsets of data for later use?
- Take another look at your data mining goals. Has this exploration altered the goals?

Related information

- [E-Retail Example--Exploring Data](#)

Verifying Data Quality

Data are rarely perfect. In fact, most data contain coding errors, missing values, or other types of inconsistencies that make analysis tricky at times. One way to avoid potential pitfalls is to conduct a thorough quality analysis of available data before modeling.

The reporting tools in IBM® SPSS® Modeler (such as the Data Audit, Table and other output nodes) can help you look for the following types of problems:

- **Missing data** include values that are blank or coded as a non-response (such as \$null\$, ?, or 999).
- **Data errors** are usually typographical errors made in entering the data.
- **Measurement errors** include data that are entered correctly but are based on an incorrect measurement scheme.
- **Coding inconsistencies** typically involve nonstandard units of measurement or value inconsistencies, such as the use of both *M* and *male* for gender.
- **Bad metadata** include mismatches between the apparent meaning of a field and the meaning stated in a field name or definition.

Be sure to take notes on such quality concerns. See the topic [Writing a Data Quality Report](#) for more information.

- [E-Retail Example--Verifying Data Quality](#)
 - [Writing a Data Quality Report](#)
-

E-Retail Example--Verifying Data Quality

A Web-Mining Scenario Using CRISP-DM

The verification of data quality is often accomplished during the course of the description and exploration processes. Some of the issues encountered by the e-retailer include:

Missing Data. The known missing data includes the unanswered questionnaires by some of the registered users. Without the extra information provided by the questionnaire, these customers may have to be left out of some of the subsequent models.

Data Errors. Most of the data sources are automatically generated, so this is not a great worry. Typographical errors in the product database can be found during the exploration process.

Measurement Errors. The greatest potential source for measurement error is the questionnaire. If any of the items are ill-advised or poorly worded, they may not provide the information the e-retailer hopes to obtain. Again, during the exploration process, it is important to pay special attention to items that have an unusual distribution of answers.

-

Writing a Data Quality Report

Based on your exploration and verification of data quality, you're now ready to prepare a report that will guide the next phase of CRISP-DM. See the topic [Verifying Data Quality](#) for more information.

Task List

As discussed earlier, there are [several types of data quality problems](#). Before moving to the next step, consider the following quality concerns and plan for a solution. Document all responses in the data quality report.

- Have you identified missing attributes and blank fields? If so, is there meaning behind such missing values?
- Are there spelling inconsistencies that may cause problems in later merges or transformations?
- Have you explored deviations to determine whether they are "noise" or phenomena worth analyzing further?
- Have you conducted a plausibility check for values? Take notes on any apparent conflicts (such as teenagers with high income levels).
- Have you considered excluding data that has no impact on your hypotheses?
- Are the data stored in flat files? If so, are the delimiters consistent among files? Does each record contain the same number of fields?

Related information

- [E-Retail Example--Verifying Data Quality](#)
 - [Ready for the next step?](#)
-

Ready for the next step?

Before preparing the data for modeling in IBM® SPSS® Modeler, consider the following points:

How well do you understand the data?

- Are all data sources clearly identified and accessed? Are you aware of any problems or restrictions?
- Have you identified key attributes from the available data?
- Did these attributes help you to formulate hypotheses?
- Have you noted the size of all data sources?
- Are you able to use a subset of data where appropriate?
- Have you computed basic statistics for each attribute of interest? Did meaningful information emerge?
- Did you use exploratory graphics to gain further insight into key attributes? Did this insight reshape any of your hypotheses?
- What are the data quality issues for this project? Do you have a plan to address these issues?
- Are the data preparation steps clear? For instance, do you know which data sources to merge and which attributes to filter or select?

Now that you're armed with both business and data understanding, it's time to use IBM SPSS Modeler to prepare your data for modeling.

Data Preparation Overview

Data preparation is one of the most important and often time-consuming aspects of data mining. In fact, it is estimated that data preparation usually takes 50-70% of a project's time and effort. Devoting adequate energy to the earlier [business understanding](#) and [data understanding](#) phases can minimize this overhead, but you still need to expend a good amount of effort preparing and packaging the data for mining.

Depending on your organization and its goals, data preparation typically involves the following tasks:

- Merging data sets and/or records
- Selecting a sample subset of data
- Aggregating records
- Deriving new attributes
- Sorting the data for modeling
- Removing or replacing blank or missing values
- Splitting into training and test data sets

 - [Deployment Overview](#)
-

Selecting Data

Based upon the [initial data collection](#) conducted in the previous CRISP-DM phase, you are ready to begin selecting the data relevant to your data mining goals. Generally, there are two ways to select data:

- **Selecting items (rows)** involves making decisions such as which accounts, products, or customers to include.
- **Selecting attributes or characteristics (columns)** involves making decisions about the use of characteristics such as transaction amount or household income.
- [E-Retail Example--Selecting Data](#)
- [Including or Excluding Data](#)

E-Retail Example--Selecting Data

A Web-Mining Scenario Using CRISP-DM

Many of the e-retailer's decisions about which data to select have already been made in earlier phases of the data mining process.

Selecting items. The initial study will be limited to the (approximately) 30,000 customers who have registered on the site, so filters need to be set up to exclude purchases and Web logs of nonregistered customers. Other filters should be established to remove calls to image files and other non-informative entries in the Web logs.

Selecting attributes. The purchase database will contain sensitive information about the e-retailer's customers, so it is important to filter attributes such as the customer name, address, phone number, and credit card numbers.

Related information

- [Including or Excluding Data](#)

Including or Excluding Data

As you decide upon subsets of data to include or exclude, be sure to document the rationale behind your decisions.

Questions to Consider

- Is a given attribute relevant to your data mining goals?
- Does the quality of a particular data set or attribute preclude the validity of your results?
- Can you salvage such data?
- Are there any constraints on using particular fields such as *gender* or *race*?

Are your decisions here different than the hypotheses formulated in the data understanding phase? If so, be sure to document your reasoning in the project report.

Related information

- [E-Retail Example--Selecting Data](#)

Cleaning Data

Cleaning your data involves taking a closer look at the problems in the data that you've chosen to include for analysis. There are several ways to clean data using the Record and Field Operation nodes in IBM® SPSS® Modeler.

Table 1. Cleaning data

Data Problem	Possible Solution
Missing data	Exclude rows or characteristics. Or, fill blanks with an estimated value.
Data errors	Use logic to manually discover errors and replace. Or, exclude characteristics.
Coding inconsistencies	Decide upon a single coding scheme, then convert and replace values.
Missing or bad metadata	Manually examine suspect fields and track down correct meaning.

The [Data Quality Report](#) prepared during the data understanding phase contains details about the types of problems particular to your data. You can use it as a starting point for data manipulation in IBM SPSS Modeler.

- [E-Retail Example--Cleaning Data](#)
- [Writing a Data Cleaning Report](#)

Related information

- [E-Retail Example--Constructing Data](#)
- [E-Retail Example--Integrating Data](#)

E-Retail Example--Cleaning Data

The e-retailer uses the data cleaning process to address the problems noted in the data quality report.

Missing data. Customers who did not complete the online questionnaire may have to be left out of some of the models later on. These customers could be asked again to fill out the questionnaire, but this will take time and money that the e-retailer cannot afford to spend. What the e-retailer can do is model the purchasing differences between customers who do and do not answer the questionnaire. If these two sets of customers have similar purchasing habits, the missing questionnaires are less worrisome.

Data errors. Errors found during the exploration process can be corrected here. For the most part, though, proper data entry is enforced on the Web site before a customer submits a page to the back-end database.

Measurement errors. Poorly worded items on the questionnaire can greatly affect the quality of the data. As with missing questionnaires, this is a difficult problem because there may not be time or money available to collect answers to a new replacement question. For problematic items, the best solution may be to go back to the selection process and filter these items from further analyses.

 - [E-Retail Example--Integrating Data](#)
-

Writing a Data Cleaning Report

Reporting your data-cleaning efforts is essential for tracking alterations to the data. Future data mining projects will benefit from having the details of your work readily available.

Task List

It's a good idea to consider the following questions when writing the report:

- What types of noise occurred in the data?
- What approaches did you use to remove the noise? Which techniques were successful?
- Are there any cases or attributes that could not be salvaged? Be sure to note data excluded due to noise.

Related information

- [E-Retail Example--Cleaning Data](#)
 - [E-Retail Example--Constructing Data](#)
 - [E-Retail Example--Integrating Data](#)
-

Constructing New Data

It is frequently the case that you'll need to construct new data. For example, it may be useful to create a new column flagging the purchase of an extended warranty for each transaction. This new field, *purchased_warranty*, can easily be generated using a Set to Flag node in IBM® SPSS® Modeler.

There are two ways to construct new data:

- Deriving attributes (columns or characteristics)
- Generating records (rows)

IBM SPSS Modeler offers a multitude of ways to construct data using its Record and Field Operations nodes.

- [E-Retail Example--Constructing Data](#)
 - [Deriving Attributes](#)
-

E-Retail Example--Constructing Data

The processing of Web logs can create many new attributes. For the events recorded in the logs, the e-retailer will want to create timestamps, identify visitors and sessions, and note the page accessed and the type of activity the event represents. Some of these variables will be used to create more attributes, such as the time between events within a session.

Further attributes can be created as a result of a merge or other data restructuring. For example, when the event-per-row Web logs are "rolled up" so that each row is a session, new attributes recording the total number of actions, total time spent, and total purchases made during the session will be created. When the Web logs are merged with the customer database so that each row is a customer, new attributes recording the number of sessions, total number of actions, total time spent, and total purchases made by each customer will be created.

After constructing new data, the e-retailer goes through an exploration process to make sure that the data creation was performed correctly.

Related information

-

Deriving Attributes

In IBM® SPSS® Modeler, you can use the following Field Operations nodes to derive new attributes:

- Create new fields derived from existing ones using a **Derive node**.
- Create a flag field using a **Set to Flag node**.

Task List

- Consider the data requirements for modeling when deriving attributes. Does the modeling algorithm expect a particular type of data, such as numeric? If so, perform the necessary transformations.
 - Do the data need be normalized before modeling?
 - Can missing attributes be constructed using aggregation, averaging, or induction?
 - Based upon your background knowledge, are there important facts (such as length of time spent at the Web site) that can be derived from existing fields?
-

Integrating Data

It is not uncommon to have multiple data sources for the same set of business questions. For example, you may have access to mortgage loan data as well as purchased demographic data for the same set of clients. If these data sets contain the same unique identifier (such as social security number), you can merge them in IBM® SPSS® Modeler using this key field.

There are two basic methods of integrating data:

- **Merging** data involves merging two data sets with similar records but different attributes. The data is merged using the same key identifier for each record (such as customer ID). The resulting data increases in columns or characteristics.
 - **Appending** data involves integrating two or more data sets with similar attributes but different records. The data is integrated based upon a similar fields (such as product name or contract length).
- [E-Retail Example--Integrating Data](#)
 - [Integration Tasks](#)
-

E-Retail Example--Integrating Data

A Web-Mining Scenario Using CRISP-DM

With multiple data sources, there are many different ways in which the e-retailer can integrate data:

- **Adding customer and product attributes to event data.** In order to model Web log events using attributes from other databases, any customer ID, product number, and purchase order number associated with each event must be correctly identified and the corresponding attributes merged to the processed Web logs. Note that the merged file replicates customer and product information every time a customer or product is associated with an event.
- **Adding purchase and Web log information to customer data.** In order to model the value of a customer, their purchases and session information must be picked out of the appropriate databases, totaled, and merged with the customer database. This involves the creation

of new attributes as discussed in the constructing data process.

After integrating databases, the e-retailer goes through an exploration process to make sure that the data merge was performed correctly.

Related information

- [Cleaning Data](#)
 - [E-Retail Example--Cleaning Data](#)
 - [Writing a Data Cleaning Report](#)
 - [E-Retail Example--Constructing Data](#)
-

Integration Tasks

Integrating data can become complex if you have not spent adequate time developing an understanding of your data. Give some thought to items and attributes that seem most relevant to the data mining goals and then get started integrating your data.

Task List

- Using Merge or Append nodes in IBM® SPSS® Modeler, integrate the data sets considered useful for modeling.
 - Consider saving the resulting output before proceeding to modeling.
 - After merging, data can be simplified by **aggregating** values. Aggregation means that new values are computed by summarizing information from multiple records and/or tables.
 - You may also need to generate new records (such as the average deduction from several years of combined tax returns).
-

Formatting Data

As a final step before model building, it is helpful to check whether certain techniques require a particular format or order to the data. For example, it is not uncommon that a sequence algorithm requires the data to be presorted before running the model. Even if the model can perform the sorting for you, it may save processing time to use a Sort node prior to modeling.

Task List

Consider the following questions when formatting data:

- Which models do you plan to use?
- Do these models require a particular data format or order?

If changes are recommended, the processing tools in IBM® SPSS® Modeler can help you apply the necessary data manipulation.

Ready for modeling?

Before building models in IBM® SPSS® Modeler, be sure you have answered the following questions.

- Are all the data accessible from within IBM SPSS Modeler?
- Based upon your initial exploration and understanding, were you able to select relevant subsets of data?
- Have you cleaned the data effectively or removed unsalvageable items? Document any decisions in the final report.
- Are multiple data sets integrated properly? Were there any merging problems that should be documented?
- Have you researched the requirements of the modeling tools that you plan to use?
- Are there any formatting issues you can address before modeling? This includes both required formatting concerns as well as tasks that may reduce modeling time.

If you can answer the above questions, then you're ready for the crux of data mining--modeling.

-

Modeling Overview

This is the point at which your hard work begins to pay off. The data you spent time preparing are brought into the analysis tools in IBM® SPSS® Modeler, and the results begin to shed some light on the business problem posed during [Business Understanding](#).

Modeling is usually conducted in multiple iterations. Typically, data miners run several models using the default parameters and then fine-tune the parameters or revert to the data preparation phase for manipulations required by their model of choice. It is rare for an organization's data mining question to be answered satisfactorily with a single model and a single execution. This is what makes data mining so interesting--there are many ways to look at a given problem, and IBM SPSS Modeler offers a wide variety of tools to help you do so.

 - [Deployment Overview](#)
-

Selecting Modeling Techniques

Although you may already have some idea about which types of modeling are most appropriate for your organization's needs, now is the time to make some firm decisions about which ones to use. Determining the most appropriate model will typically be based on the following considerations:

- **The data types available for mining.** For example, are the fields of interest categorical (symbolic)?
- **Your data mining goals.** Do you simply want to gain insight into transactional data stores and unearth interesting purchase patterns? Or do you need to produce a score indicating, for example, propensity to default on a student loan?
- **Specific modeling requirements.** Does the model require a particular data size or type? Do you need a model with easily presentable results?

For more information on the model types in IBM® SPSS® Modeler and their requirements, see the IBM SPSS Modeler documentation or online Help.

- [E-Retail Example--Modeling Techniques](#)
 - [Choosing the Right Modeling Techniques](#)
 - [Modeling Assumptions](#)
-

E-Retail Example--Modeling Techniques

The modeling techniques employed by the e-retailer are driven by the company's data mining goals:

Improved recommendations. At its simplest, this involves clustering purchase orders to determine which products are most often bought together. Customer data, and even visit records, can be added for richer results. The two-step or Kohonen network clustering techniques are suited for this type of modeling. Afterward, the clusters can be profiled using a C5.0 ruleset to determine which recommendations are most appropriate at any point during a customer's visit.

Improved site navigation. For now, the e-retailer will focus on identifying pages that are often used but require several clicks for the user to find. This entails applying a sequencing algorithm to the Web logs in order to generate the "unique paths" customers take through the Web site, and then specifically looking for sessions that have a lot of page visits without (or before) an action taken. Later, in a more in-depth analysis,

clustering techniques can be used to identify different "types" of visits and visitors, and the site content can be organized and presented according to type.

Related information

- [Choosing the Right Modeling Techniques](#)
 - [Modeling Assumptions](#)
-

Choosing the Right Modeling Techniques

Many modeling techniques are available in IBM® SPSS® Modeler. Frequently, data miners use more than one to approach the problem from a number of directions.

Task List

When deciding on which model(s) to use, consider whether the following issues have an impact on your choices:

- Does the model require the data to be split into test and training sets?
- Do you have enough data to produce reliable results for a given model?
- Does the model require a certain level of data quality? Can you meet this level with the current data?
- Are your data the proper type for a particular model? If not, can you make the necessary conversions using data manipulation nodes?

For more information on the model types in IBM SPSS Modeler and their requirements, see the IBM SPSS Modeler documentation or online Help.

Related information

- [E-Retail Example--Modeling Techniques](#)
 - [Modeling Assumptions](#)
-

Modeling Assumptions

As you begin to narrow down your modeling tools of choice, take notes on the decision-making process. Document any data assumptions as well as any data manipulations made to meet the model's requirements.

For example, both the Logistic Regression and Neural Net nodes require the data types to be fully **instantiated** (data types are known) before execution. This means you will need to add a Type node to the stream and execute it to run the data through before building and running a model. Similarly, predictive models, such as C5.0, may benefit from rebalancing the data when predicting rules for rare events. When making this type of prediction, you can often get better results by inserting a Balance node into the stream and feeding the more balanced subset into the model.

Be sure to document these types of decisions.

Related information

- [E-Retail Example--Modeling Techniques](#)
 - [Choosing the Right Modeling Techniques](#)
-

Generating a Test Design

As a final step before actually building the model, you should take a moment to consider again how the model's results will be tested. There are two parts to generating a comprehensive test design:

- Describing the criteria for "goodness" of a model
- Defining the data on which these criteria will be tested

A model's **goodness** can be measured in several ways. For supervised models, such as C5.0 and C&R Tree, measurements of goodness typically estimate the error rate of a particular model. For unsupervised models, such as Kohonen cluster nets, measurements may include criteria such as ease of interpretation, deployment, or required processing time.

Remember, model building is an iterative process. This means that you will typically test the results of several models before deciding on the ones to use and deploy.

- [Writing a Test Design](#)
 - [E-Retail Example--Test Design](#)
-

Writing a Test Design

The test design is a description of the steps you will take to test the models produced. Because modeling is an iterative process, it is important to know when to stop adjusting parameters and try another method or model.

Task List

When creating a test design, consider the following questions:

- What data will be used to test the models? Have you partitioned the data into train/test sets? (This is a commonly used approach in modeling.)
- How might you measure the success of supervised models (such as C5.0)?
- How might you measure the success of unsupervised models (such as Kohonen cluster nets)?
- How many times are you willing to rerun a model with adjusted settings before attempting another type of model?

Related information

- [E-Retail Example--Test Design](#)
-

E-Retail Example--Test Design

A Web-Mining Scenario Using CRISP-DM

The criteria by which the models are assessed depend on the models under consideration and the data mining goals:

Improved recommendations. Until the improved recommendations are presented to live customers, there is no purely objective way to assess them. However, the e-retailer may require the rules that generate the recommendations to be simple enough to make sense from a business perspective. Likewise, the rules should be complex enough to generate different recommendations for different customers and sessions.

Improved site navigation. Given the evidence of what pages customers access on the Web site, the e-retailer can objectively assess the updated site design in terms of ease of access to important pages. However, as with the recommendations, it is difficult to assess in advance how well customers will adjust to the reorganized site. If time and finances allow, some usability testing may be in order.

Related information

- [Writing a Test Design](#)
-

Building the Models

At this point, you should be well prepared to build the models you've spent so long considering. Give yourself time and room to experiment with a number of different models before making final conclusions. Most data miners typically build several models and compare the results before deploying or integrating them.

In order to track your progress with a variety of models, be sure to keep notes on the settings and data used for each model. This will help you to discuss the results with others and retrace your steps if necessary. At the end of the model-building process, you'll have three pieces of information to use in data mining decisions:

- **Parameter settings** include the notes you take on parameters that produce the best results.
 - The actual **models** produced.
 - **Descriptions of model results**, including performance and data issues that occurred during the execution of the model and exploration of its results.
- [E-Retail Example--Model Building](#)
 - [Parameter Settings](#)
 - [Running the Models](#)
 - [Model description](#)

E-Retail Example--Model Building

A Web-Mining Scenario Using CRISP-DM

Improved recommendations. Clusterings are produced for varying levels of data integration, starting with just the purchase database and then including related customer and session information. For each level of integration, clusterings are produced under varying parameter settings for the two-step and Kohonen network algorithms. For each of these clusterings, a few C5.0 rulesets are generated with different parameter settings.

Improved site navigation. The Sequence modeling node is used to generate customer paths. The algorithm allows the specification of a minimum support criterion, which is useful for focusing on the most common customer paths. Various settings for the parameters are tried.

Related information

- [Parameter Settings](#)
- [Running the Models](#)
- [Model description](#)

Parameter Settings

Most modeling techniques have a variety of parameters or settings that can be adjusted to control the modeling process. For example, decision trees can be controlled by adjusting tree depth, splits, and a number of other settings. Typically, most people build a model first using the default options and then refine parameters during subsequent sessions.

Once you have determined the parameters that produce the most accurate results, be sure to save the stream and generated model nodes. Also, taking notes on the optimal settings can help when you decide to automate or rebuild the model with new data.

Related information

- [E-Retail Example--Model Building](#)
- [Running the Models](#)
- [Model description](#)

Running the Models

In IBM® SPSS® Modeler, running models is a straightforward task. Once you've inserted the model node into the stream and edited any parameters, simply execute the model to produce viewable results. Results appear in the Generated Models navigator on the right side of the workspace. You can right-click a model to browse the results. For most models, you can insert the generated model into the stream to further evaluate and deploy the results. Models can be also be saved in IBM SPSS Modeler for easy reuse.

Related information

- [E-Retail Example--Model Building](#)
- [Parameter Settings](#)
- [Model description](#)

Model description

When examining the results of a model, be sure to take notes on your modeling experience. You can store notes with the model itself using the node annotations dialog box or the project tool.

Task list

For each model, record information such as:

- Can you draw meaningful conclusions from this model?

- Are there new insights or unusual patterns revealed by the model?
- Were there execution problems for the model? How reasonable was the processing time?
- Did the model have difficulties with data quality issues, such as a high number of missing values?
- Were there any calculation inconsistencies that should be noted?

Related information

Assessing the Model

Now that you have a set of initial models, take a closer look at them to determine which are accurate or effective enough to be final. Final can mean several things, such as "ready to deploy" or "illustrating interesting patterns." Consulting the test plan that you created earlier can help to make this assessment from your organization's point of view.

- [Comprehensive Model Assessment](#)
 - [E-Retail Example--Model Assessment](#)
 - [Keeping Track of Revised Parameters](#)
-

Comprehensive Model Assessment

For each model under consideration, it is a good idea to make a methodical assessment based on the criteria generated in your test plan. Here is where you may add the generated model to the stream and use evaluation charts or analysis nodes to analyze the effectiveness of the results. You should also consider whether the results make logical sense or whether they are too simplistic for your business goals (for example, a sequence that reveals purchases such as wine > wine > wine).

Once you've made an assessment, rank the models in order based on both objective (model accuracy) and subjective (ease of use or interpretation of results) criteria.

Task List

- Using the data mining tools in IBM® SPSS® Modeler, such as evaluation charts, analysis nodes, or cross-validation charts, evaluate the results of your model.
- Conduct a review of the results based on your understanding of the business problem. Consult data analysts or other experts who may have insight into the relevance of particular results.
- Consider whether a model's results are easily deployable. Does your organization require that results be deployed over the Web or sent back to the data warehouse?
- Analyze the impact of results on your success criteria. Do they meet the goals established during the business understanding phase?

If you were able to address the above issues successfully and believe that the current models meet your goals, it's time to move on to a more thorough evaluation of the models and a final deployment. Otherwise, take what you've learned and rerun the models with adjusted parameter settings.

E-Retail Example--Model Assessment

A Web-Mining Scenario Using CRISP-DM

Improved recommendations. One of the Kohonen networks and a two-step clustering each give reasonable results, and the e-retailer finds it difficult to choose between them. In time, the company hopes to use both, accepting the recommendations that the two techniques agree on and studying in greater detail the situations in which they differ. With a little effort and applied business knowledge, the e-retailer can develop further rules to resolve differences between the two techniques.

The e-retailer also finds that the results that include the session information are surprisingly good. There is evidence to suggest that recommendations could be tied to site navigation. A ruleset, defining where the customer is likely to go next, could be used in real time to affect the site content directly as the customer is browsing.

Improved site navigation. The Sequence model provides the e-retailer with a high level of confidence that certain customer paths can be predicted, producing results that suggest a manageable number of changes to the site design.

Related information

 - [Keeping Track of Revised Parameters](#)
-

Keeping Track of Revised Parameters

Based on what you've learned during model assessment, it's time to have another look at the models. You have two options here:

- Adjust the parameters of existing models.
- Choose a different model to address your data mining problem.

In both cases, you'll be returning to the building models task and iterate until the results are successful. Don't worry about repeating this step. It is extremely common for data miners to evaluate and rerun models several times before finding one that meets their needs. This is a good argument for building several models at once and comparing the results before adjusting the parameters for each.

-

Ready for the next step?

Before moving on to a final evaluation of the models, consider whether your initial assessment was thorough enough.

Task List

- Are you able to understand the results of the models?
- Do the model results make sense to you from a purely logical perspective? Are there apparent inconsistencies that need further exploration?
- From your initial glance, do the results seem to address your organization's business question?
- Have you used analysis nodes and lift or gains charts to compare and evaluate model accuracy?
- Have you explored more than one type of model and compared the results?
- Are the results of your model deployable?

If the results of your data modeling seem accurate and relevant, it's time to conduct a more thorough evaluation before a final deployment.

-

Evaluation Overview

At this point, you've completed most of your data mining project. You've also determined, in the Modeling phase, that the models built are technically correct and effective according to the **data mining success criteria** that you defined earlier.

Before continuing, however, you should evaluate the results of your efforts using the **business success criteria** established at the beginning of the project. This is the key to ensuring that your organization can make use of the results you've obtained. Two types of results are produced by data mining:

- The final **models** selected in the previous phase of CRISP-DM.
- Any conclusions or inferences drawn from the models themselves as well as from the data mining process. These are known as **findings**.

-

Evaluating the Results

At this stage, you formalize your assessment of whether or not the project results meet the business success criteria. This step requires a clear understanding of the stated business goals, so be sure to include key decision makers in the project assessment.

Task List

First, you need to document your assessment of whether the data mining results meet the business success criteria. Consider the following questions in your report:

- Are your results stated clearly and in a form that can be easily presented?
- Are there particularly novel or unique findings that should be highlighted?
- Can you rank the models and findings in order of their applicability to the business goals?
- In general, how well do these results answer your organization's business goals?
- What additional questions have your results raised? How might you phrase these questions in business terms?

After you have evaluated the results, compile a list of approved models for inclusion in the final report. This list should include models that satisfy both the data mining and business goals of your organization.

- [E-Retail Example--Evaluating Results](#)
-

E-Retail Example--Evaluating Results

A Web-Mining Scenario Using CRISP-DM

The overall results of the e-retailer's first experience with data mining are fairly easy to communicate from a business perspective: the study produced what are hoped to be better product recommendations and an improved site design. The improved site design is based on the customer browsing sequences, which show the site features that customers want but require several steps to reach. The evidence that the product recommendations are better is more difficult to convey, because the decision rules can become complicated. To produce the final report, the analysts will try to identify some general trends in the rulesets that can be more easily explained.

Ranking the Models. Because several of the initial models seemed to make business sense, ranking within that group was based on statistical criteria, ease of interpretation, and diversity. Thus, the model gave different recommendations for different situations.

New Questions. The most important question to come out of the study is, How can the e-retailer find out more about his or her customers? The information in the customer database plays an important role in forming the clusters for recommendations. While special rules are available for making recommendations to customers whose information is missing, the recommendations are more general in nature than those that can be made to registered customers.

Review Process

Effective methodologies usually include time for reflection on the successes and weaknesses of the process just completed. Data mining is no different. Part of CRISP-DM is learning from your experience so that future data mining projects will be more effective.

Task List

First, you should summarize the activities and decisions for each phase, including data preparation steps, model building, etc. Then for each phase, consider the following questions and make suggestions for improvement:

- Did this stage contribute to the value of the final results?
 - Are there ways to streamline or improve this particular stage or operation?
 - What were the failures or mistakes of this phase? How can they be avoided next time?
 - Were there dead ends, such as particular models that proved fruitless? Are there ways to predict such dead ends so that efforts can be directed more productively?
 - Were there any surprises (both good and bad) during this phase? In hindsight, is there an obvious way to predict such occurrences?
 - Are there alternative decisions or strategies that might have been used in a given phase? Note such alternatives for future data mining projects.
- [E-Retail Example--Review Report](#)
-

E-Retail Example--Review Report

A Web-Mining Scenario Using CRISP-DM

As a result of reviewing the process of the initial data mining project, the e-retailer has developed a greater appreciation of the interrelations between steps in the process. Initially reluctant to "backtrack" in the CRISP-DM process, the e-retailer now sees that the [cyclic nature of the process](#) increases its power. The process review has also led the e-retailer to understand that:

- A return to the exploration process is always warranted when something unusual appears in another phase of the CRISP-DM process.
 - Data preparation, especially of Web logs, requires patience, since it can take a very long time.
 - It is vital to stay focused on the business problem at hand, because once the data are ready for analysis, it's all too easy to start constructing models without regard to the bigger picture.
 - Once the modeling phase is over, business understanding is even more important in deciding how to implement results and determine what further studies are warranted.
-

Determining the Next Steps

By now, you've produced results, evaluated your data mining experiences, and may be wondering, **Where to next?** This phase helps you to answer that question in light of your business goals for data mining. Essentially, you have two choices at this point:

- **Continue to the deployment phase.** The next phase will help you to incorporate the model results into your business process and produce a final report. Even if your data mining efforts were unsuccessful, you should use the deployment phase of CRISP-DM to create a final report for distribution to the project sponsor.
- **Go back and refine or replace your models.** If you find that your results are almost, but not quite, optimal, consider another round of modeling. You can take what you've learned in this phase and use it to refine the models and produce better results.

Your decision at this point involves the accuracy and relevancy of the modeling results. If the results address your data mining and business goals, then you are ready for the deployment phase. Whatever decision you make, be sure to document the evaluation process thoroughly.

- [E-Retail Example--Next Steps](#)
-

E-Retail Example--Next Steps

A Web-Mining Scenario Using CRISP-DM

The e-retailer is fairly confident of both the accuracy and relevancy of the project results and so is continuing to the deployment phase.

At the same time, the project team is also ready to go back and augment some of the models to include predictive techniques. At this point, they're waiting for delivery of the final reports and a green light from the decision makers.

Deployment

- [Deployment Overview](#)
 - [Planning for Deployment](#)
 - [Planning Monitoring and Maintenance](#)
 - [Producing a Final Report](#)
 - [Conducting a Final Project Review](#)
-

Deployment Overview

Deployment is the process of using your new insights to make improvements within your organization. This can mean a formal integration such as the implementation of a IBM® SPSS® Modeler model producing churn scores that are then read into a data warehouse. Alternatively, deployment can mean that you use the insights gained from data mining to elicit change in your organization. For example, perhaps you discovered alarming patterns in your data indicating a shift in behavior for customers over the age of 30. These results may not be formally integrated into your information systems, but they will undoubtedly be useful for planning and making marketing decisions.

In general, the deployment phase of CRISP-DM includes two types of activities:

- Planning and monitoring the deployment of results
- Completing wrap-up tasks such as producing a final report and conducting a project review

Depending on your organization's requirements, you may need to complete one or both of these steps.

-

Planning for Deployment

Although you may be anxious to share the fruits of your data mining efforts, take time to plan for a smooth and comprehensive deployment of results.

Task List

- The first step is to summarize your results--both models and findings. This helps you determine which models can be integrated within your database systems and which findings should be presented to your colleagues.
- For each deployable model, create a step-by-step plan for deployment and integration with your systems. Note any technical details such as database requirements for model output. For example, perhaps your system requires that modeling output be deployed in a tab-delimited format.
- For each conclusive finding, create a plan to disseminate this information to strategy makers.
- Are there alternative deployment plans for both types of results that are worth mentioning?
- Consider how the deployment will be monitored. For example, how will a model deployed using IBM® SPSS® Modeler Solution Publisher be updated? How will you decide when the model is no longer applicable?
- Identify any deployment problems and plan for contingencies. For example, decision makers may want more information on modeling results and may require that you provide further technical details.
- [E-Retail Example--Deployment Planning](#)

Related information

- [Deployment Overview](#)

- [Conducting a Final Project Review](#)

E-Retail Example--Deployment Planning

A Web-Mining Scenario Using CRISP-DM

A successful deployment of the e-retailer's data mining results requires that the right information reaches the right people.

Decision makers. Decision makers need to be informed of the recommendations and proposed changes to the site, and provided with short explanations of how these changes will help. Assuming that they accept the results of the study, the people who will implement the changes need to be notified.

Web developers. People who maintain the Web site will have to incorporate the new recommendations and organization of site content. Inform them of what changes *could* happen because of future studies, so they can lay the groundwork now. Getting the team prepared for on-the-fly site construction based upon real-time sequence analysis might be helpful later.

Database experts. The people who maintain the customer, purchase, and product databases should be kept apprised of how the information from the databases is being used and what attributes may be added to the databases in future projects.

Above all, the project team needs to keep in touch with each of these groups to coordinate the deployment of results and planning for future projects.

Planning Monitoring and Maintenance

In a full-fledged deployment and integration of modeling results, your data mining work may be ongoing. For example, if a model is deployed to predict sequences of e-basket purchases, this model will likely need to be evaluated periodically to ensure its effectiveness and to make continuous improvements. Similarly, a model deployed to increase customer retention among high-value customers will likely need to be tweaked once a particular level of retention is reached. The model might then be modified and re-used to retain customers at a lower but still profitable level on the value pyramid.

Task List

Take notes on the following issues and be sure to include them in the final report.

- For each model or finding, which factors or influences (such as market value or seasonal variation) need to be tracked?
- How can the validity and accuracy of each model be measured and monitored?
- How will you determine when a model has "expired"? Give specifics on accuracy thresholds or expected changes in data, etc.
- What will occur when a model expires? Can you simply rebuild the model with newer data or make slight adjustments? Or will changes be pervasive enough as to require a new data mining project?
- Can this model be used for similar business issues once it has expired? This is where good documentation becomes critical for assessing the business purpose for each data mining project.
- [E-Retail Example--Monitoring and Maintenance](#)

Related information

- [Deployment Overview](#)
- [Planning for Deployment](#)
- [Producing a Final Report](#)
- [Conducting a Final Project Review](#)

E-Retail Example--Monitoring and Maintenance

A Web-Mining Scenario Using CRISP-DM

The immediate task for monitoring is to determine whether the new site organization and improved recommendations actually work. That is, are users able to take more direct routes to the pages that they're looking for? Have cross-sales of recommended items increased? After a few weeks of monitoring, the e-retailer will be able to determine the success of the study.

What can be handled automatically is the inclusion of new registered users. When customers register with the site, the current rulesets can be applied to their information to determine what recommendations they should be given.

Deciding when to update the rulesets for determining recommendations is a trickier task. Updating the rulesets is not an automatic process because cluster creation requires human input regarding the appropriateness of a given cluster solution.

As future projects generate more complex models, the need for and amount of monitoring will almost surely increase. When possible, the bulk of the monitoring should be automatic with regularly scheduled reports available for review. Alternatively, the creation of models that provide predictions on the fly may be a direction the company would like to take. This requires more sophistication from the team than the first data mining project.

Producing a Final Report

Writing a final report not only ties up loose ends in earlier documentation, it can also be used to communicate your results. While this may seem straightforward, it's important to present your results to the various people with a stake in the results. This can include both technical administrators who will be responsible for implementation of the modeling results as well as marketing and management sponsors who will make decisions based on your results.

Task List

First, consider the audience of your report. Are they technical developers or market-focused managers? You may need to create separate reports for each audience if their needs are disparate. In either case, your report should include most of the following points:

- A thorough description of the original business problem
- The process used to conduct data mining
- Costs of the project
- Notes on any deviations from the original project plan
- A summary of data mining results, both models and findings
- An overview of the proposed plan for deployment
- Recommendations for further data mining work, including interesting leads discovered during exploration and modeling
- [Preparing a Final Presentation](#)
- [E-Retail Example--Final Report](#)

Related information

- [Deployment Overview](#)
 - [Planning for Deployment](#)
 - [Planning Monitoring and Maintenance](#)
 - [Conducting a Final Project Review](#)
-

Preparing a Final Presentation

In addition to the project report, you may also need to present the project findings to a team of sponsors or related departments. If this is the case, you could use much of the same information in your report but presented from a broader perspective. The charts and graphs in IBM® SPSS® Modeler can easily be exported for this type of presentation.

E-Retail Example--Final Report

A Web-Mining Scenario Using CRISP-DM

The greatest deviation from the original project plan is also an interesting lead for further data mining work. The original plan called for finding out how to have customers spend more time and see more pages on the site per visit.

As it turns out, having a happy customer is not simply a matter of keeping them online. Frequency distributions of time spent per session, split on whether the session resulted in a purchase, found that the session times for most sessions resulting in purchases fall between the session times for two clusters of nonpurchase sessions.

Now that this is known, the issue is to find out whether these customers who spend a long time on the site without purchasing are just browsing or simply can't find what they're looking for. The next step is to find out how to deliver what they're looking for in order to encourage purchases.

Conducting a Final Project Review

This is the final step of the CRISP-DM methodology, and it offers you a chance to formulate your final impressions and collate the lessons learned during the data mining process.

Task List

You should conduct a brief interview with those significantly involved in the data mining process. Questions to consider during these interviews include the following:

- What are your overall impressions of the project?
- What did you learn during the process--both about data mining in general and the data available?
- Which parts of the project went well? Where did difficulties arise? Was there information that might have helped ease the confusion?

After the data mining results have been deployed, you might also interview those affected by the results such as customers or business partners. Your goal here should be to determine whether the project was worthwhile and offered the benefits it set out to create.

The results of these interviews can be summarized along with your own impressions of the project in a final report that should focus on the lessons learned from the experience of mining your stores of data.

-

E-Retail Example--Final Review

A Web-Mining Scenario Using CRISP-DM

Project member interviews. The e-retailer finds that project members most closely associated with the study from start to finish are for the most part enthusiastic about the results and look forward to future projects. The database group seems cautiously optimistic; while they appreciate the usefulness of the study, they point out the added burden on database resources. A consultant was available during the study, but going forward, another employee dedicated to database maintenance will be necessary as the scope of the project expands.

Customer interviews. Customer feedback has been largely positive so far. One issue that was not well thought out was the impact of the site design change on established customers. After a few years, the registered customers developed certain expectations about how the site is organized. Feedback from registered users is not quite as positive as from nonregistered customers, and a few greatly dislike the changes. The e-retailer needs to stay aware of this issue and carefully consider whether a change will bring in enough new customers to risk losing existing ones.

About IBM SPSS Modeler Text Analytics

IBM® SPSS® Modeler Text Analytics offers powerful text analytic capabilities, which use advanced linguistic technologies and Natural Language Processing (NLP) to rapidly process a large variety of unstructured text data and, from this text, extract and organize the key concepts. Furthermore, IBM SPSS Modeler Text Analytics can group these concepts into categories.

Around 80% of data held within an organization is in the form of text documents—for example, reports, Web pages, e-mails, and call center notes. Text is a key factor in enabling an organization to gain a better understanding of their customers' behavior. A system that incorporates NLP can intelligently extract concepts, including compound phrases. Moreover, knowledge of the underlying language allows classification of terms into related groups, such as products, organizations, or people, using meaning and context. As a result, you can quickly determine the relevance of the information to your needs. These extracted concepts and categories can be combined with existing structured data, such as demographics, and applied to modeling in IBM SPSS Modeler's full suite of data mining tools to yield better and more-focused decisions.

Linguistic systems are knowledge sensitive—the more information contained in their dictionaries, the higher the quality of the results. IBM SPSS Modeler Text Analytics is delivered with a set of linguistic resources, such as dictionaries for terms and synonyms, libraries, and templates. This product further allows you to develop and refine these linguistic resources to your context. Fine-tuning of the linguistic resources is often an iterative process and is necessary for accurate concept retrieval and categorization. Custom templates, libraries, and dictionaries for specific domains, such as CRM and genomics, are also included.

Deployment. You can deploy text mining streams using the IBM SPSS Modeler Solution Publisher for real-time scoring of unstructured data. The ability to deploy these streams ensures successful, closed-loop text mining implementations. For example, your organization can now analyze scratch-pad notes from inbound or outbound callers by applying your predictive models to increase the accuracy of your marketing message in real time.

To run IBM SPSS Modeler Text Analytics with IBM SPSS Modeler Solution Publisher, add the directory `<install_directory>/ext/bin/spss.TMWBServer` to the `$LD_LIBRARY_PATH` environment variable.

Note: The Japanese adapter for IBM SPSS Modeler Text Analytics has been deprecated starting with version 18.1.

- [Applications](#)

Upgrading IBM SPSS Modeler Text Analytics

Before installing IBM® SPSS® Modeler Text Analytics, you should save and export any TAPs, templates, and libraries from your current version that you want to use in the new version. We recommend that you save these files to a directory that will not get deleted or overwritten when you install the latest version.

After you install the latest version of IBM SPSS Modeler Text Analytics, you can load the saved TAP file, add any saved libraries, or import and load any saved templates to use them in the latest version.

Important: If you uninstall your current version without saving and exporting the files you require first, any TAP, template, and public library work performed in the previous version will be lost and unable to be used in the latest version of IBM SPSS Modeler Text Analytics.

About text mining

Today an increasing amount of information is being held in unstructured and semistructured formats, such as customer e-mails, call center notes, open-ended survey responses, news feeds, Web forms, etc. This abundance of information poses a problem to many organizations that ask themselves, "How can we collect, explore, and leverage this information?"

Text mining is the process of analyzing collections of textual materials in order to capture key concepts and themes and uncover hidden relationships and trends without requiring that you know the precise words or terms that authors have used to express those concepts. Although they are quite different, text mining is sometimes confused with information retrieval. While the accurate retrieval and storage of information is an enormous challenge, the extraction and management of quality content, terminology, and relationships contained within the information are crucial and critical processes.

Text mining and data mining

For each article of text, linguistic-based text mining returns an index of concepts, as well as information about those concepts. This distilled, structured information can be combined with other data sources to address questions such as:

- Which concepts occur together?
- What else are they linked to?
- What higher level categories can be made from extracted information?
- What do the concepts or categories predict?
- How do the concepts or categories predict behavior?

Combining text mining with data mining offers greater insight than is available from either structured or unstructured data alone. This process typically includes the following steps:

1. **Identify the text to be mined.** Prepare the text for mining. If the text exists in multiple files, save the files to a single location. For databases, determine the field containing the text.
2. **Mine the text and extract structured data.** Apply the text mining algorithms to the source text.
3. **Build concept and category models.** Identify the key concepts and/or create categories. The number of concepts returned from the unstructured data is typically very large. Identify the best concepts and categories for scoring.
4. **Analyze the structured data.** Employ traditional data mining techniques, such as clustering, classification, and predictive modeling, to discover relationships between the concepts. Merge the extracted concepts with other structured data to predict future behavior based on the concepts.

Text analysis and categorization

Text analysis, a form of qualitative analysis, is the extraction of useful information from text so that the key ideas or concepts contained within this text can be grouped into an appropriate number of categories. Text analysis can be performed on all types and lengths of text, although the approach to the analysis will vary somewhat.

Shorter records or documents are most easily categorized, since they are not as complex and usually contain fewer ambiguous words and responses. For example, with short, open-ended survey questions, if we ask people to name their three favorite vacation activities, we might expect to see many short answers, such as *going to the beach*, *visiting national parks*, or *doing nothing*. Longer, open-ended responses, on the other hand, can be quite complex and very lengthy, especially if respondents are educated, motivated, and have enough time to complete a questionnaire. If we ask people to tell us about their political beliefs in a survey or have a blog feed about politics, we might expect some lengthy comments about all sorts of issues and positions.

The ability to extract key concepts and create insightful categories from these longer text sources in a very short period of time is a key advantage of using IBM® SPSS® Modeler Text Analytics. This advantage is obtained through the combination of automated linguistic and statistical techniques to yield the most reliable results for each stage of the text analysis process.

Linguistic processing and NLP

The primary problem with the management of all of this unstructured text data is that there are no standard rules for writing text so that a computer can understand it. The language, and consequently the meaning, varies for every document and every piece of text. The only way to accurately retrieve and organize such unstructured data is to analyze the language and thus uncover its meaning. There are several different automated approaches to the extraction of concepts from unstructured information. These approaches can be broken down into two kinds, linguistic and nonlinguistic.

Some organizations have tried to employ automated nonlinguistic solutions based on statistics and neural networks. Using computer technology, these solutions can scan and categorize key concepts more quickly than human readers can. Unfortunately, the accuracy of such solutions is fairly low. Most statistics-based systems simply count the number of times words occur and calculate their statistical proximity to related concepts. They produce many irrelevant results, or noise, and miss results they should have found, referred to as silence.

To compensate for their limited accuracy, some solutions incorporate complex nonlinguistic rules that help to distinguish between relevant and irrelevant results. This is referred to as *rule-based text mining*.

Linguistics-based text mining, on the other hand, applies the principles of natural language processing (NLP)—the computer-assisted analysis of human languages—to the analysis of words, phrases, and syntax, or structure, of text. A system that incorporates NLP can intelligently extract concepts, including compound phrases. Moreover, knowledge of the underlying language allows classification of concepts into related groups, such as products, organizations, or people, using meaning and context.

Linguistics-based text mining finds meaning in text much as people do—by recognizing a variety of word forms as having similar meanings and by analyzing sentence structure to provide a framework for understanding the text. This approach offers the speed and cost-effectiveness of statistics-based systems, but it offers a far higher degree of accuracy while requiring far less human intervention.

To illustrate the difference between statistics-based and linguistics-based approaches during the extraction process, consider how each would respond to a query about **reproduction of documents**. Both statistics-based and linguistics-based solutions would have to expand the word **reproduction** to include synonyms, such as **copy** and **duplication**. Otherwise, relevant information will be overlooked. But if a statistics-based solution attempts to do this type of synonymy—searching for other terms with the same meaning—it is likely to include the term **birth** as well, generating a number of irrelevant results. The understanding of language cuts through the ambiguity of text, making linguistics-based text mining, by definition, the more reliable approach.

Understanding how the extraction process works can help you make key decisions when fine-tuning your linguistic resources (libraries, types, synonyms, and more). Steps in the extraction process include:

- Converting source data to a standard format
- Identifying candidate terms
- Identifying equivalence classes and integration of synonyms
- Assigning a type
- Indexing and, when requested, pattern matching with a secondary analyzer

Step 1. Converting source data to a standard format

In this first step, the data you import is converted to a uniform format that can be used for further analysis. This conversion is performed internally and does not change your original data.

Step 2. Identifying candidate terms

It is important to understand the role of linguistic resources in the identification of candidate terms during linguistic extraction. Linguistic resources are used every time an extraction is run. They exist in the form of templates, libraries, and compiled resources. Libraries include lists of words, relationships, and other information used to specify or tune the extraction. The compiled resources cannot be viewed or edited. However, the remaining resources can be edited in the Template Editor or, if you are in an interactive workbench session, in the Resource Editor.

Compiled resources are core, internal components of the extraction engine within IBM SPSS Modeler Text Analytics . These resources include a general dictionary containing a list of base forms with a part-of-speech code (noun, verb, adjective, and so on).

In addition to those compiled resources, several libraries are delivered with the product and can be used to complement the types and concept definitions in the compiled resources, as well as to offer synonyms. These libraries—and any custom ones you create—are made up of several dictionaries. These include type dictionaries, synonym dictionaries, and exclude dictionaries.

Once the data have been imported and converted, the extraction engine will begin identifying candidate terms for extraction. Candidate terms are words or groups of words that are used to identify concepts in the text. During the processing of the text, single words (*uniterms*) and compound words (*multiterms*) are identified using part-of-speech pattern extractors. Then, candidate sentiment keywords are identified using sentiment text link analysis.

Note: The terms in the aforementioned compiled general dictionary represent a list of all of the words that are likely to be uninteresting or linguistically ambiguous as uniterms. These words are excluded from extraction when you are identifying the uniterms. However, they are reevaluated when you are determining parts of speech or looking at longer candidate compound words (multiterms).

Step 3. Identifying equivalence classes and integration of synonyms

After candidate uniterms and multiterms are identified, the software uses a normalization dictionary to identify equivalence classes. An equivalence class is a base form of a phrase or a single form of two variants of the same phrase. The purpose of assigning phrases to equivalence

classes is to ensure that, for example, `side effect` and 副作用 are not treated as separate concepts. To determine which concept to use for the equivalence class—that is, whether `side effect` or 副作用 is used as the lead term—the extraction engine applies the following rules in the order listed:

- The user-specified form in a library.
- The most frequent form, as defined by precompiled resources.

Step 4. Assigning type

Next, types are assigned to extracted concepts. A type is a semantic grouping of concepts. Both compiled resources and the libraries are used in this step. Types include such things as higher-level concepts, positive and negative words, first names, places, organizations, and more. See the topic [Type dictionaries](#) for more information.

Linguistic systems are knowledge sensitive—the more information contained in their dictionaries, the higher the quality of the results. Modification of the dictionary content, such as synonym definitions, can simplify the resulting information. This is often an iterative process and is necessary for accurate concept retrieval. NLP is a core element of IBM SPSS Modeler Text Analytics.

- [How extraction works](#)
- [How categorization works](#)

How extraction works

During the extraction of key concepts and ideas from your responses, IBM® SPSS® Modeler Text Analytics relies on linguistics-based text analysis. This approach offers the speed and cost effectiveness of statistics-based systems. But it offers a far higher degree of accuracy, while requiring far less human intervention. Linguistics-based text analysis is based on the field of study known as natural language processing, also known as computational linguistics.

Understanding how the extraction process works can help you make key decisions when fine-tuning your linguistic resources (libraries, types, synonyms, and more). Steps in the extraction process include:

- Converting source data to a standard format
- Identifying candidate terms
- Identifying equivalence classes and integration of synonyms
- Assigning a type
- Indexing
- Matching patterns and events extraction

Step 1. Converting source data to a standard format

In this first step, the data you import is converted to a uniform format that can be used for further analysis. This conversion is performed internally and does not change your original data.

Step 2. Identifying candidate terms

It is important to understand the role of linguistic resources in the identification of candidate terms during linguistic extraction. Linguistic resources are used every time an extraction is run. They exist in the form of templates, libraries, and compiled resources. Libraries include lists of words, relationships, and other information used to specify or tune the extraction. The compiled resources cannot be viewed or edited. However, the remaining resources (templates) can be edited in the Template Editor or, if you are in an interactive workbench session, in the Resource Editor.

Compiled resources are core, internal components of the extraction engine within IBM SPSS Modeler Text Analytics. These resources include a general dictionary containing a list of base forms with a part-of-speech code (noun, verb, adjective, adverb, participle, coordinator, determiner, or preposition). The resources also include reserved, built-in types used to assign many extracted terms to the following types, `<Location>`, `<Organization>`, or `<Person>`. See the topic [Built-in types](#) for more information.

In addition to those compiled resources, several libraries are delivered with the product and can be used to complement the types and concept definitions in the compiled resources, as well as to offer other types and synonyms. These libraries—and any custom ones you create—are made up of several dictionaries. These include type dictionaries, substitution dictionaries (synonyms and optional elements), and exclude dictionaries. See the topic [Working with Libraries](#) for more information.

Once the data have been imported and converted, the extraction engine will begin identifying candidate terms for extraction. Candidate terms are words or groups of words that are used to identify concepts in the text. During the processing of the text, single words (*uniterms*) that are not in the compiled resources are considered as candidate term extractions. Candidate compound words (*multiterms*) are identified using part-of-speech pattern extractors. For example, the multiterm `sports car`, which follows the "adjective noun" part-of-speech pattern, has two components. The multiterm `fast sports car`, which follows the "adjective adjective noun" part-of-speech pattern, has three components.

Note: The terms in the aforementioned compiled general dictionary represent a list of all of the words that are likely to be uninteresting or linguistically ambiguous as uniterms. These words are excluded from extraction when you are identifying the uniterms. However, they are reevaluated when you are determining parts of speech or looking at longer candidate compound words (multiterms). Finally, a special algorithm is used to handle uppercase letter strings, such as job titles, so that these special patterns can be extracted.

Step 3. Identifying equivalence classes and integration of synonyms

After candidate uniterms and multiterms are identified, the software uses a set of algorithms to compare them and identify equivalence classes. An equivalence class is a base form of a phrase or a single form of two variants of the same phrase. The purpose of assigning phrases to equivalence classes is to ensure that, for example, **president of the company** and **company president** are not treated as separate concepts. To determine which concept to use for the equivalence class—that is, whether **president of the company** or **company president** is used as the lead term, the extraction engine applies the following rules in the order listed:

- The user-specified form in a library.
- The most frequent form in the full body of text.
- The shortest form in the full body of text (which usually corresponds to the base form).

Step 4. Assigning type

Next, types are assigned to extracted concepts. A type is a semantic grouping of concepts. Both compiled resources and the libraries are used in this step. Types include such things as higher-level concepts, positive and negative words, first names, places, organizations, and more. Additional types can be defined by the user. See the topic [Type dictionaries](#) for more information.

Step 5. Indexing

The entire set of records or documents is indexed by establishing a pointer between a text position and the representative term for each equivalence class. This assumes that all of the inflected form instances of a candidate concept are indexed as a candidate base form. The global frequency is calculated for each base form.

Step 6. Matching patterns and events extraction

IBM SPSS Modeler Text Analytics can discover not only types and concepts but also relationships among them. Several algorithms and libraries are available with this product and provide the ability to extract relationship patterns between types and concepts. They are particularly useful when attempting to discover specific opinions (for example, product reactions) or the relational links between people or objects (for example, links between political groups or genomes).

How categorization works

When creating category models in IBM® SPSS® Modeler Text Analytics, there are several different techniques you can choose to create categories. Because every dataset is unique, the number of techniques and the order in which you apply them may change. Since your interpretation of the results may be different from someone else's, you may need to experiment with the different techniques to see which one produces the best results for your text data. In IBM SPSS Modeler Text Analytics, you can create category models in a workbench session in which you can explore and fine-tune your categories further.

In this guide, category building refers to the generation of category definitions and classification through the use of one or more built-in techniques, and categorization refers to the scoring, or labeling, process whereby unique identifiers (name/ID/value) are assigned to the category definitions for each record or document.

During category building, the concepts and types that were extracted are used as the building blocks for your categories. When you build categories, the records or documents are automatically assigned to categories if they contain text that matches an element of a category's definition.

IBM SPSS Modeler Text Analytics offers you several automated category building techniques to help you categorize your documents or records quickly.

Grouping Techniques

Each of the techniques available is well suited to certain types of data and situations, but often it is helpful to combine techniques in the same analysis to capture the full range of documents or records. You may see a concept in multiple categories or find redundant categories.

Concept Root Derivation. This technique creates categories by taking a concept and finding other concepts that are related to it by analyzing whether any of the concept components are morphologically related, or share roots. This technique is very useful for identifying synonymous compound word concepts, since the concepts in each category generated are synonyms or closely related in meaning. It works with data of varying lengths and generates a smaller number of compact categories. For example, the concept **opportunities to**

advance would be grouped with the concepts **opportunity for advancement** and **advancement opportunity**. See the topic [Concept root derivation](#) for more information.

Semantic Network. This technique begins by identifying the possible senses of each concept from its extensive index of word relationships and then creates categories by grouping related concepts. This technique is best when the concepts are known to the semantic network and are not too ambiguous. It is less helpful when text contains specialized terminology or jargon unknown to the network. In one example, the concept **granny smith apple** could be grouped with **gala apple** and **winesap apple** since they are siblings of the **granny smith**. In another example, the concept **animal** might be grouped with **cat** and **kangaroo** since they are hyponyms of **animal**. This technique is available for English text only in this release. See the topic [Semantic Networks](#) for more information.

Concept Inclusion. This technique builds categories by grouping multiterm concepts (compound words) based on whether they contain words that are subsets or supersets of a word in the other. For example, the concept **seat** would be grouped with **safety seat**, **seat belt**, and **seat belt buckle**. See the topic [Concept Inclusion](#) for more information.

Co-occurrence. This technique creates categories from co-occurrences found in the text. The idea is that when concepts or concept patterns are often found together in documents and records, that co-occurrence reflects an underlying relationship that is probably of value in your category definitions. When words co-occur significantly, a co-occurrence rule is created and can be used as a category descriptor for a new subcategory. For example, if many records contain the words **price** and **availability** (but few records contain one without the other), then these concepts could be grouped into a co-occurrence rule, (**price & available**) and assigned to a subcategory of the category **price** for instance. See the topic [Co-occurrence Rules](#) for more information.

Minimum number of documents. To help determine how interesting co-occurrences are, define the minimum number of documents or records that must contain a given co-occurrence for it to be used as a descriptor in a category.

IBM SPSS Modeler Text Analytics nodes

Along with the many standard nodes delivered with IBM® SPSS® Modeler, you can also work with text mining nodes to incorporate the power of text analysis into your streams. IBM SPSS Modeler Text Analytics offers you several text mining nodes to do just that. These nodes are stored in the IBM SPSS Modeler Text Analytics tab of the node palette.

The following nodes are included:

- The File List source node generates a list of document names as input to the text mining process. This is useful when the text resides in external documents rather than in a database or other structured file. The node outputs a single field with one record for each document or folder listed, which can be selected as input in a subsequent Text Mining node. See the topic [File List node](#) for more information.
- The Web Feed source node makes it possible to read in text from Web feeds, such as blogs or news feeds in RSS or HTML formats, and use this data in the text mining process. The node outputs one or more fields for each record found in the feeds, which can be selected as input in a subsequent Text Mining node. See the topic [Web Feed node](#) for more information.
- The Language Identifier node is a process node that scans source text to determine which human language it is written in and then marks that up in a new field. Primarily designed to be used with large amounts of data, this node is particularly useful when you have more than one language in your data sources and want to process just one language. See the topic [Language Node](#) for more information.
- The Text Mining node uses linguistic methods to extract key concepts from the text, allows you to create categories with these concepts and other data, and offers the ability to identify relationships and associations between concepts based on known patterns (called text link analysis). The node can be used to explore the text data contents or to produce either a concept model or category model. The concepts and categories can be combined with existing structured data, such as demographics, and applied to modeling. See the topic [Text Mining modeling node](#) for more information.
- The Text Link Analysis node extracts concepts and also identifies relationships between concepts based on known patterns within the text. Pattern extraction can be used to discover relationships between your concepts, as well as any opinions or qualifiers attached to these concepts. The Text Link Analysis node offers a more direct way to identify and extract patterns from your text and then add the pattern results to the dataset in the stream. But you can also perform TLA using an interactive workbench session in the Text Mining modeling node. See the topic [Text Link Analysis node](#) for more information.
- When mining text from external documents, the Text Mining Output node can be used to generate an HTML page that contains links to the documents from which concepts were extracted. See the topic [File Viewer node](#) for more information.

Applications

In general, anyone who routinely needs to review large volumes of documents to identify key elements for further exploration can benefit from IBM® SPSS® Modeler Text Analytics.

Some specific applications include:

- Scientific and medical research. Explore secondary research materials, such as patent reports, journal articles, and protocol publications. Identify associations that were previously unknown (such as a doctor associated with a particular product), presenting avenues for further exploration. Minimize the time spent in the drug discovery process. Use as an aid in genomics research.

- Investment research. Review daily analyst reports, news articles, and company press releases to identify key strategy points or market shifts. Trend analysis of such information reveals emerging issues or opportunities for a firm or industry over a period of time.
 - Fraud detection. Use in banking and health-care fraud to detect anomalies and discover red flags in large amounts of text.
 - Market research. Use in market research endeavors to identify key topics in open-ended survey responses.
 - Blog and Web feed analysis. Explore and build models using the key ideas found in news feeds, blogs, etc.
 - CRM. Build models using data from all customer touch points, such as e-mail, transactions, and surveys.
-

Reading in Source Text

Data for text mining can be in any of the standard formats that are used by IBM® SPSS® Modeler, including databases or other "rectangular" formats that represent data in rows and columns, or in document formats, such as Microsoft Word, Adobe PDF, or HTML, that do not conform to this structure.

- To read in text from documents that do not conform to standard data structure, including Microsoft Word, Microsoft Excel, and Microsoft PowerPoint, in addition to Adobe PDF, XML, HTML, and others, the File List node can be used to generate a list of documents or folders as input to the text mining process. For more information, see [File List node](#).
 - To read in text from web feeds, such as blogs or news feeds in RSS or HTML formats, the Web Feed node can be used to format web feed data for input into the text mining process. For more information, see [Web Feed node](#).
 - To read in text from any of the standard data formats used by SPSS Modeler, such as a database with one or more text fields for customer comments, you can use any of the SPSS Modeler source nodes. For more information, see the SPSS Modeler node documentation.
 - When you are processing large amounts of data, which might include text in several different languages, use the Language node to identify the language used in a specific field. For more information, see [Language Node](#).
- [File List node](#)
 - [Web Feed node](#)
 - [Language Node](#)

File List node

To read in text from unstructured documents saved in formats such as Microsoft Word, Microsoft Excel, and Microsoft PowerPoint, as well as Adobe PDF, XML, HTML, and others, the File List node can be used to generate a list of documents or folders as input to the text mining process. This is necessary because unstructured text documents cannot be represented by fields and records—rows and columns—in the same manner as other data used by IBM® SPSS® Modeler.

The File List node functions as a source node.

You can find this node on the IBM SPSS Modeler Text Analytics tab of nodes palette at the bottom of the IBM SPSS Modeler window. See the topic [IBM SPSS Modeler Text Analytics nodes](#) for more information.

Important: Any directory names and file names containing characters that are not included in the machine local encoding are not supported. When attempting to execute a stream containing a File List node, any file or directory names containing these characters will cause the stream execution to fail. This can happen with foreign language directory names or file names, such as a German filename on a French locale.

Local data support. If you are connected to a remote IBM SPSS Modeler Text Analytics Server and have a stream with a File List node, the data should reside on the same machine as the IBM SPSS Modeler Text Analytics Server – or ensure that the server machine has access to the folder where the source data in the File List node is stored.

Note: You cannot use the File List node for scoring within an IBM SPSS Collaboration and Deployment Services - Scoring configuration.

- [File List node: Settings tab](#)
 - [File List Node: Other Tabs](#)
 - [Using the File List node in text mining](#)
-

File List node: Settings tab

On this tab you define the directories, file extensions, and input for this node.

Note: Text mining extraction cannot process Microsoft Office and Adobe PDF files under non-Microsoft Windows platforms. However, XML, HTML or text files can always be processed.

Any directory names and file names containing characters that are not included in the machine local encoding are not supported. When attempting to execute a stream containing a File List node, any file or directory names containing these characters will cause the stream execution to fail. This can happen with foreign language directory names or file names, such as a German filename on a French locale.

Directory. Specifies the root folder containing the documents that you want to list.

- Include subdirectories. Specifies that subdirectories should also be scanned.

File type(s) to include in list: You can select or deselect the file types and extensions you want to use. By deselecting a file extension, the files with that extension are ignored. You can filter by the following extensions:

Table 1. File type filters by file extension

• .rtf, .doc, .docx, .docm	• .xls, .xlsx, .xlsm	• .ppt, .pptx, .pptm	• .txt, .text
• .htm, .html, .shtml	• .xml	• .pdf	• .\$

Note: For more information, see [File List node](#).

If you have files with either no extension, or a trailing dot extension (for example `File01` or `File01.`), use the No extension option to select them.

Only outputs document pathnames. Select this option if the output field will contain one or more pathnames for the location(s) of where the documents reside.

Input encoding. If the output field will contain exact text, choose the relevant value from the following list:

- Automatic (European)
- UTF-8
- UTF-16
- ISO-8859-1
- ISO-8859-2
- Windows-1250
- US ascii

The output is shown as UTF-8 document text.

File List Node: Other Tabs

The Types tab is a standard tab in IBM® SPSS® Modeler nodes, as is the Annotations tab.

Related information

- [File List node](#)
- [File List node: Settings tab](#)
- [Using the File List node in text mining](#)
- [File List Node: filelistnode](#)
- [Microsoft Internet Explorer settings for Help](#)

Using the File List node in text mining

The File List node is used when the text data resides in external unstructured documents in formats such as Microsoft Word, Microsoft Excel, and Microsoft PowerPoint, as well as Adobe PDF, XML, HTML, and others.

As an example, suppose we connected a File List node to a Text Mining node in order to supply text that resides in external documents:

1. **File List node (Settings tab).** First, we added this node to the stream to specify where the text documents are stored. We selected the directory containing all of the documents on which we want to perform text mining.
2. **Text Mining node (Fields tab).** Next, we added and connected a Text Mining node to the File List node. In this node, we defined our input format, resource template, and output format. We selected the field name produced from the File List node, the text field, and other settings. See the topic [Using the Text Mining node in a stream](#) for more information.

For more information on using the Text Mining node, see [Text Mining modeling node](#).

Web Feed node

The Web Feed node can be used to prepare text data from Web feeds for the text mining process. This node accepts Web feeds in two formats:

- RSS Format. RSS is a simple XML-based standardized format for Web content. The URL for this format points to a page that has a set of linked articles such as syndicated news sources and blogs. Since RSS is a standardized format, each linked article is automatically identified and treated as a separate record in the resulting data stream. No further input is required for you to be able to identify the important text data and the records from the feed unless you want to apply a filtering technique to the text.
- HTML Format. You can define one or more URLs to HTML pages on the Input tab. Then, in the Records tab, define the record start tag as well as identify the tags that delimit the target content and assign those tags to the output fields of your choice (description, title, modified date, and so on). See the topic [Web Feed Node: Records Tab](#) for more information.

Important! If you are trying to retrieve information over the web through a proxy server, you must enable the proxy server in the `net.properties` file for both the IBM® SPSS® Modeler Text Analytics Client and Server. Follow the instructions detailed inside this file. This applies when accessing the web through the Web Feed node or retrieving an SDL Software as a Service (SaaS) license since these connections go through Java™. This file is located in `C:\Program Files\IBM\SPSS\Modeler\18.4.0\jre\lib\net.properties` by default.

The output of this node is a set of fields used to describe the records. The Description field is most commonly used since it contains the bulk of the text content. However, you may also be interested in other fields, such as the short description of a record (Short Desc field) or the record's title (Title field). Any of the output fields can be selected as input for a subsequent Text Mining node.

Note: You cannot use the Web Feed node for scoring within an IBM SPSS Collaboration and Deployment Services - Scoring configuration. You can find this node on the IBM SPSS Modeler Text Analytics tab of nodes palette at the bottom of the IBM SPSS Modeler window. See the topic [IBM SPSS Modeler Text Analytics nodes](#) for more information.

- [Web Feed Node: Input Tab](#)
- [Web Feed Node: Records Tab](#)
- [Web Feed Node: Content Filter Tab](#)
- [Using the Web Feed Node in Text Mining](#)

Web Feed Node: Input Tab

The Input tab is used to specify one or more Web addresses, or URLs, in order to capture the text data. In the context of text mining, you could specify URLs for feeds that contain text data.

Important: When working with non RSS data, you may prefer to use a web scraping tool, such as WebQL®, to automate content gathering and then referring the output from that tool using a different source node.

You can set the following parameters:

Enter or paste URLs. In this field, you can type or paste one or more URLs. If you are entering more than one, enter only one per line and use the Enter/Return key to separate lines. Enter the full URL path to the file. These URLs can be for feeds in one of two formats:

- RSS format. RSS is a simple XML-based standardized format for Web content. The URL for this format points to a page that has a set of linked articles such as syndicated news sources and blogs. Since RSS is a standardized format, each linked article is automatically identified and treated as a separate record in the resulting data stream. No further input is required for you to be able to identify the important text data and the records from the feed unless you want to apply a filtering technique to the text.
- HTML format. You can define one or more URLs to HTML pages on the Input tab. Then, in the Records tab, define the record start tag as well as identify the tags that delimit the target content and assign those tags to the output fields of your choice (description, title, modified date, and so on). When working with non RSS data, you may prefer to use a web scraping tool, such as WebQL®, to automate content gathering and then referring the output from that tool using a different source node. See the topic [Web Feed Node: Records Tab](#) for more information.

Number of most recent entries to read per URL. This field specifies the maximum number of records to read for each URL listed in the field starting with the first record found in the feed. The amount of text impacts the processing speed during extraction downstream in a Text Mining node or Text Link Analysis node.

Save and reuse previous web feeds when possible. With this option, web feeds are scanned and the processed results are cached. Then, upon subsequent stream executions, if the contents of a given feed have not changed or if the feed is inaccessible (an Internet outage, for example), the cached version is used to speed processing time. Any new content discovered in these feeds is also cached for the next time you execute the node.

- Label. If you select Save and reuse previous web feeds when possible, you must specify a label name for the results. This label is used to describe the cached feeds on the server. If no label is specified or the label is unrecognized, no reuse will be possible.

Web Feed Node: Records Tab

The Records tab is used to specify the text content of non-RSS feeds by identifying where each new record begins, as well as other relevant information regarding each record. If you know that a non-RSS feed (HTML) contains text that is in multiple records, you must identify the record start tag here or else the text will be treated as one record. While RSS feeds are standardized and do not require any tag specification on this tab, you can still preview the content in the Preview tab.

Important: When working with non RSS data, you may prefer to use a web scraping tool, such as WebQL®, to automate content gathering and then referring the output from that tool using a different source node.

URL. This drop-down list contains a list of URLs entered on the Input tab. Both HTML and RSS formatted feeds are present. If the URL address is too long for the drop-down list, it will automatically be clipped in the middle using an ellipsis to replace the clipped text, such as <http://www.ibm.com/example/start-of-address...rest-of-address/path.htm>.

- With HTML formatted feeds, if the feed contains more than one record (or entry), you can define which HTML tags contain the data corresponding to the field shown in the table. For example, you can define the start tag that indicates a new record has started, a modified date tag, or an author name.
- With RSS formatted feeds, you are not prompted to enter any tags since RSS is a standardized format. However, you can view sample results on the Preview tab if desired. All recognized RSS feeds are preceded by the RSS logo image.

Source tab. On this tab, you can view the source code for any HTML feeds. This code is not editable. You can use the Find field to locate specific tags or information on this page that you can then copy and paste into the table below. The Find field is not case sensitive and will match partial strings.

Preview tab. On this tab, you can preview how a record will be read by the Web feed node. This is particularly useful for HTML feeds since you can change how a record will be read by defining HTML tags in the table below the Preview tab.

Non-RSS record start tag. This option only applies to non-RSS feeds. If your HTML feed contains multiple text that you want to break up into multiple records, specify the HTML tag that signals the beginning of a record (such as an article or blog entry) here. If you don't define one for a non-RSS feed, Modeler will try to guess the XML format and return corresponding records. If Modeler can't guess the XML format, nothing will be returned. If your goal is to import the whole content of a page and then process it later, we recommend using separate XML readers with more powerful functionality and then import the result into Modeler Text Analytics.

Field table. This option only applies to non-RSS feeds. In this table, you can break up the text content into specific output fields by entering a start tag for any of the predefined output fields. Enter the start tag only. All matches are done by parsing the HTML and matching the table contents to the tag names and attributes found in the HTML. You can use the buttons at the bottom to copy the tags you have defined and reuse them for other feeds.

Table 1. Possible output fields for non-RSS feeds (HTML formats)

Output Field Name	Expected Tag Content
Title	The tag delimiting the record title. (optional)
Short Desc	The tag delimiting the short description or label. (optional)
Description	The tag delimiting the main text. If left blank, this field will contain all other content in either the <body> tag (if there is a single record) or the content found inside the current record (when a record delimiter has been specified).
Author	The tag delimiting the author of the text. (optional)
Contributors	The tag delimiting the names of the contributors. (optional)
Published Date	The tag delimiting the date when the text was published. If left blank, this field will contain the date when the node reads the data.
Modified Date	The tag delimiting the date when the text was modified. If left blank, this field will contain the date when the node reads the data.

When you enter a tag into the table, the feed is scanned using this tag as the minimum tag to match rather than an exact match. That is, if you entered **<div>** for the Title field, this would match any **<div>** tag in the feed, including those with specified attributes (such as **<div class="post three">**), such that **<div>** is equal to the root tag (**<div>**) and any derivative that includes an attribute and use that content for the Title output field. If you enter a root tag, any further attributes are also included.

Table 2. Examples of HTML tags used identify the text for the output fields

If you enter:	It would match:	And also match:	But not match:
<div>	<div>	<div class="post">	any other tag
<p class="auth">	<p class="auth">	<p color="black" class="auth" id="85643">	<p color="black">

Web Feed Node: Content Filter Tab

The Content Filter tab is used to apply a filter technique to RSS feed content. This tab does not apply to HTML feeds. You may want to filter if the feed contains a lot of text in the form of headers, footers, menus, advertising and so on. You can use this tab to strip out unwanted HTML tags, JavaScript, and short words or lines from the content.

Content Filtering. If you do not want to apply a cleaning technique, select None. Otherwise, select RSS Content Cleaner.

RSS Content Cleaner Options. If you select RSS Content Cleaner, you can choose to discard lines based on certain criteria. A line is delimited by an HTML tag such as <p> and but excluding in-line tags such as , , and . Please note that
 tags are processed as line breaks.

- **Discard short lines.** This option ignores lines that do not contain the minimum number of words defined here.
- **Discard lines with short words.** This option ignores lines that have more than the minimum average word length defined here.
- **Discard lines with many single character words.** This option ignores lines that contain more than a certain proportion of single character words.
- **Discard lines containing specific tags.** This option ignores text in lines that contain any of the tags specified in the field.
- **Discard lines containing specific text.** This option ignores lines that contain any of the text specified in the field.

Using the Web Feed Node in Text Mining

The Web Feed node can be used to prepare text data from Internet Web feeds for the text mining process. This node accepts Web feeds in either an HTML or RSS format. These feeds serve as input into the text mining process (a subsequent Text Mining or Text Link Analysis node).

If you use the Web Feed node, you must make sure to specify that the Text field represents actual text in the Text Mining or Text Link Analysis node to indicate that these feeds link directly to each article or blog entry.

Important! If you are trying to retrieve information over the web through a proxy server, you must enable the proxy server in the `net.properties` file for both the IBM® SPSS® Modeler Text Analytics Client and Server. Follow the instructions detailed inside this file. This applies when accessing the web through the Web Feed node or retrieving an SDL Software as a Service (SaaS) license since these connections go through Java™. This file is located in `C:\Program Files\IBM\SPSS\Modeler\18.4.0\jre\lib\net.properties` by default.

Example: Web Feed node (RSS Feed) with the Text Mining modeling node

As an example, suppose we connect a Web Feed node to a Text Mining node in order to supply text data from an RSS feed into the text mining process.

1. **Web Feed node (Input tab).** First, we added this node to the stream to specify where the feed contents are located and to verify the content structure. On the first tab, we provided the URL to an RSS feed. Since our example is for an RSS feed, the formatting is already defined, and we do not need to make any changes on the Records tab. An optional content filtering algorithm is available for RSS feeds, however in this case it was not applied.
2. **Text Mining node (Fields tab).** Next, we added and connected a Text Mining node to the Web Feed node. On this tab, we defined the text field output by the Web Feed node. In this case, we wanted to use the Description field. We also selected the option Text field represents actual text, as well as other settings.
3. **Text Mining node (Model tab).** Next, on the Model tab, we chose the build mode and resources. In this example, we chose to build a concept model directly from this node using the default resource template.

For more information on using the Text Mining node, see [Text Mining modeling node](#).

Language Node

You can use the Language node to identify the natural language of a text field within your source data.

The output of this node is a derived field that contains the detected language code.

Note: You cannot use the Language node for scoring within an IBM® SPSS® Collaboration and Deployment Services - Scoring configuration. You can find this node on the IBM SPSS Modeler Text Analytics tab of nodes palette at the bottom of the IBM SPSS Modeler window. See the topic [IBM SPSS Modeler Text Analytics nodes](#) for more information.

- [Language Node: Settings Tab](#)

Language Node: Settings Tab

On this tab you specify how to output the language details for a selected text field.

Text field Select the text field for which you want to identify the language.

Derive field name Enter a name for the derived field which will contain the detected language code. The default value is *Language*.

Default value for when language cannot be identified Specify the name of the field to be created if the language cannot be identified. The available choices are:

- Undefined If selected, the derived field contains null values.
- Supported If selected, you can choose from one of the following supported ISO languages:
 - English (EN)
 - German (DE)
 - Spanish (ES)
 - French (FR)
 - Italian (IT)
 - Dutch (NL)
 - Portuguese (PT)
- Custom If no supported language is suitable, use this option to specify that a custom value should be used. Typically this might be a 2 letter ISO language code, but can be any text string that you require.

Mining for Concepts and Categories

The Text Mining modeling node is used to generate one of two text mining model nuggets:

- *Concept model nuggets* uncover and extract salient concepts from your structured or unstructured text data.
- *Category model nuggets* score and assign documents and records to categories, which are made up of the extracted concepts (and patterns).

The extracted concepts and patterns as well as the categories from your model nuggets can all be combined with existing structured data, such as demographics, and applied using the full suite of tools from IBM® SPSS® Modeler to yield better and more focused decisions. For example, if customers frequently list login issues as the primary impediment to completing online account management tasks, you might want to incorporate “login issues” into your models.

Additionally, the Text Mining modeling node is fully integrated within IBM SPSS Modeler so that you can deploy text mining streams via IBM SPSS Modeler Solution Publisher for real-time scoring of unstructured data in applications such as PredictiveCallCenter. The ability to deploy these streams ensures successful closed-loop text mining implementations. For example, your organization can now analyze scratch-pad notes from inbound or outbound callers by applying your predictive models to increase the accuracy of your marketing message in real time. Using text mining model results in streams has been shown to improve the accuracy of predictive data models.

To run IBM SPSS Modeler Text Analytics with IBM SPSS Modeler Solution Publisher, add the directory `<install_directory>/ext/bin/spss.TMWBServer` to the `$LD_LIBRARY_PATH` environment variable.

In IBM SPSS Modeler Text Analytics, we often refer to extracted concepts and categories. It is important to understand the meaning of concepts and categories since they can help you make more informed decisions during your exploratory work and model building.

Concepts and Concept Model Nuggets

During the extraction process, the text data is scanned and analyzed in order to identify interesting or relevant single words, such as `election` or `peace`, and word phrases, such as `presidential election`,

election of the president, or peace treaties. These words and phrases are collectively referred to as *terms*. Using the linguistic resources, the relevant terms are extracted, and similar terms are grouped together under a lead term called a **concept**.

In this way, a concept could represent multiple underlying terms depending on your text and the set of linguistic resources you are using. For example, let's say we have a employee satisfaction survey and the concept **salary** was extracted. Let's also say that when you looked at the records associated with **salary**, you noticed that **salary** isn't always present in the text but instead certain records contained something similar, such as the terms **wage**, **wages**, and **salaries**. These terms are grouped under **salary** since the extraction engine deemed them as similar or determined they were synonyms based on processing rules or linguistic resources. In this case, any documents or records containing any of those terms would be treated as if they contained the word **salary**.

If you want to see what terms are grouped under a concept, you can explore the concept within an interactive workbench or look at which synonyms are shown in the concept model. See the topic [Underlying Terms in Concept Models](#) for more information.

A **concept model nugget** contains a set of concepts that can be used to identify records or documents that also contain the concept (including any of its synonyms or grouped terms). A concept model can be used in two ways. The first would be to explore and analyze the concepts that were discovered in the original source text or to quickly identify documents of interest. The second would be to apply this model to new text records or documents to quickly identify the same key concepts in the new documents/records, such as the real-time discovery of key concepts in scratch-pad data from a call center.

See the topic [Text Mining Nugget: Concept Model](#) for more information.

Categories and Category Model Nuggets

You can create **categories** that represent, in essence, higher-level concepts or topics to capture the key ideas, knowledge, and attitudes expressed in the text. Categories are made up of set of descriptors, such as *concepts*, *types*, and *rules*. Together, these descriptors are used to identify whether or not a record or document belongs in a given category. A document or record can be scanned to see whether any of its text matches a descriptor. If a match is found, the document/record is assigned to that category. This process is called **categorization**.

Categories can be built automatically using the product's robust set of automated techniques, manually using additional insight you may have regarding the data, or a combination of both. You can also load a set of prebuilt categories from a text analysis package through the Model tab of this node. Manual creation of categories or refining categories can only be done through the interactive workbench. See the topic [Text Mining Node: Model Tab](#) for more information.

A **category model nugget** contains a set of categories along with its descriptors. The model can be used to categorize a set of documents or records based on the text in each document/record. Every document or record is read and then assigned to each category for which a descriptor match was found. In this way, a document or record could be assigned to more than one category. You can use category model nuggets to see the essential ideas in open-ended survey responses or in a set of blog entries, for example.

Text Mining modeling node

The Text Mining node uses linguistic and frequency techniques to extract key concepts from the text and create categories with these concepts and other data. The node can be used to explore the text data contents or to produce either a concept model nugget or category model nugget. When you execute this modeling node, an internal linguistic extraction engine extracts and organizes the concepts, patterns, and/or categories using natural language processing methods.

You can execute the Text Mining node and automatically produce a concept or category model nugget using the Generate directly option. Alternatively, you can use a more hands-on, exploratory approach using the Build interactively mode in which not only can you extract concepts, create categories, and refine your linguistic resources, but also perform text link analysis and explore clusters. See the topic [Text Mining Node: Model Tab](#) for more information.

You can find this node on the IBM® SPSS® Modeler Text Analytics tab of nodes palette at the bottom of the IBM SPSS Modeler window. See the topic [IBM SPSS Modeler Text Analytics nodes](#) for more information.

Requirements. Text Mining modeling nodes accept text data from a Web Feed node, File List node, or any of the standard source nodes. This node is installed with IBM SPSS Modeler Text Analytics and can be accessed on the IBM SPSS Modeler Text Analytics palette.

Note: This node replaces the Text Extraction node, which was offered in old versions of the product. If you have older streams that use the old nodes or model nuggets, you must rebuild your streams using the Text Mining node.

- [Text Mining Node: Fields Tab](#)
- [Text Mining Node: Model Tab](#)
- [Text Mining node: Expert tab](#)
- [Sampling Upstream to Save Time](#)
- [Using the Text Mining node in a stream](#)

Text Mining Node: Fields Tab

Use the Fields tab to specify the field settings for the data from which you will be extracting concepts. Consider using a Sample node upstream from this node when working with larger datasets to speed processing times. See the topic [Sampling Upstream to Save Time](#) for more information.

You can set the following parameters:

ID field Select the field containing the identifier for the text records. Identifiers must be integers. The ID field serves as an index for the individual text records. Use an ID field if the text field represents the text to be mined.

Text field. Select the field containing the text to be mined. This field depends on the data source.

Language field Select the field that contains the two letter ISO language identifier. If you do not select a field, the language of each document is assumed to be that of the supplied template.

Document type. The document type specifies the structure of the text. Select one of the following types:

- Full text. Use for most documents or text sources. The entire set of text is scanned for extraction. Unlike the other options, there are no additional settings for this option.
- Structured text. Use for bibliographic forms, patents, and any files that contain regular structures that can be identified and analyzed. This document type is used to skip all or part of the extraction process. It allows you to define term separators, assign types, and impose a minimum frequency value. If you select this option, you must click the Settings button and enter text separators in the Structured Text Formatting area of the Document Settings dialog box. See the topic [Document Settings for Fields Tab](#) for more information.

Textual unity. Select the extraction mode from the following:

- Document mode. Use for documents that are short and semantically homogenous, such as articles from news agencies.
- Paragraph mode. Use for Web pages and nontagged documents. The extraction process semantically divides the documents, taking advantage of characteristics such as internal tags and syntax. If this mode is selected, scoring is applied paragraph by paragraph.

Therefore, for example, the rule **apple & orange** is true only if **apple** and **orange** are found in the same paragraph.

Note: Due to the way text is extracted from PDF documents, Paragraph mode does not work on these documents. This is because the extraction suppresses the carriage return marker.

Paragraph mode settings. This option is available only if you set the textual unity option to Paragraph mode. Specify the character thresholds to be used in any extraction. The actual size is rounded up or down to the nearest period. To ensure that the word associations produced from the text of the document collection are representative, avoid specifying an extraction size that is too small.

- Minimum. Specify the minimum number of characters to be used in any extraction.
- Maximum. Specify the maximum number of characters to be used in any extraction.

Partition mode Use the partition mode to choose whether to partition based on the type node settings or to select another partition. Partitioning separates the data into training and test samples.

Document Settings for Fields Tab

Structured Text Formatting

If you want to skip all or part of the extraction process because you have structured data or want to impose rules on how to handle the text, use the Structured text document type option and declare the fields or tags containing the text in the Structured Text Formatting section of the Document Settings dialog box. Extracted terms are derived only from the text contained within the declared fields or tags (and child tags). Any undeclared field or tag will be ignored.

In certain contexts, linguistic processing is not required, and the linguistic extraction engine can be replaced by explicit declarations. In a bibliography file where keyword fields are separated by separators such as a semicolon (;) or comma (,), it is sufficient to extract the string between two separators. For this reason, you can suspend the full extraction process and instead define special handling rules to declare term separators, assign types to the extracted text, or impose a minimum frequency count for extraction.

Use the following rules when declaring structured text elements:

- Only one field, tag, or element per line can be declared. They do not have to be present in the data.
- Declarations are case sensitive.
- If declaring a tag that has attributes, such as `<title id="_home_markdown_jenkins_workspace_Transform_in_SS3RA7_18.4.0_ta_guide_ddita_textmining_tmfc_textmining_fields_docsettings_1234">`, and you want to include all variations or, in this case, all IDs, add the tag without the attribute or the ending angle bracket (>), such as `<title`
- Add a colon after the field or tag name to indicate that this is structured text. Add this colon directly after the field or tag but before any separators, types, or frequency values, such as `author:` or `<place>:` .
- To indicate that multiple terms are contained in the field or tag and that a separator is being used to designate the individual terms, declare the separator after the colon, such as `author: ,` or `<section>: ;` .
- To assign a type to the content found in the tag, declare the type name after the colon and a separator, such as `author: ,Person` or `<place>: ;Location` . Declare type using the names as they appear in the Resource Editor.
- To define a minimum frequency count for a field or tag, declare a number at the end of the line, such as `author: ,Person1` or `<place>: ;Location5` . Where `n` is the frequency count you defined, terms found in the field or tag must occur at least `n` times in the entire set of documents or records to be extracted. This also requires you to define a separator.
- If you have a tag that contains a colon, you must precede the colon with a backslash character so that the declaration is not ignored. For example, if you have a field called `<topic:source>`, enter it as `<topic\ :source>`.

To illustrate the syntax, let's assume you have the following recurring bibliographic fields:

```
author:Morel, Kawashima
abstract:This article describes how fields are declared.
publication:Text Mining Documentation
datepub:March 2010
```

For this example, if we wanted the extraction process to focus on author and abstract but ignore the rest of the content, we would declare only the following fields:

```
author: ,Person1
abstract:
```

In this example, the `author: ,Person1` field declaration states that linguistic processing was suspended on the field contents. Instead, it states that the author field contains more than one name, which is separated from the next by a comma separator, and these names should be assigned to the Person type and that if the name occurs at least once in the entire set of documents or records, it should be extracted. Since the field `abstract:` is listed without any other declarations, the field will be scanned during extraction and standard linguistic processing and typing will be applied.

XML Text Formatting

If you want to limit the extraction process to only the text within specific XML tags, use the XML text document type option and declare the tags containing the text in the XML Text Formatting section of the Document Settings dialog box. Extracted terms are derived only from the text contained within these tags or their child tags.

Important! If you want to skip the extraction process and impose rules on term separators, assign types to the extracted text, or impose a frequency count for extracted terms, use the Structured text option described next.

Use the following rules when declaring tags for XML text formatting:

- Only one XML tag per line can be declared.
- Tag elements are case sensitive.
- If a tag has attributes, such as `<title id="_home_markdown_jenkins_workspace_Transform_in_SS3RA7_18.4.0_ta_guide_ddita_textmining_tmfc_textmining_fields_docsettings_1234">`, and you want to include all variations or, in this case, all IDs, add the tag without the attribute or the ending angle bracket (>), such as `<title`

To illustrate the syntax, let's assume you have the following XML document:

```
<section>Rules of the Road
  <title
id="_home_markdown_jenkins_workspace_Transform_in_SS3RA7_18.4.0_ta_guide_ddita_textmining_tmfc_textmining_fields_docsettings_01234">Traffic Signals</title>
    <p>Road signs are helpful.</p>
  </section>
  <p>Learning the rules is important.</p>
```

For this example, we will declare the following tags:

```
<section>
<title
```

In this example, since you have declared the tag `<section>`, the text in this tag and its nested tags, `Traffic Signals` and `Road signs are helpful`, are scanned during the extraction process. However, `Learning the rules is important` is ignored since the tag `<p>` was not explicitly declared nor was the tag nested within a declared tag.

Text Mining Node: Model Tab

Use the Model tab to specify the build method and general model settings for the node output.

You can set the following parameters:

Model name. You can generate the model name automatically based on the target or ID field (or model type in cases where no such field is specified) or specify a custom name.

Use partitioned data. If a partition field is defined, this option ensures that data from only the training partition is used to build the model.

Build mode. Specifies how the model nuggets will be produced when a stream with this Text Mining node runs. Alternatively, you can use a more hands-on, exploratory approach using the Build interactively mode in which not only can you extract concepts, create categories, and refine your linguistic resources but you can also perform text link analysis and explore clusters.

- Build interactively. When a stream runs, this option launches an interactive interface in which you can extract concepts and patterns, explore and fine-tune the extracted results, build and refine categories, fine-tune the linguistic resources (templates, synonyms, types, libraries, etc.), and build category model nuggets. See [Build Interactively](#) for more information.
- Generate directly. This option indicates that, when the stream runs, a model should automatically be created and added to the Models palette. Unlike the interactive workbench, no additional manipulation is needed from you at run time aside from the settings defined in the

node. If you select this option, model specific options appear with which you can define the type of model you want to produce. See [Generate Directly](#) for more information.

Store large models in AS. If you have a connection to IBM® SPSS® Analytic Server, select this option to store your models remotely on the server.

Note: Any model that is built and stored on a server can only be scored on that server. To resume an interactive workbench session that contains such a model, you need a connection to the original server that was used to create the session.

Copy resources from. When mining text, the extraction is based not only on the settings in the Expert tab but also on the linguistic resources. These resources serve as the basis for how to handle and process the text during extraction to get the concepts, types, and sometimes patterns. You can copy resources into this node from a resource template, a text analysis package (.tap), or an SPSS Text Analytics for Surveys project file (.tas). Make your selection and then click Load to define the template, package, or project from which the resources will be copied. At the moment that you load, a copy of the resources is stored in the node. Therefore, if you ever want to use an updated resource, you must reload it here or in an interactive workbench session. For your convenience, the date and time at which the resources were copied and loaded is shown in the node. See [Copying resources from templates and TAPs](#) for more information.

Text language. Identifies the language of the text being mined. The resources copied in the node control the language options presented. Select the language for which the resources were tuned.

- [Build Interactively](#)
 - [Generate Directly](#)
 - [Copying resources from templates and TAPs](#)
-

Build Interactively

In the Model tab of the text mining modeling node, you can choose a build mode for your model nuggets. If you choose Build interactively, then an interactive interface opens when you execute the stream. In this interactive workbench, you can:

- Extract and explore the extraction results, including concepts and typing to discover the salient ideas in your text data.
- Use a variety of methods to build and extend categories from concepts, types, TLA patterns, and rules so you can score your documents and records into these categories.
- Refine your linguistic resources (resource templates, libraries, dictionaries, synonyms, and more) so you can improve your results through an iterative process in which concepts are extracted, examined, and refined.
- Perform text link analysis (TLA) and use the TLA patterns discovered to build better category model nuggets. The Text Link Analysis node doesn't offer the same exploratory options or modeling capabilities.
- Generate clusters to discover new relationships and explore relationships between concept, types, patterns, and categories in the Visualization pane.
- Generate refined category model nuggets to the Models palette in IBM® SPSS® Modeler and use them in other streams.

Note: You cannot build an interactive model if you are creating an IBM SPSS Collaboration and Deployment Services job.

Use session work (categories, TLA, resources, etc.) from last node update. When you work in an interactive workbench session, you can update the node with session data (extraction parameters, resources, category definitions, etc.). The Use session work option allows you to relaunch the interactive workbench using the saved session data. This option is disabled the first time you use this node, since no session data could have been saved. To learn how to update the node with session data so that you can use this option, see [Updating Modeling Nodes and Saving](#).

If you launch a session *with* this option, then the extraction settings, categories, resources, and any other work from the last time you performed a node update from an interactive workbench session are available when you next launch a session. Since saved session data are used with this option, certain content, such as the resources copied from the template below, and other tabs are disabled and ignored. But if you launch a session *without* this option, only the contents of the node as they are defined now are used, meaning that any previous work you've performed in the workbench will not be available.

Note: If you change the source node for your stream after extraction results have been cached with the Use session work... option, you will need to run a new extraction once the interactive workbench session is launched if you want to get updated extraction results.

Skip extraction and reuse cached data and results. You can reuse any cached extraction results and data in the interactive workbench session. This option is particularly useful when you want to save time and reuse extraction results rather than waiting for a completely new extraction to be performed when the session is launched. In order to use this option, you must have previously updated this node from within an interactive workbench session and chosen the option to Keep the session work and cache text data with extraction results for reuse. To learn how to update the node with session data so that you can use this option, see [Updating Modeling Nodes and Saving](#).

Begin session by. Select the option indicating the view and action you want to take place first upon launching the interactive workbench session. Regardless of the view you start in, you can switch to any view once in the session.

- **Using extraction results to build categories.** This option launches the interactive workbench in the Categories and Concepts view and, if applicable, performs an extraction. In this view, you can create categories and generate a category model. You can also switch to another view. See the topic [Interactive workbench mode](#) for more information.
- **Exploring text link analysis (TLA) results.** This option launches and begins by extracting and identifying relationships between concepts within the text, such as opinions or other links in the Text Link Analysis view. You must select a template or text analysis package that

contains TLA pattern rules in order to use this option and obtain results. If you are working with larger datasets, the TLA extraction can take some time. In this case, you may want to consider using a Sample node upstream. See the topic [Exploring Text Link Analysis](#) for more information.

- **Analyzing co-word clusters.** This option launches in the Clusters view and updates any outdated extraction results. In this view, you can perform co-word cluster analysis, which produces a set of clusters. Co-word clustering is a process that begins by assessing the strength of the link value between two concepts based on their co-occurrence in a given record or document and ends with the grouping of strongly linked concepts into clusters. See the topic [Interactive workbench mode](#) for more information.

Generate Directly

In the Model tab of the text mining modeling node, you can choose a build mode for your model nuggets. If you choose Generate directly, you can set the options in the node and then just execute your stream. The output is a concept model nugget, which was placed directly in the Models palette. Unlike the interactive workbench, no additional manipulation is needed from you at execution time besides the frequency settings defined for this option in the node.

Maximum number of concepts to include in model. This option, which applies only when you build a model automatically (non-interactive), indicates that you want to create a concept model. It also states that this model should contain no more than the specified number of concepts.

- **Check concepts based on highest frequency. Top number of concepts.** Starting with the concept with the highest frequency, this is the number of concepts that will be checked. Here, frequency refers to the number of times a concept (and all its underlying terms) appears in the entire set of the documents/records. This number could be higher than the record count, since a concept can appear multiple times in a record.
- **Uncheck concepts that occur in too many records. Percentage of records.** Unchecks concepts with a record count percentage higher than the number you specified. This option is useful for excluding concepts that occur frequently in your text or in every record but have no significance in your analysis.

Optimize for speed of scoring. Selected by default, this option ensures that the model created is compact and scores at high speed. Deselecting this option creates a much larger model which scores more slowly. However, the larger model ensures that scores displayed initially in the generated concept model are the same as those obtained when scoring the same text with the model nugget.

Copying resources from templates and TAPs

When mining text, the extraction is based not only on the settings in the Expert tab but also on the linguistic resources. These resources serve as the basis for how to handle and process the text during extraction in order to get the concepts, types, and sometimes patterns. You can copy resources into this node from a *resource template*, and if you are in the Text Mining node, you can also select a *text analysis package* (TAP) or an SPSS® Text Analytics for Surveys project (.tas).

By default, resources are copied into the node from the basic template for licensed languages for your product when you add the node to the canvas. If you have licenses for multiple languages, the first language selected is used to determine the template to load automatically.

At the moment that you load, a copy of the selected resources is stored in the node. Only the contents of the template, TAP, or SPSS Text Analytics for Surveys project resources are copied while the template, TAP, or SPSS Text Analytics for Surveys itself is not linked to the node. This means that if resources are later updated, these updates are not automatically available in the node. In short, the resources loaded into the node are always used unless you either reload a new copy of the resources, or unless you update a Text Mining node and select the Use session work option. For more information on Use session work, see further in this section.

When you select a resource, choose one with the same language as your text data. You can only use resources in the languages for which you are licensed. If you want to perform text link analysis, you must select a template that contains TLA patterns. If a template contains TLA patterns, an icon will appear in the TLA column of the Load Resource Template dialog box.

Note: You cannot load TAPs or SPSS Text Analytics for Surveys projects into the Text Link Analysis node.

Resource templates

A resource template is a predefined set of libraries and advanced linguistic and nonlinguistic resources that have been fine-tuned for a particular domain or usage. In the text mining modeling node, a copy of the resources from a basic template are already loaded in the node when you add the node to the stream, but you can change templates or load a text analysis package by selecting either Resource template or Text analysis package and then clicking Load. For templates, you can then select the template in the Load Resource Template dialog box.

Note: If you do not see the template you want in the list but you have an exported copy on your machine, you can import it now. You can also export from this dialog box to share with other users. See [Importing and Exporting Templates](#) for more information.

Text analysis packages (TAPs) and Text Analysis for Surveys projects (TAS)

A text analysis package (TAP) is a predefined set of libraries and advanced linguistic and nonlinguistic resources bundled with one or more sets of predefined categories. IBM® SPSS Modeler Text Analytics offers several prebuilt TAPs, which is fine-tuned for a specific domain. You can edit these TAPs and save them to a different directory to use them to jump start your category model building. You can also create your own TAPs in the interactive session. See [Loading Text Analysis Packages](#) for more information.

If you choose to import a SPSS Text Analytics for Surveys project (.tas), it will be converted to a TAP.

Note: You cannot load TAPs or SPSS Text Analytics for Surveys projects into the Text Link Analysis node.

Using the "Use Session Work" option (Model tab)

While resources are copied into the node in the Model tab, you might also make changes later to the resources in an interactive session and want to update the text mining modeling node with these latest changes. In this case, you would select the Use session work option in the Model tab of the text mining modeling node.

If you select Use session work, the Load button is disabled in the node to indicate that those resources that came from the interactive workbench will be used instead of the resources that were loaded here previously.

To make changes to resources once you've selected the Use session work option, you can edit or switch your resources directly inside the interactive workbench session through the Resource Editor view. See [Updating Node Resources After Loading](#) for more information.

Text Mining node: Expert tab

The Expert tab contains certain advanced parameters that impact how text is extracted and handled. The parameters in this dialog box control the basic behavior, as well as a few advanced behaviors, of the extraction process. However, they represent only a portion of the options available to you. There are also a number of linguistic resources and options that impact the extraction results, which are controlled by the resource template you select on the Model tab. See the topic [Text Mining Node: Model Tab](#) for more information.

Note: This entire tab is disabled if you have selected the Build interactively mode using saved interactive workbench information on the Model tab, in which case the extraction settings are taken from the last saved workbench session.

You can set the following parameters whenever extracting:

Limit extraction to concepts with a global frequency of at least [n]. Specifies the minimum number of times a word or phrase must occur in the text in order for it to be extracted. In this way, a value of 5 limits the extraction to those words or phrases that occur at least five times in the entire set of records or documents.

In some cases, changing this limit can make a big difference in the resulting extraction results, and consequently, your categories. Let's say that you are working with some restaurant data and you do not increase the limit above 1 for this option. In this case, you might find *pizza* (1), *thin pizza* (2), *spinach pizza* (2), and *favorite pizza* (2) in your extraction results. However, if you were to limit the extraction to a global frequency of 5 or more and re-extract, you would no longer get three of these concepts. Instead you would get *pizza* (7), since *pizza* is the simplest form and also this word already existed as a possible candidate. And depending on the rest of your text, you might actually have a frequency of more than seven, depending on whether there are still other phrases with *pizza* in the text. Additionally, if *spinach pizza* was already a category descriptor, you might need to add *pizza* as a descriptor instead to capture all of the records. For this reason, change this limit with care whenever categories have already been created.

Note that this is an extraction-only feature; if your template contains terms (which they usually do), and a term for the template is found in the text, then the term will be indexed regardless of its frequency.

For example, suppose you use a Basic Resources template that includes "los angeles" under the <Location> type in the Core library; if your document contains Los Angeles only once, then Los Angeles will be part of the list of concepts. To prevent this you will need to set a filter to display concepts occurring at least the same number of times as the value entered in the Limit extraction to concepts with a global frequency of at least [n] field.

Accommodate punctuation errors. This option temporarily normalizes text containing punctuation errors (for example, improper usage) during extraction to improve the extractability of concepts. This option is extremely useful when text is short and of poor quality (as, for example, in open-ended survey responses, e-mail, and CRM data), or when the text contains many abbreviations.

Accommodate spelling for a minimum word character length of [n] This option applies a fuzzy grouping technique that helps group commonly misspelled words or closely spelled words under one concept. The fuzzy grouping algorithm temporarily strips all vowels (except the first one) and strips double/triple consonants from extracted words and then compares them to see if they are the same so that *modeling* and *modelling* would be grouped together. However, if each term is assigned to a different type, excluding the <Unknown> type, the fuzzy grouping technique will not be applied.

You can also define the minimum number of root characters required before fuzzy grouping is used. The number of root characters in a term is calculated by totaling all of the characters and subtracting any characters that form inflection suffixes and, in the case of compound-word terms, determiners and prepositions. For example, the term *exercises* would be counted as 8 root characters in the form "exercise," since the letter s at the end of the word is an inflection (plural form). Similarly, *apple sauce* counts as 10 root characters ("apple sauce") and *manufacturing of cars* counts as 16 root characters ("manufacturing car"). This method of counting is only used to check whether the fuzzy grouping should be applied but does not influence how the words are matched.

Note: If you find that certain words are later grouped incorrectly, you can exclude word pairs from this technique by explicitly declaring them in the Fuzzy Grouping: Exceptions section in the Advanced Resources tab. See the topic [Fuzzy Grouping](#) for more information.

Extract uniterms This option extracts single words (uniterms) as long as the word is not already part of a compound word and if it is either a noun or an unrecognized part of speech.

Extract nonlinguistic entities This option extracts nonlinguistic entities, such as phone numbers, social security numbers, times, dates, currencies, digits, percentages, e-mail addresses, and HTTP addresses. You can include or exclude certain types of nonlinguistic entities in the Nonlinguistic Entities: Configuration section of the Advanced Resources tab. By disabling any unnecessary entities, the extraction engine won't waste processing time. See the topic [Configuration](#) for more information.

Uppercase algorithm This option extracts simple and compound terms that are not in the built-in dictionaries as long as the first letter of the term is in uppercase. This option offers a good way to extract most proper nouns.

Group partial and full person names together when possible This option groups names that appear differently in the text together. This feature is helpful since names are often referred to in their full form at the beginning of the text and then only by a shorter version. This option attempts to match any uniterm with the <Unknown> type to the last word of any of the compound terms that is typed as <Person>. For example, if *doe* is found and initially typed as <Unknown>, the extraction engine checks to see if any compound terms in the <Person> type include *doe* as the last word, such as *john doe*. This option does not apply to first names since most are never extracted as uniterms.

Maximum nonfunction word permutation This option specifies the maximum number of nonfunction words that can be present when applying the permutation technique. This permutation technique groups similar phrases that differ from each other only by the nonfunction words (for example, *of* and *the*) contained, regardless of inflection. For example, let's say that you set this value to at most two words and both *company officials* and *officials of the company* were extracted. In this case, both extracted terms would be grouped together in the final concept list since both terms are deemed to be the same when *of the* is ignored.

Use derivation when grouping multiterms When processing Big Data, select this option to group multiterms by using derivation rules.

Note: To enable the extraction of Text Link Analysis results, you must begin the session with the Exploring text link analysis results option and also choose resources that contain TLA definitions. You can always extract TLA results later during an interactive workbench session through the Extraction Settings dialog. See the topic [Extracting data](#) for more information.

Sampling Upstream to Save Time

When you have a large amount of data, the processing times can take minutes to hours, especially when using the interactive workbench session. The greater the size of the data, the more time the extraction and categorization processes will take. To work more efficiently, you can add aIBM®

SPSS® Modeler Sample nodes upstream from your Text Mining node. Use this Sample node to take a random sample using a smaller subset of documents or records to do the first few passes.

A smaller sample is often perfectly adequate to decide how to edit your resources and even create most if not all of your categories. And once you have run on the smaller dataset and are satisfied with the results, you can apply the same technique for creating categories to the entire set of data. Then you can look for documents or records that do not fit the categories you have created and make adjustments as needed.

Note: The Sample node is a standard IBM SPSS Modeler node.

Using the Text Mining node in a stream

The Text Mining modeling node is used to access data and extract concepts in a stream. You can use any source node to access data, such as a Database node, Var. File node, Web Feed node, or Fixed File node. For text that resides in external documents, a File List node can be used.

Example 1: File List node and Text Mining node to build a concept model nugget directly

The following example shows how to use the File list node along with the Text Mining modeling node to generate the concept model nugget. For more information on using the File List node, see [File List node](#).

1. File List node (Settings tab). First, we added this node to the stream to specify where the text documents are stored. We selected the directory containing all of the documents on which we want to perform text mining.
2. Text Mining node (Fields tab). Next, we added and connected a Text Mining node to the File List node. In this node, we defined our input format, resource template, and output format. We selected the field name produced from the File List node and selected the text field, as well as other settings. See the topic [Using the Text Mining node in a stream](#) for more information.
3. Text Mining node (Model tab). Next, on the Model tab, we selected the build mode to generate a concept model nugget directly from this node. You can select a different resource template, or keep the basic resources.

Example 2: Excel File and Text Mining nodes to build a category model interactively

This example shows how the Text Mining node can also launch an interactive workbench session. For more information on the interactive workbench, see [Interactive workbench mode](#).

1. Excel source node (Data tab). First, we added this node to the stream to specify where the text is stored.
2. Text Mining node (Fields tab). Next, we added and connected a Text Mining node. On this first tab, we defined our input format. We selected a field name from the source node.
3. Text Mining node (Model tab). Next, on the Model tab, we selected to build a category model nugget interactively and to use the extraction results to build categories automatically. In this example, we loaded a copy of resources and a set of categories from a text analysis

package.

4. Interactive Workbench session. Next, we executed the stream, and the interactive workbench interface opened. After an extraction was performed, we began exploring our data and improving our categories.
-

Text Mining Nugget: Concept Model

A Text Mining concept model nugget is created whenever you successfully execute a Text Mining model node where you've selected the option to Generate a model directly in the Model tab. A text mining concept model nugget is used for the real-time discovery of key concepts in other text data, such as scratch-pad data from a call center.

The concept model nugget itself comprises a list of concepts, which have been assigned to types. You can select any or all of the concepts in that model for scoring against other data. When you execute a stream containing a Text Mining model nugget, new fields are added to the data according to the build mode selected on the Model tab of the Text Mining modeling node prior to building the model. See the topic [Concept Model: Model Tab](#) for more information.

If the model nugget was generated using translated documents, the scoring will be performed in the translated language. Similarly, if the model nugget was generated using English as the language, you can specify a translation language in the model nugget, since the documents will then be translated into English.

Text Mining model nuggets are placed in the model nugget palette (located on the Models tab in the upper right side of the IBM® SPSS® Modeler window) when they are generated.

Viewing Results

To see information about the model nugget, right-click the node in the model nuggets palette and choose Browse from the context menu (or Edit for nodes in a stream).

Adding Models to Streams

To add the model nugget to your stream, click the icon in the model nuggets palette and then click the stream canvas where you want to place the node. Or right-click the icon and choose Add to Stream from the context menu. Then connect your stream to the node, and you are ready to pass data to generate predictions.

Caution: If you want to use a scoring nugget to regenerate a modeling node that contains both the category model and the template used, we recommend that you create a TAP and use it in an interactive session, in place of the modeling node, before generating the scoring nugget.

Concept Model: Model Tab

In concept models, the Model tab displays the set of concepts that were extracted. The concepts are presented in a table format with one row for each concept. The objective on this tab is to select which of the concepts will be used for scoring.

Note: If you generated a category model nugget instead, this tab will present different information. See the topic [Category Model Nugget: Model Tab](#) for more information.

All concepts are selected for scoring by default, as shown in the check boxes in the leftmost column. A checked box means that the concept will be used for scoring. An unchecked box means that the concept will be excluded from scoring. You can check multiple rows by selecting them and clicking one of the check boxes in your selection.

To learn more about each concept, you can look at the additional information provided in each of the following columns:

Concept. This is the lead word or phrase that was extracted. In some cases, this concept represents the concept name as well as some other underlying terms associated with this concept. To see which underlying terms are part of a concept, display the Underlying Terms pane inside this tab and select the concept to see the corresponding terms at the bottom of the dialog box. See the topic [Underlying Terms in Concept Models](#) for more information.

Global. Here, global (frequency) refers to the number of times a concept (and all its underlying terms) appears in the entire set of the documents/records.

- **Bar chart.** The global frequency of this concept in the text data presented as a bar chart. The bar takes the color of the type to which the concept is assigned in order to visually distinguish the types.
- **%.** The global frequency of this concept in the text data presented as a percentage.
- **N.** The actual number of occurrences of this concept in the text data.

Docs. Here, Docs refers to the document count, meaning number of documents or records in which the concept (and all its underlying terms) appears.

- **Bar chart.** The document count for this concept presented as a bar chart. The bar takes the color of the type to which the concept is assigned in order to visually distinguish the types.
- **%.** The document count for this concept presented as a percentage.
- **N.** The actual number of documents or records containing this concept.

Type. The type to which the concept is assigned. For each concept, the Global and Docs columns appear in a color to denote the type to which this concept is assigned. A **type** is a semantic groupings of concepts. See the topic [Type dictionaries](#) for more information.

Working with Concepts

By right-clicking a cell in the table, you can display a context menu in which you can:

- **Select All.** All rows in the table will be selected.
- **Copy.** The selected concept(s) are copied to the clipboard.
- **Copy With Fields** The selected concept(s) are copied to the clipboard along with the column heading.
- **Check Selected.** Checks all check boxes for the selected rows in the table thereby including those concepts for scoring.
- **Uncheck Selected.** Unchecks all check boxes for the selected rows in the table.
- **Check All.** Checks all check boxes in the table. This results in all concepts being used in the final output.
- **Uncheck All.** Unchecks all check boxes in the table. Unchecking a concept means that it will not be used in the final output.
- **Include Concepts.** Displays the Include Concepts dialog box. See the topic [Options for Including Concepts for Scoring](#) for more information.
- [Options for Including Concepts for Scoring](#)
- [Underlying Terms in Concept Models](#)

Related information

- [Text Mining Nugget: Concept Model](#)

Options for Including Concepts for Scoring

To quickly check or uncheck those concepts that will be used for scoring, click the toolbar button for **Include Concepts..**

Figure 1. Include Concepts toolbar button

Clicking this toolbar button will open the Include Concepts dialog box to allow you to select concepts based on rules. All concepts that have a check mark on the Model tab will be included for scoring. Apply a rule in this subdialog to change which concepts will be used for scoring.

You can choose from the following options:

Check concepts based on highest frequency. Top number of concepts. Starting with the concept with the highest global frequency, this is the number of concepts that will be checked. Here, frequency refers to the number of times a concept (and all its underlying terms) appears in the entire set of the documents/records. This number could be higher than the record count, since a concept can appear multiple times in a record.

Check concepts based on document count. Minimum count. This is the lowest document count needed for the concepts to be checked. Here, document count refers to number of documents/records in which the concept (and all its underlying terms) appears.

Check concepts assigned to the type. Select a type from the drop-down list to check all concepts that are assigned to this type. Concepts are assigned to types automatically during the extraction process. A **type** is a semantic grouping of concepts. Types include such things as higher-level concepts, positive and negative words and qualifiers, contextual qualifiers, first names, places, organizations, and more. See the topic [Type dictionaries](#) for more information.

Uncheck concepts that occur in too many records. Percentage of records. Unchecks concepts with a record count percentage higher than the number you specified. This option is useful for excluding concepts that occur frequently in your text or in every record but have no significance in your analysis.

Uncheck concepts assigned to the type. Unchecks concepts matching the type that you select from the drop-down list.

Underlying Terms in Concept Models

You can see the underlying terms that are defined for the concepts that you have selected in the table. By clicking the underlying terms toggle button on the toolbar, you can display the underlying terms table in a split pane at the bottom of the dialog.

These underlying terms include the synonyms defined in the linguistic resources (regardless of whether they were found in the text or not) as well as any extracted plural/singular forms found in the text used to generate the model nugget, permuted terms, terms from fuzzy grouping, and so on.

Figure 1. Display Underlying Terms toolbar button

Note: You cannot edit the list of underlying terms. This list is generated through substitutions, synonym definitions (in the substitution dictionary), fuzzy grouping, and more—all of which are defined in the linguistic resources. In order to make changes to how terms are grouped under a concept or how they are handled, you must make changes directly in the resources (editable in the Resource Editor in the interactive workbench or in the Template Editor and then reload in the node) and then reexecute the stream to get a new model nugget with the updated results.

By right-clicking the cell containing an underlying term or concept, you can display a context menu in which you can:

- **Copy.** The selected cell is copied to the clipboard.
- **Copy With Fields.** The selected cell is copied to the clipboard along with the column headings.
- **Select All.** All cells in the table will be selected.

-

Concept model: Settings tab

The Settings tab is used to define the text field value for the new input data, if necessary. It is also the place where you define the data model for your output (scoring mode).

Note: This tab appears only when the model nugget is placed onto the canvas. It does not exist when you are accessing this dialog box directly in the Models palette.

Scoring mode: Concepts as records

With this scoring mode, a new record is created for each **concept/document** pair. Typically, there are more records in the output than there were in the input.

In addition to the input fields, the following new fields are added to the data:

Table 1. Output fields for "Concepts as records"

Field	Description
Concept	Contains the extracted concept name found in the text data field.
Type	Stores the type of the concept as a full type name, such as <i>Location</i> or <i>Person</i> . A type is a semantic grouping of concepts. See the topic Type dictionaries for more information.
Count	Displays the number of occurrences for that concept (and its underlying terms) in the text body (record/document).

When you select this option, all other options except Accommodate punctuation errors are disabled.

Scoring mode: Concepts as fields

In concept models, for each input record, a new record is created for every concept found in a given document. Therefore, there are just as many output records as there were in the input. However, each record (row) now contains one new field (column) for each concept that was selected (using the check mark) on the Model tab. The value for each concept field depends on whether you select Flags or Counts as your field value on this tab.

Note: If you are using very large data sets, for example with a Db2 database, using Concepts as fields may encounter processing problems due to the amount of data. In this case we recommend using Concepts as records instead.

Field Values. Choose whether the new field for each concept will contain a count or a flag value.

- Flags. This option is used to obtain flags with two distinct values in the output, such as Yes/No, True/False, T/F, or 1 and 2. The storage types are set automatically to reflect the values chosen. For example, if you enter numeric values for the flags, they will be automatically handled as an integer value. The storage types for flags can be string, integer, real number, or date/time. Enter a flag value for True and for False.
- Counts. Used to obtain a count of how many times the concept occurred in a given record.

Field name extension. Specify an extension for the field name. Field names are generated by using the concept name plus this extension.

- Add as. Specify where the extension should be added to the field name. Choose Prefix to add the extension to the beginning of the string. Choose Suffix to add the extension to the end of the string.

Accommodate punctuation errors. This option temporarily normalizes text containing punctuation errors (for example, improper usage) during extraction to improve the extractability of concepts. This option is extremely useful when text is short and of poor quality (as, for example, in open-ended survey responses, e-mail, and CRM data), or when the text contains many abbreviations.

Concept Model: Fields tab

The Fields tab defines the text field value for the new input data, if necessary.

Note: This tab appears only when the model nugget is placed in the stream. It does not exist when you are accessing this output directly in the Models palette.

Text field. Select the field containing the text to be mined. This field depends on the data source.

Document type. The document type specifies the structure of the text. Select one of the following types:

- Full text. Use for most documents or text sources. The entire set of text is scanned for extraction. Unlike the other options, there are no additional settings for this option.
- Structured text. Use for bibliographic forms, patents, and any files that contain regular structures that can be identified and analyzed. This document type is used to skip all or part of the extraction process. It allows you to define term separators, assign types, and impose a minimum frequency value. If you select this option, you must click the Settings button and enter text separators in the Structured Text Formatting area of the Document Settings dialog box. See the topic [Document Settings for Fields Tab](#) for more information.

Input encoding. This option is available only if you indicated that the text field represents Pathnames to documents. It specifies the default text encoding. A conversion is done from the specified or recognized encoding to **ISO-8859-1**. So even if you specify another encoding, the extraction engine will convert it to **ISO-8859-1** before it is processed. Any characters that do not fit into the **ISO-8859-1** encoding definition will be converted to spaces.

Text language. Identifies the language of the text being mined; this is the main language detected during extraction. Contact your sales representative if you are interested in purchasing a license for a supported language for which you do not currently have access.

Concept Model: Summary Tab

The Summary tab presents information about the model itself (*Analysis* folder), fields used in the model (*Fields* folder), settings used when building the model (*Build Settings* folder), and model training (*Training Summary* folder).

When you first browse a modeling node, the folders on the Summary tab are collapsed. To see the results of interest, use the expander control to the left of the folder to show the results, or click the Expand All button to show all results. To hide the results after viewing them, use the expander control to collapse the specific folder that you want to hide, or click the Collapse All button to collapse all folders.

Using Concept Model Nuggets in a Stream

When using a Text Mining modeling node, you can generate either a concept model nugget or a category model nugget (through an interactive workbench session). The following example shows how to use a concept model in a simple stream.

Example: Statistics File node with the concept model nugget

The following example shows how to use the Text Mining concept model nugget.

Figure 1. Example stream: Statistics File node with a Text Mining concept model nugget

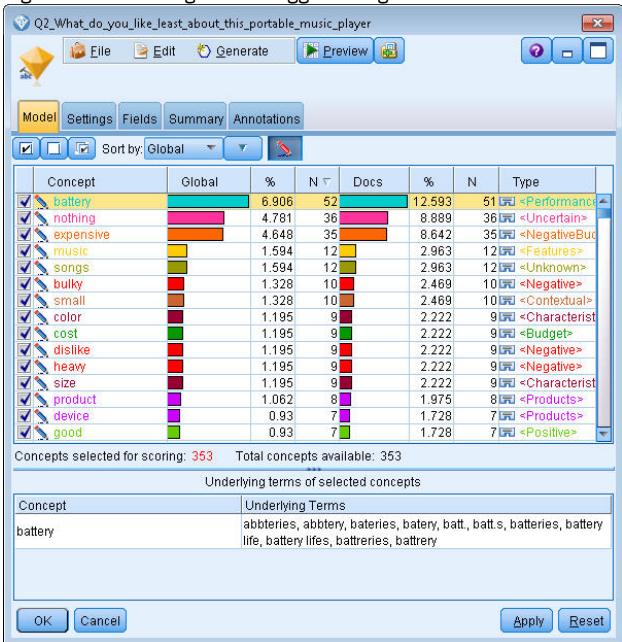

1. **Statistics File node (Data tab).** First, we added this node to the stream to specify where the text documents are stored.

Figure 2. Statistics File node dialog box: Data tab

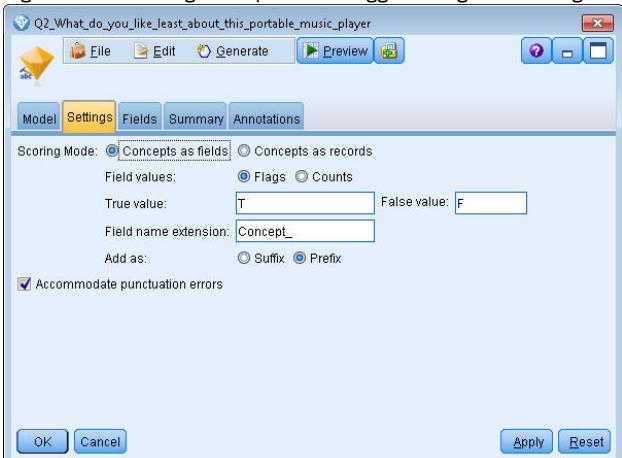

2. Text Mining concept model nugget (Model tab). Next, we added and connected a concept model nugget to the Statistics File node. We selected the concepts we wanted to use to score our data.

Figure 3. Text Mining model nugget dialog box: Model tab

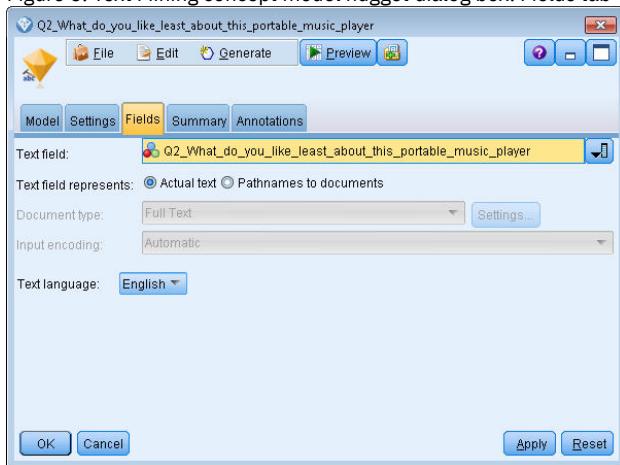

3. Text Mining concept model nugget (Settings tab). Next, we defined the output format and selected *Concepts as fields*. One new field will be created in the output for each concept selected in the Model tab. Each field name will be made up of the concept name and the prefix "Concept_".

Figure 4. Text Mining concept model nugget dialog box: Settings tab

4. Text Mining concept model nugget (Fields tab). Next, we selected the text field, Q2_What_do_you_like_least_about_this_portable_music_player, which is the field name coming from the Statistics File node. We also selected the option Text field represents: Actual text.

Figure 5. Text Mining concept model nugget dialog box: Fields tab

5. Table node. Next, we attached a table node to see the results and executed the stream. The table output opens on screen.

Figure 6. Table output scrolled to show the concept flags

Text Mining Nugget: Category Model

A Text Mining category model nugget is created whenever you generate a category model from within the interactive workbench. This modeling nugget contains a set of categories, whose definition is made up of concepts, types, TLA patterns, and/or category rules. The nugget is used to categorize survey responses, blog entries, other Web feeds, and any other text data.

If you launch an interactive workbench session in the modeling node, you can explore the extraction results, refine the resources, fine-tune your categories before you generate category models. When you execute a stream containing a Text Mining model nugget, new fields are added to the data according to the build mode selected on the Model tab of the Text Mining modeling node prior to building the model. See the topic [Category Model Nugget: Model Tab](#) for more information.

If the model nugget was generated using translated documents, the scoring will be performed in the translated language. Similarly, if the model nugget was generated using English as the language, you can specify a translation language in the model nugget, since the documents will then be translated into English.

Text Mining model nuggets are placed in the model nugget palette (located on the Models tab in the upper right side of the IBM® SPSS® Modeler window) when they are generated.

Viewing Results

To see information about the model nugget, right-click the node in the model nuggets palette and choose Browse from the context menu (or Edit for nodes in a stream).

Adding Models to Streams

To add the model nugget to your stream, click the icon in the model nuggets palette and then click the stream canvas where you want to place the node. Or right-click the icon and choose Add to Stream from the context menu. Then connect your stream to the node, and you are ready to pass data to generate predictions.

Caution: If you want to use a scoring nugget to regenerate a modeling node that contains both the category model and the template used, we recommend that you create a TAP and use it in an interactive session, in place of the modeling node, before generating the scoring nugget.

Category Model Nugget: Model Tab

For category models, the model tab displays the list of categories in the category model on the left and the descriptors for a selected category on the right. Each category is made up of a number of descriptors. For each category you select, the associated descriptors appear in the table. These descriptors can include concepts, category rules, types, and TLA patterns. The type of each descriptor, as well as some examples of what each descriptor represents, is also shown.

On this tab, the objective is to select the categories you want to use for scoring. For a category model, documents and records are scored into categories. If a document or record contains one or more of the descriptors in its text or any underlying terms, then that document or record is assigned to the category to which the descriptor belongs. These underlying terms include the synonyms defined in the linguistic resources (regardless of whether they were found in the text or not) as well as any extracted plural/singular terms found in the text used to generate the model nugget, permuted terms, terms from fuzzy grouping, and so on.

Note: If you generated a concept model nugget instead, this tab will contain different results. See the topic [Concept Model: Model Tab](#) for more information.

Category Tree

To learn more about each category, select that category and review the information that appears for the descriptors in that category. For each descriptor, you can review the following information:

- **Descriptor** name. This field contains an icon representing what kind of descriptor it is, as well as the descriptor name.

Table 1. Descriptor icons

		Concepts		TLA Patterns
		Types		Category Rules

- **Type.** This field contains the type name for the descriptor. Types are collections of similar concepts (semantic groupings), such as organization names, products, or positive opinions. Rules are not assigned to types.
- **Details.** This field contains a list of what is included in that descriptor. Depending on the number of matches, you may not see the entire list for each descriptor due to size limitations in the dialog box.

Selecting and Copying Categories

All top categories are selected for scoring by default, as shown in the check boxes in the left pane. A checked box means that the category will be used for scoring. An unchecked box means that the category will be excluded from scoring. You can check multiple rows by selecting them and clicking one of the check boxes in your selection. Also, if a category or subcategory is selected but one of its subcategories is not selected, then the checkbox shows a blue background to indicate that there is only a partial selection in the children of the selected category.

By right-clicking a category in the tree, you can display a context menu from which you can:

- **Check Selected.** Checks all check boxes for the selected rows in the table.
- **Uncheck Selected.** Unchecks all check boxes for the selected rows in the table.
- **Check All.** Checks all check boxes in the table. This results in all categories being used in the final output. You can also use the corresponding checkbox icon on the toolbar.
- **Uncheck All.** Unchecks all check boxes in the table. Unchecking a category means that it will not be used in the final output. You can also use the corresponding empty checkbox icon on the toolbar.

By right-clicking a cell in the descriptor table, you can display a context menu in which you can:

- **Copy.** The selected concept(s) are copied to the clipboard.
- **Copy With Fields.** The selected descriptor is copied to the clipboard along with the column headings.
- **Select All.** All rows in the table will be selected.

Category model nugget: Settings tab

The Settings tab is used to define the text field value for the new input data, if necessary. It is also the place where you define the data model for your output (scoring mode).

Note: This tab appears in the node dialog box only when the model nugget is placed on the canvas or in a stream. It does not exist when you are accessing this nugget directly in the Models palette.

Scoring mode: Categories as fields

With this option, there are just as many output records as there were in the input. However, each record now contains one new field for every category that was selected (using the check mark) on the Model tab. For each field, enter a flag value for True and for False, such as Yes/No, True/False, T/F, or 1 and 2. The storage types are set automatically to reflect the values chosen. For example, if you enter numeric values for the flags, they will be automatically handled as an integer value. The storage types for flags can be string, integer, real number, or date/time.

Note: If you are using very large data sets, for example with a Db2 database, using Categories as fields may encounter processing problems due to the amount of data. In this case we recommend using Categories as records instead.

Field name extension. You can choose to specify an extension prefix/suffix for the field name or you can choose to use the category codes. Field names are generated by using the category name plus this extension.

- Add as. Specify where the extension should be added to the field name. Choose Prefix to add the extension to the beginning of the string. Choose Suffix to add the extension to the end of the string.

If a subcategory is unselected. This option allows you to specify how the descriptors belonging to subcategories that were not selected for scoring will be handled. There are two options.

- The option **Exclude its descriptors completely from scoring** will cause the descriptors of subcategories that do not have checkmarks (unselected) to be ignored and unused during scoring.
- The option **Aggregate descriptors with those in parent category** will cause the descriptors of subcategories that do not have checkmarks (unselected) to be used as descriptors for the parent category (the category above this subcategory). If several levels of subcategories are unselected, the descriptors will be rolled up under the first available parent category.

Score only lowest-level matching category. Use this option to output the category only on one single line (for example, if the category is **GeneralSatisfaction/Pos**, selecting this option results in **GeneralSatisfaction/Pos**. Without this option, you'll get two lines: **GeneralSatisfaction** and **GeneralSatisfaction/Pos**).

Accommodate punctuation errors. This option temporarily normalizes text containing punctuation errors (for example, improper usage) during extraction to improve the extractability of concepts. This option is extremely useful when text is short and of poor quality (as, for example, in open-ended survey responses, e-mail, and CRM data), or when the text contains many abbreviations.

Scoring mode: Categories as records

With this option, a new record is created for each **category**, **document** pair. Typically, there are more records in the output than there were in the input. In addition to the input fields, new fields are also added to the data depending on what kind of model it is.

Table 1. Output fields for "Categories as records"

New Output Field	Description
Category	Contains the category name to which the text document was assigned. If the categories is a subcategory of another, then the full path to the category name is controlled by the value you chose in this dialog.

Values for hierarchical categories. This option controls how the names of subcategories are displayed in the output.

- Full category path. This option will output the name of the category and the full path of parent categories if applicable using slashes to separate category names from subcategory names.
- Short category path. This option will output only the name of the category but use ellipses to show the number of parent categories for the category in question.
- Bottom level category. This option will output only the name of the category without the full path or parent categories shown.

If a **subcategory** is unselected. This option allows you to specify how the descriptors belonging to subcategories that were not selected for scoring will be handled. There are two options.

- The option **Exclude its descriptors completely from scoring** will cause the descriptors of subcategories that do not have checkmarks (unselected) to be ignored and unused during scoring.
- The option **Aggregate descriptors with those in parent category** will cause the descriptors of subcategories that do not have checkmarks (unselected) to be used as descriptors for the parent category (the category above this subcategory). If several levels of subcategories are unselected, the descriptors will be rolled up under the first available parent category.

Accommodate punctuation errors. This option temporarily normalizes text containing punctuation errors (for example, improper usage) during extraction to improve the extractability of concepts. This option is extremely useful when text is short and of poor quality (as, for example, in open-ended survey responses, e-mail, and CRM data), or when the text contains many abbreviations.

Category Model Nugget: Other Tabs

The Fields tab and Settings tab for the category model nugget are the same as for the concept model nugget.

- Fields tab. See the topic [Concept Model: Fields tab](#) for more information.
- Summary tab. See the topic [Concept Model: Summary Tab](#) for more information.

Using category model nuggets in a stream

The Text Mining category model nugget is generated from an interactive workbench session. You can use this model nugget in a stream.

Example: Statistics File node with the category model nugget

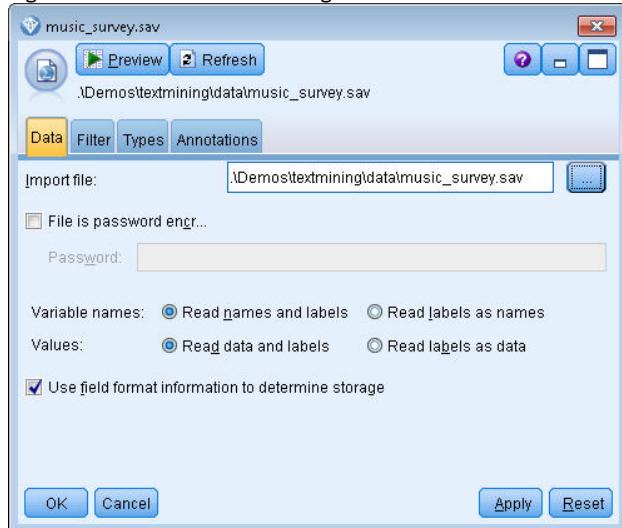

The following example shows how to use the Text Mining model nugget.

Figure 1. Example stream: Statistics File node with a Text Mining category model nugget

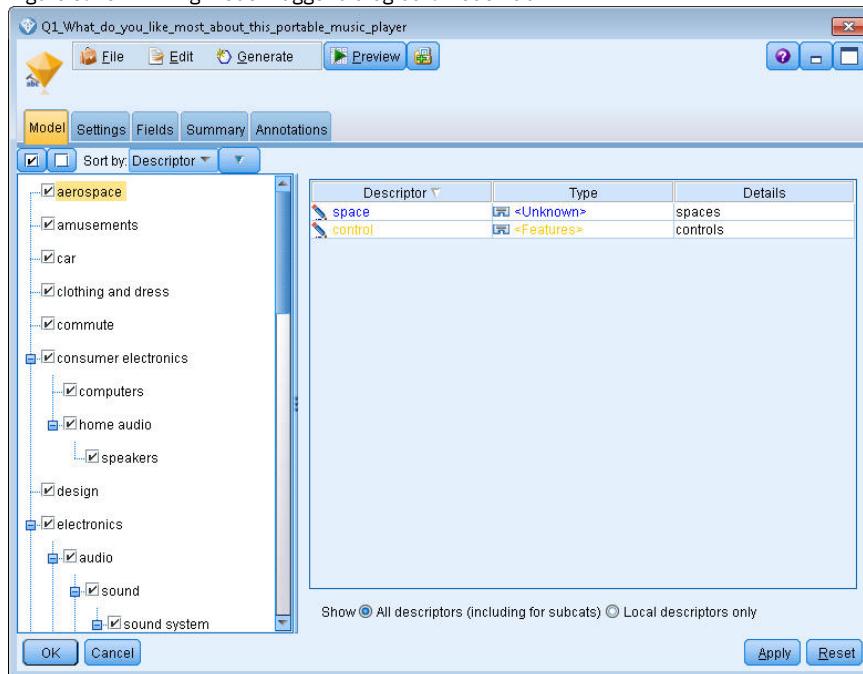

- 1. Statistics File node (Data tab).** First, we added this node to the stream to specify where the text documents are stored.

Figure 2. Statistics File node dialog box: Data tab

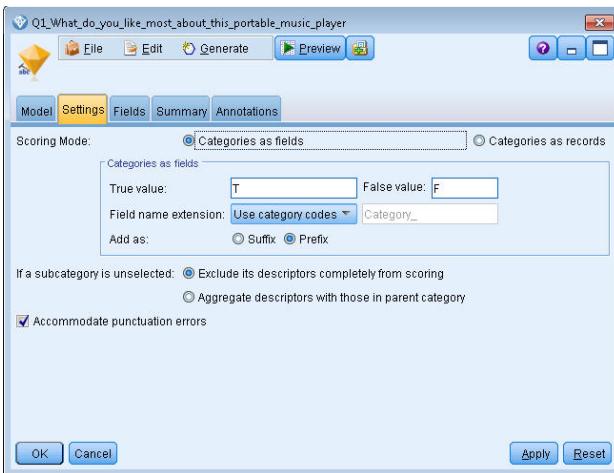

- 2. Text Mining category model nugget (Model tab).** Next, we added and connected a category model nugget to the Statistics File node. We selected the categories we wanted to use to score our data.

Figure 3. Text Mining model nugget dialog box: Model tab

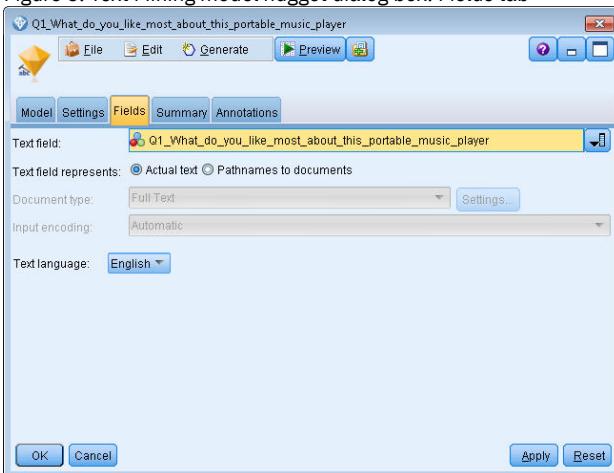

- 3. Text Mining model nugget (Settings tab).** Next, we defined the output format Categories as fields.

Figure 4. Category model nugget dialog box: Settings tab

4. **Text Mining category model nugget (Fields tab).** Next, we selected the text field variable, which is the field name coming from the Statistics File node, and selected the option Text field represents Actual text, as well as other settings.

Figure 5. Text Mining model nugget dialog box: Fields tab

5. **Table node.** Next, we attached a table node to see the results and executed the stream.

Figure 6. Table output

Table (3 fields, 844 records)			
	ID	Q1_What_do_you_like_most_about_this_portable_music_player	Category
1	1	little, light	light

13	8	portability, capacity, sound quality, durability	electronics/audio/sound
14	8	portability, capacity, sound quality, durability	electronics/audio

Mining for Text Links

- [Text Link Analysis node](#)

Text Link Analysis node

The Text Link Analysis (TLA) node adds a pattern-matching technology to text mining's concept extraction in order to identify relationships between the concepts in the text data based on known patterns. These relationships can describe how a customer feels about a product, which companies are doing business together, or even the relationships between genes or pharmaceutical agents.

For example, extracting your competitor's product name may not be interesting enough to you. Using this node, you could also learn how people feel about this product, if such opinions exist in the data. The relationships and associations are identified and extracted by matching known patterns to your text data.

You can use the TLA pattern rules inside certain resource templates shipped with IBM® SPSS® Modeler Text Analytics or create/edit your own. Pattern rules are made up of macros, word lists, and word gaps to form a Boolean query, or rule, that is compared to your input text. Whenever a TLA pattern rule matches text, this text can be exacted as a TLA result and restructured as output data. See the topic [About Text Link Rules](#) for more information.

The Text Link Analysis node offers a more direct way to identify and extract TLA pattern results from your text and then add the results to the dataset in the stream. But the Text Link Analysis node is not the only way in which you can perform text link analysis. You can also use an interactive workbench session in the Text Mining modeling node.

In the interactive workbench, you can explore the TLA pattern results and use them as category descriptors and/or to learn more about the results using drill-down and graphs. See the topic [Exploring Text Link Analysis](#) for more information. In fact, using the Text Mining node to extract TLA results is a great way to explore and fine-tune templates to your data for later use directly in the TLA node.

The output can be represented in up to 6 slots, or parts. See the topic [TLA node output](#) for more information.

You can find this node on the IBM SPSS Modeler Text Analytics tab of nodes palette at the bottom of the IBM SPSS Modeler window. See the topic [IBM SPSS Modeler Text Analytics nodes](#) for more information.

Requirements. The Text Link Analysis node accepts text data read into a field using any of the standard source nodes (Database node, Flat File node, etc.) or read into a field listing paths to external documents generated by a File List node or a Web Feed node.

Strengths. The Text Link Analysis node goes beyond basic concept extraction to provide information about the relationships *between* concepts, as well as related opinions or qualifiers that may be revealed in the data.

- [Text Link Analysis node: Fields tab](#)
- [Text Link Analysis node: Expert tab](#)
- [TLA node output](#)
- [Caching TLA Results](#)
- [Using the Text Link Analysis node in a stream](#)

Text Link Analysis node: Fields tab

Use the Fields tab to specify the field settings for the data from which you will be extracting concepts. You can set the following parameters:

ID field. Select the field containing the identifier for the text records. Identifiers must be integers. The ID field serves as an index for the individual text records. Use an ID field if the text field represents the text to be mined.

Text field. Select the field containing the text to be mined. This field depends on the data source.

Language field. Select the field that contains the two letter ISO language identifier. If you do not select a field, the language of each document is assumed to be that of the supplied template.

Document type. The document type specifies the structure of the text. Select one of the following types:

- Full text. Use for most documents or text sources. The entire set of text is scanned for extraction. Unlike the other options, there are no additional settings for this option.
- Structured text. Use for bibliographic forms, patents, and any files that contain regular structures that can be identified and analyzed. This document type is used to skip all or part of the extraction process. It allows you to define term separators, assign types, and impose a minimum frequency value. If you select this option, you must click the Settings button and enter text separators in the Structured Text Formatting area of the Document Settings dialog box. See the topic [Document Settings for Fields Tab](#) for more information.

Textual unity. Select the extraction mode from the following:

- Document mode. Use for documents that are short and semantically homogenous, such as articles from news agencies.
- Paragraph mode. Use for Web pages and nontagged documents. The extraction process semantically divides the documents, taking advantage of characteristics such as internal tags and syntax. If this mode is selected, scoring is applied paragraph by paragraph.

Therefore, for example, the rule **apple & orange** is true only if **apple** and **orange** are found in the same paragraph.

Note: Due to the way text is extracted from PDF documents, Paragraph mode does not work on these documents. This is because the extraction suppresses the carriage return marker.

Paragraph mode settings. This option is available only if you set the textual unity option to Paragraph mode. Specify the character thresholds to be used in any extraction. The actual size is rounded up or down to the nearest period. To ensure that the word associations produced from the

text of the document collection are representative, avoid specifying an extraction size that is too small.

- Minimum. Specify the minimum number of characters to be used in any extraction.
- Maximum. Specify the maximum number of characters to be used in any extraction.

Copy resources from. When mining text, the extraction is based not only on the settings in the Expert tab but also on the linguistic resources. These resources serve as the basis for how to handle and process the text during extraction to get the concepts, types, and TLA patterns. You can copy resources into this node from a resource template.

A resource template is a predefined set of libraries and advanced linguistic and nonlinguistic resources that have been fine-tuned for a particular domain or usage. These resources serve as the basis for how to handle and process data during extraction. Click Load and selecting the template from which to copy your resources.

Templates are loaded when you select them and not when the stream is executed. At the moment that you load, a copy of the resources is stored into the node. Therefore, if you ever wanted to use an updated template, you would have to reload it here. See the topic [Copying resources from templates and TAPs](#) for more information.

Text language. Identifies the language of the text being mined. The resources copied in the node control the language options presented. Select the language for which the resources were tuned.

Text Link Analysis node: Expert tab

In this node, the extraction of text link analysis (TLA) pattern results is automatically enabled. The Expert tab contains certain additional parameters that impact how text is extracted and handled. The parameters in this dialog box control the basic behavior, as well as a few advanced behaviors, of the extraction process. There are also a number of linguistic resources and options that also impact the extraction results, which are controlled by the resource template you select.

Limit extraction to concepts with a global frequency of at least [n]. Specifies the minimum number of times a word or phrase must occur in the text in order for it to be extracted. In this way, a value of 5 limits the extraction to those words or phrases that occur at least five times in the entire set of records or documents.

In some cases, changing this limit can make a big difference in the resulting extraction results, and consequently, your categories. Let's say that you are working with some restaurant data and you do not increase the limit above 1 for this option. In this case, you might find *pizza* (1), *thin pizza* (2), *spinach pizza* (2), and *favorite pizza* (2) in your extraction results. However, if you were to limit the extraction to a global frequency of 5 or more and re-extract, you would no longer get three of these concepts. Instead you would get *pizza* (7), since *pizza* is the simplest form and also this word already existed as a possible candidate. And depending on the rest of your text, you might actually have a frequency of more than seven, depending on whether there are still other phrases with *pizza* in the text. Additionally, if *spinach pizza* was already a category descriptor, you might need to add *pizza* as a descriptor instead to capture all of the records. For this reason, change this limit with care whenever categories have already been created.

Note that this is an extraction-only feature; if your template contains terms (which they usually do), and a term for the template is found in the text, then the term will be indexed regardless of its frequency.

For example, suppose you use a Basic Resources template that includes "los angeles" under the <Location> type in the Core library; if your document contains Los Angeles only once, then Los Angeles will be part of the list of concepts. To prevent this you will need to set a filter to display concepts occurring at least the same number of times as the value entered in the Limit extraction to concepts with a global frequency of at least [n] field.

Accommodate punctuation errors. This option temporarily normalizes text containing punctuation errors (for example, improper usage) during extraction to improve the extractability of concepts. This option is extremely useful when text is short and of poor quality (as, for example, in open-ended survey responses, e-mail, and CRM data), or when the text contains many abbreviations.

Accommodate spelling for a minimum word character length of [n] This option applies a fuzzy grouping technique that helps group commonly misspelled words or closely spelled words under one concept. The fuzzy grouping algorithm temporarily strips all vowels (except the first one) and strips double/triple consonants from extracted words and then compares them to see if they are the same so that **modeling** and **modelling** would be grouped together. However, if each term is assigned to a different type, excluding the <Unknown> type, the fuzzy grouping technique will not be applied.

You can also define the minimum number of root characters required before fuzzy grouping is used. The number of root characters in a term is calculated by totaling all of the characters and subtracting any characters that form inflection suffixes and, in the case of compound-word terms, determiners and prepositions. For example, the term **exercises** would be counted as 8 root characters in the form "exercise," since the letter **s** at the end of the word is an inflection (plural form). Similarly, **apple sauce** counts as 10 root characters ("apple sauce") and **manufacturing of cars** counts as 16 root characters ("manufacturing car"). This method of counting is only used to check whether the fuzzy grouping should be applied but does not influence how the words are matched.

Note: If you find that certain words are later grouped incorrectly, you can exclude word pairs from this technique by explicitly declaring them in the Fuzzy Grouping: Exceptions section in the Advanced Resources tab. See the topic [Fuzzy Grouping](#) for more information.

Extract uniterms This option extracts single words (uniterms) as long as the word is not already part of a compound word and if it is either a noun or an unrecognized part of speech.

Extract nonlinguistic entities This option extracts nonlinguistic entities, such as phone numbers, social security numbers, times, dates, currencies, digits, percentages, e-mail addresses, and HTTP addresses. You can include or exclude certain types of nonlinguistic entities in the Nonlinguistic Entities: Configuration section of the Advanced Resources tab. By disabling any unnecessary entities, the extraction engine won't waste processing time. See the topic [Configuration](#) for more information.

Uppercase algorithm This option extracts simple and compound terms that are not in the built-in dictionaries as long as the first letter of the term is in uppercase. This option offers a good way to extract most proper nouns.

Group partial and full person names together when possible This option groups names that appear differently in the text together. This feature is helpful since names are often referred to in their full form at the beginning of the text and then only by a shorter version. This option attempts to match any uniterm with the <Unknown> type to the last word of any of the compound terms that is typed as <Person>. For example, if *doe* is found and initially typed as <Unknown>, the extraction engine checks to see if any compound terms in the <Person> type include *doe* as the last word, such as *john doe*. This option does not apply to first names since most are never extracted as uniterms.

Maximum nonfunction word permutation This option specifies the maximum number of nonfunction words that can be present when applying the permutation technique. This permutation technique groups similar phrases that differ from each other only by the nonfunction words (for example, *of* and *the*) contained, regardless of inflection. For example, let's say that you set this value to at most two words and both **company officials** and **officials of the company** were extracted. In this case, both extracted terms would be grouped together in the final concept list since both terms are deemed to be the same when *of the* is ignored.

Use derivation when grouping multiterms When processing Big Data, select this option to group multiterms by using derivation rules.

TLA node output

After running the Text Link Analysis node, the data are restructured. It is important to understand the way that text mining restructures your data. If you desire a different structure for data mining, you can use nodes on the Field Operations palette to accomplish this. For example, if you were working with data in which each row represented a text record, then one row is created for each pattern uncovered in the source text data. For each row in the output, there are 15 fields:

- Six fields (Concept#, such as Concept1, Concept2, ..., and Concept6) represent any concepts found in the pattern match.
- Six fields (Type#, such as Type1, Type2, ..., and Type6) represent the type for each concept.
- Rule Name represents the name of the text link rule used to match the text and produce the output.
- A field using the name of the ID field you specified in the node and representing the record or document ID as it was in the input data
- Matched Text represents the portion of the text data in the original record or document that was matched to the TLA pattern.

Note: Any preexisting streams containing a Text Link Analysis node from a release prior to 5.0 may not be fully executable until you update the nodes. Certain improvements in later versions of IBM® SPSS® Modeler require older nodes to be replaced with the newer versions, which are both more deployable and more powerful.

It is also possible to perform an automatic translation of certain languages. This feature enables you to mine documents in a language you may not speak or read. If you want to use the translation feature, you must have access to the SDL Software as a Service (SaaS). See the topic [Translation Settings](#) for more information.

Caching TLA Results

If you cache, the text link analysis results are in the stream. To avoid repeating the extraction of text link analysis results each time the stream is executed, select the Text Link Analysis node and from the menus choose, Edit > Node > Cache > Enable. The next time the stream is executed, the output is cached in the node. The node icon displays a tiny "document" graphic that changes from white to green when the cache is filled. The cache is preserved for the duration of the session. To preserve the cache for another day (after the stream is closed and reopened), select the node and from the menus choose, Edit > Node > Cache > Save Cache. The next time you open the stream, you can reload the saved cache rather than running the translation again.

Alternatively, you can save or enable a node cache by right-clicking the node and choosing Cache from the context menu.

Using the Text Link Analysis node in a stream

The Text Link Analysis node is used to access data and extract concepts in a stream. You can use any source node to access data.

Example: Statistics File node with the Text Link Analysis node

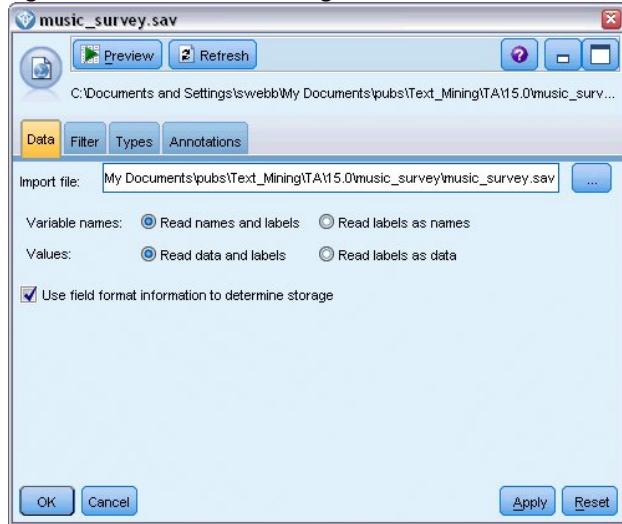

The following example shows how to use the Text Link Analysis node.

Figure 1. Example: Statistics File node with the Text Link Analysis node

1. Statistics File node (Data tab). First, we added this node to the stream to specify where the text is stored.

Figure 2. Statistics File node dialog box: Data tab

2. Text Link Analysis node (Fields tab). Next, we attached this node to the stream to extract concepts for downstream modeling or viewing. We specified the ID field and the text field name containing the data, as well as other settings.

Figure 3. Text Link Analysis node dialog box: Fields tab

3. Table node. Finally, we attached a Table node to view the concepts that were extracted from our text documents. In the table output shown, you can see the TLA pattern results found in the data after this stream was executed with a Text Link Analysis node. Some results show only one concept/type was matched. In others, the results are more complex and contain several types and concepts. Additionally, as a result of running data through the Text Link Analysis node and extracting concepts, several aspects of the data are changed. The original data in our example contained 8 fields and 405 records. After executing the Text Link Analysis node, there are now 15 fields and 640 records. There is now one row for each TLA pattern result found. For example, **ID 7** became three rows from the original because three TLA pattern results were extracted. You can use a Merge node if you want to merge this output data back into your original data.

Figure 4. Table output node

The screenshot shows a 'Table (15 fields, 640 records) #4' window. The 'Annotations' tab is selected. The preview pane displays 10 rows of data with their respective annotations:

	Concept1	Type1	Concept2	Type2	Concept3	Type3	Concept4	Type4	Concept5	Type5	Concept6	Type6	Rule Number	ID	Matched Text
1	expensive	Negative	Budget	Null	Null	Null	Null	Null	Null	Null	Null	001350	opinion	1	<expensive>
2	screen	Unknown	difficult	Nega...	Null	Null	Null	Null	Null	Null	Null	00145	topic + opinion	2	The <screen> is <hard> to see when outside
3	software	Unknown	difficult	Nega...	Null	Null	Null	Null	Null	Null	Null	00211	_opinion + topic	3	<difficult><software>
4	nothing	Uncertain	Null	Null	Null	Null	Null	Null	Null	Null	Null	00153	_topic+opinion	4	<Nothing> <*> I love it

Browsing External Source Text

- [File Viewer node](#)

File Viewer node

When you are mining a collection of documents, you can specify the full path names of files directly into your Text Mining modeling nodes. However, when outputting to a Table node, you will only see the full path name of a document rather than the text within it. The File Viewer node can be used as an analog of the Table node and it enables you to access the actual text within each of the documents without having to merge them all together into a single file.

The File Viewer node can help you better understand the results from text extraction by providing you access to the source, or untranslated, text from which concepts were extracted since it is otherwise inaccessible in the stream. This node is added to the stream after a File List node to obtain a list of links to all the files.

The result of this node is a window showing all of the document elements that were read and used to extract concepts. From this window, you can click a toolbar icon to launch the report in an external browser listing document names as hyperlinks. You can click a link to open the corresponding document in the collection. See the topic [Using the File Viewer Node](#) for more information.

You can find this node on the IBM® SPSS® Modeler Text Analytics tab of nodes palette at the bottom of the IBM SPSS Modeler window. See the topic [IBM SPSS Modeler Text Analytics nodes](#) for more information.

Note: When you are working in client-server mode and File Viewer nodes are part of the stream, document collections must be stored in a Web server directory on the server. Since the Text Mining output node produces a list of documents stored in the Web server directory, the Web server's security settings manage the permissions to these documents.

- [File Viewer Node Settings](#)
- [Using the File Viewer Node](#)

File Viewer Node Settings

You can specify the following settings for the File Viewer node.

Document field. Select the field from your data that contains the full name and path of the documents to be displayed.

Title for generated HTML page. Create a title to appear at the top of the page that contains the list of documents.

Using the File Viewer Node

The following example shows how to use the File Viewer node.

Example: File List node and a File Viewer node

Figure 1. Stream illustrating the use of a File Viewer node

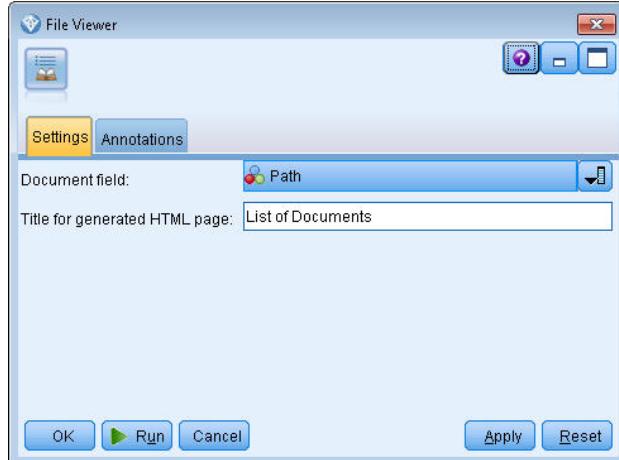

1. **File List node (Settings tab).** First, we added this node to specify where the documents are located.

Figure 2. File List node dialog box: Settings tab

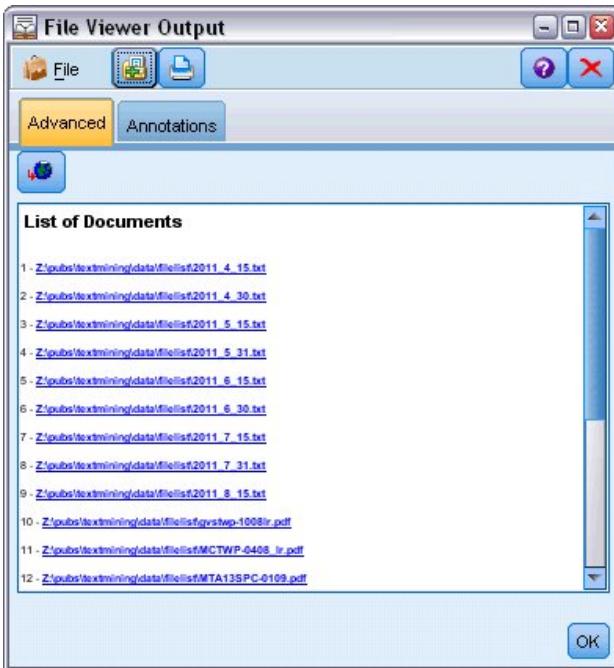

2. **File Viewer node (Settings tab).** Next, we attached the File Viewer node to produce an HTML list of documents.

Figure 3. File Viewer node dialog box: Settings tab

3. **File Viewer Output dialog.** Next, we executed the stream which outputs the list of documents in a new window.

Figure 4. File Viewer Output

4. To see the documents, we clicked the toolbar button showing a globe with a red arrow. This opened a list of document hyperlinks in our browser.

Node Properties for Scripting

IBM® SPSS® Modeler has a scripting language to allow you to execute streams from the command line. Here, you can learn about the node properties that are specific to each of the nodes delivered with IBM SPSS Modeler Text Analytics. For more information on the standard set of nodes delivered with IBM SPSS Modeler, please refer to the Scripting and Automation Guide.

File List Node: filelistnode

You can use the properties in the following table for scripting. The node itself is called `filelistnode`.

Table 1. File List node scripting properties

Scripting properties	Data type
<code>path</code>	<code>string</code>
<code>recurse</code>	<code>flag</code>
<code>word_processing</code>	<code>flag</code>
<code>excel_file</code>	<code>flag</code>
<code>powerpoint_file</code>	<code>flag</code>
<code>text_file</code>	<code>flag</code>
<code>web_page</code>	<code>flag</code>
<code>xml_file</code>	<code>flag</code>
<code>pdf_file</code>	<code>flag</code>
<code>no_extension</code>	<code>flag</code>

Note: 'Create list' parameter is no longer available and any scripts containing that option will be automatically converted into a 'Files' output.

Web Feed Node: webfeednode

You can use the properties in the following table for scripting. The node itself is called `webfeednode`.

Table 1. Web Feed node scripting properties

Scripting properties	Data type	Property description
<code>urls</code>	<code>string1 string2 ...stringn</code>	Each URL is specified in the list structure. URL list separated by “\n”
<code>recent_entries</code>	<code>flag</code>	
<code>limit_entries</code>	<code>integer</code>	Number of most recent entries to read per URL.
<code>use_previous</code>	<code>flag</code>	To save and reuse Web feed cache.
<code>use_previous_label</code>	<code>string</code>	Name for the saved Web cache.
<code>start_record</code>	<code>string</code>	Non-RSS start tag.
<code>url n .title</code>	<code>string</code>	For each URL in the list, you must define one here too. The first one will be <code>url1.title</code> , where the number matches its position in the URL list. This is the start tag containing the title of the content.
<code>url n .short_description</code>	<code>string</code>	Same as for <code>url n .title</code> .
<code>url n .description</code>	<code>string</code>	Same as for <code>url n .title</code> .
<code>url n .authors</code>	<code>string</code>	Same as for <code>url n .title</code> .
<code>url n .contributors</code>	<code>string</code>	Same as for <code>url n .title</code> .
<code>url n .published_date</code>	<code>string</code>	Same as for <code>url n .title</code> .

Scripting properties	Data type	Property description
<code>url_n.modified_date</code>	<code>string</code>	Same as for <code>url_n.title</code> .
<code>html_alg</code>	<code>None HTMLCleaner</code>	Content filtering method.
<code>discard_lines</code>	<code>flag</code>	Discard short lines. Used with <code>min_words</code>
<code>min_words</code>	<code>integer</code>	Minimum number of words.
<code>discard_words</code>	<code>flag</code>	Discard short lines. Used with <code>min_avg_len</code>
<code>min_avg_len</code>	<code>integer</code>	
<code>discard_scw</code>	<code>flag</code>	Discard lines with many single character words. Used with <code>max_scw</code>
<code>max_scw</code>	<code>integer</code>	Maximum proportion 0-100 percentage of single characters words in a line
<code>discard_tags</code>	<code>flag</code>	Discard lines containing certain tags.
<code>tags</code>	<code>string</code>	Special characters must be escaped with a backslash character \.
<code>discard_spec_words</code>	<code>flag</code>	Discard lines containing specific strings
<code>words</code>	<code>string</code>	Special characters must be escaped with a backslash character \.

Language Node: languageidentifier

You can use the properties in the following table for scripting. The node itself is called `languageidentifier`.

Table 1. Language node scripting properties

Scripting properties	Data type	Property description
<code>text</code>	<code>field</code>	
<code>language_field_name</code>	<code>string</code>	The field name that is generated as output.
<code>unidentified_language_value</code>	<code>Undefined Supported Custom</code>	Default value to be used when the language cannot be identified.
<code>unidentified_language_supported</code>	<code>en de es fr it ja nl pt</code>	Iso code. Only available if <code>unidentified_language_value</code> is <code>Supported</code> .
<code>unidentified_language_custom</code>	<code>string</code>	Only available if <code>unidentified_language_value</code> is <code>Custom</code> .

Text Mining node: TextMiningWorkbench

You can use the following parameters to define or update a node through scripting. The node itself is called `TextMiningWorkbench`.

Important: It is not possible to specify a different resource template via scripting. If you think you need a template, you must select it in the node dialog box.

Table 1. Text Mining modeling node scripting properties

Scripting properties	Data type	Property description
<code>text</code>	<code>field</code>	

Scripting properties	Data type	Property description
<code>method</code>	<code>ReadText ReadPath</code>	
<code>docType</code>	<code>integer</code>	With possible values (0,1,2) where 0 = <code>Full Text</code> , 1 = <code>Structured Text</code> , and 2 = <code>XML</code>
<code>encoding</code>	<code>Automatic "UTF-8" "UTF-16" "ISO-8859-1" "US-ASCII" "CP850" "EUC-JP" "SHIFT-JIS" "ISO2022-JP"</code>	Note that values with special characters, such as " <code>UTF-8</code> ", should be quoted to avoid confusion with a mathematical operator.
<code>unity</code>	<code>integer</code>	With possible values (0,1) where 0 = <code>Paragraph</code> and 1 = <code>Document</code>
<code>para_min</code>	<code>integer</code>	
<code>para_max</code>	<code>integer</code>	
<code>mtag</code>	<code>string</code>	Contains all the mtag settings (from Settings dialog box for XML files)
<code>mclef</code>	<code>string</code>	Contains all the mclef settings (from Settings dialog box for Structured Text files)
<code>partition</code>	<code>field</code>	
<code>custom_field</code>	<code>flag</code>	Indicates whether or not a partition field will be specified.
<code>use_model_name</code>	<code>flag</code>	
<code>model_name</code>	<code>string</code>	
<code>use_partitioned_data</code>	<code>flag</code>	If a partition field is defined, only the training data are used for model building.
<code>model_output_type</code>	<code>Interactive Model</code>	<code>Interactive</code> results in a category model. <code>Model</code> results in a concept model.
<code>use_interactive_info</code>	<code>flag</code>	For building interactively in a workbench session only.
<code>reuse_extraction_results</code>	<code>flag</code>	For building interactively in a workbench session only.
<code>interactive_view</code>	<code>Categories TIA Clusters</code>	For building interactively in a workbench session only.
<code>extract_top</code>	<code>integer</code>	This parameter is used when <code>model_type = Concept</code>
<code>use_check_top</code>	<code>flag</code>	
<code>check_top</code>	<code>integer</code>	
<code>use_uncheck_top</code>	<code>flag</code>	
<code>uncheck_top</code>	<code>integer</code>	
<code>language</code>	<code>de en es fr it ja nl pt</code>	
<code>frequency_limit</code>	<code>integer</code>	Deprecated in 14.0.
<code>concept_count_limit</code>	<code>integer</code>	Limit extraction to concepts with a global frequency of at least this value.
<code>fix_punctuation</code>	<code>flag</code>	
<code>fix_spelling</code>	<code>flag</code>	
<code>spelling_limit</code>	<code>integer</code>	
<code>extract_uniterm</code>	<code>flag</code>	
<code>extract_nonlinguistic</code>	<code>flag</code>	
<code>upper_case</code>	<code>flag</code>	
<code>group_names</code>	<code>flag</code>	
<code>permutation</code>	<code>integer</code>	Maximum nonfunction word permutation (the default is 3).

Text Mining model nugget: TMWBModelApplier

You can use the properties in the following table for scripting. The nugget itself is called `TMWBModelApplier`.

Table 1. Text Mining Model Nugget Properties

Scripting properties	Data type	Property description
----------------------	-----------	----------------------

Scripting properties	Data type	Property description
<code>scoring_mode</code>	<code>Fields Records</code>	
<code>field_values</code>	<code>Flags Counts</code>	This option is not available in the Category model nugget. For <code>Flags</code> , set to <code>TRUE</code> or <code>FALSE</code>
<code>true_value</code>	<code>string</code>	With <code>Flags</code> , define the value for true.
<code>false_value</code>	<code>string</code>	With <code>Flags</code> , define the value for false.
<code>extension_concept</code>	<code>string</code>	Specify an extension for the field name. Field names are generated by using the concept name plus this extension. Specify where to put this extension using the <code>add_as</code> value.
<code>extension_category</code>	<code>string</code>	Field name extension. You can choose to specify an extension prefix/suffix for the field name or you can choose to use the category codes. Field names are generated by using the category name plus this extension. Specify where to put this extension using the <code>add_as</code> value.
<code>add_as</code>	<code>Suffix Prefix</code>	
<code>fix_punctuation</code>	<code>flag</code>	
<code>excluded_subcategories_descriptors</code>	<code>RollUpToParent Ignore</code>	For category models only. If a subcategory is unselected. This option allows you to specify how the descriptors belonging to subcategories that were not selected for scoring will be handled. There are two options. <ul style="list-style-type: none"> Ignore. The option Exclude its descriptors completely from scoring will cause the descriptors of subcategories that do not have checkmarks (unselected) to be ignored and unused during scoring. RollUpToParent. The option Aggregate descriptors with those in parent category will cause the descriptors of subcategories that do not have checkmarks (unselected) to be used as descriptors for the parent category (the category above this subcategory). If several levels of subcategories and unselected, the descriptors will be rolled up under the first available parent category
<code>check_model</code>	<code>flag</code>	Deprecated in version 14
<code>text</code>	<code>field</code>	
<code>method</code>	<code>ReadText ReadPath</code>	
<code>docType</code>	<code>integer</code>	With possible values (0,1,2) where 0 = <code>Full Text</code> , 1 = <code>Structured Text</code> , and 2 = <code>XML</code>
<code>encoding</code>	<code>Automatic "UTF-8" "UTF-16" "ISO-8859-1" "US-ASCII" "CP850" "EUC-JP" "SHIFT-JIS" "ISO2022-JP"</code>	Note that values with special characters, such as " <code>UTF-8</code> ", should be quoted to avoid confusion with a mathematical operator.
<code>language</code>	<code>de en es fr it ja nl pt</code>	

Text Link Analysis node: `textlinkanalysis`

You can use the parameters in the following table to define or update a node through scripting. The node itself is called `textlinkanalysis`.

Important: It is not possible to specify a resource template via scripting. To select a template, you must do so from within the node dialog box.

Table 1. Text Link Analysis (TLA) node scripting properties

Scripting properties	Data type	Property description
<code>id_field</code>	<code>field</code>	
<code>text</code>	<code>field</code>	
<code>method</code>	<code>ReadText ReadPath</code>	
<code>docType</code>	<code>integer</code>	With possible values (0,1,2) where 0 = <code>Full Text</code> , 1 = <code>Structured Text</code> , and 2 = <code>XML</code>
<code>encoding</code>	<code>Automatic "UTF-8" "UTF-16" "ISO-8859-1" "US-ASCII" "CP850" "EUC-JP" "SHIFT-JIS" "ISO2022-JP"</code>	Note that values with special characters, such as " <code>UTF-8</code> ", should be quoted to avoid confusion with a mathematical operator.
<code>unity</code>	<code>integer</code>	With possible values (0,1) where 0 = <code>Paragraph</code> and 1 = <code>Document</code>
<code>para_min</code>	<code>integer</code>	
<code>para_max</code>	<code>integer</code>	
<code>mtag</code>	<code>string</code>	Contains all the mtag settings (from Settings dialog box for XML files)

Scripting properties	Data type	Property description
<code>mclef</code>	<code>string</code>	Contains all the mclef settings (from Settings dialog box for Structured Text files)
<code>language</code>	<code>de en es fr it ja nl pt</code>	
<code>concept_count_limit</code>	<code>integer</code>	Limit extraction to concepts with a global frequency of at least this value.
<code>fix_punctuation</code>	<code>flag</code>	
<code>fix_spelling</code>	<code>flag</code>	
<code>spelling_limit</code>	<code>integer</code>	
<code>extract_uniterm</code>	<code>flag</code>	
<code>extract_nonlinguistic</code>	<code>flag</code>	
<code>upper_case</code>	<code>flag</code>	
<code>group_names</code>	<code>flag</code>	
<code>permutation</code>	<code>integer</code>	Maximum nonfunction word permutation (the default is 3).

Interactive workbench mode

From a text mining modeling node, you can choose to launch an interactive workbench session during stream execution. In this workbench, you can extract key concepts from your text data, build categories, and explore text link analysis patterns and clusters, and generate category models. In this section, we discuss the workbench interface from a high-level perspective along with the major elements with which you will work, including:

- Extraction results. After an extraction is performed, these are the key words and phrases identified and extracted from your text data, also referred to as *concepts*. These concepts are grouped into *types*. Using these concepts and types, you can explore your data as well as create your categories. These are managed in the Categories and Concepts view.
- Categories. Using descriptors (such as extraction results, patterns, and rules) as a definition, you can manually or automatically create a set of categories to which documents and records are assigned based on whether or not they contain a part of the category definition. These are managed in the Categories and Concepts view.
- Clusters. *Clusters* are a grouping of concepts between which links have been discovered that indicate a relationship among them. The concepts are grouped using a complex algorithm that uses, among other factors, how often two concepts appear together compared to how often they appear separately. These are managed in the Clusters view. You can also add the concepts that make up a cluster to categories.
- Text link analysis patterns. If you have text link analysis (TLA) pattern rules in your linguistic resources or are using a resource template that already has some TLA rules, you can extract patterns from your text data. These patterns can help you uncover interesting relationships between concepts in your data. You can also use these patterns as descriptors in your categories. These are managed in the **Text Link Analysis** view.
- Linguistic resources. The extraction process relies on a set of parameters and linguistic definitions to govern how text is extracted and handled. These are managed in the form of templates and libraries in the Resource Editor view.

Potential Interactive Workbench issues

- Multiple Interactive Workbench sessions can cause sluggish behavior. SPSS® Modeler Text Analytics and SPSS Modeler share a common Java run-time engine when an interactive workbench session is launched. Depending on the number of Interactive Workbench sessions you invoke during a SPSS Modeler session, system memory may cause the application to become sluggish, even if opening and closing the same session. This effect may be especially pronounced if you are working with large data or have a machine with less than the recommended RAM setting of 4GB. If you notice your machine is slow to respond, it is recommended that you save all your work, shut down SPSS Modeler, and re-launch the application. Running SPSS Modeler Text Analytics on a machine with less than the recommended memory, particularly when working with large data sets or for prolonged periods of time, may cause Java to run out of memory and shut down. It is strongly suggested you upgrade to the recommended memory setting or larger (or use SPSS Modeler Text Analytics Server) if you work with large data.
- SPSS Modeler Client can run out of memory after multiple SPSS Modeler Text Analytics Interactive Workbench sessions are run without restarting the application. Monitor the memory usage in the status line and, if running low, close and re-open SPSS Modeler Client.

The Categories and Concepts View

The application interface is made up of several views. The Categories and Concepts view is the window in which you can create and explore categories as well as explore and tweak the extraction results. *Categories* refers to a group of closely related ideas and patterns to which documents and records are assigned through a scoring process. While *concepts* refer to the most basic level of extraction results available to use as building blocks, called descriptors, for your categories.

Figure 1. Categories and Concepts view

The Categories and Concepts view is organized into four panes, each of which can be hidden or shown by selecting its name from the View menu. See the topic [Categorizing text data](#) for more information.

Categories Pane

Located in the upper left corner, this area presents a table in which you can manage any categories you build. After extracting the concepts and types from your text data, you can begin building categories by using techniques such as semantic networks and concept inclusion, or by creating them manually. If you double-click a category name, the Category Definitions dialog box opens and displays all of the descriptors that make up its definition, such as concepts, types, and rules. See the topic [Categorizing text data](#) for more information. Not all automatic techniques are available for all languages.

When you select a row in the pane, you can then display information about corresponding documents/records or descriptors in the Data and Visualization panes.

Extraction Results Pane

Located in the lower left corner, this area presents the extraction results. When you run an extraction, the extraction engine reads through the text data, identifies the relevant concepts, and assigns a type to each. *Concepts* are words or phrases extracted from your text data. *Types* are semantic groupings of concepts stored in the form of type dictionaries. When the extraction is complete, concepts and types appear with color coding in the Extraction Results pane. See the topic [Extraction results: Concepts and types](#) for more information.

You can see the set of underlying terms for a concept by hovering your mouse over the concept name. Doing so will display a tooltip showing the concept name and up to several lines of terms that are grouped under that concept. These underlying terms include the synonyms defined in the linguistic resources (regardless of whether they were found in the text or not) as well as the any extracted plural/singular terms, permuted terms, terms from fuzzy grouping, and so on. You can copy these terms or see the full set of underlying terms by right-clicking the concept name and choosing the context menu option.

Text mining is an iterative process in which extraction results are reviewed according to the context of the text data, fine-tuned to produce new results, and then reevaluated. Extraction results can be refined by modifying the linguistic resources. This fine-tuning can be done in part directly

from the Extraction Results or Data pane but also directly in the Resource Editor view. See the topic [The Resource Editor view](#) for more information.

Note: If there are more results that can fit in the visible pane, you can use the controls at the bottom of the pane to move forwards and backwards through the results, or enter a page number to go to.

Visualization Pane

Located in the upper right corner, this area presents multiple perspectives on the commonalities in document/record categorization. Each graph or chart provides similar information but presents it in a different manner or with a different level of detail. These charts and graphs can be used to analyze your categorization results and aid in fine-tuning categories or reporting. For example, in a graph you might uncover categories that are too similar (for example, they share more than 75% of their records) or too distinct. The contents in a graph or chart correspond to the selection in the other panes. See the topic [Category Graphs and Charts](#) for more information.

Data Pane

The Data pane is located in the lower right corner. This pane presents a table containing the documents or records corresponding to a selection in another area of the view. Depending on what is selected, only the corresponding text appears in the Data pane. Once you make a selection, click a Display button to populate the Data pane with the corresponding text.

If you have a selection in another pane, the corresponding documents or records show the concepts highlighted in color to help you easily identify them in the text. You can also hover your mouse over color-coded items to display a tooltip showing name of the concept under which it was extracted and the type to which it was assigned. See the topic [The Data Pane](#) for more information.

Searching and Finding in the Categories and Concepts view

In some cases, you may need to locate information quickly in a particular section. Using the Find toolbar, you can enter the string you want to search for and define other search criteria such as case sensitivity or search direction. Then you can choose the pane in which you want to search.

To use the Find feature

1. In the Categories and Concepts view, choose Edit > Find from the menus. The Find toolbar appears above the Categories pane and Visualization panes.
2. Enter the word string that you want to search for in the text box. You can use the toolbar buttons to control the case sensitivity, partial matching, and direction of the search.
3. In the toolbar, click the name of the pane in which you want to search. If a match is found, the text is highlighted in the window.
4. To look for the next match, click the name of the pane again.

The Clusters View

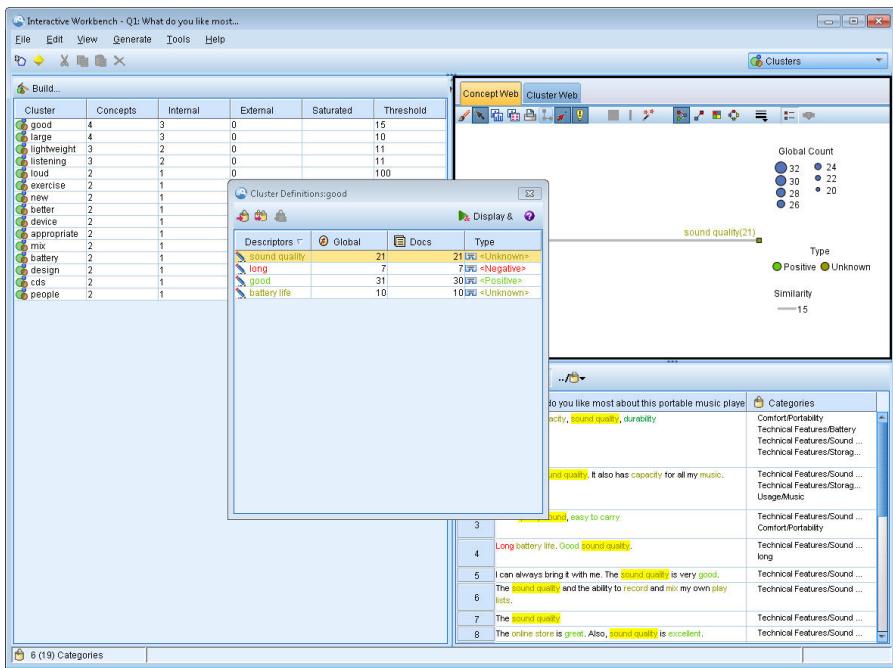

In the Clusters view, you can build and explore cluster results found in your text data. *Clusters* are groupings of concepts generated by clustering algorithms based on how often concepts occur and how often they appear together. The goal of clusters is to group concepts that co-occur together while the goal of categories is to group documents or records based on how the text they contain matches the descriptors (concepts, rules, patterns) for each category.

The more often the concepts within a cluster occur together coupled with the less frequently they occur with other concepts, the better the cluster is at identifying interesting concept relationships. Two concepts co-occur when they both appear (or one of their synonyms or terms appear) in the same document or record. See the topic [Analyzing clusters](#) for more information.

You can build clusters and explore them in a set of charts and graphs that could help you uncover relationships among concepts that would otherwise be too time-consuming to find. While you cannot add entire clusters to your categories, you can add the concepts in a cluster to a category through the Cluster Definitions dialog box. See the topic [Cluster Definitions](#) for more information.

You can make changes to the settings for clustering to influence the results. See the topic [Building Clusters](#) for more information.

Figure 1. Clusters view

The Clusters view is organized into three panes, each of which can be hidden or shown by selecting its name from the View menu. Typically, only the Clusters pane and the Visualization pane are visible.

Clusters Pane

Located on the left side, this pane presents the clusters that were discovered in the text data. You can create clustering results by clicking the Build button. Clusters are formed by a clustering algorithm, which attempts to identify concepts that occur together frequently.

Whenever a new extraction takes place, the cluster results are cleared, and you have to rebuild the clusters to get the latest results. When building the clusters, you can change some settings, such as the maximum number of clusters to create, the maximum number of concepts it can contain, or the maximum number of links with external concepts it can have. See the topic [Exploring Clusters](#) for more information.

Visualization Pane

Located in the upper right corner, this pane offers two perspectives on clustering: a Concept Web graph and a Cluster Web graph. If not visible, you can access this pane from the View menu (View > Visualization). Depending on what is selected in the clusters pane, you can view the corresponding interactions between or within clusters. The results are presented in multiple formats:

- Concept Web. Web graph showing all of the concepts within the selected cluster(s), as well as linked concepts outside the cluster.
- Cluster Web. Web graph showing the links from the selected cluster(s) to other clusters, as well as any links between those other clusters.

Note: In order to display a Cluster Web graph, you must have already built clusters with external links. External links are links between concept pairs in separate clusters (a concept within one cluster and a concept outside in another cluster). See the topic [Cluster Graphs](#) for more information.

Data Pane

The Data pane is located in the lower right corner and is hidden by default. You cannot display any Data pane results from the Clusters pane since these clusters span multiple documents/records, making the data results uninteresting. However, you can see the data corresponding to a selection within the Cluster Definitions dialog box. Depending on what is selected in that dialog box, only the corresponding text appears in the Data pane. Once you make a selection, click the Display & button to populate the Data pane with the documents or records that contain all of the concepts together.

The corresponding documents or records show the concepts highlighted in color to help you easily identify them in the text. You can also hover your mouse over color-coded items to display the concept under which it was extracted and the type to which it was assigned. The Data pane can contain multiple columns but the text field column is always shown. It carries the name of the text field that was used during extraction or a document name if the text data is in many different files. Other columns are available. See the topic [The Data Pane](#) for more information.

The Text Link Analysis view

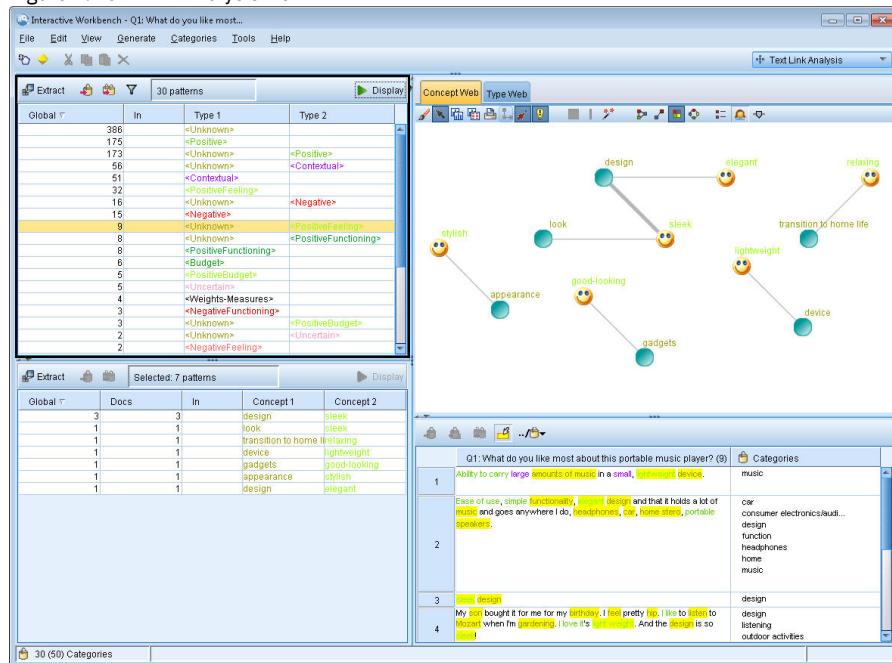

In the Text Link Analysis view, you can build and explore text link analysis patterns found in your text data. Text link analysis (TLA) is a pattern-matching technology that enables you to define TLA rules and compare them to actual extracted concepts and relationships found in your text.

Patterns are most useful when you are attempting to discover relationships between concepts or opinions about a particular subject. Some examples include wanting to extract opinions on products from survey data, genomic relationships from within medical research papers, or relationships between people or places from intelligence data.

Once you've extracted some TLA patterns, you can explore them in the Data or Visualization panes and even add them to categories in the Categories and Concepts view. There must be some TLA rules defined in the resource template or libraries you are using in order to extract TLA results. See the topic [About Text Link Rules](#) for more information.

If you chose to extract TLA pattern results, the results are presented in this view. If you have not chosen to do so, you will have to use the Extract button and choose the option to enable the extraction of patterns.

Figure 1. Text Link Analysis view

The Text Link Analysis view is organized into four panes, each of which can be hidden or shown by selecting its name from the View menu. See the topic [Exploring Text Link Analysis](#) for more information.

Type and Concept Patterns Panes

Located on the left side, the Type and Concept Pattern panes are two interconnected panes in which you can explore and select your TLA pattern results. Patterns are made up of a series of up to either six types or six concepts. The TLA pattern rule as it is defined in the linguistic resources dictates the complexity of the pattern results. See the topic [About Text Link Rules](#) for more information.

Pattern results are first grouped at the type level and then divided into concept patterns. For this reason, there are two different result panes: Type Patterns (upper left) and Concept Patterns (lower left).

- Type Patterns. The Type Patterns pane presents extracted patterns consisting of two or more related types matching a TLA pattern rule. Type patterns are shown as **<Organization> + <Location> + <Positive>**, which might provide positive feedback about an organization in a specific location.
- Concept Patterns. The Concept Patterns pane presents the extracted patterns at the concept level for all of the type pattern(s) currently selected in the Type Patterns pane above it. Concept patterns follow a structure such as **hotel + paris + wonderful**.

Just as with the extraction results in the Categories and Concepts view, you can review the results here. If you see any refinements you would like to make to the types and concepts that make up these patterns, you make those in the Extraction Results pane in the Categories and Concepts view, or directly in the Resource Editor, and reextract your patterns.

Visualization Pane

Located in the upper right corner of the Text Link Analysis view, this pane presents a web graph of the selected patterns as either type patterns or concept patterns. If not visible, you can access this pane from the View menu (View > Visualization). Depending on what is selected in the other panes, you can view the corresponding interactions between documents/records and the patterns.

The results are presented in multiple formats:

- Concept Graph. This graph presents all the concepts in the selected pattern(s). The line width and node sizes (if type icons are not shown) in a concept graph show the number of global occurrences in the selected table.
- Type Graph. This graph presents all the types in the selected pattern(s). The line width and node sizes (if type icons are not shown) in the graph show the number of global occurrences in the selected table. Nodes are represented by either a type color or by an icon.

See the topic [Text Link Analysis Graphs](#) for more information.

Data Pane

The Data pane is located in the lower right corner. This pane presents a table containing the documents or records corresponding to a selection in another area of the view. Depending on what is selected, only the corresponding text appears in the Data pane. Once you make a selection, click a Display button to populate the Data pane with the corresponding text.

If you have a selection in another pane, the corresponding documents or records show the concepts highlighted in color to help you easily identify them in the text. You can also hover your mouse over color-coded items to display a tooltip showing name of the concept under which it was extracted and the type to which it was assigned. See the topic [The Data Pane](#) for more information.

The Resource Editor view

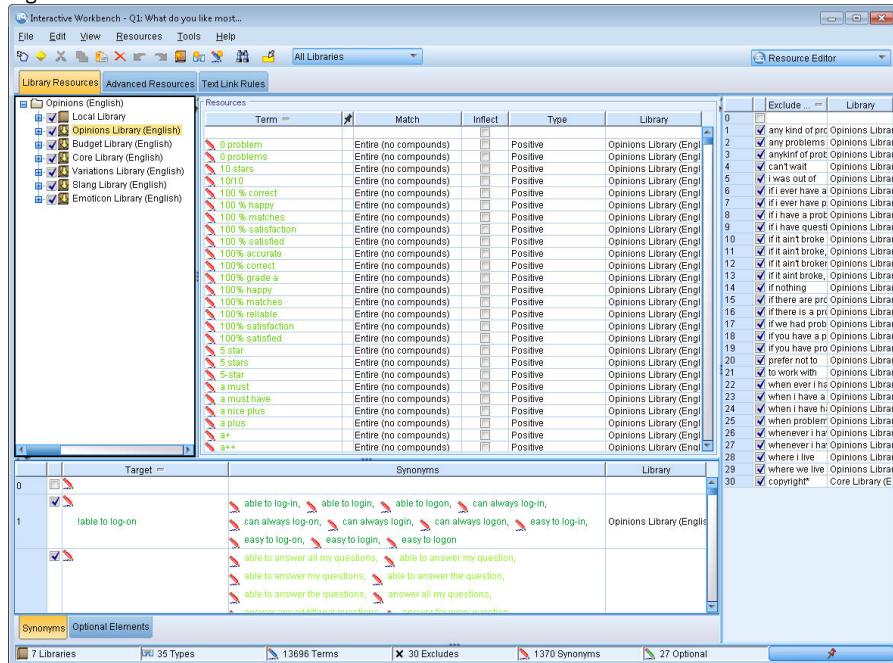

IBM® SPSS® Modeler Text Analytics rapidly and accurately captures key concepts from text data using a robust extraction engine. This engine relies heavily on linguistic resources to dictate how large amounts of unstructured, textual data should be analyzed and interpreted.

The Resource Editor view is where you can view and fine-tune the linguistic resources used to extract concepts, group them under types, discover patterns in the text data, and much more. IBM SPSS Modeler Text Analytics offers several preconfigured resource templates. Also, in some languages, you can also use the resources in a text analysis packages. See the topic [Using Text Analysis Packages](#) for more information.

Since these resources may not always be perfectly adapted to the context of your data, you can create, edit, and manage your own resources for a particular context or domain in the Resource Editor. See the topic [Working with Libraries](#) for more information.

To simplify the process of fine-tuning your linguistic resources, you can perform common dictionary tasks directly from the Categories and Concepts view through context menus in the Extraction Results and Data panes. See the topic [Refining extraction results](#) for more information.

Figure 1. Resource Editor view

The operations that you perform in the Resource Editor view revolve around the management and fine-tuning of the linguistic resources. These resources are stored in the form of templates and libraries. The Resource Editor view is organized into four parts: Library Tree pane, Type Dictionary pane, Substitution Dictionary pane, and Exclude Dictionary pane.

Note: See the topic [The Editor interface](#) for more information.

Setting Options

You can set general options for IBM® SPSS® Modeler Text Analytics in the Options dialog box. This dialog box contains the following tabs:

- **Session.** This tab contains general options and delimiters. See the topic [Options: Session Tab](#) for more information.
- **Display.** This tab contains options for the colors used in the interface. See the topic [Options: Display Tab](#) for more information.
- **Sounds.** This tab contains options for sound cues. See the topic [Options: Sounds Tab](#) for more information.

To Edit Options

1. From the menus, choose Tools > Options. The Options dialog box opens.
 2. Select the tab containing the information you want to change.
 3. Change any of the options.
 4. Click OK to save the changes.
- [Options: Session Tab](#)

- [Microsoft Internet Explorer settings for Help](#)

Options: Session Tab

On this tab, you can define some of the basic settings.

Data Pane and Category Graph Display. These options affect how data are presented in the Data pane and in the Visualization pane in the Categories and Concepts view.

- **Display limit for Data pane and Category Web.** This option sets the maximum number of documents to show or use to populate the Data panes or graphs and charts in the Categories and Concepts view.
- **Show categories for documents/records at Display time.** If selected, the documents or records are scored whenever you click Display so that any categories to which they belong can be displayed in the Categories column in the Data pane as well as in the category graphs. In some cases, especially with larger datasets, you may want to turn off this option so that data and graphs are displayed much faster.

Add to Category from Data Pane. These options affect what is added to categories when documents and records are added from the Data pane.

- **In Categories and Concepts view, copy.** Adding a document or record from the Data pane in this view will copy over either Concepts only or both Concepts and Patterns.
- **In Text Link Analysis view, copy.** Adding a document or record from the Data pane in this view will copy over either Patterns only or both Concepts and Patterns.

Resource Editor delimiter. Select the character to be used as a delimiter when entering elements, such as concepts, synonyms, and optional elements, in the Resource Editor view.

Options: Display Tab

On this tab, you can edit options affecting the overall look and feel of the application and the colors used to distinguish elements.

Note: To switch the look and feel of the product to a classic look or one from a previous release, open the User Options dialog in the Tools menu in the main IBM® SPSS® Modeler window.

Custom Colors. Edit the colors for elements appearing onscreen. For each of the elements in the table, you can change the color. To specify a custom color, click the color area to the right of the element you want to change and choose a color from the drop-down color list.

- **Non-extracted text.** Text data that was not extracted yet visible in the Data pane.
- **Highlight background.** Text selection background color when selecting elements in the panes or text in the Data pane.
- **Extraction needed background.** Background color of the Extraction Results, Patterns, and Clusters panes indicating that changes have been made to the libraries and an extraction is needed.
- **Category feedback background.** Category background color that appears after an operation.
- **Default type.** Default color for types and concepts appearing in the Data pane and Extraction Results pane. This color will apply to any custom types that you create in the Resource Editor. You can override this default color for your custom type dictionaries by editing the properties for these type dictionaries in the Resource Editor. See the topic [Creating types](#) for more information.
- **Striped table 1.** First of the two colors used in an alternating manner in the table in the Edit Forced concepts dialog box in order to differentiate each set of lines.
- **Striped table 2.** Second of the two colors used in an alternating manner in the table in the Edit Forced concepts dialog box in order to differentiate each set of lines.

Note: If you click the Reset to Defaults button, all options in this dialog box are reset to the values they had when you first installed this product.

-

Options: Sounds Tab

On this tab, you can edit options affecting sounds. Under Sound Events, you can specify a sound to be used to notify you when an event occurs. A number of sounds are available. Use the ellipsis button (...) to browse for and select a sound. The .wav files used to create sounds for IBM® SPSS® Modeler Text Analytics are stored in the *media* subdirectory of the installation directory. If you do not want sounds to be played, select Mute All Sounds. Sounds are muted by default.

Note: If you click the Reset to Defaults button, all options in this dialog box are reset to the values they had when you first installed this product.

Microsoft Internet Explorer settings for Help

Microsoft Internet Explorer Settings

Most Help features in this application use technology based on Microsoft Internet Explorer. Some versions of Internet Explorer (including the version provided with Microsoft Windows XP, Service Pack 2) will by default block what it considers to be "active content" in Internet Explorer windows on your local computer. This default setting may result in some blocked content in Help features. To see all Help content, you can change the default behavior of Internet Explorer.

1. From the Internet Explorer menus choose:
Tools > Internet Options...
2. Click the Advanced tab.
3. Scroll down to the Security section.
4. Select Allow active content to run in files on My Computer.

Generating Model Nuggets and Modeling Nodes

When you are in an interactive session, you may want to use the work you have done to generate either:

- **A text mining modeling node.** A modeling node generated from an interactive workbench session is a Text Mining node whose settings and options reflect those stored in the open interactive session. This can be useful when you no longer have the original Text Mining node or when you want to make a new version. See the topic [Mining for Concepts and Categories](#) for more information.
- **A category model nugget.** A model nugget generated from an interactive workbench session is a category model nugget. You must have at least one category in the Categories and Concepts view in order to generate a category model nugget. See the topic [Text Mining Nugget: Category Model](#) for more information.

To Generate a Text Mining Modeling Node

1. From the menus, choose Generate > Generate Modeling Node. A Text Mining modeling node is added to the working canvas using all of the settings currently in the workbench session. The node is named after the text field.

To Generate a Category Model Nugget

1. From the menus, choose Generate > Generate Model. A model nugget is generated directly onto the Model palette with the default name.

- [Closing and Ending Sessions](#)
- [Keyboard Accessibility](#)
- [Microsoft Internet Explorer settings for Help](#)

Updating Modeling Nodes and Saving

While you are working in an interactive session, we recommend that you update the modeling node from time to time to save your changes. You should also update your modeling node whenever you are finished working in the interactive workbench session and want to save your work. When you update the modeling node, the workbench session content is saved back to the Text Mining node that originated the interactive workbench session. This does not close the output window.

Important! This update will not save your stream. To save your stream, do so in the main IBM® SPSS® Modeler window after updating the modeling node.

To Update a Modeling Node

1. From the menus, choose File > Update Modeling Node. The modeling node is updated with the build and extraction settings, along with any options and categories you have.

- [Closing and Ending Sessions](#)
- [Keyboard Accessibility](#)
- [Microsoft Internet Explorer settings for Help](#)

Closing and Ending Sessions

When you are finished working in your session, you can leave the session in three different ways:

- **Save.** This option allows you to first save your work back into the originating modeling node for future sessions, as well as to publish any libraries for reuse in other sessions. See the topic [Sharing Libraries](#) for more information. After you have saved, the session window is closed, and the session is deleted from the Output manager in the IBM® SPSS® Modeler window.
- **Exit.** This option will discard any unsaved work, close the session window, and delete the session from the Output manager in the IBM SPSS Modeler window. To free up memory, we recommend saving any important work and exiting the session.
- **Close.** This option will not save or discard any work. This option closes the session window but the session will continue to run. You can open the session window again by selecting this session in the Output manager in the IBM SPSS Modeler window.

To Close a Workbench Session

1. From the menus, choose File > Close.

Keyboard Accessibility

The interactive workbench interface offers keyboard shortcuts to make the product's functionality more accessible. At the most basic level, you can press the Alt key plus the appropriate key to activate window menus (for example, Alt+F to access the File menu) or press the Tab key to scroll through dialog box controls. This section will cover the keyboard shortcuts for alternative navigation. There are other keyboard shortcuts for the IBM® SPSS® Modeler interface.

Table 1. Generic keyboard shortcuts

Shortcut key	Function
Ctrl+1	Display the first tab in a pane with tabs.
Ctrl+2	Display the second tab in a pane with tabs.
Ctrl+A	Select all elements for the pane that has focus.
Ctrl+C	Copy selected text to the clipboard.
Ctrl+E	Launch extraction in Categories and Concepts and Text Link Analysis views.
Ctrl+F	Display the Find toolbar in the Resource Editor/Template Editor, if not already visible, and put focus there.
Ctrl+I	In the Categories and Concepts view, launch the Category Definitions dialog box for the selected category. In the Cluster view, launch the Cluster Definitions dialog box for the selected cluster.
Ctrl+R	Open the Add Terms dialog box in the Resource Editor/Template Editor.
Ctrl+T	Open the Type Properties dialog box to create a new type in the Resource Editor/Template Editor.
Ctrl+V	Paste clipboard contents.
Ctrl+X	Cut selected items from the Resource Editor/Template Editor.
Ctrl+Y	Redo the last action in the view.
Ctrl+Z	Undo the last action in the view.
F1	Display Help, or when in a dialog box, display context Help for an item.
F2	Toggle in and out of edit mode in table cells.
F6	Move the focus between the main panes in the active view.
F8	Move the focus to pane splitter bars for resizing.
F10	Expand the main File menu.
up arrow, down arrow	Resize the pane vertically when the splitter bar is selected.
left arrow, right arrow	Resize the pane horizontally when the splitter bar is selected.
Home, End	Resize panes to minimum or maximum size when the splitter bar is selected.
Tab	Move forward through items in the window, pane, or dialog box.
Shift+F10	Display the context menu for an item.

Shortcut key	Function
Shift+Tab	Move back through items in the window or dialog box.
Shift+arrow	Select characters in the edit field when in edit mode (F2).
Ctrl+Tab	Move the focus forward to the next main area in the window.
Shift+Ctrl+Tab	Move the focus backward to the previous main area in the window.

Shortcuts for Dialog Boxes

Several shortcut and screen reader keys are helpful when you are working with dialog boxes. Upon entering a dialog box, you may need to press the Tab key to put the focus on the first control and to initiate the screen reader. A complete list of special keyboard and screen reader shortcuts is provided in the following table.

Table 1. Dialog box shortcuts

Shortcut key	Function
Tab	Move forward through the items in the window or dialog box.
Ctrl+Tab	Move forward from a text box to the next item.
Shift+Tab	Move back through items in the window or dialog box.
Shift+Ctrl+Tab	Move back from a text box to the previous item.
space bar	Select the control or button that has focus.
Esc	Cancel changes and close the dialog box.
Enter	Validate changes and close the dialog box (equivalent to the OK button). If you are in a text box, you must first press Ctrl+Tab to exit the text box.

Extracting Concepts and Types

Whenever you run a stream that launches the interactive workbench, an extraction is automatically performed on the text data in the stream. The end result of this extraction is a set of concepts, types, and, in the case where TLA patterns exist in the linguistic resources, patterns. You can view and work with concepts and types in the Extraction Results pane. See [How extraction works](#) for more information.

If you want to fine-tune the extraction results, you can modify the linguistic resources and re-extract. See [Refining extraction results](#) for more information. The extraction process relies on the resources and any parameters in the Extract dialog box to dictate how to extract and organize the results. You can use the extraction results to define the better part, if not all, of your category definitions.

Note: Beginning with version 18.2, extracted concept results have been improved (they're now similar to extracted concept results in IBM® SPSS® Text Analytics for Surveys).

- [Extraction results: Concepts and types](#)
- [Extracting data](#)
- [Filtering Extraction Results](#)

- [Exploring concept maps](#)
 - [Refining extraction results](#)
-

Extraction results: Concepts and types

During the extraction process, all of the text data is scanned and the relevant concepts are identified, extracted, and assigned to types. When the extraction is complete, the results appear in the Extraction Results pane located in the lower left corner of the Categories and Concepts view. The first time you launch the session, the linguistic resource template you selected in the node is used to extract and organize these concepts and types.

Note: If there are more results that can fit in the visible pane, you can use the controls at the bottom of the pane to move forwards and backwards through the results, or enter a page number to go to.

The concepts, types, and TLA patterns that are extracted are collectively referred to as **extraction results**, and they serve as the descriptors, or building blocks, for your categories. You can also use concepts, types, and patterns in your category rules. Additionally, the automatic techniques use concepts and types to build the categories.

Text mining is an iterative process in which extraction results are reviewed according to the context of the text data, fine-tuned to produce new results, and then reevaluated. After extracting, you should review the results and make any changes that you find necessary by modifying the linguistic resources. You can fine-tune the resources, in part, directly from the Extraction Results pane, Data pane, Category Definitions dialog box, or Cluster Definitions dialog box. See the topic [Refining extraction results](#) for more information. You can also do so directly in the Resource Editor view. See the topic [The Resource Editor view](#) for more information.

After fine-tuning, you can then reextract to see the new results. By fine-tuning your extraction results from the start, you can be assured that each time you reextract, you will get identical results in your category definitions, perfectly adapted to the context of the data. In this way, documents/records will be assigned to your category definitions in a more accurate, repeatable manner.

Concepts

During the extraction process, the text data is scanned and analyzed in order to identify interesting or relevant single words (such as **election** or **peace**) and word phrases (such as **presidential**

election, election of the president, or peace treaties) in the text. These words and phrases are collectively referred to as **terms**. Using the linguistic resources, the relevant terms are extracted and then similar terms are grouped together under a lead term called a **concept**.

You can see the set of underlying terms for a concept by hovering your mouse over the concept name. Doing so will display a tooltip showing the concept name and up to several lines of terms that are grouped under that concept. These underlying terms include the synonyms defined in the linguistic resources (regardless of whether they were found in the text or not) as well as the any extracted plural/singular terms, permuted terms, terms from fuzzy grouping, and so on. You can copy these terms or see the full set of underlying terms by right-clicking the concept name and choosing the context menu option.

By default, the concepts are shown in lowercase and sorted in descending order according to the document count (Doc. column). When concepts are extracted, they are assigned a type to help group similar concepts. They are color coded according to this type. Colors are defined in the type properties within the Resource Editor. See the topic [Type dictionaries](#) for more information.

Whenever a concept, type, or pattern is being used in a category definition, an icon appears in the sortable In column.

Types

Types are semantic groupings of concepts. When concepts are extracted, they are assigned a type to help group similar concepts. Several built-in types are delivered with IBM® SPSS® Modeler Text Analytics , such as **<Location>**, **<Organization>**, **<Person>**, **<Positive>**, **<Negative>** and so on. For example, the **<Location>** type groups geographical keywords and places. This type would be assigned to concepts such as **chicago**, **paris**, and **tokyo**. For most languages, concepts that are not found in any type dictionary but are extracted from the text are automatically typed as **<Unknown>** See the topic [Built-in types](#) for more information.

When you select the Type view, the extracted types appear by default in descending order by global frequency. You can also see that types are color coded to help distinguish them. Colors are part of the type properties. See the topic [Creating types](#) for more information. You can also create your own types.

Patterns

Patterns can also be extracted from your text data. However, you must have a library that contains some Text Link Analysis (TLA) pattern rules in the Resource Editor. You also have to choose to extract these patterns in the IBM SPSS Modeler Text Analytics node setting or in the Extract dialog box using the option Enable Text Link Analysis pattern extraction. See the topic [Exploring Text Link Analysis](#) for more information.

Extracting data

Whenever an extraction is needed, the Extraction Results pane becomes yellow in color and the message Press Extract Button to Extract Concepts appears below the toolbar in this pane.

You may need to extract if you do not have any extraction results yet, have made changes to the linguistic resources and need to update the extraction results, or have reopened a session in which you did not save the extraction results (Tools > Options).

Note: If you change the source node for your stream after extraction results have been cached with the Use session work... option, you will need to run a new extraction once the interactive workbench session is launched if you want to get updated extraction results.

When you run an extraction, a progress indicator appears to provide feedback on the status of the extraction. During this time, the extraction engine reads through all of the text data and identifies the relevant terms and patterns and extracts them and assigns them to a type. Then, the engine attempts groups synonyms terms under one lead term, called a concept. When the process is complete, the resulting concepts, types, and patterns appear in the Extraction Results pane.

The extraction process results in a set of concepts and types, as well as Text Link Analysis (TLA) patterns, if enabled. You can view and work with these concepts and types in the Extraction Results pane in the Categories and Concepts view. If you extracted TLA patterns, you can see those in the Text Link Analysis view.

Note: There is a relationship between the size of your dataset and the time it takes to complete the extraction process. You can always consider inserting a Sample node upstream or optimizing your machine's configuration.

To extract data

1. From the menus, choose Tools > Extract. Alternatively, click the Extract toolbar button.
2. If you chose to always display the Extraction Settings dialog, it appears so that you can make any changes. See further in this topic for descriptors of each settings.
3. Click Extract to begin the extraction process. Once the extraction begins, the progress dialog box opens. After extraction, the results appear in the Extraction Results pane. By default, the concepts are shown in lowercase and sorted in descending order according to the document count (Doc. column).

You can review the results using the toolbar options to sort the results differently, to filter the results, or to switch to a different view (concepts or types). You can also refine your extraction results by working with the linguistic resources. See the topic [Refining extraction results](#) for more information.

Potential extraction issues

Multiple Interactive Workbench sessions can cause sluggish behavior. SPSS® Modeler Text Analytics and SPSS Modeler share a common Java run-time engine when an interactive workbench session is launched. Depending on the number of Interactive Workbench sessions you invoke during a SPSS Modeler session - even if opening and closing the same session - system memory may cause the application to become sluggish. This effect may be especially pronounced if you are working with large data or have a machine with less than the recommended RAM setting of 4GB. If you notice your machine is slow to respond, it is recommended that you save all your work, shut down SPSS Modeler, and re-launch the application. Running SPSS Modeler Text Analytics on a machine with less than the recommended memory, particularly when working with large data sets or for prolonged periods of time, may cause Java to run out of memory and shut down. It is strongly suggested you upgrade to the recommended memory setting or larger (or use SPSS Modeler Text Analytics Server) if you work with large data.

For Dutch, English, French, German, Italian, Portuguese, and Spanish Text

The Extraction Settings dialog box contains some basic extraction options.

Enable Text Link Analysis pattern extraction. Specifies that you want to extract TLA patterns from your text data. It also assumes you have TLA pattern rules in one of your libraries in the Resource Editor. This option may significantly lengthen the extraction time. See the topic [Exploring Text Link Analysis](#) for more information.

Accommodate punctuation errors. This option temporarily normalizes text containing punctuation errors (for example, improper usage) during extraction to improve the extractability of concepts. This option is extremely useful when text is short and of poor quality (as, for example, in open-ended survey responses, e-mail, and CRM data), or when the text contains many abbreviations.

Accommodate spelling for a minimum word character length of [n] This option applies a fuzzy grouping technique that helps group commonly misspelled words or closely spelled words under one concept. The fuzzy grouping algorithm temporarily strips all vowels (except the first one) and strips double/triple consonants from extracted words and then compares them to see if they are the same so that **modeling** and **modelling** would be grouped together. However, if each term is assigned to a different type, excluding the **<Unknown>** type, the fuzzy grouping technique will not be applied.

You can also define the minimum number of *root* characters required before fuzzy grouping is used. The number of root characters in a term is calculated by totaling all of the characters and subtracting any characters that form inflection suffixes and, in the case of compound-word terms, determiners and prepositions. For example, the term **exercises** would be counted as 8 root characters in the form "exercise," since the letter **s** at the end of the word is an inflection (plural form). Similarly, **apple sauce** counts as 10 root characters ("apple sauce") and **manufacturing of cars** counts as 16 root characters ("manufacturing car"). This method of counting is only used to check whether the fuzzy grouping should be applied but does not influence how the words are matched.

Note: If you find that certain words are later grouped incorrectly, you can exclude word pairs from this technique by explicitly declaring them in the Fuzzy Grouping: Exceptions section in the Advanced Resources tab. See the topic [Fuzzy Grouping](#) for more information.

Extract uniterms This option extracts single words (uniterms) as long as the word is not already part of a compound word and if it is either a noun or an unrecognized part of speech.

Extract nonlinguistic entities This option extracts nonlinguistic entities, such as phone numbers, social security numbers, times, dates, currencies, digits, percentages, e-mail addresses, and HTTP addresses. You can include or exclude certain types of nonlinguistic entities in the Nonlinguistic Entities: Configuration section of the Advanced Resources tab. By disabling any unnecessary entities, the extraction engine won't waste processing time. See the topic [Configuration](#) for more information.

Uppercase algorithm This option extracts simple and compound terms that are not in the built-in dictionaries as long as the first letter of the term is in uppercase. This option offers a good way to extract most proper nouns.

Group partial and full person names together when possible This option groups names that appear differently in the text together. This feature is helpful since names are often referred to in their full form at the beginning of the text and then only by a shorter version. This option attempts to match any uniterm with the <Unknown> type to the last word of any of the compound terms that is typed as <Person>. For example, if *doe* is found and initially typed as <Unknown>, the extraction engine checks to see if any compound terms in the <Person> type include *doe* as the last word, such as *john doe*. This option does not apply to first names since most are never extracted as uniterms.

Maximum nonfunction word permutation This option specifies the maximum number of nonfunction words that can be present when applying the permutation technique. This permutation technique groups similar phrases that differ from each other only by the nonfunction words (for example, *of* and *the*) contained, regardless of inflection. For example, let's say that you set this value to at most two words and both **company officials** and **officials of the company** were extracted. In this case, both extracted terms would be grouped together in the final concept list since both terms are deemed to be the same when *of the* is ignored.

Use derivation when grouping multiterms When processing Big Data, select this option to group multiterms by using derivation rules.

Index Option for Concept Map Specifies that you want to build the map index at extraction time so that concept maps can be drawn quickly later. To edit the index settings, click Settings. See the topic [Building Concept Map Indexes](#) for more information.

Always show this dialog before starting an extraction Specify whether you want to see the Extraction Settings dialog each time you extract, if you never want to see it unless you go to the Tools menu, or whether you want to be asked each time you extract if you want to edit any extraction settings.

Filtering Extraction Results

When you are working with very large datasets, the extraction process could produce millions of results. For many users, this amount can make it more difficult to review the results effectively. Therefore, in order to zoom in on those that are most interesting, you can filter these results through the Filter dialog available in the Extraction Results pane.

Keep in mind that all of the settings in this Filter dialog are used together to filter the extraction results that are available for categories.

Filter by Frequency You can filter to display only those results with a certain global or document frequency value.

- Global frequency is the total number of times a concept appears in the entire set of documents or records and is shown in the Global column.
- Document frequency is the total number of documents or records in which a concept appears and is shown in the Docs column.

For example, if the concept **nato** appeared 800 times in 500 records, we would say that this concept has a global frequency of 800 and a document frequency of 500.

And by Type You can filter to display only those results belonging to certain types. You can choose all types or only specific types.

And by Match Text You can also filter to display only those results that match the rule you define here. Enter the set of characters to be matched in the Match text field and then select the condition in which to apply the match.

Table 1. Match text conditions

Condition	Description
Contains	The text is matched if the string occurs anywhere. (Default choice)
Starts with	Text is matched only if the concept or type starts with the specified text.
Ends with	Text is matched only if the concept or type ends with the specified text.
Exact match	The entire string must match the concept or type name.

Results Displayed in Extraction Result Pane

Here are some examples of how the results might be displayed, in English, in the Extraction Results pane toolbar based on the filters.

Table 2. Examples of filter feedback

Filter feedback	Description
404 concepts	The toolbar shows the number of results. Since there was no text matching filter and the maximum was not met, no additional icons are shown.
358 concepts !	The toolbar shows results were limited to the maximum specified in the filter, which in this case was 300. If a purple icon is present, this means that the maximum number of concepts was met. Hover over the icon for more information.
4 concepts !	The toolbar shows results were limited using a match text filter. This is shown by the magnifying glass icon.

To Filter the Results

- From the menus, choose Tools > Filter. The Filter dialog box opens.
- Select and refine the filters you want to use.
- Click OK to apply the filters and see the new results in the Extraction Results pane.

Exploring concept maps

You can create a concept map to explore how concepts are interrelated. By selecting a single concept and clicking Map, a concept map window opens so that you can explore the set of concepts that are related to the selected concept. You can filter out which concepts are displayed by editing the settings such as which types to include, what kinds of relationship to look for and so on.

Important: Before a map can be created, an index must be generated. This may take several minutes. However, once you have generated the index, you do not have regenerate it again until you re-extract. If you want the index to be generated automatically each time you extract, select that option in the extraction settings. See the topic [Extracting data](#) for more information.

Figure 1. A concept map for the selected concept

To View a Concept Map

1. In the Extraction Results pane, select a single concept.
2. In the toolbar of this pane, click the Map button. If the map index was already generated the concept map opens in a separate dialog. If the map index was not generated or was out of date, the index must be rebuilt. This process may take several minutes.
3. Click around the map to explore. If you double-click a linked concept, the map will redraw itself and show you the linked concepts for the concept you just double-clicked.
4. The top toolbar offers some basic map tools such as moving back to a previous map, filtering links according to relationship strengths, and also opening the filter dialog to control the types of concepts that appear as well as the kinds of relationships to represent. A second toolbar line contains graph editing tools. See the topic [Using Graph Toolbars and Palettes](#) for more information.
5. If you are unsatisfied with the kinds of links being found, review the settings for this map show on the right side of the map.

Map Settings: Include Concepts from Selected Types

Only those concepts belonging to the selected types in the table are shown in the map. To hide concepts from a certain type, deselect that type in the table.

Map Settings: Relationships to Display

Show co-occurrence links If you want to show co-occurrence links, choose the mode. The mode affects how the link strength was calculated.

- *Discover (similarity metric)*. With this metric, the strength of the link is calculated using more complex calculation that takes into account how often two concepts appear apart as well as how often they appear together. A high strength value means that a pair of concepts tend to appear more frequently together than to appear apart. With the following formula, any floating point values are converted to integers.

Figure 2. Similarity coefficient formula

$$\text{similarity coefficient} = \frac{(C_{IJ})^2}{(C_I \times C_J)}$$

In this formula, C_I is the number of documents or records in which the concept I occurs.

C_J is the number of documents or records in which the concept J occurs.

C_{IJ} is the number of documents or records in which concept pair I and J co-occurs in the set of documents.

- *Organize (document metric)*. The strength of the links with this metric is determined by the raw count of co-occurrences. In general, the more frequent two concepts are, the more likely they are to occur together at times. A high strength value means that a pair of concepts appear together frequently.

Show other links (confidence metric). You can choose other links to display; these may be semantic, derivation (morphological), or inclusion (syntactical) and are related to how many steps removed a concept is from the concept to which it is linked. These can help you tune resources, particularly synonymy or to disambiguate. For short descriptions of each of these grouping techniques, see [Advanced linguistic settings](#)

Note: Keep in mind that if these were not selected when the index was built or if no relationships were found, then none will be displayed. See the topic [Building Concept Map Indexes](#) for more information.

Map Settings: Map Display Limits

Apply extraction results filter. If you do not want to use all of the concepts, you can use the filter in the extraction results pane to limit what is shown. Then select this option and IBM® SPSS® Modeler Text Analytics will look for related concepts using this filtered set. See the topic [Filtering Extraction Results](#) for more information.

Minimum strength. Set the minimum link strength here. Any related concepts with a relationship strength lower than this limit will be hidden from the map.

Maximum concepts on map. Specify the maximum number of relationships to show on the map.

- [Building Concept Map Indexes](#)

Building Concept Map Indexes

Before a map can be created, an index of concept relationships must be generated. Whenever you create a concept map, IBM® SPSS® Modeler Text Analytics refers to this index. You can choose which relationships to index by selecting the techniques in this dialog.

Grouping techniques. Choose one or more technique. For short descriptions of each of these techniques, see [About linguistic techniques](#) Not all techniques are available for all text languages.

Prevent pairing of specific concepts. Select this checkbox to stop the process from grouping or pairing two concepts together in the output. To create or manage concept pairs, click Manage Pairs. See the topic [Managing Link Exception Pairs](#) for more information.

Building the index may take several minutes. However, once you have generated the index, you do not have to regenerate it again until you re-extract or unless you want to change the settings to include more relationships. If you want to generate an index whenever you extract, you can select that option in the extraction settings. See the topic [Extracting data](#) for more information.

Refining extraction results

Extraction is an iterative process whereby you can extract, review the results, make changes to them, and then re-extract to update the results. Since accuracy and continuity are essential to successful text mining and categorization, fine-tuning your extraction results from the start ensures that each time you re-extract, you will get precisely the same results in your category definitions. In this way, records and documents will be assigned to your categories in a more accurate, repeatable manner.

The extraction results serve as the building blocks for categories. When you create categories using these extraction results, records and documents are automatically assigned to categories if they contain text that matches one or more category descriptors. Although you can begin categorizing before making any refinements to the linguistic resources, it is useful to review your extraction results at least once before beginning.

As you review your results, you may find elements that you want the extraction engine to handle differently. Consider the following examples:

- Unrecognized synonyms. Suppose you find several concepts you consider to be synonymous, such as **smart**, **intelligent**, **bright**, and **knowledgeable**, and they all appear as individual concepts in the extraction results. You could create a synonym definition in which **intelligent**, **bright**, and **knowledgeable** are all grouped under the target concept **smart**. Doing so would group all of these together with **smart**, and the global frequency count would be higher as well. See the topic [Adding synonyms](#) for more information.
- Mistyped concepts. Suppose that the concepts in your extraction results appear in one type and you would like them to be assigned to another. In another example, imagine that you find 15 vegetable concepts in your extraction results and you want them all to be added to a new type called **<Vegetable>**. For most languages, concepts that are not found in any type dictionary but are extracted from the text are automatically typed as **<Unknown>**. You can add concepts to types. See the topic [Adding concepts to types](#) for more information.
- Insignificant concepts. Suppose that you find a concept that was extracted and has a very high frequency count—that is, it is found in many records or documents. However, you consider this concept to be insignificant to your analysis. You can exclude it from extraction. See the topic [Excluding concepts from extraction](#) for more information.
- Incorrect matches. Suppose that in reviewing the records or documents that contain a certain concept, you discover that two words were incorrectly grouped together, such as **faculty** and **facility**. This match may be due to an internal algorithm, referred to as fuzzy grouping, that temporarily ignores double or triple consonants and vowels in order to group common misspellings. You can add these words to a list of word pairs that should not be grouped. See the topic [Fuzzy Grouping](#) for more information.
- Unextracted concepts. Suppose that you expect to find certain concepts extracted but notice that a few words or phrases were not extracted when you review the record or document text. Often these words are verbs or adjectives that you are not interested in. However, sometimes you do want to use a word or phrase that was not extracted as part of a category definition. To extract the concept, you can force a term into a type dictionary. See the topic [Forcing Words into Extraction](#) for more information.

Many of these changes can be performed directly from the Extraction Results pane, Data pane, Category Definitions dialog box, or Cluster Definitions dialog box by selecting one or more elements and right-clicking your mouse to access the context menus.

After making your changes, the pane background color changes to show that you need to re-extract to view your changes. See the topic [Extracting data](#) for more information. If you are working with larger data sets, it may be more efficient to re-extract after making several changes rather than after each change.

Note: You can view the entire set of editable linguistic resources used to produce the extraction results in the Resource Editor view (View > Resource Editor). These resources appear in the form of libraries and dictionaries in this view. You can customize the concepts and types directly within the libraries and dictionaries. See the topic [Working with Libraries](#) for more information.

- [Adding synonyms](#)
- [Adding concepts to types](#)
- [Excluding concepts from extraction](#)
- [Forcing Words into Extraction](#)

Adding synonyms

Synonyms associate two or more words that have the same meaning. Synonyms are often also used to group terms with their abbreviations or to group commonly misspelled words with the correct spelling. By using synonyms, the frequency for the target concept is greater, which makes it far easier to discover similar information that is presented in different ways in your text data.

The linguistic resource templates and libraries delivered with the product contain many predefined synonyms. However, if you discover unrecognized synonyms, you can define them so that they will be recognized the next time you extract.

The first step is to decide what the target, or lead, concept will be. The *target concept* is the word or phrase under which you want to group all synonym terms in the final results. During extraction, the synonyms are grouped under this target concept. The second step is to identify all of the synonyms for this concept. The target concept is substituted for all synonyms in the final extraction. A term must be extracted to be a synonym. However, the target concept does not need to be extracted for the substitution to occur. For example, if you want **intelligent** to be replaced by **smart**, then **intelligent** is the synonym and **smart** is the target concept.

If you create a new synonym definition, a new target concept is added to the dictionary. You must then add synonyms to that target concept. Whenever you create or edit synonyms, these changes are recorded in synonym dictionaries in the Resource Editor. If you want to view the entire contents of these synonym dictionaries or if you want to make a substantial number of changes, you may prefer to work directly in the Resource Editor. See the topic [Substitution/Synonym dictionaries](#) for more information.

Any new synonyms will automatically be stored in the first library listed in the library tree in the Resource Editor view—by default, this is the Local Library.

Note: If you look for a synonym definition and cannot find it through the context menus or directly in the Resource Editor, a match may have resulted from an internal fuzzy grouping technique. See the topic [Fuzzy Grouping](#) for more information.

To create a new synonym

1. In either the Extraction Results pane , Data pane, Category Definitions dialog box, or Cluster Definitions dialog box, select the concept(s) for which you want to create a new synonym.
2. From the menus, choose **Edit > Add to Synonym > New**. The Create Synonym dialog box opens.
3. Enter a target concept in the Target text box. This is the concept under which all of the synonyms will be grouped.
4. If you want to add more synonyms, enter them in the Synonyms list box. Use the global separator to separate each synonym term. See the topic [Options: Session Tab](#) for more information.
5. Click OK to apply your changes. The dialog box closes and the Extraction Results pane background color changes, indicating that you need to reextract to see your changes. If you have several changes, make them before you reextract.

To add a synonym

1. In either the Extraction Results pane , Data pane, Category Definitions dialog box, or Cluster Definitions dialog box, select the concept(s) that you want to add to an existing synonym definition.
2. From the menus, choose **Edit > Add to Synonym**. The menu displays a set of the synonyms with the most recently created at the top of the list. Select the name of the synonym to which you want to add the selected concept(s). If you see the synonym that you are looking for, select it, and the concept(s) selected are added to that synonym definition. If you do not see it, select **More** to display the All Synonyms dialog box.
3. In the All Synonyms dialog box, you can sort the list by natural sort order (order of creation) or in ascending or descending order. Select the name of the synonym to which you want to add the selected concept(s) and click OK. The dialog box closes, and the concepts are added to the synonym definition.

Adding concepts to types

Whenever an extraction is run, the extracted concepts are assigned to types in an effort to group terms that have something in common. IBM® SPSS® Modeler Text Analytics is delivered with many built-in types. See the topic [Built-in types](#) for more information. For most languages, concepts that are not found in any type dictionary but are extracted from the text are automatically typed as **<Unknown>**

When reviewing your results, you may find some concepts that appear in one type that you want assigned to another, or you may find that a group of words really belongs in a new type by itself. In these cases, you would want to reassign the concepts to another type or create a new type altogether.

For example, suppose that you are working with survey data relating to automobiles and you are interested in categorizing by focusing on different areas of the vehicles. You could create a type called **<Dashboard>** to group all of the concepts relating to gauges and knobs found on the dashboard of the vehicles. Then you could assign concepts such as **gas gauge**, **heater**, **radio**, and **odometer** to that new type.

In another example, suppose that you are working with survey data relating to universities and colleges and the extraction typed **Johns Hopkins** (the university) as a <Person> type rather than as an <Organization> type. In this case, you could add this concept to the <Organization> type.

Whenever you create a type or add concepts to a type's term list, these changes are recorded in type dictionaries within your linguistic resource libraries in the Resource Editor. If you want to view the contents of these libraries or make a substantial number of changes, you may prefer to work directly in the Resource Editor. See the topic [Adding terms](#) for more information.

To add a concept to a type

1. In either the Extraction Results pane , Data pane, Category Definitions dialog box, or Cluster Definitions dialog box, select the concept(s) that you want to add to an existing type.
2. Right-click to open the context menu.
3. From the menus, choose **Edit** > **Add to Type**. The menu displays a set of the types with the most recently created at the top of the list. Select the type name to which you want to add the selected concept(s). If you see the type name that you are looking for, select it, and the concept(s) selected are added to that type. If you do not see it, select **More** to display the All Types dialog box.
4. In the All Types dialog box, you can sort the list by natural sort (order of creation) or in ascending or descending order. Select the name of the type to which you want to add the selected concept(s) and click **OK**. The dialog box closes, and they are added as terms to the type.

To create a new type

1. In either the Extraction Results pane , Data pane, Category Definitions dialog box, or Cluster Definitions dialog box, select the concepts for which you want to create a new type.
2. From the menus, choose **Edit** > **Add to Type** > **New**. The Type Properties dialog box opens.
3. Enter a new name for this type in the Name text box and make any changes to the other fields. See the topic [Creating types](#) for more information.
4. Click **OK** to apply your changes. The dialog box closes and the Extraction Results pane background color changes, indicating that you need to re-extract to see your changes. If you have several changes, make them before you re-extract.

Excluding concepts from extraction

When reviewing your results, you may occasionally find concepts that you did not want extracted or used by any automated category building techniques. In some cases, these concepts have a very high frequency count and are completely insignificant to your analysis. In this case, you can mark a concept to be excluded from the final extraction. Typically, the concepts you add to this list are fill-in words or phrases used in the text for continuity but that do not add anything important and may clutter the extraction results. By adding concepts to the exclude dictionary, you can make sure that they are never extracted.

By excluding concepts, all variations of the excluded concept disappear from your extraction results the next time that you extract. If this concept already appears as a descriptor in a category, it will remain in the category with a zero count after re-extraction.

When you exclude, these changes are recorded in an exclude dictionary in the Resource Editor. If you want to view all of the exclude definitions and edit them directly, you may prefer to work directly in the Resource Editor. See the topic [Exclude dictionaries](#) for more information.

To exclude concepts

1. In either the Extraction Results pane , Data pane, Category Definitions dialog box, or Cluster Definitions dialog box, select the concept(s) that you want to exclude from the extraction.
2. Right-click to open the context menu.
3. Select **Exclude from Extraction**. The concept is added to the exclude dictionary in the Resource Editor and the Extraction Results pane background color changes, indicating that you need to re-extract to see your changes. If you have several changes, make them before you re-extract.

Note: Any words that you exclude will automatically be stored in the first library listed in the library tree in the Resource Editor—by default, this is the Local Library.

Forcing Words into Extraction

When reviewing the text data in the Data pane after extraction, you may discover that some words or phrases were not extracted. Often, these words are verbs or adjectives that you are not interested in. However, sometimes you do want to use a word or phrase that was not extracted as part of a category definition.

If you would like to have these words and phrases extracted, you can force a term into a type library. See the topic [Forcing terms](#) for more information.

Important! Marking a term in a dictionary as forced is not foolproof. By this, we mean that even though you have explicitly added a term to a dictionary, there are times when it may not be present in the Extraction Results pane after you have reextracted or it does appear but not exactly as you have declared it. Although this occurrence is rare, it can happen when a word or phrase was already extracted as part of a longer phrase. To prevent this, apply the Entire (no compounds) match option to this term in the type dictionary. See the topic [Adding terms](#) for more information.

Categorizing text data

In the Categories and Concepts view , you can create *categories* that represent, in essence, higher-level concepts, or topics, that will capture the key ideas, knowledge, and attitudes expressed in the text.

As of the release of IBM® SPSS® Modeler Text Analytics 14, categories can also have a hierarchical structure, meaning they can contain subcategories and those subcategories can also have subcategories of their own and so on. You can import predefined category structures, formerly called code frames, with hierarchical categories as well as build these hierarchical categories inside the product.

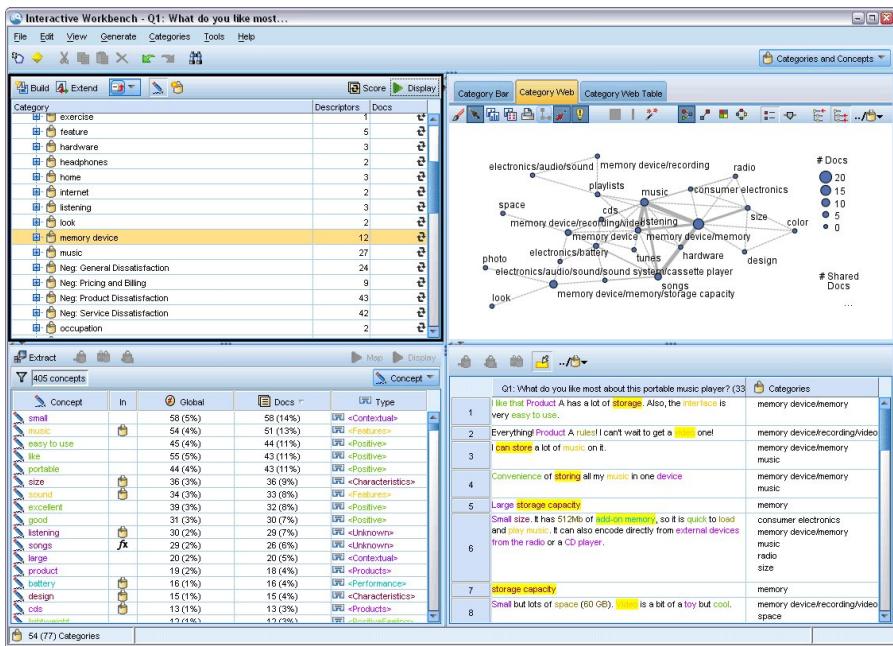

In effect, hierarchical categories enable you to build a tree structure with one or more subcategories to group items such as different concept or topic areas more accurately. A simple example can be related to leisure activities; answering a question such as *What activity would you like to do if you had more time?* you may have top categories such as *sports, art and craft, fishing*, and so on; down a level, below *sports*, you may have subcategories to see if this is *ball games, water-related*, and so on.

Categories are made up of a set of descriptors, such as *concepts, types, patterns* and *category rules*. Together, these descriptors are used to identify whether or not a document or record belongs to a given category. The text within a document or record can be scanned to see whether any text matches a descriptor. If a match is found, the document/record is assigned to that category. This process is called *categorization*.

You can work with, build, and visually explore your categories using the data presented in the four panes of the Categories and Concepts view, each of which can be hidden or shown by selecting its name from the View menu.

- Categories pane. Build and manage your categories in this pane. See the topic [The Categories Pane](#) for more information.
- Extraction Results pane. Explore and work with the extracted concepts and types in this pane. See the topic [Extraction results: Concepts and types](#) for more information.
- Visualization pane. Visually explore your categories and how they interact in this pane. See the topic [Category Graphs and Charts](#) for more information.
- Data pane. Explore and review the text contained within documents and records that correspond to selections in this pane. See the topic [The Data Pane](#) for more information.

Figure 1. Categories and Concepts view

While you might start with a set of categories from a text analysis package (TAP) or import from a predefined category file, you might also need to create your own. Categories can be created automatically using the product's robust set of automated techniques, which use extraction results (concepts, types, and patterns) to generate categories and their descriptors. Categories can also be created manually using additional insight you may have regarding the data. However, you can only create categories manually or fine-tune them through the interactive workbench. See the topic [Text Mining Node: Model Tab](#) for more information. You can create category definitions manually by dragging and dropping extraction results into the categories. You can enrich these categories or any empty category by adding category rules to a category, using your own predefined categories, or a combination.

Each of the techniques and methods is well suited for certain types of data and situations, but often it will be helpful to combine techniques in the same analysis to capture the full range of documents or records. And in the course of categorization, you may see other changes to make to the linguistic resources.

- [Editing and Refining Categories](#)

The Categories Pane

The Categories pane is the area in which you can build and manage your categories. This pane is located in the upper left corner of the Categories and Concepts view. After extracting the concepts and types from your text data, you can begin building categories automatically using techniques such as concept inclusion, co-occurrence, and so on or manually. See the topic [Building categories](#) for more information.

Each time a category is created or updated, the documents or records can be scored by clicking the Score button to see whether any text matches a descriptor in a given category. If a match is found, the document or record is assigned to that category. The end result is that most, if not all, of the documents or records are assigned to categories based on the descriptors in the categories.

Note: If there are more categories that can fit in the visible pane, you can use the controls at the bottom of the pane to move forwards and backwards through the categories, or enter a page number to go to.

Category Tree Table

The tree table in this pane presents the set of categories, subcategories, and descriptors. The tree also has several columns presenting information for each tree item. The following columns may be available for display:

- **Code** Lists the code value for each category. This column is hidden by default. You can display this column through the menus: View > Categories Pane.
- **Category**. Contains the category tree showing the name of the category and subcategories. Additionally if the descriptors toolbar icon is clicked, the set of descriptors will also be displayed.
- **Descriptors**. Provides the number of descriptors that make up its definition. This count does not include the number of descriptors in the subcategories. No count is given when a descriptor name is shown in the Categories column. You can display or hide the descriptors themselves in the tree through the menus: View > Categories Pane > All Descriptors.
- **Docs** After scoring, this column provides the number of documents or records that are categorized into a category and all of its subcategories. So if 5 records match your top category based on its descriptors, and 7 different records match a subcategory based on its descriptors, the total doc count for the top category is a sum of the two-- in this case it would be 12. However, if the same record matched the top category and its subcategory, then the count would be 11.

When no categories exist, the table still contains two rows. The top row, called All Documents, is the total number of documents or records. A second row, called Uncategorized, shows the number of documents/records that have yet to be categorized.

For each category in the pane, a small yellow bucket icon precedes the category name. If you double-click a category, or choose View > Category Definitions in the menus, the Category Definitions dialog box opens and presents all of the elements, called *descriptors*, that make up its definition, such as concepts, types, patterns, and category rules. See the topic [About Categories](#) for more information. By default, the category tree table does not show the descriptors in the categories. If you want to see the descriptors directly in the tree rather than in the Category Definitions dialog box, click the toggle button with the pencil icon in the toolbar. When this toggle button is selected, you can expand your tree to see the descriptors as well.

Scoring Categories

The Docs. column in the category tree table displays the number of documents or records that are categorized into that specific category. If the numbers are out of date or are not calculated, an icon appears in that column. You can click Score on the pane toolbar to recalculate the number of documents. Keep in mind that the scoring process can take some time when you are working with larger datasets.

Selecting Categories in the Tree

When making selections in the tree, you can only select sibling categories -- that is to say, if you select top level categories, you can not also select a subcategory. Or if you select 2 subcategories of a given category, you cannot simultaneously select a subcategory of another category. Selecting a discontiguous category will result in the loss of the previous selection.

Displaying in Data and Visualization Panes

When you select a row in the table, you can click the Display button to refresh the Visualization and Data panes with information corresponding to your selection. If a pane is not visible, clicking Display will cause the pane to appear.

Refining Your Categories

Categorization may not yield perfect results for your data on the first try, and there may well be categories that you want to delete or combine with other categories. You may also find, through a review of the extraction results, that there are some categories that were not created that you would find useful. If so, you can make manual changes to the results to fine-tune them for your particular context. See the topic [Editing and Refining Categories](#) for more information.

Methods and Strategies for Creating Categories

If you have not yet extracted or your extraction results are out of date, the use of one of the category building or extending techniques will prompt you for an extraction automatically. After you have applied a technique, the concepts and types that were grouped into a category are still available for category building with other techniques. This means that you may see a concept in multiple categories unless you choose not to reuse them.

In order to help you create the best categories, please review the following:

Methods for Creating Categories

Because every dataset is unique, the number of category creation methods and the order in which you apply them may change over time. Additionally, since your text mining goals may be different from one set of data to the next, you may need to experiment with the different methods to see which one produces the best results for the given text data. None of the automatic techniques will perfectly categorize your data; therefore we recommend finding and applying one or more automatic techniques that work well with your data.

Besides using text analysis packages (TAPs, *.tap) with prebuilt category sets, you can also categorize your responses using any combination of the following methods:

- **Automatic building techniques.** Several linguistic-based and frequency-based category options are available to automatically build categories for you. See the topic [Building categories](#) for more information.
- **Automatic extending techniques.** Several linguistic techniques are available to extend existing categories by adding and enhancing descriptors so that they capture more records. See the topic [Extending categories](#) for more information.
- **Manual techniques.** There are several manual methods, such as drag-and-drop. See the topic [Creating Categories Manually](#) for more information.

Strategies for Creating Categories

The following list of strategies is by no means exhaustive but it can provide you with some ideas on how to approach the building of your categories.

- When you define the Text Mining node, select a category set from a text analysis package (TAP) so that you begin your analysis with some prebuilt categories. These categories may sufficiently categorize your text right from the start. However, if you want to add more

categories, you can edit the Build Categories settings (Categories > Build Settings). Open the Advanced Settings: Linguistics dialog and choose the Category input option Unused extraction results and build the additional categories.

- When you define the node, select a category set from a TAPin the Categories and Concepts view in the Interactive Workbench. Next, drag and drop unused concepts or patterns into the categories as you deem appropriate. Then, extend the existing categories you've just edited (Categories > Extend Categories) to obtain more descriptors that are related to the existing category descriptors.
- Build categories automatically using the advanced linguistic settings (Categories > Build Categories). Then, refine the categories manually by deleting descriptors, deleting categories, or merging similar categories until you are satisfied with the resulting categories. Additionally, if you originally built categories **without** using the Generalize with wildcards where possible option, you can also try to simplify the categories automatically using the Extend Categories using the Generalize option.
- Import a predefined category file with very descriptive category names and/or annotations. Additionally, if you originally imported **without** choosing the option to import or generate descriptors from category names, you can later use the Extend Categories dialog and choose the Extend empty categories with descriptors generated from the category name. option. Then, extend those categories a second time but use the grouping techniques this time.
- Manually create a first set of categories by sorting concepts or concept patterns by frequency and then dragging and dropping the most interesting ones to the Categories pane. Once you have that initial set of categories, use the Extend feature (Categories > Extend Categories) to expand and refine all of the selected categories so they'll include other related descriptors and thereby match more records.

After applying these techniques, we recommend that you review the resulting categories and use manual techniques to make minor adjustments, remove any misclassifications, or add records or words that may have been missed. Additionally, since using different techniques may produce redundant categories, you could also merge or delete categories as needed. See the topic [Editing and Refining Categories](#) for more information.

Tips for Creating Categories

In order to help you create better categories, you can review some tips that can help you make decisions on your approach.

Tips on Category-to-Document Ratio

The categories into which the documents and records are assigned are not often mutually exclusive in qualitative text analysis for at least two reasons:

- First, a general rule of thumb says that the longer the text document or record, the more distinct the ideas and opinions expressed. Thus, the chances that a document or record can be assigned multiple categories is greatly increased.
- Second, often there are various ways to group and interpret text documents or records that are not logically separate. In the case of a survey with an open-ended question about the respondent's political beliefs, we could create categories, such as *Liberal* and *Conservative*, or *Republican* and *Democrat*, as well as more specific categories, such as *Socially Liberal*, *Fiscally Conservative*, and so forth. These categories do not have to be mutually exclusive and exhaustive.

Tips on Number of Categories to Create

Category creation should flow directly from the data—as you see something interesting with respect to your data, you can create a category to represent that information. In general, there is no recommended upper limit on the number of categories that you create. However, it is certainly possible to create too many categories to be manageable. Two principles apply:

- **Category frequency.** For a category to be useful, it has to contain a minimum number of documents or records. One or two documents may include something quite intriguing, but if they are one or two out of 1,000 documents , the information they contain may not be frequent enough in the population to be practically useful.
- **Complexity.** The more categories you create, the more information you have to review and summarize after completing the analysis. However, too many categories, while adding complexity, may not add useful detail.

Unfortunately, there are no rules for determining how many categories are too many or for determining the minimum number of records per category. You will have to make such determinations based on the demands of your particular situation.

We can, however, offer advice about where to start. Although the number of categories should not be excessive, in the early stages of the analysis it is better to have too many rather than too few categories. It is easier to group categories that are relatively similar than to split off cases into

new categories, so a strategy of working from more to fewer categories is usually the best practice. Given the iterative nature of text mining and the ease with which it can be accomplished with this software program, building more categories is acceptable at the start.

Choosing the Best Descriptors

The following information contains some guidelines for choosing or making the best descriptors (concepts, types, TLA patterns, and category rules) for your categories. Descriptors are the building blocks of categories. When some or all of the text in a document or record matches a descriptor, the document or record is matched to the category.

Unless a descriptor contains or corresponds to an extracted concept or pattern, it will not be matched to any documents or records. Therefore, use concepts, types, patterns, and category rules as described in the following paragraphs.

Since concepts represent not only themselves but also a set of underlying terms that can range from plural/singular forms, to synonyms, to spelling variations, only the concept itself should be used as a descriptor or as part of a descriptor. To learn more about the underlying terms for any given concept, click on the concept name in the Extraction Results pane of the Categories and Concepts view. When you hover over the concept name, a tooltip appears and displays any of the underlying terms found in your text during the last extraction. Not all concepts have underlying terms. For example, if **car** and **vehicle** were synonyms but **car** was extracted as the concept with **vehicle** as an underlying term, then you only want to use **car** in a descriptor since it will automatically match document or records with **vehicle**.

Concepts and Types as Descriptors

Use a concept as a descriptor when you want to find all documents or records containing that concept (or any of its underlying terms). In this case, the use of a more complex category rule is not needed since the exact concept name is sufficient. Keep in mind that when you use resources that extract opinions, sometimes concepts can change during TLA pattern extraction to capture the truer sense of the sentence (refer to the example in the next section on TLA).

For example, a survey response indicating each person's favorite fruits such as "*Apple and pineapple are the best*" could result in the extraction of **apple** and **pineapple**. By adding the concept **apple** as a descriptor to your category, all responses containing the concept **apple** (or any of its underlying terms) are matched to that category.

However, if you are interested in simply knowing which responses mention **apple** in any way, you can write a category rule such as * **apple** * and you will also capture responses that contain concepts such as **apple**, **apple sauce**, or **french apple tart**.

You can also capture all the documents or records that contain concepts that were typed the same way by using a type as a descriptor directly such as <Fruit>. Please note that you cannot use * with types.

See the topic [Extraction results: Concepts and types](#) for more information.

Text Link Analysis (TLA) Patterns as Descriptors

Use a TLA pattern result as a descriptor when you want to capture finer, nuanced ideas. When text is analyzed during TLA extraction, the text is processed one sentence, or clause, at a time rather than looking at the entire text (the document or record). By considering all of the parts of a single sentence together, TLA can identify opinions, relationships between two elements, or a negation, for example, and understand the truer sense. You can use concept patterns or type patterns as descriptors. See the topic [Type and Concept Patterns](#) for more information.

For example, if we had the text "*the room was not that clean*", the following concepts could be extracted: **room** and **clean**. However, if TLA extraction was enabled in the extraction setting, TLA could detect that **clean** was used in a negative way and actually corresponds to **not clean**, which is a synonym of the concept **dirty**. Here, you can see that using the concept **clean** as a descriptor on its own would match this text but could also capture other document or records mentioning cleanliness. Therefore, it might be better to use the TLA concept pattern with **dirty** as output concept since it would match this text and likely be a more appropriate descriptor.

Category Business Rules as Descriptors

Category rules are statements that automatically classify documents or records into a category based on a logical expression using extracted concepts, types, and patterns as well as Boolean operators. For example, you could write an expression that means *include all records that contain the extracted concept **embassy** but not **argentina** in this category*.

You can write and use category rules as descriptors in your categories to express several different ideas using &, |, and ! () Booleans. For detailed information on the syntax of these rules and how to write and edit them, see [Using Category Rules](#).

- Use a category rule with the & (AND) Boolean operator to help you find documents or records in which 2 or more concepts occur. The 2 or more concepts connected by & operators do not need to occur in the same sentence or phrase, but can occur anywhere in the same document or record to be considered a match to the category. For example, if you create the category rule `food & cheap` as a descriptor, it would match a record containing the text, "the food was pretty expensive, but the rooms were cheap" despite the fact that `food` was not the noun being called `cheap` since the text contained both `food` and `cheap`.
- Use a category rule with the ! () (NOT) Boolean operator as a descriptor to help you find documents or records in which some things occur but others do not. This can help avoid grouping information that may seem related based on words but not on context. For example, if you create the category rule `<Organization> & !(ibm)` as a descriptor, it would match the following text `SPSS Inc. was a company founded in 1967` and not match the following text `the software company was acquired by IBM..`
- Use a category rule with the | (OR) Boolean operator as a descriptor to help you find documents or records containing one of several concepts or types. For example, if you create the category rule `(personnel|staff|team|coworkers) & bad` as a descriptor, it would match any documents or records in which any of those nouns are found with the concept `bad`.
- Use types in category rules to make them more generic and possibly more deployable. For example, if you were working with hotel data, you might be very interested in learning what customers think about hotel personnel. Related terms might include words such as receptionist, waiter, waitress, reception desk, front desk and so on. You could, in this case, create a new type called `<HotelStaff>` and add all of the preceding terms to that type. While it is possible to create one category rule for every kind of staff such as `[* waitress * & nice], [* desk * & friendly], [* receptionist * & accommodating]`, you could create a single, more generic category rule using the `<HotelStaff>` type to capture all responses that have favorable opinions of the hotel staff in the form of `[<HotelStaff> & <Positive>]`.

Note: You can use both + and & in category rules when including TLA patterns in those rules. See the topic [Using TLA Patterns in Category Rules](#) for more information.

Example of how concepts, TLA, or category rules as descriptors match differently

The following example demonstrates how using a concept as a descriptor, category rule as a descriptor, or using a TLA pattern as a descriptor affects how documents or records are categorized. Let's say you had the following 5 records.

- A: "awesome restaurant staff, excellent food and rooms comfortable and clean."
- B: "restaurant personnel was awful, but rooms were clean."
- C: "Comfortable, clean rooms."
- D: "My room was not that clean."
- E: "Clean."

Since the records include the word `clean` and you want to capture this information, you could create one of the descriptors shown in the following table. Based on the essence you are trying to capture, you can see how using one kind of descriptor over another can produce different results.

Table 1. How Example Records Matched Descriptors

Descriptor	A	B	C	D	E	Explanation
<code>clean</code>	match	match	match	match	match	Descriptor is an extracted concept. Every record contained the concept <code>clean</code> , even record D since without TLA, it is not known automatically that "not <code>clean</code> " means <code>dirty</code> by the TLA rules.
<code>clean + .</code>	-	-	-	-	match	Descriptor is a TLA pattern that represents <code>clean</code> by itself. Matched only the record where <code>clean</code> was extracted with no associated concept during TLA extraction.
<code>[clean]</code>	match	match	match	-	match	Descriptor is a category rule that looks for a TLA rule that contains <code>clean</code> on its own or with something else. Matched all records where a TLA output containing <code>clean</code> was found regardless of whether <code>clean</code> was linked to another concept such as <code>room</code> and in any slot position.

About Categories

Categories refer to a group of closely related concepts, opinions, or attitudes. To be useful, a category should also be easily described by a short phrase or label that captures its essential meaning.

For example, if you are analyzing survey responses from consumers about a new laundry soap, you can create a category labeled *odor* that contains all of the responses describing the smell of the product. However, such a category would not differentiate between those who found the smell pleasant and those who found it offensive. Since IBM® SPSS® Modeler Text Analytics is capable of extracting opinions when using the appropriate resources, you could then create two other categories to identify respondents who *enjoyed the odor* and respondents who *disliked the odor*.

You can create and work with your categories in the Categories pane in the upper left pane of the Categories and Concepts view window. Each category is defined by one or more descriptors. **Descriptors** are concepts, types, and patterns, as well as category rules that have been used to define a category.

If you want to see the descriptors that make up a given category, you can click the pencil icon in the Categories pane toolbar and then expand the tree to see the descriptors. Alternatively, select the category and open the Category Definitions dialog box (View > Category Definitions).

When you build categories automatically using category building techniques such as concept inclusion, the techniques will use concepts and types as the descriptors to create your categories. If you extract TLA patterns, you can also add patterns or parts of those patterns as category descriptors. See the topic [Exploring Text Link Analysis](#) for more information. And if you build clusters, you can add the concepts in a cluster to new or existing categories. Lastly, you can manually create category rules to use as descriptors in your categories. See the topic [Using Category Rules](#) for more information.

-

Category Properties

In addition to descriptors, categories also have properties you can edit in order to rename categories, add a label, or add an annotation.

The following properties exist:

- **Name.** This name appears in the tree by default. When a category is created using an automated technique, it is given a name automatically.

- **Label.** Using labels is helpful in creating more meaningful category descriptions for use in other products or in other tables or graphs. If you choose the option to display the label, then the label is used in the interface to identify the category.
- **Code.** The code number corresponds to the code value for this category. .
- **Annotation.** You can add a short description for each category in this field. When a category is generated by the Build Categories dialog, a note is added to this annotation automatically. You can also add sample text to an annotation directly from the Data pane by selecting the text and choosing Categories > Add to Annotation from the menus.

The Data Pane

As you create categories, there may be times when you might want to review some of the text data you are working with. For example, if you create a category in which 640 documents are categorized, you might want to look at some or all of those documents to see what text was actually written. You can review records or documents in the Data pane, which is located in the lower right. If not visible by default, choose View > Panes > Data from the menus.

The Data pane presents one row per document or record corresponding to the selection in the Categories pane, Extraction Results pane, or the Category Definitions dialog box up to a certain display limit. By default, the number of documents or records shown in the Data pane is limited in order to allow you to see your data more quickly. However, you can adjust this in the Options dialog box. If you are dealing with very large datasets, the speed of display may be improved by turning off the option to show categories. See the topic [Options: Session Tab](#) for more information.

Note: If there are more records that can fit in the visible pane, you can use the controls at the bottom of the pane to move forwards and backwards through the records, or enter a page number to go to.

Displaying and refreshing the Data pane

The Data pane does not refresh its display automatically because with larger datasets automatic data refreshing could take some time to complete. Therefore, whenever you make a selection in another pane in this view or the Category Definitions dialog box, click Display to refresh the contents of the Data pane.

Text Documents or Records

If your text data is in the form of records and the text is relatively short in length, the text field in the Data pane displays the text data in its entirety. However, when working with records and larger datasets, the text field column shows a short piece of the text and opens a Text Preview pane to the right to display more or all of the text of the record you have selected in the table. If your text data is in the form of individual documents, the Data pane shows the document's filename. When you select a document, the Text Preview pane opens with the selected document's text.

Colors and Highlighting

Whenever you display the data, concepts and descriptors found in those documents or records are highlighted in color to help you easily identify them in the text. The color coding corresponds to the types to which the concepts belong. You can also hover your mouse over color-coded items to display the concept under which it was extracted and the type to which it was assigned. Any text that was not extracted appears in black. Typically, these unextracted words are often connectors (*and* or *with*), pronouns (*me* or *they*), and verbs (*is*, *have*, or *take*).

Data Pane Columns

While the text field column is always visible, you can also display other columns. To display other columns, choose View > Data Pane from the menus, and then select the column that you want to display in the Data pane. The following columns may be available for display:

- "Text field name" (#)/Documents. Adds a column for the text data from which concepts and type were extracted. If your data is in documents, the column is called Documents and only the document filename or full path is visible. To see the text for those documents you must look in the Text Preview pane. The number of rows in the Data pane is shown in parentheses after this column name. There may be times when not all documents or records are shown due to a limit in the Options dialog used to increase the speed of loading. If the maximum is reached, the number will be followed by - Max. See [Options: Session Tab](#) for more information.
- Categories. Lists each of the categories to which a record belongs. Whenever this column is shown, refreshing the Data pane may take a bit longer so as to show the most up-to-date information.

- Force In. Lists the categories into which you have forced a document. Documents can be forced into the category through the Edit > Force In menu selection. See [Forcing documents into categories](#) for more information.
 - Force Out. Lists the categories from which you have removed a document. Documents can be forced out of a category through the Edit > Force Out menu selection. For example, this might be used when a respondent's sarcasm causes a response to be miscategorized. See [Forcing documents into categories](#) for more information.
 - Category Counts. Lists the number of the categories to which a record belongs.
 - Relevance Ranks. Provides a rank for each record in a single category. This rank shows how well the record fits into the category compared to the other records in that category. Select a category in the Categories pane (upper left pane) to see the rank. See [Category Relevance](#) for more information.
 - Response Flags. Adds a column that shows any flags you may be using. Click inside this column to change the type of flag that you assign to documents. You might flag documents with a "complete" flag or an "important" flag, or remove flags. This is useful for reviewing the completeness of a category model. See [Flagging responses](#) for more information.
- [Category Relevance](#)
 - [Flagging responses](#)
-

Category Relevance

To help you build better categories, you can review the relevance of the documents or records in each category as well as the relevance of all categories to which a document or record belongs.

Relevance of a Category to a Record

Whenever a document or record appears in the Data pane, all categories to which it belongs are listed in the Categories column. When a document or record belongs to multiple categories, the categories in this column appear in order from the most to the least relevant match. The category listed first is thought to correspond best to this document or record. See the topic [The Data Pane](#) for more information.

Relevance of a Record to a Category

When you select a category, you can review the relevance of each of its records in the Relevance Rank column in the Data pane. This relevance rank indicates how well the document or record fits into the selected category compared to the other records in that category. To see the rank of the records for a single category, select this category in the Categories pane (upper left pane) and the rank for document or record appears in the column. This column is not visible by default but you can choose to display it. See the topic [The Data Pane](#) for more information.

The lower the number for the record's rank, the better the fit or the more relevant this record is to the selected category such that 1 is the best fit. If more than one record has the same relevance, each appears with the same rank followed by an equal sign (=) to denote they have equal relevance. For example, you might have the following ranks 1=, 1=, 3, 4, and so on, which means that there are two records that are equally considered as best matches for this category.

Tip: You could add the text of the most relevant record to the category annotation to help provide a better description of the category. Add the text directly from the Data pane by selecting the text and choosing Categories > Add to Annotation from the menus.

Flagging responses

To help you monitor your progress, you can mark documents using flags in the Data pane. This feature is only available if the source document contains a unique ID. If the source document doesn't contain a unique ID, you can add a Derive node between the source document and the Text Mining node.

There are many reasons why you might want to mark a document, including:

- To mark off documents that you have manually reviewed so that you know where to pick up later
- To mark off a document that you are unsure about how to handle

Once you mark a document with a flag, you can continue to work with the documents. They are purely for your own record-keeping. You can choose from the following flags:

Table 1. Flag descriptions

Flag	Description
	Complete flag to denote documents that you deem finished.
	Important flag to denote documents that you deem important.

To mark a document with a flag:

1. From within the Data pane, right-click the document that you want to mark.
2. From the context menu, choose View > Data Pane > Response Flags and then select the type of flag that you want to use (Important Flag or Complete Flag). The selected flag is assigned. If the Flag column in the Data pane is not visible, it appears.

To clear flags:

1. From within the Data pane, right-click the documents for which you want to remove a flag.
2. From the context menu, choose Mark Responses With > Clear Flags. The selected flags are removed.

Building categories

While you may have categories from a text analysis package, you can also build categories automatically using a number of linguistic and frequency techniques. Through the Build Categories Settings dialog box, you can apply the automated linguistic and frequency techniques to produce categories from either concepts or from concept patterns.

In general, categories can be made up of different kinds of descriptors (types, concepts, TLA patterns, category rules). When you build categories using the automated category building techniques, the resulting categories are named after a concept or concept pattern (depending on the input you select) and each contains a set of descriptors. These descriptors may be in the form of category rules or concepts and include all the related concepts discovered by the techniques.

After building categories, you can learn a lot about the categories by reviewing them in the Categories pane or exploring them through the graphs and charts. You can then use manual techniques to make minor adjustments, remove any misclassifications, or add records or words that may have been missed. After you have applied a technique, the concepts, types, and patterns that were grouped into a category are still available for other techniques. Also, since using different techniques may also produce redundant or inappropriate categories, you can also merge or delete categories. See the topic [Editing and Refining Categories](#) for more information.

Important! In earlier releases, co-occurrence and synonym rules were surrounded by square brackets. In this release, square brackets now indicate a text link analysis pattern result. Instead, co-occurrence and synonym rules will be encapsulated by parentheses such as **(speaker systems | speakers)**.

To build categories

1. From the menus, choose Categories > Build Categories. Unless you have chosen to never prompt, a message box is displayed.
2. Choose whether you want to build now or edit the settings first.
 - Click Build Now to begin building categories using the current settings. The settings selected by default are often sufficient to begin the categorization process. The category building process begins and a progress dialog appears.
 - Click Edit to review and modify the build settings.

Note: The maximum number of categories that can be displayed is 10,000. A warning is displayed if this number is reached or exceeded. If this happens you should change your Build or Extend Categories options to reduce the number of categories built.

Inputs

The categories are built from descriptors derived from either type patterns or types. In the table, you can select the individual types or patterns to include in the category building process.

Type patterns. If you select type patterns, categories are built from patterns rather than types and concepts on their own. In that way, any records or documents containing a concept pattern belonging to the selected type pattern are categorized. So, if you select the **<Budget>** and **<Positive>** type pattern in the table, categories such as **cost & <Positive>** or **rates & excellent** could be produced.

When using type patterns as input for automated category building, there are times when the techniques identify multiple ways to form the category structure. Technically, there is no single right way to produce the categories; however you might find one structure more suited to your analysis than another. To help customize the output in this case, you can designate a type as the preferred focus. All the top-level categories

produced will come from a concept of the type you select here (and no other type). Every subcategory will contain a text link pattern from this type. Choose this type in the Structure categories by pattern type: field and the table will be updated to show only the applicable patterns containing the selected type. More often than not, <Unknown> will be preselected for you. This results in all of the patterns containing the type <Unknown> being selected. The table displays the types in descending order starting with the one with the greatest number of records or documents (Doc. count).

Types. If you select types, the categories will be built from the concepts belonging to the selected types. So if you select the <Budget> type in the table, categories such as **cost** or **price** could be produced since **cost** and **price** are concepts assigned to the <Budget> type.

By default, only the types that capture the most records or documents are selected. This pre-selection allows you to quickly focus in on the most interesting types and avoid building uninteresting categories. The table displays the types in descending order starting with the one with the greatest number of records or documents (Doc. count). Types from the **Opinions** library are deselected by default in the types table.

The input you choose affects the categories you obtain. When you choose to use Types as input, you can see the clearly related concepts more easily. For example, if you build categories using Types as input, you could obtain a category **Fruit** with concepts such as **apple**, **pear**, **citrus fruits**, **orange** and so on. If you choose Type Patterns as input instead and select the pattern <Unknown> + <Positive>, for example, then you might get a category **fruit** + <Positive> with one or two kinds of fruit such as **fruit** + **tasty** and **apple** + **good**. This second result only shows 2 concept patterns because the other occurrences of fruit are not necessarily positively qualified. And while this might be good enough for your current text data, in longitudinal studies where you use different document sets, you may want to manually add in other descriptors such as **citrus fruit** + **positive** or use types. Using types alone as input will help you to find all possible fruit.

Techniques

Because every dataset is unique, the number of methods and the order in which you apply them may change over time. Since your text mining goals may be different from one set of data to the next, you may need to experiment with the different techniques to see which one produces the best results for the given text data.

You do not need to be an expert in these settings to use them. By default, the most common and average settings are already selected. Therefore, you can bypass the advanced setting dialogs and go straight to building your categories. Likewise, if you make changes here, you do not have to come back to the settings dialog each time since the latest settings are always retained.

Select either the linguistic or frequency techniques and click the Advanced Settings button to display the settings for the techniques selected. None of the automatic techniques will perfectly categorize your data; therefore we recommend finding and applying one or more automatic techniques that work well with your data. You cannot build using linguistic and frequency techniques simultaneously.

- Advanced linguistic techniques. See the topic [Advanced linguistic settings](#) for more information.
 - Advanced frequency techniques. See the topic [Advanced Frequency Settings](#) for more information.

Advanced linguistic settings

When you build categories, you can select from a number of advanced linguistic category building techniques such as *concept inclusion* and *semantic networks* (English text only). These techniques can be used individually or in combination with each other to create categories.

Keep in mind that because every dataset is unique, the number of methods and the order in which you apply them may change over time. Since your text mining goals may be different from one set of data to the next, you may need to experiment with the different techniques to see which one produces the best results for the given text data. None of the automatic techniques will perfectly categorize your data; therefore we recommend finding and applying one or more automatic techniques that work well with your data.

The following areas and fields are available within the Advanced Settings: Linguistics dialog box:

Input and Output

Category input Select from what the categories will be built:

- Unused extraction results. This option enables categories to be built from extraction results that are not used in any existing categories. This minimizes the tendency for records to match multiple categories and limits the number of categories produced.
- All extraction results. This option enables categories to be built using any of the extraction results. This is most useful when no or few categories already exist.

Category output Select the general structure for the categories that will be built:

- Hierarchical with subcategories. This option enables the creation of subcategories and sub-subcategories. You can set the depth of your categories by choosing the maximum number of levels (Maximum levels created field) that can be created. If you choose 3, categories

could contain subcategories and those subcategories could also have subcategories.

- Flat categories (single level only). This option enables only one level of categories to be built, meaning that no subcategories will be generated.

Grouping Techniques

Each of the techniques available is well suited to certain types of data and situations, but often it is helpful to combine techniques in the same analysis to capture the full range of documents or records. You may see a concept in multiple categories or find redundant categories.

Concept Inclusion. This technique builds categories by grouping multiterm concepts (compound words) based on whether they contain words that are subsets or supersets of a word in the other. For example, the concept **seat** would be grouped with **safety seat**, **seat belt**, and **seat belt buckle**. See the topic [Concept Inclusion](#) for more information.

Semantic Network. This technique begins by identifying the possible senses of each concept from its extensive index of word relationships and then creates categories by grouping related concepts. This technique is best when the concepts are known to the semantic network and are not too ambiguous. It is less helpful when text contains specialized terminology or jargon unknown to the network. In one example, the concept **granny smith apple** could be grouped with **gala apple** and **winesap apple** since they are siblings of the granny smith. In another example, the concept **animal** might be grouped with **cat** and **kangaroo** since they are hyponyms of **animal**. This technique is available for English text only in this release. See the topic [Semantic Networks](#) for more information.

Note: The Maximum search distance option is only available if you select Semantic Network.

Maximum search distance Select how far you want the techniques to search before producing categories. The lower the value, the fewer results you will get—however, these results will be less noisy and are more likely to be significantly linked or associated with each other. The higher the value, the more results you might get—however, these results may be less reliable or relevant. While this option is globally applied to all techniques, its effect is greatest on co-occurrences and semantic networks.

Prevent pairing of specific concepts. Select this checkbox to stop the process from grouping or pairing two concepts together in the output. To create or manage concept pairs, click [Manage Pairs...](#) See the topic [Managing Link Exception Pairs](#) for more information.

Generalize with wildcards where possible Select this option to allow the product to generate generic rules in categories using the asterisk wildcard. For example, instead of producing multiple descriptors such as **[apple tart + .]** and **[apple sauce + .]**, using wildcards might produce **[apple * + .]**. If you generalize with wildcards, you will often get exactly the same number of records or documents as you did before. However, this option has the advantage of reducing the number and simplifying category descriptors. Additionally, this option increases the ability to categorize more records or documents using these categories on new text data (for example, in longitudinal/wave studies).

Other Options for Building Categories

In addition to selecting the grouping techniques to apply, you can edit several other build options as follow:

Maximum number of top level categories created. Use this option to limit the number of categories that can be generated when you click the Build Categories button next. In some cases, you might get better results if you set this value high and then delete any of the uninteresting categories.

Minimum number of descriptors and/or subcategories per category. Use this option to define the minimum number of descriptors and subcategories a category must contain in order to be created. This option helps limit the creation of categories that do not capture a significant number of records or documents.

Allow descriptors to appear in more than one category When selected, this option allows descriptors to be used in more than one of the categories that will be built next. This option is generally selected since items commonly or "naturally" fall into two or more categories and allowing them to do so usually leads to higher quality categories. If you do not select this option, you reduce the overlap of records in multiple categories and depending on the type of data you have, this might be desirable. However, with most types of data, restricting descriptors to a single category usually results in a loss of quality or category coverage. For example, let's say you had the concept **car seat manufacturer**. With this option, this concept could appear in one category based on the text **car seat** and in another one based on **manufacturer**. But if this option is not selected, although you may still get both categories, the concept **car seat manufacturer** will only appear as a descriptor in the category it best matches based on several factors including the number of records in which **car seat** and **manufacturer** each occur.

Resolve duplicate category names by Select how to handle any new categories or subcategories whose names would be the same as existing categories. You can either merge the new ones (and their descriptors) with the existing categories with the same name. Alternatively, you can choose to skip the creation of any categories if a duplicate name is found in the existing categories.

- [Managing Link Exception Pairs](#)
-

Managing Link Exception Pairs

During category building, clustering, and concept mapping, the internal algorithms group words by known associations. To prevent two concepts from being paired, or linked together, you can turn on this feature in Build Categories Advanced Settings dialog, Build Clusters dialog, and Concept Map Index Settings dialog and click the Manage Pairs button.

In the resulting Manage Link Exceptions dialog, you can add, edit, or delete concept pairs. Enter one pair per line. Entering pairs here will prevent the pairing from occurring when building or extending categories, clustering, and concept mapping. Enter words exactly as you want them, for example the accented version of word is not equal to the unaccented version of the word.

For example, if you wanted to make sure that **hot dog** and **dog** are not grouped, you could add the pair as a separate line in the table.

About linguistic techniques

When you build or extend your categories, you can select from a number of advanced linguistic category building techniques including *concept inclusion* and *semantic networks* (English only). These techniques can be used individually or in combination with each other to create categories.

You do not need to be an expert in these settings to use them. By default, the most common and average settings are already selected. If you want, you can bypass this advanced setting dialog and go straight to building or extending your categories. Likewise, if you make changes here, you do not have to come back to the settings dialog each time since it will remember what you last used.

However, keep in mind that because every dataset is unique, the number of methods and the order in which you apply them may change over time. Since your text mining goals may be different from one set of data to the next, you may need to experiment with the different techniques to see which one produces the best results for the given text data. None of the automatic techniques will perfectly categorize your data; therefore we recommend finding and applying one or more automatic techniques that work well with your data.

The main automated linguistic techniques for category building are:

- Concept inclusion. This technique creates categories by taking a concept and finding other concepts that include it. See the topic [Concept Inclusion](#) for more information.
 - Semantic network. This technique begins by identifying the possible senses of each concept from its extensive index of word relationships and then creates categories by grouping related concepts. See the topic [Semantic Networks](#) for more information. This option is only available for English text.
 - [Concept root derivation](#)
 - [Concept Inclusion](#)
 - [Semantic Networks](#)
 - [Co-occurrence Rules](#)
-

Concept root derivation

The concept root derivation technique creates categories by taking a concept and finding other concepts that are related to it through analyzing whether any of the concept components are morphologically related. A component is a word. The technique attempts to group concepts by looking at the endings (suffixes) of each component in a concept and finding other concepts that could be derived from them. The idea is that when words are derived from each other, they are likely to share or be close in meaning. In order to identify the endings, internal language-specific rules are used. For example, the concept **opportunities to advance** would be grouped with the concepts **opportunity for advancement** and **advancement opportunity**.

You can use concept root derivation on any sort of text. By itself, it produces fairly few categories, and each category tends to contain few concepts. The concepts in each category are either synonyms or situationally related. You may find it helpful to use this algorithm even if you are building categories manually; the synonyms it finds may be synonyms of those concepts you are particularly interested in.

Note: You can prevent concepts from being grouped together by specifying them explicitly. See the topic [Managing Link Exception Pairs](#) for more information.

Term componentization and de-inflecting

When the concept root derivation or the concept inclusion techniques are applied, the terms are first broken down into components (words) and then the components are de-inflected. When a technique is applied, the concepts and their associated terms are loaded and split into

components based on separators, such as spaces, hyphens, and apostrophes. For example, the term **system administrator** is split into components such as **{administrator, system}**.

However, some parts of the original term may not be used and are referred to as stop words. In English, some of these ignorable components might include **a, and, as, by, for, from, in, of, on, or, the, to, and with**.

For example, the term **examination of the data** has the component set **{data, examination}**, and both **of** and **the** are considered ignorable. Additionally, component order is not in a component set. In this way, the following three terms could be equivalent: **cough relief for**

child, child relief from a cough, and relief of child

cough since they all have the same component set **{child, cough, relief}**. Each time a pair of terms are identified as being equivalent, the corresponding concepts are merged to form a new concept that references all of the terms.

Additionally, since the components of a term may be inflected, language-specific rules are applied internally to identify equivalent terms regardless of inflectional variation, such as plural forms. In this way, the terms **level of support** and **support levels** can be identified as equivalent since the de-inflected singular form would be **level**.

How concept root derivation works

After terms have been componentized and de-inflected (see previous section), the concept root derivation algorithm analyzes the component endings, or suffixes, to find the component root and then groups the concepts with other concepts that have the same or similar roots. The endings are identified using a set of linguistic derivation rules specific to the text language. For example, there is a derivation rule for English language text that states that a concept component ending with the suffix **ical** might be derived from a concept having the same root stem and ending with the suffix **ic**. Using this rule (and the de-inflection), the algorithm would be able to group the concepts **epidemiologic study** and **epidemiological studies**.

Since terms are already componentized and the ignorable components (for example, **in** and **of**) have been identified, the concept root derivation algorithm would also be able to group the concept **studies in epidemiology** with **epidemiological studies**.

The set of component derivation rules has been chosen so that most of the concepts grouped by this algorithm are synonyms: the concepts **epidemiologic studies, epidemiological studies, studies in epidemiology** are all equivalent terms. To increase completeness, there are some derivation rules that allow the algorithm to group concepts that are situationally related. For example, the algorithm can group concepts such as **empire builder** and **empire building**.

Concept Inclusion

The concept inclusion technique builds categories by taking a concept and, using lexical series algorithms, identifies concepts included in other concepts. The idea is that when words in a concept are a subset of another concept, it reflects an underlying semantic relationship. Inclusion is a powerful technique that can be used with any type of text.

This technique works well in combination with semantic networks but can be used separately. Concept inclusion may also give better results when the documents or records contain lots of domain-specific terminology or jargon. This is especially true if you have tuned the dictionaries beforehand so that the special terms are extracted and grouped appropriately (with synonyms).

How Concept Inclusion Works

Before the concept inclusion algorithm is applied, the terms are componentized and de-inflected. See the topic [Concept root derivation](#) for more information. Next, the concept inclusion algorithm analyzes the component sets. For each component set, the algorithm looks for another component set that is a subset of the first component set.

For example, if you have the concept **continental breakfast**, which has the component set **{breakfast, continental}**, and you have the concept **breakfast**, which has the component set **{breakfast}**, the algorithm would conclude that **continental breakfast** is a kind of **breakfast** and group these together.

In a larger example, if you have the concept **seat** in the Extraction Results pane and you apply this algorithm, then concepts such as **safety seat, leather seat, seat belt, seat belt buckle, infant seat carrier, and car seat laws** would also be grouped in that category.

Since terms are already componentized and the ignorable components (for example, **in** and **of**) have been identified, the concept inclusion algorithm would recognize that the concept **advanced spanish course** includes the concept **course in spanish**.

Note: You can prevent concepts from being grouped together by specifying them explicitly. See the topic [Managing Link Exception Pairs](#) for more information.

Semantic Networks

In this release, the semantic networks technique is only available for English language text.

This technique builds categories using a built-in network of word relationships. For this reason, this technique can produce very good results when the terms are concrete and are not too ambiguous. However, you should not expect the technique to find many links between highly technical/specialized concepts. When dealing with such concepts, you may find the concept inclusion and concept root derivation techniques to be more useful.

How Semantic Network Works

The idea behind the semantic network technique is to leverage known word relationships to create categories of synonyms or hyponyms. A **hyponym** is when one concept is a sort of second concept such that there is a hierarchical relationship, also known as an ISA relationship. For example, if **animal** is a concept, then **cat** and **kangaroo** are hyponyms of **animal** since they are sorts of animals.

In addition to synonym and hyponym relationships, the semantic network technique also examines part and whole links between any concepts from the <Location> type. For example, the technique will group the concepts **normandy**, **provence**, and **france** into one category because Normandy and Provence are parts of France.

Semantic networks begin by identifying the possible senses of each concept in the semantic network. When concepts are identified as synonyms or hyponyms, they are grouped into a single category. For example, the technique would create a single category containing these three concepts: **eating apple**, **dessert apple**, and **granny smith** since the semantic network contains the information that: 1) **dessert apple** is a synonym of an **eating apple**, and 2) **granny smith** is a sort of **eating apple** (meaning it is a hyponym of **eating apple**).

Taken individually, many concepts, especially uniterms, are ambiguous. For example, the concept **buffet** can denote a sort of meal or a piece of furniture. If the set of concepts includes **meal**, **furniture** and **buffet**, then the algorithm is forced to choose between grouping **buffet** with **meal** or with **furniture**. Be aware that in some cases the choices made by the algorithm may not be appropriate in the context of a particular set of records or documents.

The semantic network technique can outperform concept inclusion with certain types of data. While both the semantic network and concept inclusion recognize that **apple pie** is a sort of **pie**, only the semantic network recognizes that **tart** is also a sort of **pie**.

Semantic networks will work in conjunction with the other techniques. For example, suppose that you have selected both the semantic network and inclusion techniques and that the semantic network has grouped the concept **teacher** with the concept **tutor** (because a tutor is a kind of teacher). The inclusion algorithm can group the concept **graduate tutor** with **tutor** and, as a result, the two algorithms collaborate to produce an output category containing all three concepts: **tutor**, **graduate tutor**, and **teacher**.

Options for Semantic Network

There are a number of additional settings that might be of interest with this technique.

- Change the Maximum search distance. Select how far you want the techniques to search before producing categories. The lower the value, the fewer results produced—however, these results will be less noisy and are more likely to be significantly linked or associated with each other. The higher the value, the more results you will get—however, these results may be less reliable or relevant.

For example, depending on the distance, the algorithm searches from **Danish pastry** up to **coffee roll** (its parent), then **bun** (grand parent) and on upwards to **bread**.

By reducing the search distance, this technique produces smaller categories that might be easier to work with if you feel that the categories being produced are too large or group too many things together.

Important! Additionally, we recommend that you do not apply the option Accommodate spelling errors for a minimum root character limit of (defined on the Expert tab of the node or in the Extract dialog box) for fuzzy grouping when using this technique since some false groupings can have a largely negative impact on the results.

 - [Concept root derivation](#)
 - [Concept Inclusion](#)
 - [Co-occurrence Rules](#)
 - [Microsoft Internet Explorer settings for Help](#)
-

Co-occurrence Rules

Co-occurrence rules enable you to discover and group concepts that are strongly related within the set of documents or records. The idea is that when concepts are often found together in documents and records, that co-occurrence reflects an underlying relationship that is probably of value in your category definitions. This technique creates co-occurrence rules that can be used to create a new category, extend a category, or as input to another category technique. Two concepts strongly co-occur if they frequently appear together in a set of records and rarely separately in any of the other records. This technique can produce good results with larger datasets with at least several hundred documents or records.

For example, if many records contain the words **price** and **availability**, these concepts could be grouped into a co-occurrence rule, (**price & available**). In another example, if the concepts **peanut butter**, **jelly**, **sandwich** appear more often together than apart, they would be grouped into a concept co-occurrence rule (**peanut butter & jelly & sandwich**).

Important! In earlier releases, co-occurrence and synonym rules were surrounded by square brackets. In this release, square brackets now indicate a text link analysis pattern result. Instead, co-occurrence and synonym rules will be encapsulated by parentheses such as (**speaker systems | speakers**).

How Co-occurrence Rules Works

This technique scans the documents or records looking for two or more concepts that tend to appear together. Two or more concepts strongly co-occur if they frequently appear together in a set of documents or records and if they seldom appear separately in any of the other documents or records.

When co-occurring concepts are found, a category rule is formed. These rules consist of two or more concepts connected using the & Boolean operator. These rules are logical statements that will automatically classify a document or record into a category if the set of concepts in the rule all co-occur in that document or record.

Options for Co-occurrence Rules

If you are using the co-occurrence rule technique, you can fine-tune several settings that influence the resulting rules:

- Change the Maximum search distance. Select how far you want the technique to search for co-occurrences. As you increase the search distance, the minimum similarity value required for each co-occurrence is lowered; as a result, many co-occurrence rules may be produced, but those which have a low similarity value will often be of little significance. As you reduce the search distance, the minimum required similarity value increases; as a result, fewer co-occurrence rules are produced, but they will tend to be more significant (stronger).
- Minimum number of documents. The minimum number of records or documents that must contain a given pair of concepts for it to be considered as a co-occurrence; the lower you set this option, the easier it is to find co-occurrences. Increasing the value results in fewer, but more significant, co-occurrences. As an example, suppose that the concepts "apple" and "pear" are found together in 2 records (and that neither of the two concepts occurs in any other records). With Minimum number of documents set to 2 (the default), the co-occurrence technique will create a category rule (apple and pear). If the value is raised to 3, the rule will no longer be created.

Note: With small datasets (< 1000 responses) you may not find any co-occurrences with the default settings. If so, try increasing the search distance value.

Note: You can prevent concepts from being grouped together by specifying them explicitly. See the topic [Managing Link Exception Pairs](#) for more information.

Advanced Frequency Settings

You can build categories based on a straightforward and mechanical frequency technique. With this technique, you can build one category for each item (type, concept, or pattern) that was found above a given record or document count. Additionally, you can build a single category for all of the less frequently occurring items. By count, we refer to the number of records or documents containing the extracted concept (and any of its synonyms), type, or pattern in question as opposed to the total number of occurrences in the entire text.

Grouping frequently occurring items can yield interesting results, since it may indicate a common or significant response. The technique is very useful on the unused extraction results after other techniques have been applied. Another application is to run this technique immediately after extraction when no other categories exist, edit the results to delete uninteresting categories, and then extend those categories so that they match even more records or documents. See the topic [Extending categories](#) for more information.

Instead of using this technique, you could sort the concepts or concept patterns by descending number of records or documents in the Extraction Results pane and then drag and drop the top ones into the Categories pane to create the corresponding categories.

The following fields are available within the Advanced Settings: Frequencies dialog box:

Generate category descriptors at. Select the kind of input for descriptors. See the topic [Building categories](#) for more information.

- Concepts level. Selecting this option means that concepts or concept patterns frequencies will be used. Concepts will be used if types were selected as input for category building and concept patterns are used, if type patterns were selected. In general, applying this technique to the concept level will produce more specific results, since concepts and concept patterns represent a lower level of measurement.
- Types level. Selecting this option means that type or type patterns frequencies will be used. Types will be used if types were selected as input for category building and type patterns are used, if type patterns were selected. Applying this technique to the type level allows you to obtain a quick view regarding the kind of information present given.

Minimum doc. count for items to have their own category. This option allows you to build categories from frequently occurring items. This option restricts the output to only those categories containing a descriptor that occurred in at least X number of records or documents, where X is the value to enter for this option.

Group all remaining items into a category called. This option allows you to group all concepts or types occurring infrequently into a single 'catch-all' category with the name of your choice. By default, this category is named *Other*.

Category input. Select the group to which to apply the techniques:

- Unused extraction results. This option enables categories to be built from extraction results that are not used in any existing categories. This minimizes the tendency for records to match multiple categories and limits the number of categories produced.
- All extraction results. This option enables categories to be built using any of the extraction results. This is most useful when no or few categories already exist.

Resolve duplicate category names by. Select how to handle any new categories or subcategories whose names would be the same as existing categories. You can either merge the new ones (and their descriptors) with the existing categories with the same name. Alternatively, you can choose to skip the creation of any categories if a duplicate name is found in the existing categories.

-

Extending categories

Extending is a process through which descriptors are added or enhanced automatically to 'grow' existing categories. The objective is to produce a better category that captures related records or documents that were not originally assigned to that category.

The automatic grouping techniques you select will attempt to identify concepts, TLA patterns, and category rules related to existing category descriptors. These new concepts, patterns, and category rules are then added as new descriptors or added to existing descriptors. The grouping techniques for extending include *concept root derivation*, *concept inclusion*, *semantic networks* (English only), and *co-occurrence rules*. The Extend empty categories with descriptors generated from the category name method generates descriptors using the words in the category names, therefore, the more descriptive the category names, the better the results.

Note: The frequency techniques are not available when extending categories.

Extending is a great way to interactively improve your categories. Here are some examples of when you might extend a category:

- After dragging/dropping concept patterns to create categories in the Categories pane
- After creating categories by hand and adding simple category rules and descriptors
- After importing a predefined category file in which the categories had very descriptive names
- After refining the categories that came from the TAP you chose

You can extend a category multiple times. For example, if you imported a predefined category file with very descriptive names, you could extend using the Extend empty categories with descriptors generated from the category name option to obtain a first set of descriptors, and then extend those categories again. However, in other cases, extending multiple times may result in too generic a category if the descriptors are extended wider and wider. Since the build and extend grouping techniques use similar underlying algorithms, extending directly after building categories is unlikely to produce more interesting results.

Tip:

- If you attempt to extend and do not want to use the results, you can always undo the operation (Edit > Undo) immediately after having extended.
- Extending can produce two or more category rules in a category that match exactly the same set of documents since rules are built independently during the process. If desired, you can review the categories and remove redundancies by manually editing the category description. See the topic [Editing Category Descriptors](#) for more information.

To extend categories

1. In the Categories pane, select the categories you want to extend.
 2. From the menus, choose Categories > Extend Categories. Unless you have chosen the option to never prompt, a message box appears.
 3. Choose whether you want to build now or edit the settings first.
- Click Extend Now to begin extending categories using the current settings. The process begins and a progress dialog appears.
 - Click Edit to review and modify the settings.

After attempting to extend, any categories for which new descriptors were found are flagged by the word Extended in the Categories pane so that you can quickly identify them. The Extended text remains until you either extend again, edit the category in another way, or clear these through the context menu.

Note: The maximum number of categories that can be displayed is 10,000. A warning is displayed if this number is reached or exceeded. If this happens you should change your Build or Extend Categories options to reduce the number of categories built.

Each of the techniques available when building or extending categories is well suited to certain types of data and situations, but often it is helpful to combine techniques in the same analysis to capture the full range of documents or records. In the interactive workbench, the concepts and types that were grouped into a category are still available the next time you build categories. This means that you may see a concept in multiple categories or find redundant categories.

The following areas and fields are available within the Extend Categories: Settings dialog box:

Extend with. Select what input will be used to extend the categories:

- Unused extraction results. This option enables categories to be built from extraction results that are not used in any existing categories. This minimizes the tendency for records to match multiple categories and limits the number of categories produced.
- All extraction results. This option enables categories to be built using any of the extraction results. This is most useful when no or few categories already exist.

Grouping techniques

For short descriptions of each of these techniques, see [Advanced linguistic settings](#). These techniques include:

- Concept root derivation
- Semantic network (English text only, and not used if the Generalize only option is selected.)
- Concept inclusion
- Co-occurrence and Minimum number of docs suboption.

A number of types are permanently excluded from the semantic networks technique since those types will not produce relevant results. They include <Positive>, <Negative>, <IP>, other non linguistic types, etc.

Maximum search distance Select how far you want the techniques to search before producing categories. The lower the value, the fewer results you will get—however, these results will be less noisy and are more likely to be significantly linked or associated with each other. The higher the value, the more results you might get—however, these results may be less reliable or relevant. While this option is globally applied to all techniques, its effect is greatest on co-occurrences and semantic networks.

Prevent pairing of specific concepts. Select this checkbox to stop the process from grouping or pairing two concepts together in the output. To create or manage concept pairs, click Manage Pairs... See the topic [Managing Link Exception Pairs](#) for more information.

Where possible: Choose whether to simply extend, generalize the descriptors using wildcards, or both.

- Extend and generalize. This option will extend the selected categories and then generalize the descriptors. When you choose to generalize, the product will create generic category rules in categories using the asterisk wildcard. For example, instead of producing multiple descriptors such as [apple tart + .] and [apple sauce + .], using wildcards might produce [apple * + .]. If you generalize with wildcards, you will often get exactly the same number of records or documents as you did before. However, this option has the advantage of reducing the number and simplifying category

descriptors. Additionally, this option increases the ability to categorize more records or documents using these categories on new text data (for example, in longitudinal/wave studies).

- Extend only. This option will extend your categories without generalizing. It can be helpful to first choose the Extend only option for manually-created categories and then extend the same categories again using the Extend and generalize option.
- Generalize only. This option will generalize the descriptors without extending your categories in any other way.

Note: Selecting this option disables the Semantic network option; this is because the Semantic network option is only available when a description is to be extended.

Other options for extending categories

In addition to selecting the techniques to apply, you can edit any of the following options:

Maximum number of items to extend a descriptor by. When extending a descriptor with items (concepts, types, and other expressions), define the maximum number of items that can be added to a single descriptor. If you set this limit to 10, then no more than 10 additional items can be added to an existing descriptor. If there are more than 10 items to be added, the techniques stop adding new items after the tenth is added.

Doing so can make a descriptor list shorter but doesn't guarantee that the most interesting items were used first. You may prefer to cut down the size of the extension without penalizing quality by using the Generalize with wildcards where possible option. This option only applies to descriptors that contain the Booleans & (AND) or ! (NOT).

Also extend subcategories. This option will also extend any subcategories below the selected categories.

Extend empty categories with descriptors generated from the category name. This method applies only to empty categories, which have 0 descriptors. If a category already contains descriptors, it will not be extended in this way. This option attempts to automatically create descriptors for each category based on the words that make up the name of the category. The category name is scanned to see if words in the name match any extracted concepts. If a concept is recognized, it is used to find matching concept patterns and these both are used to form descriptors for the category. This option produces the best results when the category names are both long and descriptive. This is a quick method for generating category descriptors, which in turn enable the category to capture records that contain those descriptors. This option is most useful when you import categories from somewhere else or when you create categories manually with long descriptive names.

Generate descriptors as. This option only applies if the preceding option is selected.

- Concepts. Choose this option to produce the resulting descriptors in the form of concepts, regardless of whether they have been extracted from the source text.
- Patterns. Choose this option to produce the resulting descriptors in the form of patterns, regardless of whether the resulting patterns or any patterns have been extracted.

Creating Categories Manually

In addition to creating categories using the automated category building techniques and the rule editor, you can also create categories manually. The following manual methods exist:

- Creating an empty category into which you will add elements one by one. See the topic [Creating New or Renaming Categories](#) for more information.
- Dragging terms, types, and patterns into the categories pane. See the topic [Creating Categories by Drag-and-Drop](#) for more information.
- [Creating New or Renaming Categories](#)
- [Creating Categories by Drag-and-Drop](#)

Creating New or Renaming Categories

You can create empty categories in order to add concepts and types into them. You can also rename your categories.

To Create a New Empty Category

1. Go to the Categories pane.
2. From the menus, choose Categories > Create Empty Category. The Category Properties dialog box opens.
3. Enter a name for this category in the Name field.
4. Click OK to accept the name and close the dialog box. The dialog box closes and a new category name appears in the pane.

You can now begin adding to this category. See the topic [Adding Descriptors to Categories](#) for more information.

To Rename a Category

1. Select a category and choose Categories > Rename Category. The Category Properties dialog box opens.
2. Enter a new name for this category in the Name field.
3. Click OK to accept the name and close the dialog box. The dialog box closes and a new category name appears in the pane.

- [Microsoft Internet Explorer settings for Help](#)

Creating Categories by Drag-and-Drop

The drag-and-drop technique is manual and is not based on algorithms. You can create categories in the Categories pane by dragging:

- Extracted concepts, types, or patterns from the Extraction Results pane into the Categories pane.
- Extracted concepts from the Data pane into the Categories pane.
- Entire rows from the Data pane into the Categories pane. This will create a category made up of all of the extracted concepts and patterns contained in that row.

Note: The Extraction Results pane supports multiple selection to facilitate the dragging and dropping of multiple elements.

Important! You cannot drag and drop concepts from the Data pane that were not extracted from the text. If you want to force the extraction of a concept that you found in your data, you must add this concept to a type. Then run the extraction again. The new extraction results will contain the concept that you just added. You can then use it in your category. See the topic [Adding concepts to types](#) for more information.

To create categories using drag-and-drop:

1. From the Extraction Results pane or the Data pane, select one or more concepts, patterns, types, records, or partial records.
2. While holding the mouse button down, drag the element to an existing category or to the pane area to create a new category.
3. When you have reached the area where you would like to drop the element, release the mouse button. The element is added to the Categories pane. The categories that were modified appear with a special background color. This color is called the category feedback background. See the topic [Setting Options](#) for more information.

Note: The resulting category was automatically named. If you want to change a name, you can rename it. See the topic [Creating New or Renaming Categories](#) for more information.

If you want to see which records are assigned to a category, select that category in the Categories pane. The data pane is automatically refreshed and displays all of the records for that category.

Using Category Rules

You can create categories in many ways. One of these ways is to define category rules to express ideas. Category rules are statements that automatically classify documents or records into a category based on a logical expression using extracted concepts, types, and patterns as well as Boolean operators. For example, you could write an expression that means *include all records that contain the extracted concept embassy but not argentina in this category*.

While some category rules are produced automatically when building categories using grouping techniques such as *co-occurrence* and *concept root derivation* (Categories > Build Settings > Advanced Settings: Linguistics), you can also create category rules manually in the rule editor using your category understanding of the data and context. Each rule is attached to a single category so that each document or record matching the rule is then scored into that category.

Category rules help enhance the quality and productivity of your text mining results and further quantitative analysis by allowing you to categorize responses with greater specificity. Your experience and business knowledge might provide you with a specific understanding of your data and context. You can leverage this understanding to translate that knowledge into category rules to categorize your documents or records even more efficiently and accurately by combining extracted elements with Boolean logic.

The ability to create these rules enhances coding precision, efficiency, and productivity by allowing you to layer your business knowledge onto the product's extraction technology.

You can perform the following with rules:

- Create and test a rule. See the topic [Creating Category Rules](#) for more information.
- Edit or delete a rule. See the topic [Editing and Deleting Rules](#) for more information.

Note: For examples of how rules match text, see [Category Rule Examples](#)

Category Rule Syntax

While some category rules are produced automatically when building categories using grouping techniques such as *co-occurrence* and *concept root derivation* (Categories > Build Settings > Advanced Settings: Linguistics), you can also create category rules manually in the rule editor. Each rule is a descriptor of a single category; therefore, each document or record matching the rule is automatically scored into that category.

Note: For examples of how rules match text, see [Category Rule Examples](#)

When you are creating or editing a rule, you must have it open in the rule editor. You can add concepts, types, or patterns as well as use wildcards to extend the matches. When you use extracted concepts, types and patterns, you can benefit from finding all related concepts.

Important! To avoid common errors, we recommend dragging and dropping concepts directly from the Extraction Results pane, Text Link Analysis panes, or the Data pane into the rule editor or adding them via the context menus whenever possible.

When concepts, types, and patterns are recognized, an icon appears next to the text.

Table 1. Extraction icons

Icon	Description
	Extracted concept
	Extracted type
	Extracted pattern

Rule Syntax and Operators

The following table contains the characters with which you'll define your rule syntax. Use these characters along with the concepts, types, and patterns to create your rule.

Table 2. Supported syntax

Character	Description
&	The "and" boolean. For example, <code>a & b</code> contains both <code>a</code> and <code>b</code> such as: - <code>invasion & united states - 2016 & olympics - good & apple</code>
	The "or" boolean is inclusive, which means that if any or all of the elements are found, a match is made. For example, <code>a b</code> contains either <code>a</code> or <code>b</code> such as: - <code>attack france - condominium apartment</code>
! ()	The "not" boolean. For example, <code>!(a)</code> does not contain <code>a</code> . such as, <code>!(good & hotel)</code> , <code>assassination & !(austria)</code> , or <code>!(gold) & !(copper)</code>
*	A wildcard representing anything from a single character to a whole word depending how it is used. See the topic Using Wildcards in Category Rules for more information.
()	An expression delimiter. Any expression within the parenthesis is evaluated first.
+	The pattern connector used to form an order-specific pattern. When present, the square brackets must be used. See the topic Using TLA Patterns in Category Rules for more information.
[]	The pattern delimiter is required if you are looking to match based on an extracted TLA pattern inside of a category rule. The content within the brackets refers to TLA patterns and will never match concepts or types based on simple co-occurrence. If you did not extract this TLA pattern, then no match will be possible. See the topic Using TLA Patterns in Category Rules for more information. Do not use square brackets if you are looking to match concepts and types instead of patterns. Note: In older versions, co-occurrence and synonym rules generated by the category building techniques used to be surrounded by square brackets. In all new versions, square brackets now indicate the presence of a TLA pattern. Instead, rules produced by the co-occurrence technique and synonyms will be encapsulated in parentheses, such as <code>(speaker systems speakers)</code> .

The `&` and `|` operators are commutative such that `a & b = b & a` and `a | b = b | a`.

Escaping Characters with Backslash

If you have a concept that contains any character that is also a syntax character you must place a backslash in front of that character so that the rule is properly interpreted. The backslash (\) character is used to escape characters that otherwise have a special meaning. When you drag and drop into the editor, backslashing is done for you automatically.

The following rule syntax characters must be preceded by a backslash if you want it treated as it is rather than as rule syntax:

`\& \! \+ \< \> \(\) \[\] *`

For example, since the concept `r&d` contains the "and" operator (`&`), the backslash is required when it is typed into the rule editor, such as: `r\&d`.

Using TLA Patterns in Category Rules

Text link analysis patterns can be explicitly defined in category rules to allow you to obtain even more specific and contextual results. When you define a pattern in a category rule, you are bypassing the more simple concept extraction results and only matching documents and records based on extracted text link analysis pattern results.

Important! In order to match documents using TLA patterns in your category rules, you must have run an extraction with text link analysis enabled. The category rule will look for the matches found during that process. If you did not choose to explore TLA results in the Model tab of

your Text Mining node, you can choose to enable TLA extraction in the extraction settings within the interactive session and then re-extract. See the topic [Extracting data](#) for more information.

Delimiting with square brackets. A TLA pattern must be surrounded by square brackets [] if you are using it inside of a category rule. The pattern delimiter is required if you are looking to match based on an extracted TLA pattern. Since category rules can contain, types, concepts, or patterns, the brackets clarify to the rule that the contents within the brackets refers to extracted TLA pattern. If you did not extract this TLA pattern, then no match will be possible. If you see a pattern without brackets such as `apple + good` in the Categories pane, this likely means that the pattern was added directly to the category outside of the category rule editor. For example, if you add a concept pattern directly to category from the text link analysis view, it will not appear with square brackets. However, when using a pattern within a category rule, you must encapsulate the pattern within the square brackets inside the category rule such as `[banana + ! (good)]`.

Using the + sign in patterns. In IBM® SPSS® Modeler Text Analytics, you can have up to a 6-part, or -slot, pattern. To indicate that the order is important, use the + sign to connect each element, such as `[company1 + acquired + company2]`. Here the order is important since it would change the meaning of which company was acquiring. Order is not determined by the sentence structure but rather by how the TLA pattern output is structured. For example, if you have the text "I love Paris" and you want to extract this idea, the TLA pattern is likely to be `[paris + like]` or `[<Location> + <Positive>]` rather than `[<Positive> + <Location>]` since the default opinion resources generally place opinions in the second position in 2 part patterns. So it can be helpful to use the pattern directly as a descriptor in your category to avoid issues. However, if you need to use a pattern as part of a more complex statement, pay particular attention to order of the elements within the patterns presented in the Text Link Analysis view since order plays a big role in whether a match can be found.

For example, let's say you had the two following sample texts the expression: "I like pineapple" and "I hate pineapple. However, I like strawberries". The expression `like & pineapple` would match both texts as it is a concept expression and not a text link rule (not enclosed in brackets). The expression `pineapple + like` matches only "I like pineapple" since in the second text, the word `like` is associated to `strawberries` instead.

Grouping with patterns. You can simplify your rules with your own patterns. Let's say you want to capture the following three expressions, `cayenne peppers + like`, `chili peppers + like`, and `peppers + like`. You can group them into a single category rule such as `[* peppers & like]`. If you had another expression `hot peppers + good`, you can group those four with a rule such as `[* peppers + <Positive>]`.

Order in patterns. In order to better organize output, the text link analysis rules supplied in the templates you installed with your product attempt to output basic patterns in the same order regardless of word order in the sentence. For example, if you had a record containing the text, "Good presentations." and another record containing "the presentations were good", both text are matched by the same rule and output in the same order as `presentation + good` in the concept pattern results rather than `presentation + good` and also `good + presentation`. And in two-slot pattern such as those in the example, the concepts assigned to types in the Opinions library will be presented last in the output by default such as `apple + bad`.

Table 1. Pattern syntax and boolean usage

Expression	Matches a document or record that
<code>[]</code>	Contains any TLA pattern. The pattern delimiter is required <i>in category rules</i> if you are looking to match based on an extracted TLA pattern. The content within the brackets refers to TLA patterns not simple concepts and types. If you did not extract this TLA pattern, then no match will be possible. If you wanted to create a rule that did not include any patterns, you could use <code>! ([])</code> .
<code>[a]</code>	Contains a pattern of which at least one element is <code>a</code> regardless of its position in the pattern. For example, <code>[deal]</code> can match <code>[deal + good]</code> or just <code>[deal + .]</code>
<code>[a + b]</code>	Contains a concept pattern. For example, <code>[deal + good]</code> . Note: If you only want to capture this pattern without adding any other elements, we recommend adding the pattern directly to your category rather than making a rule with it.
<code>[a + b + c]</code>	Contains a concept pattern. The + sign denotes that the order of the matching elements is important. For example, <code>[company1 + acquired + company2]</code> .
<code>[<A> +]</code>	Contains any pattern with type <code><A></code> in the first slot and type <code></code> in the second slot, and there are exactly two slots. The + sign denotes that the order of the matching elements is important. For example, <code>[<Budget> + <Negative>]</code> . Note: If you only want to capture this pattern without adding any other elements, we recommend adding the pattern directly to your category rather than making a rule with it.
<code>[<A> &]</code>	Contains any type pattern with type <code><A></code> and type <code></code> . For example, <code>[<Budget> & <Negative>]</code> . This TLA pattern will never be extracted; however, when written as such it is really equal to <code>[<Budget> + <Negative>] [<Negative> + <Budget>]</code> . The order of the matching elements is unimportant. Additionally, other elements might be in the pattern but it must have at least <code><Budget></code> and <code><Negative></code> .

Expression	Matches a document or record that
[a + .]	Contains a pattern where a is the only concept and there is nothing in any other slots for that pattern. For example, [deal + .] matches the concept pattern where the only output is the concept deal . If you added the concept deal as a category descriptor, you would get all records with deal as a concept including positive statements about a deal. However, using [deal + .] will match only those records pattern results representing deal and no other relationships or opinions and would not match deal + fantastic . Note: If you only want to capture this pattern without adding any other elements, we recommend adding the pattern directly to your category rather than making a rule with it.
[< A > + <>]	Contains a pattern where < A > is the only type. For example, [< Budget > + <>] matches the pattern where the only output is a concept of the type < Budget >. Note: You can use the <> to denote an empty type only when putting it after the pattern + symbol in type pattern such as [< Budget > + <>] but not [price + <>]. Note: If you only want to capture this pattern without adding any other elements, we recommend adding the pattern directly to your category rather than making a rule with it.
[a + !(b)]	Contains at least one pattern that includes the concept a but does not include the concept b . Must include at least one pattern. For example, [price + !(high)] or for types, [!(< Fruit > < Vegetable >) + < Positive >]
!([< A > & < B >])	Does not contain a specific pattern. For example, !([< Budget > & < Negative >]).

Note: For examples of how rules match text, see [Category Rule Examples](#)

Related information

- [Category Rule Syntax](#)
- [Using Wildcards in Category Rules](#)
- [Category Rule Examples](#)
- [Creating Category Rules](#)
- [Editing and Deleting Rules](#)
- [Microsoft Internet Explorer settings for Help](#)

Using Wildcards in Category Rules

Wildcards can be added to concepts in rules in order to extend the matching capabilities. The asterisk * wildcard can be placed before and/or after a word to indicate how concepts can be matched. There are two types of wildcard uses:

- **Affix wildcards.** These wildcards immediately prefix or suffix without any space separating the string and the asterisk. For example, **operat*** could match *operat*, *operate*, *operates*, *operations*, *operational*, and so on.
- **Word wildcards.** These wildcards prefix or suffix a concept with a space between the concept and the asterisk. For example, * **operation** could match *operation*, *surgical operation*, *post operation*, and so on. Additionally, a word wildcard can be used along side an affix wildcard such as, * **operat*** *, which could match *operation*, *surgical operation*, *telephone operator*, *operatic aria*, and so on. As you can see in this last example, we recommend that wildcards be used with care so as not to cast the net too widely and capture unwanted matches.

Exceptions!

- A wildcard can never stand on its own. For example, (**apple** | *) would not be accepted.
- A wildcard can never be used to match type names. <**Negative***> will not match any type names at all.
- You cannot filter out certain types from being matched to concepts found through wildcards. The type to which the concept is assigned is used automatically.
- A wildcard can never be in the middle of a word sequence, whether it is end or beginning of a word (open* account) or a standalone component (open * account). You cannot use wildcards in type names either. For example, **word*** **word**, such as **apple*** **recipe**, will not match *applesauce recipe*, *apple pie*, *apple* and so on. In another example, **word *** **word**, such as **apple *** **toast**, will not match *apple cinnamon toast* or anything else at all since the asterisk appears between two other words. However, **apple *** would match *apple cinnamon toast*, *apple*, *apple pie* and so on.

Table 1. Wildcard usage

Expression	Matches a document or record that
* apple	Contains a concept that ends with letter written but may have any number of letters as a prefix. For example: * apple ends with the letters <i>apple</i> but can take a prefix such as: - apple - pineapple - crabapple

Expression	Matches a document or record that
apple*	Contains a concept that starts with letters written but may have any number of letters as a suffix. For example: apple* starts with the letters apple but can take a suffix or no suffix such as: - apple - applesauce - applejack For example, apple* & !(pear* quince) , which contains a concept that starts with the letters apple but not a concept starting with the letters pear or the concept quince , would NOT match: apple & quince but could match: - applesauce - apple & orange
product	Contains a concept that contains the letters written product , but may have any number of letters as either a prefix or suffix or both. For example: *product* could match: - product - byproduct - unproductive
* loan	Contains a concept that contains the word loan but may be a compound with another word placed before it. For example, * loan could match: - loan - car loan - home equity loan For example, [* delivery + <Negative>] contains a concept that ends in the word delivery in the first position and contains a type <Negative> in the second position could match the following concept patterns: - package delivery + slow overnight delivery + late
event *	Contains a concept that contains the word event but may be a compound followed by another word. For example, event * could match: - event - event location - event planning committee
* apple *	Contains a concept that might start with any word followed by the word apple possibly followed by another word. * means 0 or n, so it also matches apple . For example, * apple * could match: - gala applesauce - granny smith apple crumble - famous apple pie - apple For example, [* reservation * * + <Positive>], which contains a concept with the word reservation (regardless of where it is in the concept) in the first position and contains a type <Positive> in the second position could match the concept patterns: - reservation system + good - online reservation + good

Note: For examples of how rules match text, see [Category Rule Examples](#)

Category Rule Examples

To help demonstrate how rules are matched to records differently based on the syntax used to express them, consider the following example.

Example Records

Imagine you had two records:

- **Record A:** “when I checked my wallet, I saw I was missing 5 dollars.”
- **Record B:** “\$5 was found at the picnic area, but the blanket was missing.”

The following two tables show what might be extracted for concepts and types as well as concept patterns and type patterns.

Concepts and Types Extracted From Example

Table 1. Example Extracted Concepts and Types

Extracted Concept	Concepts Typed As
wallet	<Unknown>
missing	<Negative>
USD5	<Currency>
blanket	<Unknown>
picnic area	<Unknown>

TLA Patterns Extracted From Example

Table 2. Example Extracted TLA Pattern Output

Extracted Concept Patterns	Extracted Type Patterns	From Record
picnic area + .	<Unknown> + <>	Record B
wallet + .	<Unknown> + <>	Record A
blanket + missing	<Unknown> + <Negative>	Record B
USD5 + .	<Currency> + <>	Record B
USD5 + missing	<Currency> + <Negative>	Record A

How Possible Category Rules Match

The following table contains some syntax that could be entered in the category rule editor. Not all rules here work and not all match the same records. See how the different syntax affects the records matched.

Table 3. Sample Rules

Rule Syntax	Result
<code>USD5 & missing</code>	Matches both records A and B since they both contain the extracted concept <code>missing</code> and the extracted concept <code>USD5</code> . This is equivalent to: <code>(USD5 & missing)</code>
<code>missing & USD5</code>	Matches both records A and B since they both contain the extracted concept <code>missing</code> and the extracted concept <code>USD5</code> . This is equivalent to: <code>(missing & USD5)</code>
<code>missing & <Currency></code>	Matches both records A and B since they both contain the extracted concept <code>missing</code> and a concept matching the type <code><Currency></code> . This is equivalent to: <code>(missing & <Currency>)</code>
<code><Currency> & missing</code>	Matches both records A and B since they both contain the extracted concept <code>missing</code> and a concept matching the type <code><Currency></code> . This is equivalent to: <code>(<Currency> & missing)</code>
<code>[USD5 + missing]</code>	Matches A but not B since record B did not produce any TLA pattern output containing <code>USD5 + missing</code> (see previous table). This is equivalent to the TLA pattern output: <code>USD5 + missing</code>
<code>[missing + USD5]</code>	Matches neither record A nor B since no extracted TLA pattern (see previous table) match the order expressed here with <code>missing</code> in the first position. This is equivalent to the TLA pattern output: <code>USD5 + missing</code>
<code>[missing & USD5]</code>	Matches A but not B since no such TLA pattern was extracted from record B. Using the character <code>&</code> indicates that order is unimportant when matching; therefore, this rule looks for a pattern match to either <code>[missing + USD5]</code> or <code>[USD5 + missing]</code> . Only <code>[USD5 + missing]</code> from record A has a match.
<code>[missing + <Currency>]</code>	Matches neither record A nor B since no extracted TLA pattern matched this order. This has no equivalent, since a TLA output is only based on terms <code>(USD5 + missing)</code> or on types <code>(<Currency> + <Negative>)</code> , but does not mix concepts and types.
<code>[<Currency> + <Negative>]</code>	Matches record A but not B since no TLA pattern was extracted from record B. This is equivalent to the TLA output: <code><Currency> + <Negative></code>
<code>[<Negative> + <Currency>]</code>	Matches neither record A nor B since no extracted TLA pattern matched this order. In the <code>Opinions</code> template, by default, when a <i>topic</i> is found with an <i>opinion</i> , the <i>topic</i> (<code><Currency></code>) occupies the first slot position and <i>opinion</i> (<code><Negative></code>) occupies the second slot position.

- [Creating Category Rules](#)
- [Editing and Deleting Rules](#)
- [Microsoft Internet Explorer settings for Help](#)

Creating Category Rules

When you are creating or editing a rule, you must have the rule open in the rule editor. You can add concepts, types, or patterns as well as use wildcards to extend the matches. When you use recognized concepts, types and patterns, you benefit since it will find all related concepts. For example, when you use a concept, all of its associated terms, plural forms, and synonyms are also matched to the rule. Likewise, when you use a type, all of its concepts are also captured by the rule.

You can open the rule editor by editing an existing rule or by right-clicking the category name and choosing Create Rule.

You can use context menus, drag-and-drop, or manually enter concepts, types, and patterns into the editor. Then combine these with Boolean operators (`&`, `!`, `()`, `|`) and brackets to form your rule expressions. To avoid common errors, we recommend dragging and dropping concepts directly from the Extraction Results pane or the Data pane into the rule editor. Pay close attention to the syntax of the rules to avoid errors. See the topic [Category Rule Syntax](#) for more information.

Note: For examples of how rules match text, see [Category Rule Examples](#).

To Create a Rule

1. If you have not yet extracted any data or your extraction is out of date, do so now. See the topic [Extracting data](#) for more information.
Note: If you filter an extraction in such a way that there are no longer any concepts visible, an error message is displayed when you attempt to create or edit a category rule. To prevent this, modify your extraction filter so that concepts are available.
2. In the Categories pane, select the category in which you want to add your rule.

3. From the menus choose Categories > Create Rule. The category rule editor pane opens in the window.
4. In the Rule Name field, enter a name for your rule. If you do not provide a name, the expression will be used as the name automatically. You can rename this rule later.
5. In the larger expression text field, you can:
 - Enter text directly in the field or drag-and-drop from another pane. Use only extracted concepts, types, and patterns. For example, if you enter the word **cats** but only the singular form, **cat**, appears in your Extraction Results pane, the editor will not be able to recognize **cats**. In this last case, the singular form might automatically include the plural, otherwise you could use a wildcard. See the topic [Category Rule Syntax](#) for more information.
 - Select the concepts, types, or patterns you want to add to rules and use the menus.
 - Add Boolean operators to link elements in your rule together. Use the toolbar buttons to add the "and" Boolean &, the "or" Boolean |, the "not" Boolean !(), parentheses (), and brackets for patterns [] to your rule.
6. Click the Test Rule button to verify that your rule is well-formed. See the topic [Category Rule Syntax](#) for more information. The number of documents or records found appears in parentheses next to the text Test result. To the right of this text, you can see the elements in your rule that were recognized or any error messages. If the graphic next to the type, pattern, or concept appears with a red question mark, this indicates that the element does not match any known extractions. If it does not match, then the rule will not find any records.
7. To test a part of your rule, select that part and click Test Selection.
8. Make any necessary changes and retest your rule if you found problems.
9. When finished, click Save & Close to save your rule again and close the editor. The new rule name appears in the category.

Editing and Deleting Rules

After you have created and saved a rule, you can edit that rule at any time. See the topic [Category Rule Syntax](#) for more information.

If you no longer want a rule, you can delete it.

To Edit Rules

1. In the Descriptors table in Category Definitions dialog box, select the rule.
2. From the menus choose Categories > Edit Rule or double-click the rule name. The editor opens with the selected rule.
3. Make any changes to the rule using extraction results and the toolbar buttons.
4. Retest your rule to make sure that it returns the expected results.
5. Click Save & Close to save your rule again and close the editor.

To Delete a Rule

1. In the Descriptors table in Category Definitions dialog box, select the rule.
2. From the menus, choose Edit > Delete. The rule is deleted from the category.

Importing and Exporting Predefined Categories

If you have your own categories stored in an Microsoft Excel (*.xls, *.xlsx) file, you can import them into IBM® SPSS® Modeler Text Analytics . See the topic [Importing Predefined Categories](#) for more information.

You can also export the categories you have in an open interactive workbench session out to an Microsoft Excel (*.xls, *.xlsx) file. When you export your categories, you can choose to include or exclude some additional information such as descriptors and scores. See the topic [Exporting Categories](#) for more information.

If your predefined categories do not have codes or you want new codes, you can automatically generate a new set of codes for the set of categories in the categories pane by choosing Categories > Manage Categories > Autogenerate Codes from the menus. This will remove any existing codes and renumber them all automatically.

- [Compact Format](#)
- [Indented Format](#)
- [Exporting Categories](#)
- [Microsoft Internet Explorer settings for Help](#)

Importing Predefined Categories

You can import your predefined categories into IBM® SPSS® Modeler Text Analytics . Before importing, make sure the predefined category file is in an Microsoft Excel (*.xls, *.xlsx) file and is structured in one of the supportive formats. You can also choose to have the product automatically detect the format for you. The following formats are supported:

- Flat list format: See the topic [Flat List Format](#) for more information.
- Compact format: See the topic [Compact Format](#) for more information.
- Indented format: See the topic [Indented Format](#) for more information.

To Import Predefined Categories

1. From the interactive workbench menus, choose Categories > Manage Categories > Import Predefined Categories. An Import Predefined Categories wizard is displayed.
2. From the Look In drop-down list, select the drive and folder in which the file is located.
3. Select the file from the list. The name of the file appears in the File Name text box.
4. Select the worksheet containing the predefined categories from the list. The worksheet name appears in the Worksheet field.
5. To begin choosing the data format, click Next.
6. Choose the format for your file or choose the option to allow the product to attempt to automatically detect the format. The autodetection works best on the most common formats.
 - Flat list format: See the topic [Flat List Format](#) for more information.
 - Compact format: See the topic [Compact Format](#) for more information.
 - Indented format: See the topic [Indented Format](#) for more information.
7. To define the additional import options, click Next. If you choose to have the format automatically detected, you are directed to the final step.
8. If one or more rows contain column headers or other extraneous information, select the row number from which you want to start importing in the Start import at row option. For example, if your category names begin on row 7, you must enter the number 7 for this option in order to import the file correctly.
9. If your file contains category codes, choose the option Contains category codes. Doing so helps the wizard properly recognize your data.
10. Review the color-coded cells and legend to make sure that the data has been correctly identified. Any errors detected in the file are shown in red and referenced below the format preview table. If the wrong format was selected, go back and choose another one. If you need to make corrections to your file, make those changes and restart the wizard by selecting the file again. You must correct all errors before you can finish the wizard.
11. To review the set of categories and subcategories that will be imported and to define how to create descriptors for these categories, click Next.
12. Review the set of categories that will be imported in the table. If you do not see the keywords you expected to see as descriptors, it may be that they were not recognized during the import. Make sure they are properly prefixed and appear in the correct cell.
13. Choose how you want to handle any pre-existing categories in your session.
 - Replace all existing categories. This option purges all existing categories and then the newly imported categories are used alone in their place.
 - Append to existing categories. This option will import the categories and merge any common categories with the existing categories. When adding to existing categories, you need to determine how you want any duplicates handled. One choice (option: Merge) is to merge any categories being imported with existing categories if they share a category name. Another choice (option: Exclude from import) is to prohibit the import of categories if one with the same name exists.
14. Import keywords as descriptors is an option to import the keywords identified in your data as descriptors for the associated category.

15. Extend categories by deriving descriptors is an option that will generate descriptors from the words that represent the name of the category, or subcategory, and/or the words that make up the annotation. If the words match extracted results, then those are added as descriptors to the category. This option produces the best results when the category names or annotations are both long and descriptive. This is a quick method for generating the category descriptors that enable the category to capture records that contain those descriptors.
 - From field allows you to select from what text the descriptors will be derived, the names or categories and subcategories, the words in the annotations, or both.
 - As field allows you to choose to create these descriptors in the form of concepts or TLA patterns. If TLA extraction has not taken place, the options of patterns are disabled in this wizard.
16. To import the predefined categories into the Categories pane, click Finish.

Flat List Format

In the flat list format, there is only one top level of categories without any hierarchy, meaning no subcategories or subnets. Category names are in a single column.

The following information can be contained in a file of this format:

- Optional **codes** column contains numerical values that uniquely identify each category. If you specify that the data file does contain codes (Contains category codes option in the Content Settings step), then a column containing unique codes for each category must exist in the cell directly to the left of category name. If your data does not contain codes, but you want to create some codes later, you can always generate codes later (Categories > Manage Categories > Autogenerate Codes).
- A **required category names** column contains all of the names of the categories. This column is required to import using this format.
- Optional **annotations** in the cell immediately to the right of the category name. This annotation consists of text that describes your categories/subcategories.
- Optional **keywords** can be imported as descriptors for categories. In order to be recognized, these keywords must exist in the cell directly below the associated category/subcategory name and the list of keywords must be prefixed by the underscore (_) character such as `_firearms, weapons / guns`. The keyword cell can contain one or more words used to describe each category. These words will be imported as descriptors or ignored depending on what you specify in the last step of the wizard. Later, descriptors are compared to the extracted results from the text. If a match is found, then that record or document is scored into the category containing this descriptor.

Table 1. Flat list format with codes, keywords, and annotations

Column A	Column B	Column C
Category code (<i>optional</i>)	Category name	Annotation
	<code>_Descriptor/keyword list (<i>optional</i>)</code>

 - [Indented Format](#)
 - [Exporting Categories](#)
 - [Microsoft Internet Explorer settings for Help](#)
-

Compact Format

The compact format is structured similarly to the flat list format except that the compact format is used with hierarchical categories. Therefore, a code level column is required to define the hierarchical level of each category and subcategory.

The following information can be contained in a file of this format:

- A **required code level** column contains numbers that indicate the hierarchical position for the subsequent information in that row. For example, if values 1, 2 or 3 are specified and you have both categories and subcategories, then 1 is for categories, 2 is for subcategories, and 3 is for sub-subcategories. If you have only categories and subcategories, then 1 is for categories and 2 is for subcategories. And so on, until the desired category depth.
- Optional **codes** column contains values that uniquely identify each category. If you specify that the data file does contain codes (Contains category codes option in the Content Settings step), then a column containing unique codes for each category must exist in the cell directly to the left of category name. If your data does not contain codes, but you want to create some codes later, you can always generate codes later (Categories > Manage Categories > Autogenerate Codes).
- A **required category names** column contains all of the names of the categories and subcategories. This column is required to import using this format.
- Optional **annotations** in the cell immediately to the right of the category name. This annotation consists of text that describes your categories/subcategories.
- Optional **keywords** can be imported as descriptors for categories. In order to be recognized, these keywords must exist in the cell directly below the associated category/subcategory name and the list of keywords must be prefixed by the underscore (_) character such as `_firearms, weapons / guns`. The keyword cell can contain one or more words used to describe each category. These words will be imported as descriptors or ignored depending on what you specify in the last step of the wizard. Later, descriptors are compared to the extracted results from the text. If a match is found, then that record or document is scored into the category containing this descriptor.

Table 1. Compact format example with codes

Column A	Column B	Column C
Hierarchical code level	Category code (<i>optional</i>)	Category name
Hierarchical code level	Subcategory code (<i>optional</i>)	Subcategory name

Table 2. Compact format example without codes

Column A	Column B
Hierarchical code level	Category name
Hierarchical code level	Subcategory name

- [Indented Format](#)
- [Exporting Categories](#)
- [Microsoft Internet Explorer settings for Help](#)

Indented Format

In the Indented file format, the content is hierarchical, which means it contains categories and one or more levels of subcategories. Furthermore, its structure is indented to denote this hierarchy. Each row in the file contains either a category or subcategory, but subcategories are indented from the categories and any sub-subcategories are indented from the subcategories, and so on. You can manually create this structure in Microsoft Excel or use one that was exported from another product and saved into an Microsoft Excel format.

- **Top level category codes and category names** occupy the columns A and B, respectively. Or, if no codes are present, then the category name is in column A.
- **Subcategory codes and subcategory names** occupy the columns B and C, respectively. Or, if no codes are present, then the subcategory name is in column B. The subcategory is a member of a category. You cannot have subcategories if you do not have top level categories.

Table 1. Indented structure with codes

Column A	Column B	Column C	Column D
Category code (<i>optional</i>)	Category name		
	Subcategory code (<i>optional</i>)	Subcategory name	
		Sub-subcategory code (<i>optional</i>)	Sub-subcategory name

Table 2. Indented structure without codes

Column A	Column B	Column C
Category name		
	Subcategory name	
		Sub-subcategory name

The following information can be contained in a file of this format:

- Optional **codes** must be values that uniquely identify each category or subcategory. If you specify that the data file does contain codes (Contains category codes option in the Content Settings step), then a unique code for each category or subcategory must exist in the cell directly to the left of category/subcategory name. If your data does not contain codes, but you want to create some codes later, you can always generate codes later (Categories > Manage Categories > Autogenerate Codes).
- A **required name** for each category and subcategory. Subcategories must be indented from categories by one cell to the right in a separate row.
- Optional **annotations** in the cell immediately to the right of the category name. This annotation consists of text that describes your categories/subcategories.
- Optional **keywords** can be imported as descriptors for categories. In order to be recognized, these keywords must exist in the cell directly below the associated category/subcategory name and the list of keywords must be prefixed by the underscore (_) character such as firearms, weapons / guns. The keyword cell can contain one or more words used to describe each category. These words will be imported as descriptors or ignored depending on what you specify in the last step of the wizard. Later, descriptors are compared to the extracted results from the text. If a match is found, then that record or document is scored into the category containing this descriptor.

Important! If you use a code at one level, you must include a code for each category and subcategory. Otherwise, the import process will fail.

Related information

Exporting Categories

You can also export the categories you have in an open interactive workbench session into an Microsoft Excel (*.xls, *.xlsx) file format. The data that will be exported comes largely from the current contents of the Categories pane or from the category properties. Therefore, we recommend that you score again if you plan to also export the Docs. score value.

Table 1. Category export options

Always gets exported...	Exported optionally...
<ul style="list-style-type: none"> • Category codes, if present • Category (and subcategory) names • Code levels, if present (<i>Flat/Compact</i> format) • Column headings (<i>Flat/Compact</i> format) 	<ul style="list-style-type: none"> • Docs. scores • Category annotations • Descriptor names • Descriptors counts

Important! When you export descriptors, they are converted to text strings and prefixed by an underscore. If you re-import into this product, the ability to distinguish between descriptors that are patterns, those that are category rules, and those that are plain concepts is lost. If you intend to reuse these categories in this product, we highly recommend making a text analysis package (TAP) file instead since the TAP format will preserve all descriptors as they are currently defined as well as all your categories, codes, and also the linguistic resources used. TAP files can be used in both IBM® SPSS® Modeler Text Analytics and IBM SPSS Text Analytics for Surveys . See the topic [Using Text Analysis Packages](#) for more information.

To Export Predefined Categories

1. From the interactive workbench menus, choose Categories > Manage Categories > Export Categories. An Export Categories wizard is displayed.
2. Choose the location and enter the name of the file that will be exported.
3. Enter a name for the output file in the File Name text box.
4. To choose the format into which you will export your category data, click Next.
5. Choose the format from the following:
 - Flat or Compact list format: See the topic [Flat List Format](#) for more information. Flat list contains no subcategories. See the topic [Compact Format](#) for more information. Compact list format contains hierarchical categories.
 - Indented format: See the topic [Indented Format](#) for more information.
6. To begin choosing the content to be exported and to review the proposed data, click Next.
7. Review the content for the exported file.
8. Select or unselect the additional content settings to be exported such as Annotations or Descriptor names.
9. To export the categories, click Finish.

Using Text Analysis Packages

A text analysis package, also called a TAP, serves as a template for text response categorization. Using a TAP is an easy way for you to categorize your text data with minimal intervention since it contains the prebuilt category sets and the linguistic resources that are needed to code a vast number of records quickly and automatically. Using the linguistic resources, text data is analyzed and mined in order to extract key concepts. Based on key concepts and patterns that are found in the text, the records can be categorized into the category set you selected in the TAP. You can make your own TAP or update one.

A TAP is made up of the following elements:

- Category Set(s). A category set is essentially made up of predefined categories, category codes, descriptors for each category, and lastly, a name for the whole category set. Descriptors are linguistic elements (concepts, types, patterns, and rules) such as the term *cheap* or the pattern *good price*. Descriptors are used to define a category so that when the text matches any category descriptor, the document or record is put into the category.
- Linguistic Resources. Linguistic resources are a set of libraries and advanced resources that are tuned to extract key concepts and patterns. These extraction concepts and patterns, in turn, are used as the descriptors that enable records to be placed into a category in the category set.

The following tasks are possible with text analysis packages.

- Make text analysis packages. See [Making Text Analysis Packages](#) for more information.
- Load text analysis packages. Or you can load an SPSS® Text Analytics for Surveys project (.tas), which will be converted to a text analysis package. See [Loading Text Analysis Packages](#) for more information.
- Update text analysis packages. See [Updating Text Analysis Packages](#) for more information.

After you select the TAP and choose a category set, SPSS Modeler Text Analytics can extract and categorize your records.

Note: TAPs can be created and used interchangeably between SPSS Text Analytics for Surveys and SPSS Modeler Text Analytics . However, note that scoring on rules might be different in SPSS Modeler Text Analytics depending on whether you load a text analysis package (TAP) from SPSS Modeler Text Analytics directly, or whether you load a TAP from IBM® SPSS Text Analytics for Surveys . We recommend that you use TAPs that are made within SPSS Modeler Text Analytics ; this is because TAPs that are made in IBM SPSS Text Analytics for Surveys might be created by using a different version of the linguistic resources.

- [Making Text Analysis Packages](#)
 - [Loading Text Analysis Packages](#)
 - [Updating Text Analysis Packages](#)
-

Making Text Analysis Packages

Whenever you have a session with at least one category and some resources, you can make a text analysis package (TAP) from the contents of the open interactive workbench session. The set of categories and descriptors (concepts, types, rules or TLA pattern outputs) can be made into a TAP along with all of the linguistic resources open in the resource editor.

You can see the language for which the resources were created. The language is set in the Advanced Resources tab of the Template Editor or Resource Editor.

To Make a Text Analysis Package

1. From the menus, choose File > Text Analysis Packages > Make Package. The Make Package dialog appears.
2. Browse to the directory in which you will save the TAP. By default, TAPs are saved into the \TAP subdirectory of the product installation directory.
3. Enter a name for the TAP in the File Name field.
4. Enter a label in the Package Label field. When you enter a file name, this name automatically appears as the label but you can change this label.
5. To exclude a category set from the TAP, unselect the Include checkbox. Doing so will ensure that it is not added to your package. By default, one category set per question is included in the TAP. There must always be at least one category set in the TAP.
6. Rename any category sets. The New Category Set column contains generic names by default, which are generated by adding the `cat_` prefix to the text variable name. A single click in the cell makes the name editable. Enter or a click elsewhere applies the rename. If you rename a category set, the name changes in the TAP only and does not change the variable name in the open session.
7. Reorder the category sets if desired using the arrow keys to the right of the category set table.
8. Click Save to make the text analysis package. The dialog box closes.

-

Loading Text Analysis Packages

When configuring a text mining modeling node, you must specify the resources that will be used during extraction. Instead of choosing a resource template, you can select a text analysis package (TAP) or an SPSS® Text Analytics for Surveys project (.tas) in order to copy not only its resources but also a category set into the node. If you select a .tas file, it will be converted to a TAP.

TAPs are most interesting when creating a category model interactively since you can use the category set as a starting point for categorization. When you run the stream, the interactive workbench session launches and this set of categories appears in the Categories pane. In this way, you score your documents and records immediately using these categories and then continue to refine, build, and extend these categories until they satisfy your needs. See [Methods and Strategies for Creating Categories](#) for more information.

Beginning in version 14, you can also see the language for which the resources in the TAP were defined when you click Load and choose the TAP.

To load a TAP or a TAS

1. Edit the Text Mining modeling node.
 2. On the Models tab, choose *Text analysis package* in the Copy Resources From section.
 3. Click Load. The Load Text Analysis Package dialog opens.
 4. Browse to the location of the TAP or the SPSS Text Analytics for Surveys project (.tas) containing the resources and category set you want to copy into the node. By default, they're saved to the \TAP subdirectory of your product installation directory.
 5. Enter a name for the TAP in the File Name field. The label is displayed automatically.
 6. Select the category set you want to use. This is the set of categories that will appear in the interactive workbench session. You can then tweak and improve these categories manually or using the Build or Extend categories options.
 7. Click Load to copy the contents of the text analysis package or SPSS Text Analytics for Surveys project into the node. The dialog box closes. When the contents are loaded, they're copied into the node; therefore, any changes you make to the external resources and categories will not be reflected unless you explicitly update it and reload it.
-

Updating Text Analysis Packages

If you make improvements to a category set, linguistic resources, or make a whole new category set, you can update a text analysis package (TAP) to make it easier to reuse these improvements later. To do so, you must be in the open session containing the information you want to put in the TAP. When you update, you can choose to append category sets, replace resources, change the package label, or rename/reorder category sets.

To update a text analysis package

1. From the menus, choose File > Text Analysis Packages > Update Package. The Update Package dialog appears.
2. Browse to the directory containing the text analysis package you want to update.
3. Enter a name for the TAP in the File Name field.
4. To replace the linguistic resources inside the TAP with those in the current session, select the Replace the resources in this package with those in the open session option. It generally makes sense to update the linguistic resources since they were used to extract the key concepts and patterns used to create the category definitions. Having the most recent linguistic resources ensures that you get the best results in categorizing your records. If you do not select this option, the linguistic resources that were already in the package are kept unchanged.
5. To update only the linguistic resources, make sure that you select the Replace the resources in this package with those in the open session option and select only the current category sets that were already in the TAP.
6. To include the new category set from the open session into the TAP, select the checkbox for each category set to be added. You can add one, multiple or none of the category sets.
7. To remove category sets from the TAP, deselect the corresponding Include checkbox. You might choose to remove a category set that was already in the TAP since you are adding an improved one. To do so, deselect the Include checkbox for the corresponding category set in the Current Category Set column. There must always be at least one category set in the TAP.
8. Rename category sets if needed. A single click in the cell makes the name editable. Enter or a click elsewhere applies the rename. If you rename a category set, the name changes in the TAP only and does not change the variable name in the open session. If two category sets have the same name, the names will appear in red until you correct the duplicate.

9. To create a new package with the session contents merged with the contents of the selected TAP, click Save As New. The Save As Text Analysis Package dialog appears. See following instructions.
10. Click Update to save the changes you made to the selected TAP.

To save a text analysis package

1. Browse to the directory in which you will save the TAP file. By default, TAP files are saved into the \TAP subdirectory of the installation directory.
 2. Enter a name for the TAP file in the File name field.
 3. Enter a label in the Package label field. When you enter a file name, this name is automatically used as the label. However, you can rename this label. You must have a label.
 4. Click Save to create the new package.
-

Editing and Refining Categories

Once you create some categories, you will invariably want to examine them and make some adjustments. In addition to refining the linguistic resources, you should review your categories by looking for ways to combine or clean up their definitions as well as checking some of the categorized documents or records. You can also review the documents or records in a category and make adjustments so that categories are defined in such a way that nuances and distinctions are captured.

You can use the built-in, automated, category-building techniques to create your categories; however, you are likely to want to perform a few tweaks to these categories. After using one or more technique, a number of new categories appear in the window. You can then review the data in a category and make adjustments until you are comfortable with your category definitions. See the topic [About Categories](#) for more information.

Here are some options for refining your categories:

- [Adding Descriptors to Categories](#)
- [Editing Category Descriptors](#)
- [Moving Categories](#)
- [Flattening Categories](#)
- [Merging or Combining Categories](#)
- [Forcing documents into categories](#)
- [Deleting Categories](#)

-

Adding Descriptors to Categories

After using automated techniques, you will most likely still have extraction results that were not used in any of the category definitions. You should review this list in the Extraction Results pane. If you find elements that you would like to move into a category, you can add them to an existing or new category.

To Add a Concept or Type to a Category

1. From within the Extraction Results and Data panes, select the elements that you want to add to a new or existing category.
2. From the menus, choose Categories > Add to Category. The All Categories dialog box displays the set of categories. Select the category to which you want to add the selected elements. If you want to add the elements to a new category, select New Category. A new category appears in the Categories pane using the name of the first selected element.

Editing Category Descriptors

Once you have created some categories, you can open each category to see all of the descriptors that make up its definition. Inside the Category Definitions dialog box, you can make a number of edits to your category descriptors. Also, if categories are shown in the category tree, you can also work with them there.

To Edit a Category

1. Select the category you want to edit in the Categories pane.
2. From the menus, choose View > Category Definitions. The Category Definitions dialog box opens.
3. Select the descriptor you want to edit and click the corresponding toolbar button.

The following table describes each toolbar button that you can use to edit your category definitions.

Table 1. Toolbar buttons and descriptions

Icons	Description
	Deletes the selected descriptors from the category.
	Moves the selected descriptors to a new or existing category.
	Moves the selected descriptors in the form of an & category rule to a category. See the topic Using Category Rules for more information.
	Moves each of the selected descriptors as its own new category
	Updates what is displayed in the Data pane and the Visualization pane according to the selected descriptors

Moving Categories

If you want to place a category into another existing category or move descriptors into another category, you can move it.

To Move a Category

1. In the Categories pane, select the categories that you would like to move into another category.
2. From the menus, choose Categories > Move to Category. The menu presents a set of categories with the most recently created category at the top of the list. Select the name of the category to which you want to move the selected concepts.
 - If you see the name you are looking for, select it, and the selected elements are added to that category.
 - If you do not see it, select More to display the All Categories dialog box, and select the category from the list.

Flattening Categories

When you have a hierarchical category structure with categories and subcategories, you can flatten your structure. When you flatten a category, all of the descriptors in the subcategories of that category are moved into the selected category and the now empty subcategories are deleted. In this way, all of the documents that used to match the subcategories are now categorized into the selected category.

To Flatten a Category

1. In the Categories pane, select a category (top level or subcategory) that you would like to flatten.
2. From the menus, choose Categories > Flatten Categories. The subcategories are removed and the descriptors are merged into the selected category.

-

Merging or Combining Categories

If you want to combine two or more existing categories into a new category, you can merge them. When you merge categories, a new category is created with a generic name. All of the concepts, types, and patterns used in the category descriptors are moved into this new category. You can later rename this category by editing the category properties.

To Merge a Category or Part of a Category

1. In the Categories pane, select the elements you would like to merge together.
2. From the menus, choose Categories > Merge Categories. The Category Properties dialog box is displayed in which you enter a name for the newly created category. The selected categories are merged into the new category as subcategories.

Forcing documents into categories

Forcing documents into and out of categories enables you to override the category definitions created by the automatic category building techniques without changing the actual category definition. You may find that although the document contains terms that are used to define a

particular category, the document itself should not be in that category. In this case, you can force the document out of that category without having to remove the terms from the category definition.

Forcing is used in special cases where a document fits (or does not fit) a category, but for one reason or another (for example, it contains a particular term) is assigned (or not assigned) to that category. For example, this can occur when a respondent uses sarcasm in his or her response, such as "*The pizza was great. I am sure everyone loves burnt, cold pizza.*" Let's suppose that you had a category called **Pos: [<Food> + <Positive>]** to capture positive opinions regarding the food that a restaurant serves, and this response is assigned to that category. In this case, you might want to force this response out of the category.

To force in or out of categories

1. From within the Data pane, select the document that you want to force into or out of a particular category.
2. From the menus, choose **Categories > Force In** or **Categories > Force Out**. A submenu displays the list of categories from which you can select.
3. Select the category to which or from which you want to force this document. If you have created many categories, some may not be visible in the submenu.
 - In this case, choose **More** at the bottom of the submenu. The **All Categories** dialog box opens, in which you can select the category and click **OK** to apply the change.
 - If you want to force the document into a new category, select **Create Empty Category**. A new category appears in the category tree using a generic name.

Whenever a category contains one or more forced documents, a pseudo-category called either Force In or Force Out is displayed below the category name in the tree.

To clear a forced state

1. From within the Data pane, select the document that you no longer want to force into or out of a category.
2. From the menus, choose **Categories > Force In** to force in, or choose **Categories > Force Out** to force out. The categories in which the document is forced out of or into are preceded by a check mark.
3. Select the category in the submenu that is checked and for which you want to remove the force. The check mark is removed and the document is no longer forced.

To clear all forced states

1. From within the Data pane, select a record containing a Force In or Force Out.
2. From the menus, choose **Categories > Clear All > Force Ins** or **Categories > Clear All > Force Outs**. The forced state on the documents is cleared and they are no longer forced into or out of the categories.

Note: This feature is only available if your source text contains a unique ID. If the source text doesn't have a unique ID, you can add a Derive node between the source document and the Text Mining node. This feature only has an impact when running an interactive session. When you deploy the category model for non-interactive scoring, this piece of information is not preserved or used since it is based on a document ID.

Deleting Categories

If you no longer want to keep a category, you can delete it.

To Delete a Category

1. In the Categories pane, select the category or categories that you would like to delete.
2. From the menus, choose **Edit > Delete**.

Analyzing clusters

You can build and explore concept clusters in the Clusters view (View > Clusters). A *cluster* is a grouping of related concepts generated by clustering algorithms based on how often these concepts occur in the document/record set and how often they appear together in the same document, also known as *cooccurrence*. Each concept in a cluster cooccurs with at least one other concept in the cluster. The goal of clusters is to group concepts that co-occur together while the goal of categories is to group documents or records based on how the text they contain matches the descriptors (concepts, rules, patterns) for each category.

A good cluster is one with concepts that are strongly linked and cooccur frequently and with few links to concepts in other clusters. When working with larger datasets, this technique may result in significantly longer processing times.

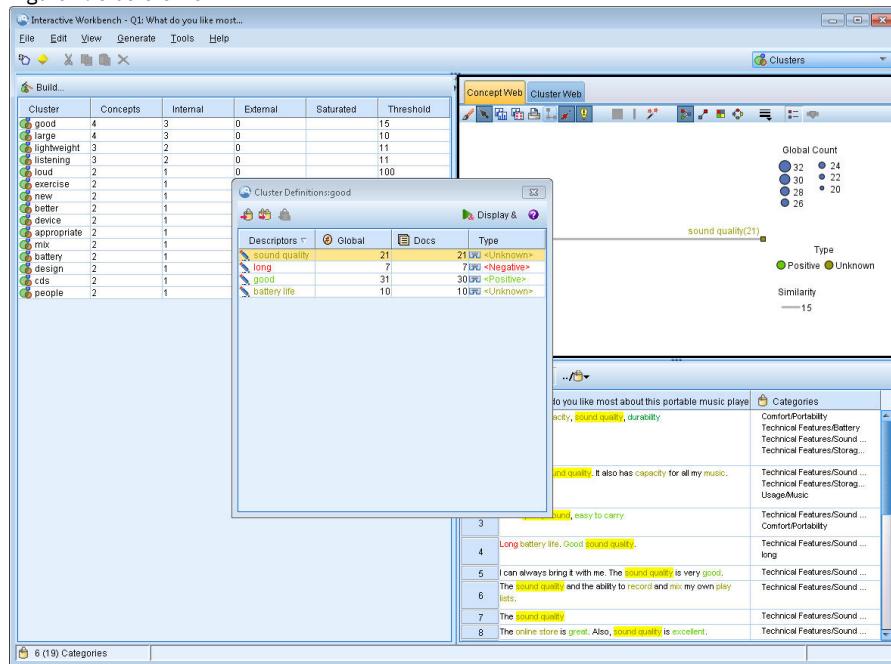

Clustering is a process that begins by analyzing a set of concepts and looking for concepts that cooccur often in documents. Two concepts that cooccur in a document are considered to be a concept pair. Next, the clustering process assesses the *similarity value* of each concept pair by comparing the number of documents in which the pair occur together to the number of documents in which each concept occurs. See the topic [Calculating Similarity Link Values](#) for more information.

Lastly, the clustering process groups similar concepts into clusters by aggregation and takes into account their link values and the settings defined in the Build Clusters dialog box. By aggregation, we mean that concepts are added or smaller clusters are merged into a larger cluster until the cluster is saturated. A cluster is *saturated* when additional merging of concepts or smaller clusters would cause the cluster to exceed the settings in the Build Clusters dialog box (number of concepts, internal links, or external links). A cluster takes the name of the concept within the cluster that has the highest overall number of links to other concepts within the cluster.

In the end, not all concept pairs end up together in the same cluster since there may be a stronger link in another cluster or saturation may prevent the merging of the clusters in which they occur. For this reason, there are both internal and external links.

- *Internal links* are links between concept pairs within a cluster. Not all concepts are linked to each other in a cluster. However, each concept is linked to at least one other concept inside the cluster.
- *External links* are links between concept pairs in separate clusters (a concept within one cluster and a concept outside in another cluster).

Figure 1. Clusters view

The Clusters view is organized into three panes, each of which can be hidden or shown by selecting its name from the View menu:

- Clusters pane You can build and manage your clusters in this pane. See the topic [Exploring Clusters](#) for more information.
- Visualization pane You can visually explore your clusters and how they interact in this pane. See the topic [Cluster Graphs](#) for more information.
- Data pane You can explore and review the text contained within documents and records that correspond to selections in the Cluster Definitions dialog box. See the topic [Cluster Definitions](#) for more information.
- [Building Clusters](#)
- [Exploring Clusters](#)

Building Clusters

When you first access the Clusters view, no clusters are visible. You can build the clusters through the menus (Tools > Build Clusters) or by clicking the Build... button on the toolbar. This action opens the Build Clusters dialog box in which you can define the settings and limits for

building your clusters.

Note: Whenever the extraction results no longer match the resources, this pane becomes yellow as does the Extraction Results pane. You can reextract to get the latest extraction results and the yellow coloring will disappear. However, each time an extraction is performed the Clusters pane is cleared, and you will have to rebuild your clusters. Likewise clusters are not saved from one session to another.

The following areas and fields are available within the Build Clusters dialog box:

Inputs

Inputs table Clusters are built from descriptors derived from certain types. In the table, you can select the types to include in the building process. The types that capture the most records or documents are preselected by default.

Concepts to cluster: Select the method of selecting the concepts you want to use for clustering. By reducing the number of concepts, you can speed up the clustering process. You can cluster using a number of top concepts, a percentage of top concepts, or using all the concepts:

- Number based on doc. count When you select Top number of concepts, enter the number of concepts to be considered for clustering. The concepts are chosen based on those that have the highest doc count value. Doc count is the number of documents or records in which the concept appears. The maximum value is 150,000.
- Percentage based on doc. count When you select Top percentage of concepts, enter the percentage of concepts to be considered for clustering. The concepts are chosen based on this percentage of concepts with the highest doc count value.

Output Limits

Maximum number of clusters to create This value is the maximum number of clusters to generate and display in the Clusters pane. During the clustering process, saturated clusters are presented before unsaturated ones, and therefore, many of the resulting clusters will be saturated. In order to see more unsaturated clusters, you can change this setting to a value greater than the number of saturated clusters.

Maximum concepts in a cluster This value is the maximum number of concepts a cluster can contain.

Minimum concepts in a cluster This value is the minimum number of concepts that must be linked in order to create a cluster.

Maximum number of internal links This value is the maximum number of internal links a cluster can contain. Internal links are links between concept pairs within a cluster.

Maximum number of external links This value is the maximum number of links to concepts outside of the cluster. External links are links between concept pairs in separate clusters.

Minimum link value This value is the smallest link value accepted for a concept pair to be considered for clustering. Link value is calculated using a similarity formula. See the topic [Calculating Similarity Link Values](#) for more information.

Prevent pairing of specific concepts. Select this checkbox to stop the process from grouping or pairing two concepts together in the output. To create or manage concept pairs, click Manage Pairs. See the topic [Managing Link Exception Pairs](#) for more information.

- [Calculating Similarity Link Values](#)

Related information

- [Exploring Clusters](#)
- [Cluster Definitions](#)
- [Microsoft Internet Explorer settings for Help](#)

Calculating Similarity Link Values

Knowing only the number of documents in which a concept pair cooccurs does not in itself tell you how similar the two concepts are. In these cases, the similarity value can be helpful. The similarity link value is measured using the cooccurrence document count compared to the individual document counts for each concept in the relationship. When calculating similarity, the unit of measurement is the number of documents (doc count) in which a concept or concept pair is found. A concept or concept pair is "found" in a document if it occurs *at least* once in the document. You can choose to have the line thickness in the Concept graph represent the similarity link value in the graphs.

The algorithm reveals those relationships that are strongest, meaning that the tendency for the concepts to appear together in the text data is much higher than their tendency to occur independently. Internally, the algorithm yields a similarity coefficient ranging from 0 to 1, where a value of 1 means that the two concepts always appear together and never separately. The similarity coefficient result is then multiplied by 100 and rounded to the nearest whole number. The similarity coefficient is calculated using the formula shown in the following figure.

Figure 1. Similarity coefficient formula

$$\text{similarity coefficient} = \frac{(C_{IJ})^2}{(C_I \times C_J)}$$

Where:

- C_I is the number of documents or records in which the concept I occurs.
- C_J is the number of documents or records in which the concept J occurs.
- C_{IJ} is the number of documents or records in which concept pair I and J cooccurs in the set of documents.

For example, suppose that you have 5,000 documents. Let I and J be extracted concepts and let IJ be a concept pair cooccurrence of I and J . The following table proposes two scenarios to demonstrate how the coefficient and link value are calculated.

Table 1. Concept frequencies example

Concept/Pair	Scenario A	Scenario B
Concept: I	Occurs in 20 docs	Occurs in 30 docs
Concept: J	Occurs in 20 docs	Occurs in 60 docs
Concept Pair: IJ	Cooccurs in 20 docs	Cooccurs in 20 docs
Similarity coefficient	1	0.22222
Similarity link value	100	22

In scenario A, the concepts I and J as well as the pair IJ occur in 20 documents, yielding a similarity coefficient of 1, meaning that the concepts always occur together. The similarity link value for this pair would be 100.

In scenario B, concept I occurs in 30 documents and concept J occurs in 60 documents, but the pair IJ occurs in only 20 documents. As a result, the similarity coefficient is 0.22222. The similarity link value for this pair would be rounded down to 22.

- [Microsoft Internet Explorer settings for Help](#)

Exploring Clusters

After you build clusters, you can see a set of results in the Clusters pane. For each cluster, the following information is available in the table:

- **Cluster.** This is the name of the cluster. Clusters are named after the concept with the highest number of internal links.
- **Concepts.** This is the number of concepts in the cluster. See the topic [Cluster Definitions](#) for more information.
- **Internal.** This is the number of internal links in the cluster. Internal links are links between concept pairs within a cluster.
- **External.** This is the number of external links in the cluster. External links are links between concept pairs when one concept is in one cluster and the other concept is in another cluster.
- **Sat.** If a symbol is present, this indicates that this cluster could have been larger but one or more limits would have been exceeded, and therefore, the clustering process ended for that cluster and is considered to be *saturated*. At the end of the clustering process, saturated clusters are presented before unsaturated ones and therefore, many of the resulting clusters will be saturated. In order to see more unsaturated clusters, you can change the Maximum number of clusters to create setting to a value greater than the number of saturated clusters or decrease the Minimum link value. See the topic [Building Clusters](#) for more information.
- **Threshold.** For all of the cooccurring concept pairs in the cluster, this is the lowest similarity link value of all in the cluster. See the topic [Calculating Similarity Link Values](#) for more information. A cluster with a high threshold value signifies that the concepts in that cluster have a higher overall similarity and are more closely related than those in a cluster whose threshold value is lower.

To learn more about a given cluster, you can select it and the visualization pane on the right will show two graphs to help you explore the cluster(s). See the topic [Cluster Graphs](#) for more information. You can also cut and paste the contents of the table into another application.

Whenever the extraction results no longer match the resources, this pane becomes yellow as does the Extraction Results pane. You can reextract to get the latest extraction results and the yellow coloring will disappear. However, each time an extraction is performed, the Clusters pane is cleared and you will have to rebuild your clusters. Likewise clusters are not saved from one session to another.

- [Building Clusters](#)
- [Cluster Definitions](#)
- [Microsoft Internet Explorer settings for Help](#)

Cluster Definitions

You can see all of the concepts inside a cluster by selecting it in the Clusters pane and opening the Cluster Definitions dialog box (View > Cluster Definitions).

All of the concepts in the selected cluster appear in the Cluster Definitions dialog box. If you select one or more concepts in the Cluster Definitions dialog box and click Display &, the Data pane will display all of the records or documents in which *all of the selected concepts appear together*. However, the Data pane does not display any text records or documents when you select a cluster in the Clusters pane. For general information on the Data pane, see [in](#).

Selecting concepts in this dialog box also changes the concept web graph. See the topic [Cluster Graphs](#) for more information. Similarly, when you select one or more concepts in the Cluster Definitions dialog box, the Visualization pane will show all of the external and internal links from those concepts.

Column Descriptions

Icons are shown so that you can easily identify each descriptor.

Table 1. Columns and Descriptor Icons

Columns	Description
Descriptors	The name of the concept.
 Global	Shows the number of times this descriptor appears in the entire dataset, also known as the global frequency.
 Docs	Shows the number of documents or records in which this descriptor appears, also known as the document frequency.
Type	Shows the type or types to which the descriptor belongs. If the descriptor is a category rule, no type name is shown in this column.

Toolbar Actions

From this dialog box, you can also select one or more concepts to use in a category. There are several ways to do this but it is most interesting to select concepts that cooccur in a cluster and add them as a category rule. See the topic [Co-occurrence Rules](#) for more information. You can use the toolbar buttons to add the concepts to categories.

Table 2. Toolbar buttons to add concepts to categories

Icons	Description
	Add the selected concepts to a new or existing category
	Add the selected concepts in the form of an & category rule to a new or existing category. See the topic Using Category Rules for more information.
	Add each of the selected concepts as its own new category
	Updates what is displayed in the Data pane and the Visualization pane according to the selected descriptors

Note: You can also add concepts to a type, as synonyms, or as exclude items using the context menus.

Related information

Exploring Text Link Analysis

In the Text Link Analysis (TLA) view, you can explore text link analysis pattern results. Text link analysis is a pattern-matching technology that enables you to define pattern rules and compare these to actual extracted concepts and relationships found in your text.

For example, extracting ideas about an organization may not be interesting enough to you. Using TLA, you could also learn about the links between this organization and other organizations or the people within an organization. You can also use TLA to extract opinions on products or, for some languages, the relationships between genes.

Once you've extracted some TLA pattern results, you can review them in the Type and Concept Patterns panes of the Text Link Analysis view. See the topic [Type and Concept Patterns](#) for more information. You can further explore them in the Data or Visualization panes in this view. Possibly most importantly, you can add them to categories.

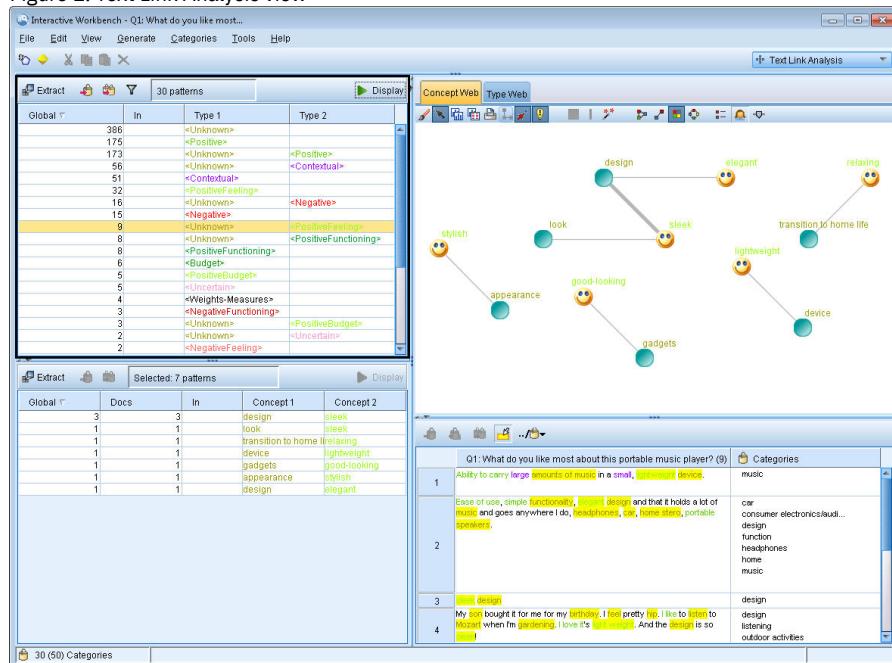

If you have not already chosen to do so, you can click Extract and choose Enable Text Link Analysis pattern extraction in the Extract Settings dialog box. See the topic [Extracting TLA Pattern Results](#) for more information.

There must be some TLA pattern rules defined in the resource template or libraries you are using in order to extract TLA pattern results. You can use the TLA patterns in certain resource templates shipped with IBM® SPSS® Modeler Text Analytics. The kind of relationships and patterns you can extract depend entirely on the TLA rules defined in your resources. You can define your own TLA rules. Patterns are made up of macros, word lists, and word gaps to form a Boolean query, or rule, that is compared to your input text. See the topic [About Text Link Rules](#) for more information.

Whenever a TLA pattern rule matches text, this text can be extracted as a pattern and restructured as output data. The results are then visible in the Text Link Analysis view panes. Each pane can be hidden or shown by selecting its name from the View menu:

- Type and Concept Patterns Panes. You can build and explore your patterns in these two panes. See the topic [Type and Concept Patterns](#) for more information.
- Visualization pane. You can visually explore how the concepts and types in your patterns interact in this pane. See the topic [Text Link Analysis Graphs](#) for more information.
- Data pane. You can explore and review text contained within documents and records that correspond to selections in another pane. See the topic [Data Pane](#) for more information.

Figure 1. Text Link Analysis view

- [Extracting TLA Pattern Results](#)
- [Type and Concept Patterns](#)
- [Filtering TLA Results](#)
- [Data Pane](#)
- [Type Reassignment Rules](#)

Extracting TLA Pattern Results

The extraction process results in a set of concepts and types, as well as Text Link Analysis (TLA) patterns, if enabled. If you extracted TLA patterns you can see those in the Text Link Analysis view. Whenever the extraction results are not in sync with the resources, the Patterns panes become yellow in color indicating that a reextraction would produce different results.

You have to choose to extract these patterns in the node setting or in the Extract dialog box using the option Enable Text Link Analysis pattern extraction. See the topic [Extracting data](#) for more information.

Note: There is a relationship between the size of your dataset and the time it takes to complete the extraction process. See the installation instructions for performance statistics and recommendations. You can always consider inserting a Sample node upstream or optimizing your machine's configuration.

To Extract Data

1. From the menus, choose Tools > Extract. Alternatively, click the Extract toolbar button.

2. Change any of the options you want to use. Keep in mind that the option Enable Text Link Analysis pattern extraction must be selected on this tab as well as having TLA rules in your template in order to extract TLA pattern results. See the topic [Extracting data](#) for more information.
3. Click Extract to begin the extraction process.

Once the extraction begins, the progress dialog box opens. If you want to abort the extraction, click Cancel. When the extraction is complete, the dialog box closes and the results appear in the pane. See the topic [Type and Concept Patterns](#) for more information.

-

Type and Concept Patterns

Patterns are made up of two parts, a combination of concepts and types. Patterns are most useful when you are attempting to discover opinions about a particular subject or relationships between concepts. For example, extracting your competitor's product name may not be interesting enough to you. In this case, you can look at the extracted patterns to see if you can find examples where a document or record contains text expressing that the product is good, bad, or expensive.

Patterns can consist of up to six types or six concepts. For this reason, the rows in both patterns panes contain up to six slots, or positions. Each slot corresponds to an element's specific position in the TLA pattern rule as it is defined in the linguistic resources. In the interactive workbench, if a slot contains no values, it is not shown in the table. For example, if the longest pattern results contain no more than four slots, the last two are not shown. See the topic [About Text Link Rules](#) for more information.

When you extract pattern results, they are first grouped at the type level and then divided into concept patterns. For this reason, there are two different result panes: Type Patterns (upper left) and Concept Patterns (lower left). To see all concept patterns returned, select all of the type patterns. The bottom concept patterns pane will then display all concept patterns up to the maximum rank value (as defined in the Filter dialog box).

Type Patterns This pane presents pattern results consisting of one or more related types matching a TLA pattern rule. Type patterns are shown as <Organization> + <Location> + <Positive>, which might provide positive feedback about an organization in a specific location. The syntax is as follows:

```
<Type1> + <Type2> + <Type3> + <Type4> + <Type5> + <Type6>
```

Concept Patterns This pane presents the pattern results at the concept level for all of the type pattern(s) currently selected in the Type Patterns pane above it. Concept patterns follow a structure such as **hotel + paris + wonderful**. The syntax is as follows:

```
concept1 + concept2 + concept3 + concept4 + concept5 + concept6
```

When pattern results use less than the six maximum slots, only the necessary number of slots (or columns) are displayed. Any empty slots found between two filled slots are discarded such that the pattern <Type1>+<>+<Type2>+<>+<>+<> can be represented by <Type1>+<Type3>. For a concept pattern, this would be **concept1+.+concept2** (where . represents a null value).

Just as with the extraction results in the Categories and Concepts view, you can review the results here. If you see any refinements you would like to make to the types and concepts that make up these patterns, you make those in the Extraction Results pane in the Categories and Concepts view or directly in the Resource Editor and reextract your patterns. Whenever a concept, type, or pattern is used in a category definition as is or as part of a rule, a category or rule icon appears in the In column in the Pattern or Extraction Results table.

Note: If there are more results that can fit in the visible pane, you can use the controls at the bottom of the pane to move forwards and backwards through the results, or enter a page number to go to.

- [Type Web Graph](#)
- [Microsoft Internet Explorer settings for Help](#)

Filtering TLA Results

When you are working with very large datasets, the extraction process could produce millions of results. For many users, this amount can make it more difficult to review the results effectively. You can, however, filter these results in order to zoom in on those that are most interesting. You can change the settings in the Filter dialog box to limit what patterns are shown. All of these settings are used together.

In the TLA view, the Filter dialog box contains the following areas and fields.

Filter by Frequency You can filter to display only those results with a certain global or document frequency value.

- Global frequency is the total number of times a pattern appears in the entire set of documents or records and is shown in the Global column.
- Document frequency is the total number of documents or records in which a pattern appears and is shown in the Docs column.

For example, if a pattern appeared 300 times in 500 records, we would say that this pattern has a global frequency of 300 and a document frequency of 500.

And by Match Text You can also filter to display only those results that match the rule you define here. Enter the set of characters to be matched in the Match text field, and select whether to look for this text within concept or type names by identifying the slot number or all of them. Then select the condition in which to apply the match (you do not need to use angled brackets to denote the beginning or end of a type name). Select either And or Or from the drop-down list so that the rule matches both statements or just one of them, and define the second text matching statement in the same manner as the first.

Table 1. Match text conditions

Condition	Description
Contains	Text is matched if the string occurs anywhere. (Default choice)
Starts with	Text is matched only if the concept or type starts with the specified text.
Ends with	Text is matched only if the concept or type ends with the specified text.
Exact Match	The entire string must match the concept or type name.

Results Displayed in Patterns Pane

Suppose you are using an English version of the software; here are some examples of how the results might be displayed on the Patterns pane toolbar based on the filters.

Figure 1. Filter results example 1

In this example, the toolbar shows that the number of patterns returned was limited because of the rank maximum specified in the filter. If a purple icon is present, this means that the maximum number of patterns was met. Hover over the icon for more information. See the preceding explanation of the And by Rank filter.

Figure 2. Filter results example 2

In this example, the toolbar shows results were limited using a match text filter (see magnifying glass icon). You can hover over the icon to see what the match text is.

To Filter the Results

1. From the menus, choose Tools > Filter. The Filter dialog box opens.
2. Select and refine the filters you want to use.
3. Click OK to apply the filters and see the new results.

-

Data Pane

As you extract and explore text link analysis patterns, you may want to review some of the data you are working with. For example, you may want to see the actual records in which a group of patterns were discovered. You can review records or documents in the Data pane, which is located in the lower right. If not visible by default, choose **View > Panes > Data** from the menus.

The Data pane presents one row per document or record corresponding to a selection in the view, up to a certain display limit. By default, the number of documents or records shown in the Data pane is limited in order to make it faster for you to see your data. However, you can adjust this in the Options dialog box. See [Options: Session Tab](#) for more information.

Note: If there are more results that can fit in the visible pane, you can use the controls at the bottom of the pane to move forwards and backwards through the results, or enter a page number to go to.

Displaying and refreshing the Data pane

The Data pane does not refresh its display automatically, because with larger datasets automatic data refreshing could take some time to complete. Therefore, whenever you select type or concept patterns in this view, you can click **Display** to refresh the contents of the Data pane.

Text Documents or Records

If your text data is in the form of records and the text is relatively short in length, the text field in the Data pane displays the text data in its entirety. However, when working with records and larger datasets, the text field column shows a short piece of the text and opens a Text Preview pane to the right to display more or all of the text of the record you have selected in the table. If your text data is in the form of individual documents, the Data pane shows the document's filename. When you select a document, the Text Preview pane opens with the selected document's text.

Colors and Highlighting

Whenever you display the data, concepts and descriptors found in those documents or records are highlighted in color to help you easily identify them in the text. The color coding corresponds to the types to which the concepts belong. You can also hover your mouse over color-coded items to display the concept under which it was extracted and the type to which it was assigned. Any text that was not extracted appears in black. Typically, these unextracted words are often connectors (*and* or *with*), pronouns (*me* or *they*), and verbs (*is*, *have*, or *take*).

Data Pane Columns

While the text field column is always visible, you can also display other columns. To display other columns, choose **View > Data Pane** from the menus, and then select the column that you want to display in the Data pane. The following columns may be available for display:

- "Text field name" (#)/Documents. Adds a column for the text data from which concepts and type were extracted. If your data is in documents, the column is called Documents and only the document filename or full path is visible. To see the text for those documents you must look in the Text Preview pane. The number of rows in the Data pane is shown in parentheses after this column name. There may be times when not all documents or records are shown due to a limit in the Options dialog used to increase the speed of loading. If the maximum is reached, the number will be followed by - Max. See [Options: Session Tab](#) for more information.
- Categories. Lists each of the categories to which a record belongs. Whenever this column is shown, refreshing the Data pane may take a bit longer so as to show the most up-to-date information.
- Force In. Lists the categories into which you have forced a document. Documents can be forced into the category through the **Edit > Force In** menu selection. See [Forcing documents into categories](#) for more information.
- Force Out. Lists the categories from which you have removed a document. Documents can be forced out of a category through the **Edit > Force Out** menu selection. For example, this might be used when a respondent's sarcasm causes a response to be miscategorized. See [Forcing documents into categories](#) for more information.
- Category Counts. Lists the number of the categories to which a record belongs.
- Relevance Ranks. Provides a rank for each record in a single category. This rank shows how well the record fits into the category compared to the other records in that category. Select a category in the Categories pane (upper left pane) to see the rank. See [Category Relevance](#) for more information.
- Response Flags. Adds a column that shows any flags you may be using. Click inside this column to change the type of flag that you assign to documents. You might flag documents with a "complete" flag or an "important" flag, or remove flags. This is useful for reviewing the completeness of a category model. See [Flagging responses](#) for more information.
- [Flagging responses](#)

Flagging responses

To help you monitor your progress, you can mark documents using flags in the Data pane. This feature is only available if the source document contains a unique ID. If the source document doesn't contain a unique ID, you can add a Derive node between the source document and the Text Mining node.

There are many reasons why you might want to mark a document, including:

- To mark off documents that you have manually reviewed so that you know where to pick up later
- To mark off a document that you are unsure about how to handle

Once you mark a document with a flag, you can continue to work with the documents. They are purely for your own record-keeping. You can choose from the following flags:

Table 1. Flag descriptions

Flag	Description
🏁	Complete flag to denote documents that you deem finished.
🚩	Important flag to denote documents that you deem important.

To mark a document with a flag:

1. From within the Data pane, right-click the document that you want to mark.
2. From the context menu, choose View > Data Pane > Response Flags and then select the type of flag that you want to use (Important Flag or Complete Flag). The selected flag is assigned. If the Flag column in the Data pane is not visible, it appears.

To clear flags:

1. From within the Data pane, right-click the documents for which you want to remove a flag.
2. From the context menu, choose Mark Responses With > Clear Flags. The selected flags are removed.

Type Reassignment Rules

Type Reassignment Rules (TRRs) aim to transform a sequence of types, macros, and/or tokens into a new concept with a specific type. Specifically, they're used in Opinions templates to catch opinions with a change in polarity. For example, in the phrase "**not that bad**," the word "**bad**" is a *negative* opinion. But in this context, the real meaning is "**not bad**" – which is a *positive*.

Up until version 18.2, this change in polarity was managed by specific Text Link Analysis (TLA) rules:

Figure 1. TLA rules

Element	Quantity	Example Token
{ mAdvNeg mSupportNeg mSupportNegPart mMisNeg }	Exactly 1	it's just not
{ mSupport mAdverb mToo }	0 or 1	?
mEmpty	Between 0 and 5	?
{ Neg Contextual }	Exactly 1	bad

Concept 1	Type 1	Concept 2	Type 2	Concept 3	Type 3	Concept 4	Type 4
good (4)	Positive						

Because of the different opinion types (**Positive**, **PositiveAttitude**, **PositiveBudget**, **PositiveCompetence**, **PositiveFeeling**, **PositiveFunctioning**, **PositiveRecommendation**, **Negative**, **NegativeAttitude**, **NegativeBudget**, **NegativeCompetence**, **NegativeFeeling**, **NegativeFunctioning**, **NegativeRecommendation**, and **Contextual**), it involved writing specific TLA rules:

- For each type. For example:

```
"not + xxx + <NegativeBudget>" => "<PositiveBudget>"
```

or

```
"not + xxx + <PositiveAttitude>" => "<NegativeAttitude>"
```

- For many syntactic contexts. For example:

```
* topic + negation + opinion ("hotel wasn't good")
* negation + opinion + topic ("it was not a good hotel")
* negation + opinion ("not very good")
* topic + opinion + negation + opinion ("hotel was well-located but not that good")
```

```
* 2 topics + negation + opinion ("room and swimming pool weren't always clean")
* ...
```

Beginning with version 18.2, the new approach is to "catch" such sequences (any negation + any empty word + a specific opinion), select the words to appear in the new concept (a standardized negation – for instance, "not" – and the opinion), and define a type for this new concept (aka, "pseudo-term"). This new concept can then be used in TLA rules.

As a consequence, the following rule will match any sequence containing a topic followed by an opinion, whether the opinion is a term (**comfortable**) or a psuedo-term (**not economical**), regardless of specific opinion sub-type (Attitude, Budget, etc).

```
#@# Bed was extremely comfortable
[pattern(190)]
name=topic + opinion_190
value=$mTopic {$_mEmpty|$_mToo} {0,3} {$_mOpinionPos|$_mOpinionNeg|$_Contextual}
output(1)=$1$t#1\$_3$t#3
```

Along with changing polarity for opinions, you can also use TRRs to help fine-tune your dictionary. For example, let's suppose you have a type called **Anatomy** with body parts such as **heart**, **chest**, **breast**, and **adrenal gland** – and another type called **MedicalProcedures** with procedures such as **biopsy**, **needle**

biopsy, **MRI**, and **CT scan**. It would be nearly impossible to list all the medical procedures correctly associated with an organ. So you could create two TRRs to identify potential medical procedures as seen in the following figures. Then once extraction is performed, you can add a filter on the type **PotentialMedicalProcedures**, review the candidate terms, and then add them to the **MedicalProcedures** type.

Figure 2. TRR for anatomy + medical procedures

Element	Quantity	Example Token
1 \$g Anatomy	Exactly 1	
2 \$g MedicalProcedures	Exactly 1	

Concept	Type
\$g PotentialMedicalProcedures	

Figure 3. TRR for medical procedures + anatomy

Element	Quantity	Example Token
1 \$g MedicalProcedures	Exactly 1	scan
2 \$g Anatomy	Exactly 1	of

Concept	Type
scan (4) (1)	\$g MedicalProcedures

Syntax

```
#@# not that expensive
[typeReassignmentRule]
name=TRR_"not" NegativeBudget
value=$mAllNeg {$_mAdverb|$_mBe|$_mHave|$_mSupport|$_mDet|that|more|$_mQuant} {0,3} $NegativeBudget
output=not $3\$_PositiveBudget
```

- "name" must be unique (**TRR_"not"**). It can't be used in a macro or in a TLA rule. Only the type defined in the output can be used.
 - "value" is a sequence of elements to match. The elements can be types (**\$NegativeBudget**), macros (**\$mAllNeg**) or tokens (**more**). Some elements can be required, optional, or have a specific quantity.
 - "output" is a SINGLE pair of concept+type (**not \$3\\$_PositiveBudget**). Note that in the output you can use an available type (one that is defined in the template) or you can create a new type.
- The output type can also reference a matched element (for example, **#2**). This feature is especially useful when there is no change in type between the value and the output. For example:

```
#@# could not have been any more pleased
[typeReassignmentRule]
name=TRR_"couldn't be more" opinion
value=$mNotNeg {$_mOpinionPos|$_mOpinionNeg|$_Contextual}
output=$2\$_#2
```

As in TLA rules, a more specific TRR must be defined before a more generic one. To ensure all TRRs are defined in the correct order, you can use the Get Tokens feature to test each TRR in sequence. If a TRR doesn't match, but matches another definition, you can move it down (or up).

Special cases

In some cases, it is necessary to still have access to the individual elements of the sequence and not to a TRR. This typically concerns coordination over negation. In the phrase "not that fashionable or eyecatching," the coordination "or" doesn't allow for discovering that, in this context, "eyecatching" actually means "not eyecatching."

In this case, we recommend using a specific rule such as:

```
#@# not that fashionable or eyecatching
[pattern(263)]
name="not" + 2 Positive_263
value=($mAdvNeg|$mSupportNeg|$mMiscNeg) @{0,1} $PositiveFeeling or $PositiveFeeling
output(1)=not $3\tNegativeFeeling
output(2)=not $5\tNegativeFeeling
```

Although the first part of the rule `(($mAdvNeg | $mSupportNeg | $mMiscNeg) @{0,1} $PositiveFeeling or $PositiveFeeling)` may match a TRR, the TLA rule will have priority.

If you write a more generic rule such as the following example, the same restrictions that existed in version 18.1.1 and prior will still apply. The new concept created (pseudo-concept) may have an incorrect type (`<Negative>` instead of `<NegativeFeeling>`), and you may end up with a TLA concept with two different types. A workaround is to create the corresponding term (not `xxx`) with the correct type.

```
#@# not that fashionable or eyecatching
[pattern(263)]
name="not" + 2 Positive_263
value=($mAdvNeg|$mSupportNeg|$mMiscNeg) @{0,1} $mPos or $mPos
output(1)=not $3\tNegative
output(2)=not $5\tNegative
```

Advantages

- The main advantage of using TRRs is to have less TLA rules.
- A less obvious advantage is that TRRs ensure that a pseudo-term will mostly result in the correct type (but keep in mind the restriction mentioned previously). In the past, some "`not + positiveXXX`" were typed as `Negative` instead of `NegativeXXX`, because some specific TLA rules were missing.
- If a user adds a specific opinion type (for example, `NegativeNoise`), there is no need to replicate specific TLA rules to invert polarity. The user just needs to create the relevant TRR.

Visualizing Graphs

The Categories and Concepts view, Clusters view, and Text Link Analysis view all have a visualization pane in the upper right corner of the window. You can use this pane to visually explore your data. The following graphs and charts are available.

- **Categories and Concepts view.** This view has three graphs and charts: *Category Bar*, *Category Web*, and *Category Web Table*. In this view, the graphs are only updated when you click Display. See the topic [Category Graphs and Charts](#) for more information.
- **Clusters view.** This view has two web graphs: *Concept Web Graph* and *Cluster Web Graph*. See the topic [Cluster Graphs](#) for more information.
- **Text Link Analysis view.** This view has two web graphs: *Concept Web Graph* and *Type Web Graph*. See the topic [Text Link Analysis Graphs](#) for more information.
- [Category Graphs and Charts](#)
- [Cluster Graphs](#)
- [Text Link Analysis Graphs](#)
- [Using Graph Toolbars and Palettes](#)

Related information

- [Category Graphs and Charts](#)
- [Cluster Graphs](#)
- [Text Link Analysis Graphs](#)
- [Using Graph Toolbars and Palettes](#)
- [Microsoft Internet Explorer settings for Help](#)

Category Graphs and Charts

When building your categories, it is important to take the time to review the category definitions, the documents or records they contain, and how the categories overlap. The visualization pane offers several perspectives on your categories. The Visualization pane is located in the upper right corner of the Categories and Concepts view . If it is not already visible, you can access this pane from the View menu (View > Panes > Visualization).

In this view, the visualization pane offers three perspectives on the commonalities in document or record categorization. The charts and graphs in this pane can be used to analyze your categorization results and aid in fine-tuning categories or reporting. When refining categories, you can use this pane to review your category definitions to uncover categories that are too similar (for example, they share more than 75% of their documents or records) or too distinct. If two categories are too similar, it might help you decide to combine the two categories. Alternatively, you might decide to refine the category definitions by removing certain descriptors from one category or the other.

Depending on what is selected in the Extraction Results pane, Categories pane, or in the Category Definitions dialog box, you can view the corresponding interactions between documents/records and categories on each of the tabs in this pane. Each presents similar information but in a different manner or with a different level of detail. However, in order to refresh a graph for the current selection, click Display on the toolbar of the pane or dialog box in which you have made your selection.

The Visualization pane in the Categories and Concepts view offers the following graphs and charts:

- **Category Bar Chart.** A table and bar chart present the overlap between the documents/records corresponding to your selection and the associated categories. The bar chart also presents ratios of the documents/records in categories to the total number of documents/records. See the topic [Category Bar Chart](#) for more information.
- **Category Web Graph.** This graph presents the document/record overlap for the categories to which the documents/records belong according to the selection in the other panes. See the topic [Category Web Graph](#) for more information.
- **Category Web Table.** This table presents the same information as the Category Web tab but in a table format. The table contains three columns that can be sorted by clicking the column headers. See the topic [Category Web Table](#) for more information.

See the topic [Categorizing text data](#) for more information.

- [Microsoft Internet Explorer settings for Help](#)

Category Bar Chart

This tab displays a table and bar chart showing the overlap between the documents/records corresponding to your selection and the associated categories. The bar chart also presents ratios of the documents/records in categories to the total number of documents or records . You cannot edit the layout of this chart. You can, however, sort the columns by clicking the column headers.

The chart contains the following columns:

- **Category.** This column presents the name of the categories in your selection. By default, the most common category in your selection is listed first.
- **Bar.** This column presents, in a visual manner, the ratio of the documents or records in a given category to the total number of documents or records.
- **Selection %.** This column presents a percentage based on the ratio of the total number of documents or records for a category to the total number of documents or records represented in the selection.
- **Docs.** This column presents the number of documents or records in a selection for the given category.

Related information

- [Category Graphs and Charts](#)
- [Category Web Graph](#)
- [Category Web Table](#)
- [Microsoft Internet Explorer settings for Help](#)

Category Web Graph

This tab displays a category web graph. The web presents the documents or records overlap for the categories to which the documents or records belong according to the selection in the other panes. If category labels exist, these labels appear in the graph. You can choose a graph layout (network, circle, directed, or grid) using the toolbar buttons in this pane.

In the web, each node represents a category. Using your mouse, you can select and move the nodes within the pane. The size of the node represents the relative size based on the number of documents or records for that category in your selection. The thickness and color of the line between two categories denotes the number of common documents or records they have. If you hover your mouse over a node in Explore mode, a ToolTip displays the name (or label) of the category and the overall number of documents or records in the category.

Note: By default, the Explore mode is enabled for the graphs on which you can move nodes. However, you can switch to Edit mode to edit your graph layouts including colors, fonts, legends, and more. For more information, see [Using Graph Toolbars and Palettes](#).

If you copy the graph data, using the Copy Visualization Data button, and paste it into a spreadsheet or text editor, you will see that the data is given column headers such as V1, V2, through to V7. These columns contain the following information:

- V1, V2 These values correspond to the screen coordinates (X and Y, respectively).
- V3, V5 List the category concept.
- Size, V6 Shows the number of documents the concepts were found in.
- V7 Currently unused.

Related information

- [Category Graphs and Charts](#)
- [Category Bar Chart](#)
- [Category Web Table](#)
- [Microsoft Internet Explorer settings for Help](#)

Category Web Table

This tab displays the same information as the Category Web tab but in a table format. The table contains three columns that can be sorted by clicking the column headers:

- **Count.** This column presents the number of shared, or common, documents or records between the two categories.
- **Category 1.** This column presents the name of the first category followed by the total number of documents or records it contains, shown in parentheses.
- **Category 2.** This column presents the name of the second category followed by the total number of documents or records it contains, shown in parentheses.

Related information

- [Category Graphs and Charts](#)

- [Microsoft Internet Explorer settings for Help](#)

Fixing Errors

Sometimes a visualization cannot be rendered. In this case, the Unable to Render Visualization dialog box appears.

To revert to the state of the visualization before the error occurred, click Undo. Alternatively, you can click Continue to proceed in spite of the error. After continuing, no visualization is displayed until you fix the problem.

Cluster Graphs

After building your clusters, you can explore them visually in the web graphs in the Visualization pane. The visualization pane offers two perspectives on clustering: a Concept Web graph and a Cluster Web graph. The web graphs in this pane can be used to analyze your clustering results and aid in uncovering some concepts and rules you may want to add to your categories. The Visualization pane is located in the upper

right corner of the Clusters view. If it isn't already visible, you can access this pane from the View menu (View > Panes > Visualization). By selecting a cluster in the Clusters pane, you can automatically display the corresponding graphs in the Visualization pane.

Note: By default, the graphs are in the interactive/selection mode in which you can move nodes. However, you can edit your graph layouts in Edit mode, including colors and fonts, legends, and more. See the topic [Using Graph Toolbars and Palettes](#) for more information.

The Clusters view has two web graphs.

- **Concept Web Graph.** This graph presents all of the concepts within the selected cluster(s) as well as linked concepts outside the cluster. This graph can help you see how the concepts within a cluster are linked and any external links. See the topic [Concept Web Graph](#) for more information.
- **Cluster Web Graph.** This graph presents the selected cluster(s) with all of the external links between the selected clusters shown as dotted lines. See the topic [Cluster Web Graph](#) for more information.

See the topic [Analyzing clusters](#) for more information.

- [Concept Web Graph](#)
- [Cluster Web Graph](#)

Related information

- [Visualizing Graphs](#)
- [Category Graphs and Charts](#)
- [Text Link Analysis Graphs](#)
- [Using Graph Toolbars and Palettes](#)
- [Concept Web Graph](#)
- [Cluster Web Graph](#)
- [Microsoft Internet Explorer settings for Help](#)

Concept Web Graph

This tab displays a web graph showing all of the concepts within the selected cluster(s) as well as linked concepts outside the cluster. This graph can help you see how the concepts within a cluster are linked and any external links. Each concept in a cluster is represented as a node, which is color coded according to the type color. See the topic [Creating types](#) for more information.

The internal links between the concepts within a cluster are drawn and the line thickness of each link is directly related to either the doc count for each concept pair's co-occurrence or the similarity link value, depending on your choice on the graph toolbar. The external links between a cluster's concepts and those concepts outside the cluster are also shown.

If concepts are selected in the Cluster Definitions dialog box, the Concept Web graph will display those concepts and any associated internal and external links to those concepts. Any links between other concepts that do not include one of the selected concepts do not appear on the graph.

Note: By default, the graphs are in the interactive/selection mode in which you can move nodes. However, you can edit your graph layouts in Edit mode including colors and fonts, legends, and more. For more information, see [Using Graph Toolbars and Palettes](#).

If you copy the graph data, using the Copy Visualization Data button, and paste it into a spreadsheet or text editor, you will see that the data is given column headers such as V1, V2, through to V7. These columns contain the following information:

- V1, V2 These values correspond to the screen coordinates (X and Y, respectively).
- V3, V6 List the concept type.
- V4, V5 Shows the concept label.
- V7 Currently unused.

Related information

- [Cluster Graphs](#)
- [Cluster Web Graph](#)
- [Microsoft Internet Explorer settings for Help](#)

Cluster Web Graph

This tab displays a web graph showing the selected cluster(s). The external links between the selected clusters as well as any links between other clusters are all shown as dotted lines. In a Cluster Web graph, each node represents an entire cluster and the thickness of lines drawn between them represents the number of external links between two clusters.

Important! In order to display a Cluster Web graph, you must have already built clusters with external links. External links are links between concept pairs in separate clusters (a concept within one cluster and a concept outside in another cluster).

For example, let's say we have two clusters. **Cluster A** has three concepts: **A1**, **A2**, and **A3**. **Cluster B** has two concepts: **B1** and **B2**. The following concepts are linked: **A1-A2**, **A1-A3**, **A2-B1** (External), **A2-B2** (External), **A1-B2** (External), and **B1-B2**. This means that in the Cluster Web graph, the line thickness would represent the three external links.

Note: By default, the graphs are in the interactive/selection mode in which you can move nodes. However, you can edit your graph layouts in Edit mode including colors and fonts, legends, and more. See the topic [Using Graph Toolbars and Palettes](#) for more information.

Text Link Analysis Graphs

After extracting your Text Link Analysis (TLA) patterns, you can explore them visually in the web graphs in the Visualization pane. The visualization pane offers two perspectives on TLA patterns: a concept (pattern) web graph and a type (pattern) web graph. The web graphs in this pane can be used to visually represent patterns. The Visualization pane is located in the upper right corner of the Text Link Analysis. If it isn't already visible, you can access this pane from the View menu (View > Panes > Visualization). If there is no selection, then the graph area is empty.

Note: By default, the graphs are in the interactive/selection mode in which you can move nodes. However, you can edit your graph layouts in Edit mode including colors and fonts, legends, and more. See the topic [Using Graph Toolbars and Palettes](#) for more information.

The Text Link Analysis view has two web graphs.

- **Concept Web Graph.** This graph presents all the concepts in the selected pattern(s). The line width and node sizes (if type icons are not shown) in a concept graph show the number of global occurrences in the selected table. See the topic [Concept Web Graph](#) for more information.
- **Type Web Graph.** This graph presents all the types in the selected pattern(s). The line width and node sizes (if type icons are not shown) in the graph show the number of global occurrences in the selected table. Nodes are represented by either a type color or by an icon. See the topic [Type Web Graph](#) for more information.

See the topic [Exploring Text Link Analysis](#) for more information.

Concept Web Graph

This web graph presents all of the concepts represented in the current selection. For example, if you selected a type pattern that had three matching concept patterns, this graph would show three sets of linked concepts. The line width and node sizes in a concept graph represent the global frequency counts. The graph visually represents the same information as what is selected in the patterns panes. The types of each concept are presented either by a color or by an icon depending on what you select on the graph toolbar. See the topic [Using Graph Toolbars and Palettes](#) for more information.

-

Type Web Graph

This web graph presents each type pattern for the current selection. For example, if you selected two concept patterns, this graph would show one node per type in the selected patterns and the links between those it found in the same pattern. The line width and node sizes represent the global frequency counts for the set. The graph visually represents the same information as what is selected in the patterns panes. In addition to the type names appearing in the graph, the types are also identified either by their color or by a type icon, depending on what you select on the graph toolbar. See the topic [Using Graph Toolbars and Palettes](#) for more information.

Using Graph Toolbars and Palettes

For each graph, there is a toolbar that provides you with quick access to some common palettes from which you can perform a number of actions with your graphs. Each view (Categories and Concepts, Clusters, and Text Link Analysis) has a slightly different toolbar. You can choose between the *Explore* view mode or the *Edit* view mode.

While *Explore* mode allows you to analytically explore the data and values represented by the visualization, *Edit* mode allows you to change the visualization's layout and look. For example, you can change the fonts and colors to match your organization's style guide. To select this mode, choose *View* > *Visualization Pane* > *Edit Mode* from the menus (or click the toolbar icon).

In *Edit* mode, there are several toolbars that affect different aspects of the visualization's layout. If you find that there are any you don't use, you can hide them to increase the amount of space in the dialog box in which the graph is displayed. To select or deselect toolbars, click on the relevant toolbar or palette name on the *View* menu.

Table 1. Text Analytics Toolbar buttons

Button/List	Description
	Enables Edit mode. Switch to the Edit mode to change the look of the graph, such as enlarging the font, changing the colors to match your corporate style guide, or removing labels and legends.
	Enables Explore mode. By default, the Explore mode is turned on, which means that you can move and drag nodes around the graph as well as hover over graph objects to reveal additional ToolTip information.
	Select a type of web display for the graphs in the Categories and Concepts view as well as the Text Link Analysis view. <ul style="list-style-type: none">• Circle Layout A general layout that can be applied to any graph. It lays out a graph assuming that links are undirected and treats all nodes the same. Nodes are only placed around the perimeter of a circle.• Network Layout A general layout that can be applied to any graph. It lays out a graph assuming that links are undirected and treats all nodes the same. Nodes are placed freely within the layout.• Directed Layout A layout that should only be used for directed graphs. This layout produces treelike structures from root nodes down to leaf nodes and organizes by colors. Hierarchical data tends to display nicely with this layout.• Grid Layout A general layout that can be applied to any graph. It lays out a graph assuming that links are undirected and treats all nodes the same. Nodes are only placed at grid points within the space.

Button/List	Description
	Link size representation. Choose what the thickness of the line represents in the graph. This only applies to the Clusters view. The Clusters web graph only shows the number of external links between clusters. You can choose between: <ul style="list-style-type: none"> Similarity Thickness indicates the number of external links between two clusters Co-occurrence Thickness indicates the number of documents in which a co-occurrence of descriptors takes place.
	A toggle button that, when pressed, displays the legend. When the button is not pushed, the legend is not shown.
	A toggle button that, when pressed, displays the type icons in the graph rather than type colors. This only applies to Text Link Analysis view.
	A toggle button that, when pressed, displays the Links Slider beneath the graph. You can filter the results by sliding the arrow.
	Will display the graph for highest level of categories selected rather than for their subcategories.
	Will display the graph for lowest level of categories selected.
	This option controls how the names of subcategories are displayed in the output. <ul style="list-style-type: none"> Full category path This option will output the name of the category and the full path of parent categories if applicable using slashes to separate category names from subcategory names. Short category path This option will output only the name of the category but use ellipses to show the number of parent categories for the category in question. Bottom level category This option will output only the name of the category without the full path or parent categories shown.

Session Resource Editor

IBM® SPSS® Modeler Text Analytics rapidly and accurately captures and extracts key concepts from text data. This extraction process relies heavily on linguistic resources to dictate how to extract information from text data. By default, these resources come from resource templates.

IBM SPSS Modeler Text Analytics is shipped with a set of specialized **resource templates** that contain a set of linguistic and nonlinguistic resources, in the form of libraries and advanced resources, to help define how your data will be handled and extracted. See the topic [Templates and Resources](#) for more information.

In the node dialog box, you can load a copy of the template's resources into the node. Once inside an interactive workbench session, you can customize these resources specifically for this node's data, if you wish. During an interactive workbench session, you can work with your resources in the Resource Editor view. Whenever an interactive session is launched, an extraction is performed using the resources loaded in the node dialog box, unless you have cached your data and extraction results in your node.

Editing resources in the Resource Editor

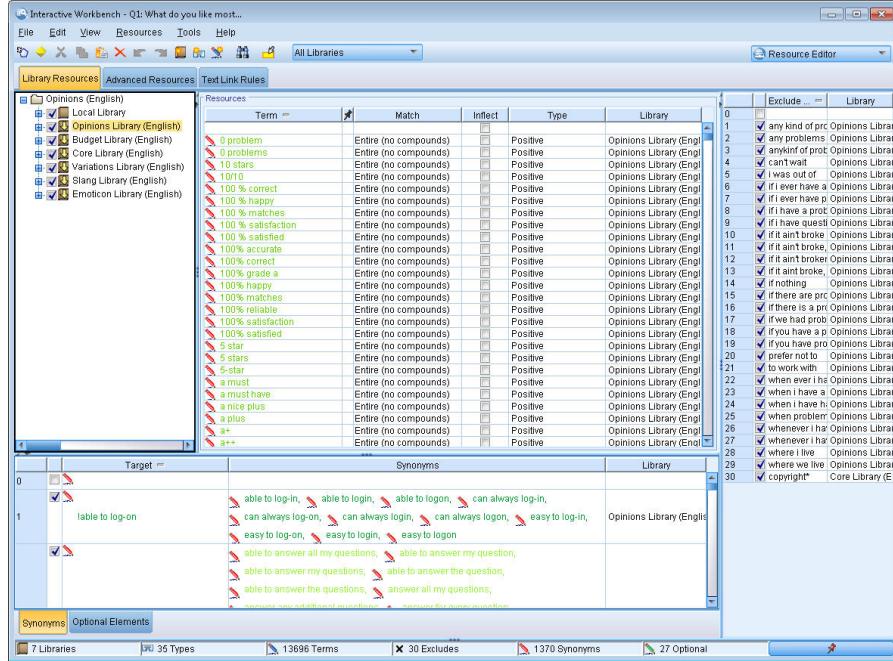

The Resource Editor offers access to the set of resources used to produce the extraction results (concepts, types, and patterns) for an interactive workbench session. This editor is very similar to the Template Editor except that in the Resource Editor you are editing the resources for this session. When you are finished working on your resources and any other work you've done, you can update the modeling node to save this work so that it can be restored in a subsequent interactive workbench session. See the topic [Updating Modeling Nodes and Saving](#) for more information.

If you want to work directly on the templates used to load resources into nodes, we recommend you use the Template Editor. Many of the tasks you can perform inside the Resource Editor are performed just like they are in the Template Editor, such as:

- Working with libraries. See the topic [Working with Libraries](#) for more information.
- Creating type dictionaries. See the topic [Creating types](#) for more information.
- Adding terms to dictionaries. See the topic [Adding terms](#) for more information.
- Creating synonyms. See the topic [Defining synonyms](#) for more information.
- Importing and exporting templates. See the topic [Importing and Exporting Templates](#) for more information.
- Publishing libraries. See the topic [Publishing Libraries](#) for more information.

For Dutch, English, French, German, Italian, Portuguese, and Spanish Text

Figure 1. Resource Editor view

Making and Updating Templates

Whenever you make changes to your resources and want to reuse them in the future, you can save the resources as a template. When doing so, you can choose to save using an existing template name or by providing a new name. Then, whenever you load this template in the future, you'll be able to obtain the same resources. See the topic [Copying resources from templates and TAPs](#) for more information.

Note: You can also publish and share your libraries. See the topic [Sharing Libraries](#) for more information.

To Make (or Update) a Template

1. From the menus in the Resource Editor view, choose Resources > Make Resource Template. The Make Resource Template dialog box opens.

2. Enter a new name in the Template Name field, if you want to make a new template. Select a template in the table, if you want to overwrite an existing template with the currently loaded resources.
3. Click Save to make the template.

Important! Since templates are loaded when you select them in the node and not when the stream is executed, please make sure to reload the resource template in any other nodes in which it is used if you want to get the latest changes. See the topic [Updating Node Resources After Loading](#) for more information.

Switching resource templates

If you want to replace the resources currently loaded in the session with a copy of those from another template, you can switch to those resources. Doing so will overwrite any resources currently loaded in the session. If you are switching resources in order to have some predefined Text Link Analysis (TLA) pattern rules, make sure to select a template that has them marked in the TLA column.

Switching resources is particularly useful when you want to restore the session work (categories, patterns, and resources) but want to load an updated copy of the resources from a template without losing your other session work. You can select the template whose contents you want to copy into the Resource Editor and click OK. This replaces the resources you have in this session. Make sure you update the modeling node at the end of your session if you want to keep these changes next time you launch the interactive workbench session.

Note: If you switch to the contents of another template during an interactive session, the name of the template listed in the node will still be the name of the last template loaded and copied. In order to benefit from these resources or other session work, update your modeling node before exiting the session and select the Use session work option in the node. See the topic [Updating Modeling Nodes and Saving](#) for more information.

To switch resources

1. From the menus in the Resource Editor view, choose Resources > Switch Resource Templates. The Switch Resources dialog box opens.
2. Select the template you want to use from those shown in the table.
3. Click OK to abandon those resources currently loaded and load a copy of those in the selected template in their place. If you have made changes to your resources and want to save your libraries for a future use, you can publish, update, and share them before switching. See the topic [Sharing Libraries](#) for more information.

Templates and Resources

IBM® SPSS® Modeler Text Analytics rapidly and accurately captures and extracts key concepts from text data. This extraction process relies heavily on linguistic resources to dictate how to extract information from text data. See the topic [How extraction works](#) for more information. You can fine-tune these resources in the Resource Editor view.

When you install the software, you also get a set of specialized resources. These shipped resources allow you to benefit from years of research and fine-tuning for specific languages and specific applications. Since the shipped resources may not always be perfectly adapted to the context of your data, you can edit these resource templates or even create and use custom libraries uniquely fine-tuned to your organization's data. These resources come in various forms and each can be used in your session. Resources can be found in the following:

- **Resource templates.** Templates are made up of a set of libraries, types, and some advanced resources which together form a specialized set of resources adapted to a particular domain or context such as product opinions.
- **Text analysis packages (TAP).** In addition to the resources stored in a template, TAPs also bundle together one or more specialized category sets generated using those resources so that both the categories and the resources are stored together and reusable. See the

topic [Using Text Analysis Packages](#) for more information.

- **Libraries.** Libraries are used as building blocks for both TAPs and templates. They can also be added individually to resources in your session. Each library is made up of several dictionaries used to define and manage types, synonyms, and exclude lists. While libraries are also delivered individually, they are prepackaged together in templates and TAPs. See the topic [Working with Libraries](#) for more information.

Note: During extraction, some compiled internal resources are also used. These compiled resources contain a large number of definitions complementing the types in the Core library. These compiled resources cannot be edited.

The Resource Editor offers access to the set of resources used to produce the extraction results (concepts, types, and patterns). There are a number of tasks you might perform in the Resource Editor and they include:

- **Working with libraries.** See the topic [Working with Libraries](#) for more information.
 - **Creating type dictionaries.** See the topic [Creating types](#) for more information.
 - **Adding terms to dictionaries.** See the topic [Adding terms](#) for more information.
 - **Creating synonyms.** See the topic [Defining synonyms](#) for more information.
 - **Updating the resources in TAPs.** See the topic [Updating Text Analysis Packages](#) for more information.
 - **Making templates.** See the topic [Making and Updating Templates](#) for more information.
 - **Importing and exporting templates.** See the topic [Importing and Exporting Templates](#) for more information.
 - **Publishing libraries.** See the topic [Publishing Libraries](#) for more information.

Template Editor vs. Resource Editor

There are two main methods for working with and editing your templates, libraries, and their resources. You can work on linguistic resources in the Template Editor or the Resource Editor.

Template Editor

The Template Editor allows you to create and edit resource templates without an interactive workbench session and independent of a specific node or stream. You can use this editor to create or edit resource templates before loading them into the Text Link Analysis node and the Text Mining modeling node.

The Template Editor is accessible through the main IBM® SPSS® Modeler toolbar from the Tools > Text Analytics Template Editor menu.

Resource Editor

The Resource Editor, which is accessible within an interactive workbench session, allows you to work with the resources in the context of a specific node and dataset. When you add a Text Mining modeling node to a stream, you can load a copy of a resource template's content or a copy of a text analysis package (category sets and resources) to control how text is extracted for text mining. When you launch an interactive workbench session, in addition to creating categories, extracting text link analysis patterns, and creating category models, you can also fine-tune the resources for that session's data in the integrated Resource Editor view. See the topic [Editing resources in the Resource Editor](#) for more information.

Whenever you work on the resources in an interactive workbench session, those changes apply only to that session. If you want to save your work (resources, categories, patterns, etc.) so you can continue in a subsequent session, you must update the modeling node. See the topic [Updating Modeling Nodes and Saving](#) for more information.

If you want to save your changes back to the original template, whose contents were copied into the modeling node, so that this updated template can be loaded into other nodes, you can make a template from the resources. See the topic [Making and Updating Templates](#) for more information.

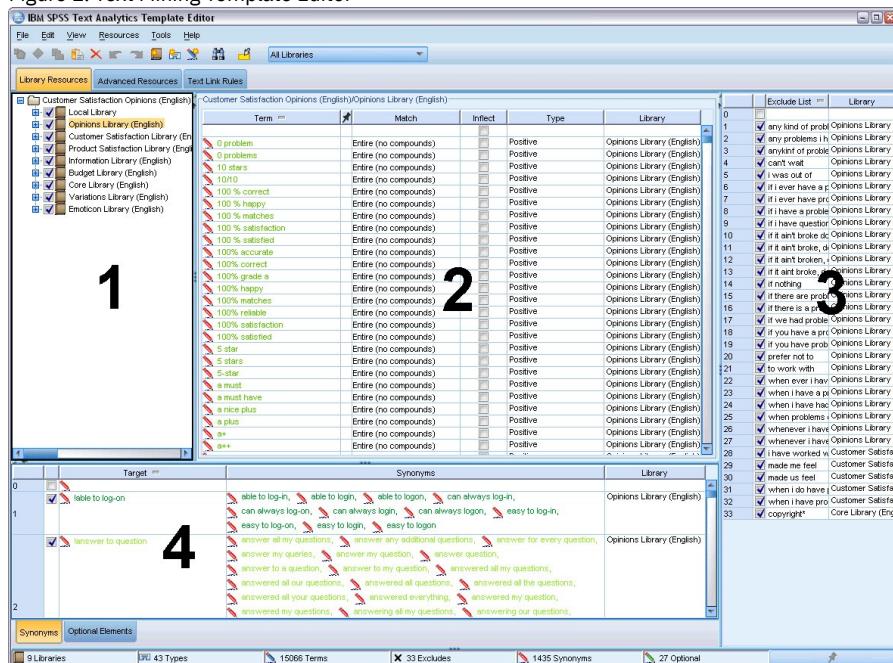

Note: If you make changes to templates or libraries and save them to a backup directory, and then upgrade your version of IBM SPSS Modeler Text Analytics, you will be given the option of importing your custom templates and libraries. The first time you run a SPSS Modeler Text Analytics stream or open the Resource Editor after an upgrade, default templates and libraries are copied to your machine. A Saved templates warning or a Saved libraries warning (or both) is displayed with a list of the templates and/or libraries that are updated as part of the product upgrade, and you are given the option of importing your custom templates and libraries from the directory in which you saved them. After clicking OK in the warning message, you can open the Manage resource templates dialog or the Manage libraries dialog at any time to choose which custom templates or libraries you want to import.

The Editor interface

The operations that you perform in the Template Editor or Resource Editor revolve around the management and fine-tuning of the linguistic resources. These resources are stored in the form of templates and libraries. See the topic [Type dictionaries](#) for more information.

Library Resources tab

Figure 1. Text Mining Template Editor

The interface is organized into four parts, as follows:

1. Library Tree pane. Located in the upper left corner, this pane displays a tree of the libraries. You can enable and disable libraries in this tree as well as filter the views in the other panes by selecting a library in the tree. You can perform many operations in this tree using the context menus. If you expand a library in the tree, you can see the set of types it contains. You can also filter this list through the View menu if you want to focus on a particular library only.

2. Term Lists from Type Dictionaries pane. Located to the right of the library tree, this pane displays the term lists of the type dictionaries for the libraries selected in the tree. A **type dictionary** is a collection of terms to be grouped under one label, or type, name. When the extraction engine reads your text data, it compares words found in the text to the terms in the type dictionaries. If an extracted concept appears as a term

in a type dictionary, then that type name is assigned. You can think of the type dictionary as a distinct dictionary of terms that have something in common. For example, the `<Location>` type in the Core library contains concepts such as `new orleans`, `great britain`, and `new york`. These terms all represent geographical locations. A library can contain one or more type dictionaries. See the topic [Type dictionaries](#) for more information.

3. Exclude Dictionary pane. Located on the right side, this pane displays the collection of terms that will be excluded from the final extraction results. The terms appearing in this exclude dictionary do not appear in the Extraction Results pane. Excluded terms can be stored in the library of your choosing. However, the Exclude Dictionary pane displays all of the excluded terms for all libraries visible in the library tree. See the topic [Exclude dictionaries](#) for more information.

4. Substitution Dictionary pane. Located in the lower left, this pane displays synonyms and optional elements, each in their own tab. Synonyms and optional elements help group similar terms under one lead, or target, concept in the final extraction results. This dictionary can contain known synonyms and user-defined synonyms and elements, as well as common misspellings paired with the correct spelling. Synonym definitions and optional elements can be stored in the library of your choosing. However, the substitution dictionary pane displays all of the contents for all libraries visible in the library tree. While this pane displays all synonyms or optional elements from all libraries, the substitutions for all of the libraries in the tree are shown together in this pane. A library can contain only one substitution dictionary. See the topic [Substitution/Synonym dictionaries](#) for more information.

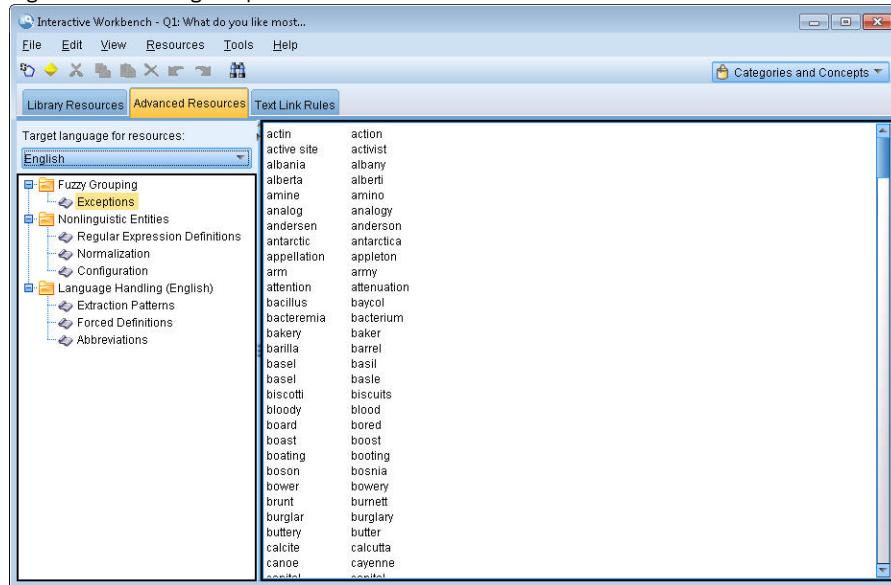

Notes:

- If you want to filter so that you see only the information pertaining to a single library, you can change the library view using the drop-down list on the toolbar. It contains a top-level entry called All Libraries as well as an additional entry for each individual library. See the topic [Viewing Libraries](#) for more information.

Advanced Resources tab

The advanced resources are available from the second tab of the editor view. You can review and edit the advanced resources in this tab. See the topic [About Advanced Resources](#) for more information.

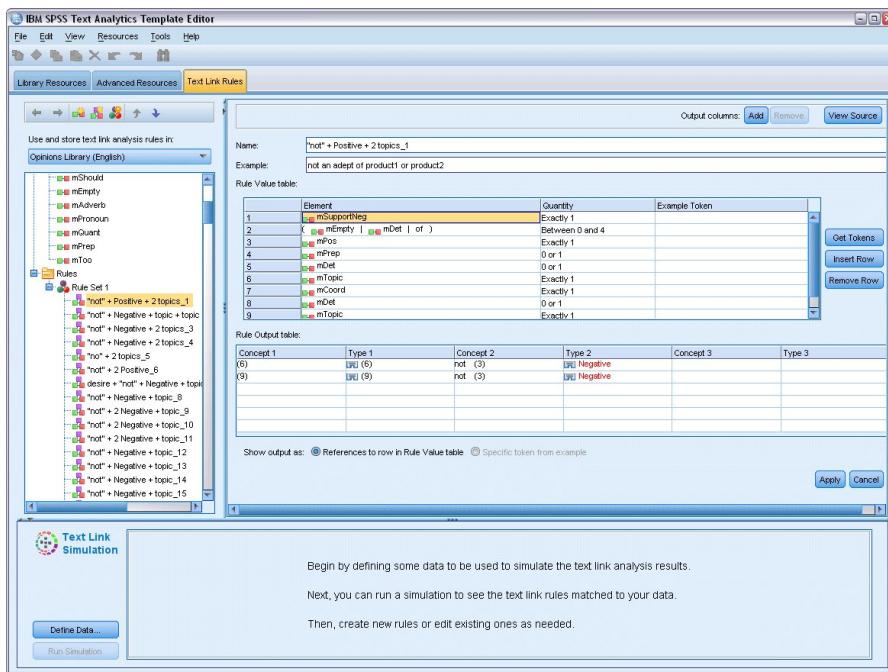

Figure 2. Text Mining Template Editor - Advanced Resources tab

Text Link Rules tab

Since version 14, the text link analysis rules are editable in their own tab of the editor view. You can work in the rule editor, create your own rules, and even run simulations to see how your rules impact the TLA results. See the topic [About Text Link Rules](#) for more information.

Figure 3. Text Mining Template Editor - Text Link Rules tab

Opening Templates

When you launch the Template Editor, you are prompted to open a template. Likewise, you can open a template from the File menu. If you want a template that contains some Text Link Analysis (TLA) rules, make sure to select a template that has an icon in the TLA column. The language for which a template was created is shown in the Language column.

If you want to import a template that isn't shown in the table or if you want to export a template, you can use the buttons in the Open Template dialog box. See the topic [Importing and Exporting Templates](#) for more information.

To Open a Template

1. From the menus in the Template Editor, choose File > Open Resource Template. The Open Resource Template dialog box opens.
2. Select the template you want to use from those shown in the table.
3. Click OK to open this template. If you currently have another template open in the editor, clicking OK will abandon that template and display the template you selected here. If you have made changes to your resources and want to save your libraries for a future use, you can publish, update, and share them before opening another. See the topic [Sharing Libraries](#) for more information.

- [Microsoft Internet Explorer settings for Help](#)

Saving Templates

In the Template Editor, you can save the changes you made to a template. You can choose to save using an existing template name or by providing a new name.

If you make changes to a template that you've already loaded into a node at a previous time, you will have to reload the template contents into the node to get the latest changes. See the topic [Copying resources from templates and TAPs](#) for more information.

Or, if you are using the option Use saved interactive work in the Model tab of the Text Mining node, meaning you are using resources from a previous interactive workbench session, you'll need to switch to this template's resources from within the interactive workbench session. See the topic [Switching resource templates](#) for more information.

Note: You can also publish and share your libraries. See the topic [Sharing Libraries](#) for more information.

To Save a Template

1. From the menus in the Template Editor, choose File > Save Resource Template. The Save Resource Template dialog box opens.
2. Enter a new name in the Template name field, if you want to save this template as a new template. Select a template in the table, if you want to overwrite an existing template with the currently loaded resources.
3. If desired, enter a description to display a comment or annotation in the table.
4. Click Save to save the template.

Important! Since resources from templates or TAPs are loaded/copied into the node, you must update the resources by reloading them if you make changes to a template and want to benefit from these changes in an existing stream. See the topic [Updating Node Resources After Loading](#) for more information.

Updating Node Resources After Loading

By default, when you add a node to a stream, a set of resources from a default template are loaded and embedded into your node. And if you change templates or use a TAP, when you load them, a copy of those resources then overwrites the resources. Since templates and TAPs are not linked to the node directly, any changes you make to a template or TAP are not automatically available in a preexisting node. In order to benefit from those changes, you would have to update the resources in that node. The resources can be updated in one of two ways.

Method 1: Reloading Resources in Model Tab

If you want to update the resources in the node using a new or updated template or TAP, you can reload it in the Model tab of the node. By reloading, you will replace the copy of the resources in the node with a more current copy. For your convenience, the updated time and date will appear on the Model tab along with the originating template's name. See the topic [Copying resources from templates and TAPs](#) for more information.

However, if you are working with interactive session data in a Text Mining modeling node and you have selected the Use session work option on the Model tab, the saved session work and resources will be used and the Load button is disabled. It is disabled because, at one time during an interactive workbench session, you chose the Update Modeling Node option and kept the categories, resources, and other session work. In that case, if you want to change or update those resources, you can try the next method of switching the resources in the Resource Editor.

Method 2: Switching Resources in the Resource Editor

Anytime you want to use different resources during an interactive session, you can exchange those resources using the Switch Resources dialog box. This is especially useful when you want to reuse existing category work but replace the resources. In this case, you can select the Use session work option on the Model tab of a Text Mining modeling node. Doing so will disable the ability to reload a template through the node dialog box and instead keep the settings and changes you made during your session. Then you can launch the interactive workbench session by executing the stream and switch the resources in the Resource Editor. See the topic [Switching resource templates](#) for more information.

In order to keep session work for subsequent sessions, including the resources, you need to update the modeling node from within the interactive workbench session so that the resources (and other data) are saved back to the node. See the topic [Updating Modeling Nodes and Saving](#) for more information.

Note: If you switch to the contents of another template during an interactive session, the name of the template listed in the node will still be the name of the last template loaded and copied. In order to benefit from these resources or other session work, update your modeling node before exiting the session.

Managing Templates

There are also some basic management tasks you might want to perform from time to time on your templates, such as renaming your templates, importing and exporting templates, or deleting obsolete templates. These tasks are performed in the Manage Templates dialog box. Importing and exporting templates enables you to share templates with other users. See the topic [Importing and Exporting Templates](#) for more information.

Note: You cannot rename or delete the templates that are installed (or shipped) with this product. Instead, if you want to rename, you can open the installed template and make a new one with the name of your choice. You can delete your custom templates; however, if you try to delete a shipped template, it will be reset to the version originally installed.

To Rename a Template

1. From the menus, choose Resources > Manage Resource Templates. The Manage Templates dialog box opens.
2. Select the template you want to rename and click Rename. The name box becomes an editable field in the table.
3. Type a new name and press the Enter key. A confirmation dialog box opens.
4. If you are satisfied with the name change, click Yes. If not, click No.

To Delete a Template

1. From the menus, choose Resources > Manage Resource Templates. The Manage Templates dialog box opens.
2. In the Manage Templates dialog box, select the template you want to delete.
3. Click Delete. A confirmation dialog box opens.
4. Click Yes to delete or click No to cancel the request. If you click Yes, the template is deleted.

Importing and Exporting Templates

You can share templates with other users or machines by importing and exporting them. Templates are stored in an internal database but can be exported as *.lrt files to your hard drive.

Since there are circumstances under which you might want to import or export templates, there are several dialog boxes that offer those capabilities.

- Open Template dialog box in the Template Editor
- Load Resources dialog box in the Text Mining modeling node and Text Link Analysis node.
- Manage Templates dialog box in the Template Editor and the Resource Editor.

To Import a Template

1. In the dialog box, click Import. The Import Template dialog box opens.
2. Select the resource template file (*.lrt) to import and click Import. You can save the template you are importing with another name or overwrite the existing one. The dialog box closes, and the template now appears in the table.

To Export a Template

1. In the dialog box, select the template you want export and click Export. The Select Directory dialog box opens.
2. Select the directory to which you want to export and click Export. This dialog box closes, and the template is exported and carries the file extension (*.lrt)

Exiting the Template Editor

When you are finished working in the Template Editor, you can save your work and exit the editor.

To Exit the Template Editor

1. From the menus, choose File > Close. The Save and Close dialog box opens.
2. Select Save changes to template in order to save the open template before closing the editor.
3. Select Publish libraries if you want to publish any of the libraries in the open template before closing the editor. If you select this option, you will be prompted to select the libraries to publish. See the topic [Publishing Libraries](#) for more information.

Related information

- [Managing Templates](#)
- [Importing and Exporting Templates](#)

- [Importing resource files](#)
- [Microsoft Internet Explorer settings for Help](#)

Backing Up Resources

You may want to back up your resources from time to time as a security measure.

Important! When you restore, the entire contents of your resources will be wiped clean and only the contents of the backup file will be accessible in the product. This includes any open work.

Note: You can only backup and restore to the same major version of your software. For example, if you backup from version 15, you cannot restore that backup to version 16.

To Back Up the Resources

1. From the menus, choose Resources > Backup Tools > Backup Resources. The Backup dialog box opens.
2. Enter a name for your backup file and click Save. The dialog box closes, and the backup file is created.

To Restore the Resources

1. From the menus, choose Resources > Backup Tools > Restore Resources. An alert warns you that restoring will overwrite the current contents of your database.
2. Click Yes to proceed. The dialog box opens.
3. Select the backup file you want to restore and click Open. The dialog box closes, and resources are restored in the application.

Importing resource files

If you have made changes directly in resource files outside of this product, you can import them into a selected library by selecting that library and proceeding with the import. When you import a directory, you can import all of supported files into a specific open library as well. You can only import *.txt files.

Each imported file must contain only one entry per line, and if the contents are structured as:

- A list words or phrases (one per line). The file is imported as a term list for a type dictionary, where the type dictionary takes the name of the file minus the extension.
- A list of entries such as `term1 <TAB> term2`, then it is imported as a list of synonyms, where `term1` is the set of the underlying term and `term2` is the target term.

To import a single resource file

1. From the menus, choose Resources > Import Files > Import Single File. The Import File dialog box opens.
2. Select the file you want to import and click Import. The file contents are transformed into an internal format and added to your library.

To import all files in a directory

1. From the menus, choose Resources > Import Files > Import Entire Directory. The Import Directory dialog box opens.
 2. Select the library in which you want all of the resource files imported from the Import list. If you select the Default option, a new library will be created using the name of the directory as its name.
 3. Select the directory from which to import the files. Subdirectories will not be read.
 4. Click Import. The dialog box closes and the content from those imported resource files now appears in the editor in the form of dictionaries and advanced resource files.
-

Working with Libraries

The resources used by the extraction engine to extract and group terms from your text data always contain one or more libraries. You can see the set of libraries in the library tree located in the upper left part of the Template Editor and Resource Editor. The libraries are composed of three kinds of dictionaries:

- Type dictionaries
- Substitution dictionaries
- Exclude dictionaries

See the topic [About Library Dictionaries](#) for more information.

The resource template or the resources from the TAP you chose includes several libraries to enable you to immediately begin extracting concepts from your text data. However, you can create your own libraries as well and also publish them so you can reuse them. See the topic [Publishing Libraries](#) for more information.

For example, suppose that you frequently work with text data related to the automotive industry. After analyzing your data, you decide that you would like to create some customized resources to handle industry-specific vocabulary or jargon. Using the Template Editor , you can create a new template, and in it a library to extract and group automotive terms. Since you will need the information in this library again, you publish your library to a central repository, accessible in the **Manage Libraries** dialog box, so that it can be reused independently in different stream sessions .

Suppose that you are also interested in grouping terms that are specific to different subindustries, such as electronic devices, engines, cooling systems, or even a particular manufacturer or market. You can create a library for each group and then publish the libraries so that they can be used with multiple sets of text data. In this way, you can add the libraries that best correspond to the context of your text data.

Note: Additional resources can be configured and managed in the Advanced Resources tab. Some apply to all of the libraries and manage nonlinguistic entities, fuzzy grouping exceptions, and so on. Additionally, you can edit the text link analysis pattern rules, which are library-specific, in the Text Link Rules tab as well. See the topic [About Advanced Resources](#) for more information.

Shipped libraries

By default, several libraries are installed with IBM® SPSS® Modeler Text Analytics. You can use these preformatted libraries to access thousands of predefined terms and synonyms as well as many different types. These shipped libraries are fine-tuned to several different domains and are available in several different languages.

There are a number of libraries but the most commonly used are as follows:

- Local library. Used to store user-defined dictionaries. It is an empty library added by default to all resources. It contains an empty type dictionary too. It is most useful when making changes or refinements to the resources directly (such as adding a word to a type) from the Categories and Concepts view, Clusters view, and the Text Link Analysis view . In this case, those changes and refinements are automatically stored in the first library listed in the library tree in the Resource Editor; by default, this is the *Local Library*. You cannot publish this library because it is specific to the session data. If you want to publish its contents, you must rename the library first.
- Core library. Used in most cases, since it comprises the basic five built-in types representing people, locations, organizations, products, and unknown. While you may see only a few terms listed in one of its type dictionaries, the types represented in the Core library are actually complements to the robust types found in the internal, compiled resources delivered with your text-mining product. These internal, compiled resources contain thousands of terms for each type. For this reason, while you may not see a term in the type dictionary term list, it can still be extracted and typed with a Core type. This explains how names such as *George* can be extracted and typed as *<Person>* when only *John* appears in the *<Person>* type dictionary in the Core library. Similarly, if you do not include the Core library, you may still see these types in your extraction results, since the compiled resources containing these types will still be used by the extraction engine.
- Opinions library. Used most commonly to extract opinions and sentiments from text data. This library includes thousands of words representing attitudes, qualifiers, and preferences that—when used in conjunction with other terms—indicate an opinion about a subject. This library includes a number of built-in types, synonyms, and excludes. It also includes a large set of pattern rules used for text link analysis. To benefit from the text link analysis rules in this library and the pattern results they produce, this library must be specified in the Text Link Rules tab. See the topic [About Text Link Rules](#) for more information.
- Budget library. Used to extract terms referring to the cost of something. This library includes many words and phrases that represent adjectives, qualifiers, and judgments regarding the price or quality of something.
- Variations library. Used to include cases where certain language variations require synonym definitions to properly group them. This library includes only synonym definitions.

Although some of the libraries shipped outside the templates resemble the contents in some templates, the templates have been specifically tuned to particular applications and contain additional advanced resources. We recommend that you try to use a template that was designed for the kind of text data you are working with and make your changes to those resources rather than just adding individual libraries to a more generic template.

Compiled resources are also delivered with IBM SPSS Modeler Text Analytics. They are always used during the extraction process and contain a large number of complementary definitions to the built-in type dictionaries in the default libraries. Since these resources are compiled, they cannot be viewed or edited. You can, however, force a term that was typed by these compiled resources into any other dictionary. See the topic [Forcing terms](#) for more information.

Creating Libraries

You can create any number of libraries. After creating a new library, you can begin to create type dictionaries in this library and enter terms, synonyms, and excludes.

To Create a Library

1. From the menus, choose Resources > New Library. The Library Properties dialog opens.
2. Enter a name for the library in the Name text box.
3. If desired, enter a comment in the Annotation text box.
4. Click Publish if you want to publish this library now before entering anything in the library. See the topic [Sharing Libraries](#) for more information. You can also publish later at any time.
5. Click OK to create the library. The dialog box closes and the library appears in the tree view. If you expand the libraries in the tree, you will see that an empty type dictionary has been automatically included in the library. In it, you can immediately begin adding terms. See the topic [Adding terms](#) for more information.

Adding public libraries

If you want to reuse a library from another session data, you can add it to your current resources as long as it is a public library. A *public library* is a library that has been published. See the topic [Publishing Libraries](#) for more information.

When you add a public library, a *local* copy is embedded into your session data. You can make changes to this library; however, you must republish the public version of the library if you want to share the changes.

When adding a public library, a Resolve Conflicts dialog box may appear if any conflicts are discovered between the terms and types in one library and the other local libraries. You must resolve these conflicts or accept the proposed resolutions in order to complete this operation. See the topic [Resolving Conflicts](#) for more information.

Note: If you always update your libraries when you launch an interactive workbench session or publish when you close one, you are less likely to have libraries that are out of sync. See the topic [Sharing Libraries](#) for more information.

To add a library

1. From the menus, choose Resources > Add Library. The Add Library dialog box opens.
 2. Select the library or libraries in the list.
 3. Click Add. If any conflicts occur between the newly added libraries and any libraries that were already there, you will be asked to verify the conflict resolutions or change them before completing the operation. See the topic [Resolving Conflicts](#) for more information.
-

Finding Terms and Types

You can search in the various panes in the editor using the Find feature. In the editor, you can choose Edit > Find from the menus and the Find toolbar appears. You can use this toolbar to find one occurrence at a time. By clicking Find again, you can find subsequent occurrences of your search term.

When searching, the editor searches only the library or libraries listed in the drop-down list on the Find toolbar. If All Libraries is selected, the program will search everything in the editor.

When you start a search, it begins in the area that has the focus. The search continues through each section, looping back around until it returns to the active cell. You can reverse the order of the search using the directional arrows. You can also choose whether or not your search is case sensitive.

To Find Strings in the View

1. From the menus, choose Edit > Find. The Find toolbar is displayed.
2. Enter the string for which you want to search.
3. Click the Find button to begin the search. The next occurrence of the term or type is then highlighted.
4. Click the button again to move from occurrence to occurrence.

Using an asterisk in terms

Using an asterisk (*) in terms is especially useful if you are dealing with an agglutinative language that creates new words by compounding other words together without intervening spaces. For example, the German word *Übernachtungspreis*, which is made up of: *Übernachtung* + *s* + *Preis*.

As an example, if you search in terms for *preis** in the type **Budget**, it will match extracted concepts such as *preiserhöhung*. In the same way, **preis* will match *Übernachtung* and **preis** will match *Übernachtungspreiserhöhung*.

Viewing Libraries

You can display the contents of one particular library or all libraries. This can be helpful when dealing with many libraries or when you want to review the contents of a specific library before publishing it. Changing the view only impacts what you see in this Library Resources tab but does not disable any libraries from being used during extraction. See the topic [Disabling Local Libraries](#) for more information.

The default view is All Libraries, which shows all libraries in the tree and their contents in other panes. You can change this selection using the drop-down list on the toolbar or through a menu selection (View > Libraries) When a single library is being viewed, all items in other libraries disappear from view but are still read during the extraction.

To Change the Library View

1. From the menus in the Library Resources tab, choose View > Libraries. A menu with all of the local libraries opens.
2. Select the library that you want to see or select the All Libraries option to see the contents of all libraries. The contents of the view are filtered according to your selection.

Managing Local Libraries

Local libraries are the libraries inside your interactive workbench session or inside a template, as opposed to public libraries. See the topic [Managing Public Libraries](#) for more information. There are also some basic local library management tasks that you might want to perform, including:

- Renaming a local library. See the topic [Renaming Local Libraries](#) for more information.
 - Disabling or enabling a local library. See the topic [Disabling Local Libraries](#) for more information.
 - Deleting a local library. See the topic [Deleting Local Libraries](#) for more information.
- [Renaming Local Libraries](#)
 - [Disabling Local Libraries](#)
 - [Deleting Local Libraries](#)

-

Renaming Local Libraries

You can rename local libraries. If you rename a local library, you will disassociate it from the public version, if a public version exists. This means that subsequent changes can no longer be shared with the public version. You can republish this local library under its new name. This also means that you will not be able to update the original public version with any changes that you make to this local version.

Note: You cannot rename a public library.

1. From the menus, choose Edit > Library Properties. The Library Properties dialog box opens.

To Rename a Local Library

1. In the tree view, select the library that you want to rename.
2. Enter a new name for the library in the Name text box.
3. Click OK to accept the new name for the library. The dialog box closes and the library name is updated in the tree view.

-

Disabling Local Libraries

If you want to temporarily exclude a library from the extraction process, you can deselect the check box to the left of the library name in the tree view. This signals that you want to keep the library but want the contents ignored when checking for conflicts and during extraction.

To Disable a Library

1. In the library tree pane, select the library you want to disable.
2. Click the spacebar. The check box to the left of the name is cleared.

Related information

- [Managing Local Libraries](#)
 - [Renaming Local Libraries](#)
 - [Deleting Local Libraries](#)
 - [Microsoft Internet Explorer settings for Help](#)
-

Deleting Local Libraries

You can remove a library without deleting the public version of the library and vice versa. Deleting a local library will delete the library and all of its content from session only. Deleting a local version of a library does not remove that library from other sessions or the public version. See the topic [Managing Public Libraries](#) for more information.

To Delete a Local Library

1. In the tree view, select the library you want to delete.
2. From the menus, choose Edit > Delete to delete the library. The library is removed.
3. If you have never published this library before, a message asking whether you would like to delete or keep this library opens. Click Delete to continue or Keep if you would like to keep this library.

Note: One library must always remain.

Managing Public Libraries

In order to reuse local libraries, you can publish them and then work with them and see them through the Manage Libraries dialog box (Resources > Manage Libraries). See the topic [Sharing Libraries](#) for more information. Some basic public library management tasks that you might want to perform include importing, exporting, or deleting a public library. You cannot rename a public library.

Importing Public Libraries

1. In the Manage Libraries dialog box, click Import.... The Import Library dialog box opens.
2. Select the library file (*.lib) that you want to import and if you also want to add this library locally, select Add library to current project.
3. Click Import. The dialog box closes. If a public library with the same name already exists, you will be asked to rename the library that you are importing or to overwrite the current public library.

Exporting Public Libraries

You can export public libraries into the .lib format so that you can share them.

1. In the Manage Libraries dialog box, select the library that you want to export in the list.
2. Click Export. The Select Directory dialog box opens.
3. Select the directory to which you want to export and click Export. The dialog box closes and the library file (*.lib) is exported.

Deleting Public Libraries

You can remove a local library without deleting the public version of the library and vice versa. However, if the library is deleted from this dialog box, it can no longer be added to any session resources until a local version is published again.

If you delete a library that was installed with the product, the originally installed version is restored.

1. In the Manage Libraries dialog box, select the library that you want to delete. You can sort the list by clicking on the appropriate header.
2. Click Delete to delete the library. IBM® SPSS® Modeler Text Analytics verifies whether the local version of the library is the same as the public library. If so, the library is removed with no alert. If the library versions differ, an alert opens to ask you whether you want to keep or remove the public version is issued.

Sharing Libraries

Libraries allow you to work with resources in a way that is easy to share among multiple interactive workbench sessions. Libraries can exist in two states, or versions. Libraries that are editable in the editor and part of an interactive workbench session are called **local libraries**. While working with in an interactive workbench session, you may make a lot of changes in the *Vegetables* library, for example. If your changes could be useful with other data, you can make these resources available by creating a **public library** version of the *Vegetables* library. A public library, as the name implies, is available to any other resources in any interactive workbench session.

You can see the public libraries in the Manage Libraries dialog box. Once this public library version exists, you can add it to the resources in other contexts so that these custom linguistic resources can be shared.

The shipped libraries are initially public libraries. It is possible to edit the resources in these libraries and then create a new public version. Those new versions would then be accessible in other interactive workbench sessions.

As you continue to work with your libraries and make changes, your library versions will become desynchronized. In some cases, a local version might be more recent than the public version, and in other cases, the public version might be more recent than the local version. It is also possible for both the public and local versions to contain changes that the other does not if the public version was updated from within another interactive workbench session. If your library versions become desynchronized, you can synchronize them again. Synchronizing library versions consists of republishing and/or updating local libraries.

Whenever you launch an interactive workbench session or close one, you will be prompted to synchronize any libraries that need updating or republishing. Additionally, you can easily identify the synchronization state of your local library by the icon appearing beside the library name in the tree view or by viewing the Library Properties dialog box. You can also choose to do so at any time through menu selections. The following table describes the five possible states and their associated icons.

Table 1. Local library synchronization states

Icon	Local library status description
	Unpublished—The local library has never been published.
	Synchronized—The local and public library versions are identical. This also applies to the <i>Local Library</i> , which cannot be published because it is intended to contain only session-specific resources.
	Out of date—The public library version is more recent than the local version. You can update your local version with the changes.
	Newer—The local library version is more recent than the public version. You can republish your local version to the public version.
	Out of sync—Both the local and public libraries contain changes that the other does not. You must decide whether to update or publish your local library. If you update, you will lose the changes that you made since the last time you updated or published. If you choose to publish, you will overwrite the changes in the public version.

Note: If you always update your libraries when you launch an interactive workbench session or publish when you close one, you are less likely to have libraries that are out of synchronization.

You can republish a library any time you think that the changes in the library would benefit other streams that may also contain this library. Then, if your changes would benefit other streams, you can update the local versions in those streams. In this way, you can create streams for each context or domain that applies to your data by creating new libraries and/or adding any number of public libraries to your resources.

If a public version of a library is shared, there is a greater chance that differences between local and public versions will arise. Whenever you launch or close and publish from an interactive workbench session or open or close a template from the Template Editor, a message is displayed to enable you to publish and/or update any libraries whose versions are not in sync with those in the Manage Libraries dialog box. If the public library version is more recent than the local version, a dialog box asking whether you would like to update opens. You can choose whether to keep the local version as is instead of updating with the public version or merge the updates into the local library.

- [Managing Public Libraries](#)
- [Microsoft Internet Explorer settings for Help](#)

Publishing Libraries

If you have never published a particular library, publishing entails creating a public copy of your local library in the database. If you are republishing a library, the contents of the local library will replace the existing public version's contents. After republishing, you can update this library in any other stream sessions so that their local versions are in sync with the public version. Even though you can publish a library, a local version is always stored in the session.

Important! If you make changes to your local library and, in the meantime, the public version of the library was also changed, your library is considered to be out of sync. We recommend that you begin by updating the local version with the public changes, make any changes that you want, and then publish your local version again to make both versions identical. If you make changes and publish first, you will overwrite any changes in the public version.

To Publish Local Libraries to the Database

1. From the menus, choose Resources > Publish Libraries. The Publish Libraries dialog box opens, with all libraries in need of publishing selected by default.
2. Select the check box to the left of each library that you want to publish or republish.
3. Click Publish to publish the libraries to the Manage Libraries database.

Related information

- [Sharing Libraries](#)
- [Updating Libraries](#)
- [Resolving Conflicts](#)
- [Microsoft Internet Explorer settings for Help](#)

Updating Libraries

Whenever you launch or close an interactive workbench session , you can update or publish any libraries that are no longer in sync with the public versions. If the public library version is more recent than the local version, a dialog box asking whether you would like to update the library opens. You can choose whether to keep the local version instead of updating with the public version or replacing the local version with the public one. If a public version of a library is more recent than your local version, you can update the local version to synchronize its content with that of the public version. Updating means incorporating the changes found in the public version into your local version.

Note: If you always update your libraries when you launch an interactive workbench session or publish when you close one , you are less likely to have libraries that are out of sync. See the topic [Sharing Libraries](#) for more information.

To Update Local Libraries

1. From the menus, choose Resources > Update Libraries. The Update Libraries dialog box opens, with all libraries in need of updating selected by default.
2. Select the check box to the left of each library that you want to publish or republish.
3. Click Update to update the local libraries.

Related information

- [Publishing Libraries](#)
- [Resolving Conflicts](#)
- [Microsoft Internet Explorer settings for Help](#)

Resolving Conflicts

Local versus Public Library Conflicts

Whenever you launch a stream session , IBM® SPSS® Modeler Text Analytics performs a comparison of the local libraries and those listed in the Manage Libraries dialog box. If any local libraries in your session are not in sync with the published versions, the Library Synchronization Warning dialog box opens. You can choose from the following options to select the library versions that you want to use here:

- **All libraries local to file.** This option keeps all of your local libraries as they are. You can always republish or update them later.
- **All published libraries on this machine.** This option will replace the shown local libraries with the versions found in the database.
- **All more recent libraries.** This option will replace any older local libraries with the more recent public versions from the database.
- **Other.** This option allows you to manually select the versions that you want by choosing them in the table.

Forced Term Conflicts

Whenever you add a public library or update a local library, conflicts and duplicate entries may be uncovered between the terms and types in this library and the terms and types in the other libraries in your resources. If this occurs, you will be asked to verify the proposed conflict resolutions or change them before completing the operation in the Edit Forced Terms dialog box. See the topic [Forcing terms](#) for more information.

The Edit Forced Terms dialog box contains each pair of conflicting terms or types. Alternating background colors are used to visually distinguish each conflict pair. These colors can be changed in the Options dialog box. See the topic [Options: Display Tab](#) for more information. The Edit Forced Terms dialog box contains two tabs:

- **Duplicates.** This tab contains the duplicated terms found in the libraries. If a pushpin icon appears after a term, it means that this occurrence of the term has been forced. If a black X icon appears, it means that this occurrence of the term will be ignored during extraction because it has been forced elsewhere.
- **User Defined.** This tab contains a list of any terms that have been forced manually in the type dictionary term pane and not through conflicts.

Note: The Edit Forced Terms dialog box opens after you add or update a library. If you cancel out of this dialog box, you will not be canceling the update or addition of the library.

To Resolve Conflicts

1. In the Edit Forced Terms dialog box, select the radio button in the Use column for the term that you want to force.
2. When you have finished, click OK to apply the forced terms and close the dialog box. If you click Cancel, you will cancel the changes you made in this dialog box.

About Library Dictionaries

The resources used to extract text data are stored in the form of templates and libraries. A library can be made up of three dictionaries.

- The **type dictionary** contains a collection of terms grouped under one label, or type name. When the extraction engine reads your text data, it compares the words found in the text to the terms defined in your type dictionaries. During extraction, inflected forms of a type's terms and synonyms are grouped under a target term called concept. Extracted concepts are assigned to the type dictionary in which they appear as terms. You can manage your type dictionaries in the upper left and center panes of the editor—the library tree and the term pane. See the topic [Type dictionaries](#) for more information.
- The **substitution dictionary** contains a collection of words defined as synonyms or as optional elements used to group similar terms under one target term, called a concept in the final extraction results. You can manage your substitution dictionaries in the lower left pane of the editor using the Synonyms tab and the Optional tab. See the topic [Substitution/Synonym dictionaries](#) for more information.
- The **exclude dictionary** contains a collection of terms and types that will be removed from the final extraction results. You can manage your exclude dictionaries in the rightmost pane of the editor. See the topic [Exclude dictionaries](#) for more information.

See the topic [Working with Libraries](#) for more information.

Type dictionaries

A *type dictionary* is made up of a type name, or label, and a list of terms. Type dictionaries are managed in the upper left and center panes of Library Resources tab in the editor. You can access this view with View > Resource Editor in the menus, if you are in an interactive workbench

session. Otherwise, you can edit dictionaries for a specific template in the Template Editor.

When the extraction engine reads your text data, it compares words found in the text to the terms defined in your type dictionaries. Terms are words or phrases in the type dictionaries in your linguistic resources.

When a word matches a term, it is assigned to the type name for that term. When the resources are read during extraction, the terms that were found in the text then go through several processing steps before they become concepts in the Extraction Results pane. If multiple terms belonging to the same type dictionary are determined to be synonymous by the extraction engine, then they are grouped under the most frequently occurring term and called a *concept* in the Extraction Results pane. For example, if the terms **question** and **query** might appear under the concept name **question** in the end.

Figure 1. Library tree and term pane

The screenshot shows the SPSS Modeler Text Analytics interface. On the left, the 'Library Resources' pane displays a tree view of type dictionaries. Under 'Local Library', there are several checked entries: 'Product Satisfaction Opinions (English)', 'Product Satisfaction Library (English)', 'Opinions Library (English)', 'Budget Library (English)', 'Core Library (English)', and 'Variations Library (English)'. The 'Product Satisfaction Library (English)' node has its own expanded tree with terms like 'after taste', 'age', 'appearance', etc. The 'Term' column lists the words from the type dictionary, 'Match' indicates the matching option (e.g., 'Entire Term', 'Entire And Any'), 'Inflect' shows if inflected forms are generated, 'Type' categorizes the term (e.g., 'Characteristics'), and 'Library' shows the source type dictionary for each term.

Term	Match	Inflect	Type	Library
after taste	Entire Term	✓	Characteristics	Product Satisfaction Library (English)
after-taste	Entire And Any	✓	Characteristics	Product Satisfaction Library (English)
aftertaste	Entire Term	✓	Characteristics	Product Satisfaction Library (English)
age	Entire And Any	✓	Characteristics	Product Satisfaction Library (English)
appearance	Entire And Any	✓	Characteristics	Product Satisfaction Library (English)
aroma	Entire And Any	✓	Characteristics	Product Satisfaction Library (English)
attribute	Entire And Any	✓	Characteristics	Product Satisfaction Library (English)
audio	Entire And Any	✓	Characteristics	Product Satisfaction Library (English)
behaviour	Entire And Any	✓	Characteristics	Product Satisfaction Library (English)
can carry	Entire Term	✗	Characteristics	Product Satisfaction Library (English)
can store	Entire Term	✗	Characteristics	Product Satisfaction Library (English)
capacity	Entire And Any	✓	Characteristics	Product Satisfaction Library (English)
characteristic	Entire And Any	✓	Characteristics	Product Satisfaction Library (English)
characteristic	Entire And Any	✓	Characteristics	Product Satisfaction Library (English)
color	Entire And Any	✓	Characteristics	Product Satisfaction Library (English)
coloring	Entire And Any	✓	Characteristics	Product Satisfaction Library (English)
colour	Entire And Any	✓	Characteristics	Product Satisfaction Library (English)
colouring	Entire And Any	✓	Characteristics	Product Satisfaction Library (English)
comfort	Entire And Any	✓	Characteristics	Product Satisfaction Library (English)
component	Entire And Any	✓	Characteristics	Product Satisfaction Library (English)
comfort	Entire And Any	✓	Characteristics	Product Satisfaction Library (English)
consistence	Entire And Any	✓	Characteristics	Product Satisfaction Library (English)

The list of type dictionaries is shown in the library tree pane on the left. The content of each type dictionary appears in the center pane. Type dictionaries consist of more than just a list of terms. The manner in which words and word phrases in your text data are matched to the terms defined in the type dictionaries is determined by the match option defined. A **match option** specifies how a term is anchored with respect to a candidate word or phrase in the text data. See the topic [Adding terms](#) for more information.

Additionally, you can extend the terms in your type dictionary by specifying whether you want to automatically generate and add inflected forms of the terms to the dictionary. By generating the inflected forms, you automatically add plural forms of singular terms, singular forms of plural terms, and adjectives to the type dictionary. See the topic [Adding terms](#) for more information.

Note: For most languages, concepts that are not found in any type dictionary but are extracted from the text are automatically typed as **<Unknown>**

Using an asterisk in terms

Using an asterisk (*) in terms is especially useful if you are dealing with an agglutinative language that creates new words by compounding other words together without intervening spaces. For example, the German word *Übernachtungspreis*, which is made up of: *Übernachtung* + s + *Preis*.

As an example, if you search in terms for **preis*** in the type **Budget**, it will match extracted concepts such as **preiserhöhung**. In the same way, ***preis** will match **Übernachtung** and ***preis*** will match **Übernachtungspreiserhöhung**.

- [Built-in types](#)
- [Creating types](#)
- [Adding terms](#)
- [Forcing terms](#)
- [Renaming types](#)
- [Moving types](#)
- [Disabling and deleting types](#)

Built-in types

IBM® SPSS® Modeler Text Analytics is delivered with a set of linguistic resources in the form of shipped libraries and compiled resources. The shipped libraries contain a set of built-in type dictionaries such as **<Location>**, **<Organization>**, **<Person>**, and **<Product>**.

These type dictionaries are used by the extraction engine to assign types to the concepts it extracts such as assigned the type **<Location>** to the concept **paris**. Although a large number of terms have been defined in the built-in type dictionaries, they do not cover every possibility. Therefore, you can add to them or create your own. For a description of the contents of a particular shipped type dictionary, read the annotation in the Type Properties dialog box. Select the type in the tree and choose Edit > Properties from the context menu.

Note:

In addition to the shipped libraries, the compiled resources (also used by the extraction engine) contain a large number of definitions complementary to the built-in type dictionaries, but their content is not visible in the product. You can, however, force a term that was typed by the compiled dictionaries into any other dictionary. See [Forcing terms](#) for more information.

Creating types

You can create type dictionaries to help group similar terms. When terms appearing in this dictionary are discovered during the extraction process, they will be assigned to this type name and extracted under a concept name. Whenever you create a library, an empty type library is always included so that you can begin entering terms immediately.

If you are analyzing text about food and want to group terms relating to vegetables, you could create your own <Vegetables> type dictionary. You could then add terms such as **carrot**, **broccoli**, and **spinach** if you feel that they are important terms that will appear in the text. Then, during extraction, if any of these terms are found, they are extracted as concepts and assigned to the <Vegetables> type.

You do not have to define every form of a word or expression, because you can choose to generate the inflected forms of terms. By choosing this option, the extraction engine will automatically recognize singular or plural forms of the terms among other forms as belonging to this type. This option is particularly useful when your type contains mostly nouns, since it is unlikely you would want inflected forms of verbs or adjectives.

The Type Properties dialog box contains the following fields.

Name. The name you give to the type dictionary you are creating. We recommend that you do not use spaces in type names, especially if two or more type names start with the same word.

Note: There are some constraints about type names and the use of symbols. For example, do not use symbols such as "@" or "!" within the name. Default match. The default match attribute instructs the extraction engine how to match this term to text data. Whenever you add a term to this type dictionary, this is the match attribute automatically assigned to it. You can always change the match choice manually in the term list. Options include: Entire Term, Start, End, Any, Start or End, Entire and Start, Entire and End, Entire and (Start or End), and Entire (no compounds). See the topic [Adding terms](#) for more information.

Add to. This field indicates the library in which you will create your new type dictionary.

Generate inflected forms by default. This option tells the extraction engine to use grammatical morphology to capture and group similar forms of the terms that you add to this dictionary, such as singular or plural forms of the term. This option is particularly useful when your type contains mostly nouns. When you select this option, all new terms added to this type will automatically have this option although you can change it manually in the list.

Font color. This field allows you to distinguish the results from this type from others in the interface. If you select Use parent color, the default type color is used for this type dictionary, as well. This default color is set in the options dialog box. See the topic [Options: Display Tab](#) for more information. If you select Custom, select a color from the drop-down list.

Annotation. This field is optional and can be used for any comments or descriptions.

To create a type dictionary

1. Select the library in which you would like to create a new type dictionary.
2. From the menus, choose Tools > New Type. The Type Properties dialog box opens.
3. Enter the name of your type dictionary in the Name text box and choose the options you want.
4. Click OK to create the type dictionary. The new type is visible in the library tree pane and appears in the center pane. You can begin adding terms immediately. For more information, see [Adding terms](#).

Note: These instructions show you how to make changes within the Resource Editor view or the Template Editor . Keep in mind that you can also do this kind of fine-tuning directly from the Extraction Results pane , Data pane, Categories pane, or Cluster Definitions dialog box in the other views. See the topic [Refining extraction results](#) for more information.

Adding terms

The library tree pane displays libraries and can be expanded to show the type dictionaries that they contain. In the center pane, a term list displays the terms in the selected library or type dictionary, depending on the selection in the tree.

In the Resource Editor, you can add terms to a type dictionary directly in the term pane or through the Add New Terms dialog box. The terms that you add can be single words or compound words. You will always find a blank row at the top of the list to allow you to add a new term.

Note: These instructions show you how to make changes within the Resource Editor view or the Template Editor . Keep in mind that you can also do this kind of fine-tuning directly from the Extraction Results pane , Data pane, Categories pane, or Cluster Definitions dialog box in the other views. See the topic [Refining extraction results](#) for more information.

Term column

In this column, enter single or compound words into the cell. The color in which the term appears depends on the color for the type in which the term is stored or forced. You can change type colors in the Type Properties dialog box. See the topic [Creating types](#) for more information.

Force column

In this column, by putting a pushpin icon into this cell, the extraction engine knows to ignore any other occurrences of this same term in other libraries. See the topic [Forcing terms](#) for more information.

Match column

In this column, select a match option to instruct the extraction engine how to match this term to text data. See the table for examples. You can change the default value by editing the type properties. See the topic [Creating types](#) for more information. From the menus, choose Edit > Change Match. The following are the basic match options since combinations of these are also possible:

- Start. If the term in the dictionary matches the first word in a concept extracted from the text, this type is assigned. For example, if you enter **apple**, **apple tart** will be matched.
- End. If the term in the dictionary matches the last word in a concept extracted from the text, this type is assigned. For example, if you enter **apple**, **cider apple** will be matched.
- Any. If the term in the dictionary matches any word of a concept extracted from the text, this type is assigned. For example, if you enter **apple**, the Any option will type **apple tart**, **cider apple**, and **cider apple tart** the same way.
- Entire Term. If the entire concept extracted from the text matches the exact term in the dictionary, this type is assigned. Adding a term as Entire term, Entire and Start, Entire and End, Entire and Any, or Entire (no compounds) will force the extraction of a term. Furthermore, since the **<Person>** type extracts only two part names, such as *edith piaf* or *mohandas gandhi*, you may want to explicitly add the first names to this type dictionary if you are trying to extract a first name when no last name is mentioned. For example, if you want to catch all instances of *edith* as a name, you should add **edith** to the **<Person>** type using Entire term or Entire and Start.
- Entire (no compounds). If the entire concept extracted from the text matches the exact term in the dictionary, this type is assigned and the extraction is stopped to prohibit the extraction from matching the term to a longer compound. For example, if you enter **apple**, the Entire (no compound) option will type **apple** and not extract the compound **apple sauce** unless it is forced in somewhere else.

In the following table, assume that the term **apple** is in a type dictionary. Depending on the match option, this table shows which concepts would be extracted and typed if they were found in the text.

Table 1. Matching Examples

Match options for the term: 	Extracted concepts			
	apple	apple tart	ripe apple	homemade apple tart
Entire Term	✓			
Start		✓		
End			✓	
Start or End		✓	✓	
Entire and Start	✓	✓		
Entire and End	✓		✓	
Entire and (Start or End)	✓	✓	✓	
Any		✓	✓	✓
Entire and Any	✓	✓	✓	✓
Entire (no compounds)	✓	never extracted	never extracted	never extracted

Inflect column

In this column, select whether the extraction engine should generate inflected forms of this term during extraction so that they are all grouped together. The default value for this column is defined in the Type Properties but you can change this option on a case-by-case basis directly in the column. From the menus, choose Edit > Change Inflection.

Type column

In this column, select a type dictionary from the drop-down list. The list of types is filtered according to your selection in the library tree pane. The first type in the list is always the default type selected in the library tree pane. From the menus, choose Edit > Change Type.

Library column

In this column, the library in which your term is stored appears. You can drag and drop a term into another type in the library tree pane to change its library.

To add a single term to a type dictionary

1. In the library tree pane, select the type dictionary to which you want to add the term.
2. In the term list in the center pane, type your term in the first available empty cell and set any options you want for this term.

To add multiple terms to a type dictionary

1. In the library tree pane, select the type dictionary to which you want to add terms.
2. From the menus, choose Tools > New Terms. The Add New Terms dialog box opens.
3. Enter the terms you want to add to the selected type dictionary by typing the terms or copying and pasting a set of terms. If you enter multiple terms, you must separate them using the delimiter that is defined in the Options dialog, or add each term on a new line. See the topic [Setting Options](#) for more information.
4. Click OK to add the terms to the dictionary. The match option is automatically set to the default option for this type library. The dialog box closes and the new terms appear in the dictionary.

Forcing terms

If you want a term to be assigned to a particular type, you can add it to the corresponding type dictionary. However, if there are multiple terms with the same name, the extraction engine must know which type should be used. Therefore, you will be prompted to select which type should be used. This is called *forcing* a term into a type. This option is most useful when overriding the type assignment from a compiled (internal, non-editable) dictionary. In general, we recommend avoiding duplicate terms altogether.

Forcing will not *remove* the other occurrences of this term; rather, they will be ignored by the extraction engine. You can later change which occurrence should be used by forcing or unforcing a term. You may also need to force a term into a type dictionary when you add a public library or update a public library.

You can see which terms are forced or ignored in the Force column, the second column in the term pane. If a pushpin icon appears, this means that this occurrence of the term has been forced. If a black X icon appears, this means that this occurrence of the term will be ignored during extraction because it has been forced elsewhere. Additionally, when you force a term, it will appear in the color for the type in which it was forced. This means that if you forced a term that is in both **Type 1** and **Type 2** into **Type 1**, any time you see this term in the window, it will appear in the font color defined for **Type 1**.

1.

You can double-click the icon in order to change the status. If the term appears elsewhere, a Resolve Conflicts dialog box opens to allow you to select which occurrence should be used.

Renaming types

You can rename a type dictionary or change other dictionary settings by editing the type properties.

Important: We recommend that you do not use spaces in type names, especially if two or more type names start with the same word. We also recommend that you do not rename the types in the Core or Opinions libraries or change their default match attributes.

To rename a type

1. In the library tree pane, select the type dictionary you want to rename.
2. Right-click your mouse and choose Type Properties from the context menu. The Type Properties dialog box opens.
3. Enter the new name for your type dictionary in the Name text box.
4. Click OK to accept the new name. The new type name is visible in the library tree pane.

Moving types

You can drag a type dictionary to another location within a library or to another library in the tree.

To reorder a type within a library

1. In the library tree pane, select the type dictionary you want to move.
2. From the menus, choose Edit > Move Up to move the type dictionary up one position in the library tree pane or Edit > Move Down to move it down one position.

To move a type to another library

1. In the library tree pane, select the type dictionary you want to move.
2. Right-click your mouse and choose Type Properties from the context menu. The Type Properties dialog box opens. (You can also drag and drop the type into another library).
3. In the Add To list box, select the library to which you want to move the type dictionary.
4. Click OK. The dialog box closes, and the type is now in the library you selected.

Disabling and deleting types

If you want to temporarily remove a type dictionary, you can disable it by deselecting the check box to the left of the dictionary name in the library tree pane. This signals that you want to keep the dictionary in your library but want the contents ignored during conflict checking and during the extraction process.

You can also permanently delete type dictionaries from a library.

To disable a type dictionary

1. In the library tree pane, select the type dictionary you want to disable.
2. Click the spacebar. The check box to the left of the type name is cleared.

To delete a type dictionary

1. In the library tree pane, select the type dictionary you want to delete.
2. From the menus, choose Edit > Delete to delete the type dictionary.

Substitution/Synonym dictionaries

A *substitution dictionary* is a collection of terms that help to group similar terms under one target term. Substitution dictionaries are managed in the bottom pane of the Library Resources tab. You can access this view with View > Resource Editor in the menus, if you are in an interactive workbench session. Otherwise, you can edit dictionaries for a specific template in the Template Editor.

You can define two forms of substitutions in this dictionary: *synonyms* and *optional elements*. You can click the tabs in this pane to switch between them.

After you run an extraction on your text data, you may find several concepts that are synonyms or inflected forms of other concepts. By identifying optional elements and synonyms, you can force the extraction engine to map these to one single target term.

Substituting using synonyms and optional elements reduces the number of concepts in the Extraction Results pane by combining them together into more significant, representative concepts with higher frequency Doc. counts.

Synonyms

Synonyms associate two or more words that have the same meaning. You can also use synonyms to group terms with their abbreviations or to group commonly misspelled words with the correct spelling. You can define these synonyms on the Synonyms tab.

A synonym definition is made up of two parts. The first is a Target term, which is the term under which you want the extraction engine to group all synonym terms. Unless this target term is used as a synonym of another target term or unless it is excluded, it is likely to become the concept that appears in the Extraction Results pane. The second is the list of synonyms that will be grouped under the target term.

For example, if you want **automobile** to be replaced by **vehicle**, then **automobile** is the synonym and **vehicle** is the target term.

You can enter any words into the Synonym column, but if the word is not found during extraction and the term had a match option with **Entire**, then no substitution can take place. However, the target term does not need to be extracted for the synonyms to be grouped under this term.

Optional elements

Optional elements identify optional words in a compound term that can be ignored during extraction in order to keep similar terms together even if they appear slightly different in the text. Optional elements are single words that, if removed from a compound, could create a match with another term. These single words can appear anywhere within the compound--at the beginning, middle, or end. You can define optional elements on the Optional tab.

For example, to group the terms **ibm** and **ibm corp** together, you should declare **corp** to be treated as an optional element in this case. In another example, if you designate the term **access** to be an optional element and during extraction both **internet access speed** and **internet speed** are found, they will be grouped together under the term that occurs most frequently.

- [Defining synonyms](#)
 - [Defining optional elements](#)
 - [Disabling and Deleting Substitutions](#)
-

Defining synonyms

On the Synonyms tab, you can enter a synonym definition in the empty line at the top of the table. Begin by defining the target term and its synonyms. You can also select the library in which you would like to store this definition. During extraction, all occurrences of the synonyms will be grouped under the target term in the final extraction. See the topic [Adding terms](#) for more information.

For example, if your text data includes a lot of telecommunications information, you may have these terms: **cellular phone**, **wireless phone**, and **mobile phone**. In this example, you may want to define **cellular** and **mobile** as synonyms of **wireless**. If you define these synonyms, then every extracted occurrence of **cellular phone** and **mobile phone** will be treated as the same term as **wireless phone** and will appear together in the term list.

When you are building your type dictionaries, you may enter a term and then think of three or four synonyms for that term. In that case, you could enter all of the terms and then your target term into the substitution dictionary and then drag the synonyms.

Synonym substitution is also applied to the inflected forms (such as the plural form) of the synonym. Depending on the context, you may want to impose constraints on how terms are substituted. Certain characters can be used to place limits on how far the synonym processing should go:

- Exclamation mark (!). When the exclamation mark directly precedes the synonym **!synonym**, this indicates that no inflected forms of the synonym will be substituted by the target term. However, an exclamation mark directly preceding the target term **!target-term** means that you do not want any part of the compound target term or variants to receive any further substitutions.
- Asterisk (*). An asterisk placed directly after a synonym, such as **synonym***, means that you want this word to be replaced by the target term. For example, if you defined **manage*** as the synonym and **management** as the target, then **associate managers** will be replaced by the target term **associate management**. You can also add a space and an asterisk after the word **(synonym *)** such as **internet ***. If you defined the target as **internet** and the synonyms as **internet * *** and **web ***, then **internet access card** and **web portal** would be replaced with **internet**. You cannot begin a word or string with the asterisk wildcard in this dictionary.
- Caret (^). A caret and a space preceding the synonym, such as **^ synonym**, means that the synonym grouping applies only when the term begins with the synonym. For example, if you define **^ wage** as the synonym and **income** as the target and both terms are extracted, then they will be grouped together under the term **income**. However, if **minimum wage** and **income** are extracted, they will not be grouped together, since **minimum wage** does not begin with **wage**. A space must be placed between this symbol and the synonym.
- Dollar sign (\$). A space and a dollar sign following the synonym, such as **synonym \$**, means that the synonym grouping applies only when the term ends with the synonym. For example, if you define **cash \$** as the synonym and **money** as the target and both terms are extracted, then they will be grouped together under the term **money**. However, if **cash cow** and **money** are extracted, they will not be grouped together, since **cash cow** does not end with **cash**. A space must be placed between this symbol and the synonym.
- Caret (^) and dollar sign (\$). If the caret and dollar sign are used together, such as **^ synonym \$**, a term matches the synonym only if it is an exact match. This means that no words can appear before or after the synonym in the extracted term in order for the synonym grouping to take place. For example, you may want to define **^ van \$** as the synonym and **truck** as the target so that only **van** is grouped with **truck**, while **marie van guerin** will be left unchanged. Additionally, whenever you define a synonym using the caret and dollar signs and this word appears anywhere in the source text, the synonym is automatically extracted.

To add a synonym entry

1. With the substitution pane displayed, click the Synonyms tab in the lower left corner.
2. In the empty line at the top of the table, enter your target term in the Target column. The target term you entered appears in color. This color represents the type in which the term appears or is forced, if that is the case. If the term appears in black, this means that it does not appear in any type dictionaries.
3. Click the second cell to the right of the target and enter the set of synonyms. Separate each entry using the global delimiter as defined in the Options dialog box. See the topic [Setting Options](#) for more information. The terms that you enter appear in color. This color represents the type in which the term appears. If the term appears in black, this means that it does not appear in any type dictionaries.

4. Click the last cell to select the library in which you want to store this synonym definition.

Note: These instructions show you how to make changes within the Resource Editor view or the Template Editor . Keep in mind that you can also do this kind of fine-tuning directly from the Extraction Results pane , Data pane, Categories pane, or Cluster Definitions dialog box in the other views. See the topic [Refining extraction results](#) for more information.

Defining optional elements

On the Optional tab, you can define optional elements for any library you want. These entries are grouped together for each library. As soon as a library is added to the library tree pane, an empty optional element line is added to the Optional tab.

All entries are transformed into lowercase words automatically. The extraction engine will match entries to both lowercase and uppercase words in the text.

Note: Terms are delimited using the delimiter defined in the Options dialog. See the topic [Setting Options](#) for more information. If the optional element that you are entering includes the same delimiter as part of the term, a backslash must precede it.

To add an entry

1. With the substitution pane displayed, click the Optional tab in the lower left corner of the editor.
2. Click in the cell in the Optional Elements column for the library to which you want to add this entry.
3. Enter the optional element. Separate each entry using the global delimiter as defined in the Options dialog box. See the topic [Setting Options](#) for more information.

Disabling and Deleting Substitutions

You can remove an entry in a temporary manner by disabling it in your dictionary. By disabling an entry, the entry will be ignored during extraction.

You can also delete any obsolete entries in your substitution dictionary.

To Disable an Entry

1. In your dictionary, select the entry you want to disable.
2. Click the spacebar. The check box to the left of the entry is cleared.

Note: You can also deselect the check box to the left of the entry to disable it.

To Delete a Synonym Entry

1. In your dictionary, select the entry you want to delete.
2. From the menus, choose Edit > Delete or press the Delete key on your keyboard. The entry is no longer in the dictionary.

To Delete an Optional Element Entry

1. In your dictionary, double-click the entry you want to delete.
2. Manually delete the term.
3. Press Enter to apply the change.

- [Microsoft Internet Explorer settings for Help](#)

Exclude dictionaries

An *exclude dictionary* is a list of words, phrases, or partial strings. Any terms matching or containing an entry in the exclude dictionary will be ignored or excluded from extraction. Exclude dictionaries are managed in the right pane of the editor. Typically, the terms that you add to this list are fill-in words or phrases that are used in the text for continuity but that do not really add anything important to the text and may clutter the extraction results. By adding these terms to the exclude dictionary, you can make sure that they are never extracted.

Exclude dictionaries are managed in the upper right pane of Library Resources tab in the editor. You can access this view with View > Resource Editor in the menus, if you are in an interactive workbench session. Otherwise, you can edit dictionaries for a specific template in the Template Editor .

In the exclude dictionary, you can enter a word, phrase, or partial string in the empty line at the top of the table. You can add character strings to your exclude dictionary as one or more words or even partial words using the asterisk as a wildcard. The entries declared in the exclude dictionary will be used to bar concepts from extraction. If an entry is also declared somewhere else in the interface, such as in a type dictionary, it is shown with a strike-through in the other dictionaries, indicating that it is currently excluded. This string does not have to appear in the text data or be declared as part of any type dictionary to be applied.

Note: If you add a concept to the exclude dictionary that also acts as the target in a synonym entry, then the target and all of its synonyms will also be excluded. See the topic [Defining synonyms](#) for more information.

Using wildcards (*)

can use the asterisk wildcard to denote that you want the exclude entry to be treated as a partial string. Any terms found by the extraction engine that contain a word that begins or ends with a string entered in the exclude dictionary will be excluded from the final extraction. However, there are two cases where the wildcard usage is not permitted:

- Dash character (-) preceded by an asterisk wildcard, such as *-
- Apostrophe (') preceded by an asterisk wildcard, such as *'

Table 1. Examples of exclude entries

Entry	Example	Results
word	<i>next</i>	No concepts (or its terms) will be extracted if they contain the word <i>next</i> .
phrase	<i>for example</i>	No concepts (or its terms) will be extracted if they contain the phrase <i>for example</i> .
partial	<i>copyright*</i>	Will exclude any concepts (or its terms) matching or containing the variations of the word <i>copyright</i> , such as copyrighted, copyrighting, copyrights, or copyright 2010 .
partial	<i>*ware</i>	Will exclude any concepts (or its terms) matching or containing the variations of the word <i>ware</i> , such as freeware, shareware, software, hardware, beware, or silverware .

To add entries

- In the empty line at the top of the table, enter a term. The term that you enter appears in color. This color represents the type in which the term appears. If the term appears in black, this means that it does not appear in any type dictionaries.

To disable entries

You can temporarily remove an entry by disabling it in your exclude dictionary. By disabling an entry, the entry will be ignored during extraction.

1. In your exclude dictionary, select the entry that you want to disable.
2. Click the spacebar. The check box to the left of the entry is cleared.

Note: You can also deselect the check box to the left of the entry to disable it.

To delete entries

You can delete any unneeded entries in your exclude dictionary.

1. In your exclude dictionary, select the entry that you want to delete.
2. From the menus, choose Edit > Delete. The entry is no longer in the dictionary.

About Advanced Resources

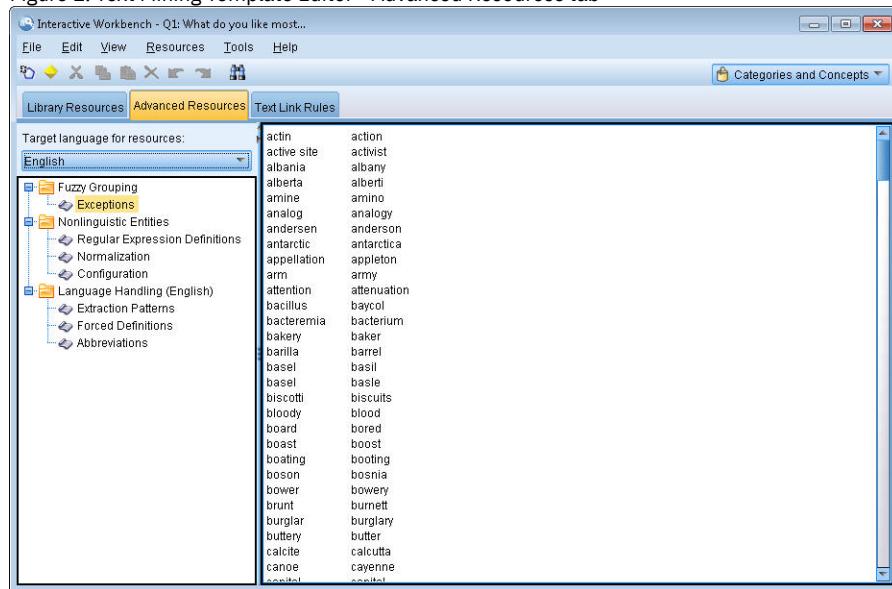

In addition to type, exclude and substitution dictionaries, you can also work with a variety of advanced resource settings such as Fuzzy Grouping settings or nonlinguistic type definitions. You can work with these resources in the Advanced Resources tab in the Template Editor or Resource Editor view.

When you go to the Advanced Resources tab, you can edit the following information:

- Target language for resources. Used to select the language for which the resources will be created and tuned. See the topic [Target Language for Resources](#) for more information.
- Fuzzy Grouping (Exceptions). Used to exclude word pairs from the fuzzy grouping (spelling error correction) algorithm. See the topic [Fuzzy Grouping](#) for more information.

- Nonlinguistic Entities. Used to enable and disable which nonlinguistic entities can be extracted, as well as the regular expressions and the normalization rules that are applied during their extraction. See the topic [Nonlinguistic Entities](#) for more information.
- Language Handling. Used to declare the special ways of structuring sentences (extraction patterns and forced definitions) and using abbreviations for the selected language. See the topic [Language Handling](#) for more information.

Figure 1. Text Mining Template Editor - Advanced Resources tab

Note: You can use the Find/Replace toolbar to find information quickly or to make uniform changes to a section. For more information, see [Replacing](#).

To Edit Advanced Resources

1. Locate and select the resource section that you want to edit. The contents appear in the right pane.
2. Use the menu or the toolbar buttons to cut, copy, or paste content, if necessary.
3. Edit the file(s) that you want to change using the formatting rules in this section. Your changes are saved as soon as you make them. Use the undo or redo arrows on the toolbar to revert to the previous changes.

Finding

In some cases, you may need to locate information quickly in a particular section. For example, if you perform text link analysis, you may have hundreds of macros and pattern definitions. Using the Find feature, you can find a specific rule quickly. To search for information in a section, you can use the Find toolbar.

To Use the Find Feature

1. Locate and select the resource section that you want to search. The contents appear in the right pane of the editor.
2. From the menus, choose Edit > Find. The Find toolbar appears at the upper right of the Edit Advanced Resources dialog box.
3. Enter the word string that you want to search for in the text box. You can use the toolbar buttons to control the case sensitivity, partial matching, and direction of the search.
4. Click Find to start the search. If a match is found, the text is highlighted in the window.
5. Click Find again to look for the next match.

Note: When working in the Text Link Rules tab, the Find option is only available when you view the source code.

Replacing

In some cases, you may need to make broader updates to your advanced resources. The Replace feature can help you to make uniform updates to your content.

To Use the Replace Feature

1. Locate and select the resource section in which you want to search and replace. The contents appear in the right pane of the editor.
2. From the menus, choose Edit > Replace. The Replace dialog box opens.
3. In the Find what text box, enter the word string that you want to search for.
4. In the Replace with text box, enter the string that you want to use in place of the text that was found.
5. Select Match whole word only if you want to find or replace only complete words.
6. Select Match case if you want to find or replace only words that match the case exactly.
7. Click Find Next to find a match. If a match is found, the text is highlighted in the window. If you do not want to replace this match, click Find Next again until you find a match that you want to replace.
8. Click Replace to replace the selected match.
9. Click Replace to replace all matches in the section. A message opens with the number of replacements made.
10. When you are finished making your replacements, click Close. The dialog box closes.

Note: If you made a replacement error, you can undo the replacement by closing the dialog box and choosing Edit > Undo from the menus. You must perform this once for every change that you want to undo.

Target Language for Resources

Resources are created for a particular text language. The language for which these resources are tuned is defined in the Advanced Resources tab. You can switch to another language if necessary by selecting that language in the Target language for resources combobox. Additionally, the language listed here will appear as the language for any text analysis packages you create with these resources.

Important: You will rarely ever need to change the language in your resources. Doing so can cause issues when your resources no longer match the extraction language. Though rarely employed, you might change a language if you planned to use the **All** language option during extraction because you expected to have text in more than one language. By changing the language, you can access, for example, the language handling resources for extraction patterns, abbreviations and force definitions for the secondary language you are interested in. However, keep in mind that before publishing or saving the resource changes you've made or running another extraction, set the language back to the primary language you are interested in extracting.

Fuzzy Grouping

In the Text Mining node and Extraction Settings, if you select Accommodate spelling for a minimum root character limit of, you have enabled the fuzzy grouping algorithm.

Fuzzy grouping helps to group commonly misspelled words or closely spelled words by temporarily stripping all vowels (except for the first vowel) and double or triple consonants from extracted words and then comparing them to see if they are the same. During the extraction process, the fuzzy grouping feature is applied to the extracted terms and the results are compared to determine whether any matches are found. If so, the original terms are grouped together in the final extraction list. They are grouped under the term that occurs most frequently in the data.

Note: If the two terms being compared are assigned to different types, excluding the <Unknown> type, then the fuzzy grouping technique is not be applied to this pair. In other words, the terms must belong to the same type or the <Unknown> type in order for the technique to be applied. If you enabled this feature and found that two words with similar spelling were incorrectly grouped together, you may want to exclude them from fuzzy grouping. You can do this by entering the incorrectly matched pairs into the Exceptions section in the Advanced Resources tab. See the topic [About Advanced Resources](#) for more information.

The following example demonstrates how fuzzy grouping is performed. If fuzzy grouping is enabled, these words appear to be the same and are matched in the following manner:

color -> colr	mountain -> montn
colour -> colr	montana -> montn
modeling -> modlng	furniture -> furntr
modelling -> modlng	furnature -> furntr

In the preceding example, you would most likely want to exclude **mountain** and **montana** from being grouped together. Therefore, you could enter them in the Exceptions section in the following manner:

mountain montana

Important: In some cases, fuzzy grouping exceptions do not stop 2 words from being paired because certain synonym rules are being applied. In that case, you may want to try entering synonyms using the exclamation mark wildcard (!) to prohibit the words from becoming synonymous in the output. For more information, see [Defining synonyms](#).

Formatting Rules for Fuzzy Grouping Exceptions

- Define only one exception pair per line.
- Use simple or compound words.
- Use only lowercase characters for the words. Uppercase words will be ignored.
- Use a **TAB** character to separate each word in a pair.

Nonlinguistic Entities

When working with certain kinds of data, you might be very interested in extracting dates, social security numbers, percentages, or other nonlinguistic entities. These entities are explicitly declared in the configuration file, in which you can enable or disable the entities. See the topic [Configuration](#) for more information. In order to optimize the output from the extraction engine, the input from nonlinguistic processing is normalized to group like entities according to predefined formats. See the topic [Normalization](#) for more information.

Note: You can turn on and off nonlinguistic entity extraction in the extraction settings.

Available Nonlinguistic Entities

The nonlinguistic entities in the following table can be extracted. The type name is in parentheses.

Table 1. Nonlinguistic entities that can be extracted

Addresses	(<Address>)
Amino acids	(<Aminoacid>)
Currencies	(<Currency>)
Dates	(<Date>)
Delay	(<Delay>)
Digits	(<Digit>)
E-mail addresses	(<email>)
HTTP/URL addresses	(<url>)
IP address	(<IP>)
Organizations	(<Organization>)
Percentages	(<Percent>)
Products	(<Product>)
Proteins	(<Gene>)
Phone numbers	(<PhoneNumber>)
Times	(<Time>)
U.S. social security	(<SocialSecurityNumber>)
Weights and measures	(<Weights-Measures>)

Cleaning Text for Processing

Before nonlinguistic entities extraction occurs, the input text is cleaned. During this step, the following temporary changes are made so that nonlinguistic entities can be identified and extracted as such:

- Any sequence of two or more spaces is replaced by a single space.
- Tabulations are replaced by space.
- Single end-of-line characters or sequence characters are replaced by a space, while multiple end-of-line sequences are marked as end of a paragraph. End of line can be denoted by carriage returns (CR) and line feed (LF) or even both together.
- HTML and XML tags are temporarily stripped and ignored.

Regular Expression Definitions

When extracting nonlinguistic entities, you may want to edit or add to the regular expression definitions that are used to identify regular expressions. This is done in the Regular Expression Definitions section in the Advanced Resources tab. See the topic [About Advanced Resources](#) for more information.

The file is broken up into distinct sections. The first section is called `[macros]`. In addition to that section, an additional section can exist for each nonlinguistic entity. You can add sections to this file. Within each section, rules are numbered (`regexp1`, `regexp2`, and so on). These rules

must be numbered sequentially from 1–n. Any break in numbering will cause the processing of this file to be suspended altogether.

In certain cases, an entity is language dependent. An entity is considered to be language dependent if it takes a value other than 0 for the language parameter in the configuration file. See the topic [Configuration](#) for more information. When an entity is language dependent, the language must be used to prefix the section name, such as `[english/PhoneNumber]`. That section would contain rules that apply only to English phone numbers when the `PhoneNumber` entity is given a value of 2 for the language.

Important! If you make changes to this file or any other in the editor and the extraction engine no longer works as desired, use the Reset to Original option on the toolbar to reset the file to the original shipped content. This file requires a certain level of familiarity with regular expressions. If you require additional assistance in this area, please contact IBM® Corp. for help.

Special Characters . [] {} () \ * + ? | ^ \$

All characters match themselves except for the following special characters, which are used for a specific purpose in expressions: . [{ () \ * + ? | ^ \$ To use these characters as such, they must be preceded by a backslash (\) in the definition.

For example, if you were trying to extract Web addresses, the full stop character is very important to the entity, therefore, you must backslash it such as:

```
www\.[a-z]+\.[a-z]+
```

Repetition Operators and Quantifiers ? + * {}

To enable the definitions to be more flexible, you can use several wildcards that are standard to regular expressions. They are * ? +

- Asterisk * indicates that there are *zero or more* of the preceding string. For example, `ab*c` matches "ac", "abc", "abbbc", and so on.
- Plus sign + indicates that there is *one or more* of the preceding string. For example, `ab+c` matches "abc", "abbc", "abbbc", but not "ac".
- Question mark ? indicates that there is *zero or one* of the preceding string. For example, `model?ing` matches both "modeling" and "modeling".
- Limiting repetition with brackets {} indicates the bounds of the repetition. For example, `[0-9]{n}` matches a digit repeated exactly n times. For example, `[0-9]{4}` will match "1998", but neither "33" nor "19983".

`[0-9]{n,}` matches a digit repeated *n or more* times. For example, `[0-9]{3,}` will match "199" or "1998", but not "19".

`[0-9]{n,m}` matches a digit repeated between *n and m times inclusive*. For example, `[0-9]{3,5}` will match "199", "1998" or "19983", but not "19" nor "19983".

Optional Spaces and Hyphens

In some cases, you want to include an optional space in a definition. For example, if you wanted to extract currencies such as "uruguayan pesos", "uruguayan peso", "uruguay pesos", "uruguay peso", "pesos" or "peso", you would need to deal with the fact that there may be two words separated by a space. In this case, this definition should be written as `(uruguayan |uruguay)?pesos?`. Since uruguayan or uruguay are followed by a space when used with pesos/peso, the optional space must be defined within the optional sequence `(uruguayan |uruguay)`. If the space was not in the optional sequence such as `(uruguayan|uruguay)?pesos?`, it would not match on "pesos" or "peso" since the space would be required.

If you are looking for a series of things including a hyphen characters (-) in a list, then the hyphen must be defined last. For example, if you are looking for a comma (,) or a hyphen (-), use `[,-]` and never `[-,]`.

Order of Strings in Lists and Macros

You should always define the longest sequence before a shorter one or else the longest will never be read since the match will occur on the shorter one. For example, if you were looking for strings "billion" or "bill", then "billion" must be defined before "bill". So for instance `(billion|bill)` and not `(bill|billion)`. This also applies to macros, since macros are lists of strings.

Order of Rules in the Definition Section

Define one rule per line. Within each section, rules are numbered (`regexp1`, `regexp2`, and so on). These rules must be numbered sequentially from 1–n. Any break in numbering will cause the processing of this file to be suspended altogether. To disable an entry, place a # symbol at the beginning of each line used to define the regular expression. To enable an entry, remove the # character before that line.

In each section, the most specific rules must be defined before the most general ones to ensure proper processing. For example, if you were looking for a date in the form "month year" and in the form "month", then the "month year" rule must be defined before the "month" rule. Here is how it should be defined:

```
#@# January 1932
regexp1=$ (MONTH) ,? [0-9]{4}

#@# January
regexp2=$ (MONTH)
```

and not

```
#@# January
regexp1=$ (MONTH)
```

```
#@# January 1932
regexp2=$ (MONTH) ,? [0-9]{4}
```

Using Macros in Rules

Whenever a specific sequence is used in several rules, you can use a macro. Then, if you need to change the definition of this sequence, you will need to change it only once, and not in all the rules referring to it. For example, assuming you had the following macro:

```
MONTH=( (january|february|march|april|june|july|august|september|october|
november|december) |(jan|feb|mar|apr|may|jun|jul|aug|sep|oct|nov|dec) (\.)?)
```

Whenever you refer to the name of the macro, it must be enclosed in \$(), such as: `regexp1=$ (MONTH)`

All macros must be defined in the `[macros]` section.

 - [Normalization](#)
 - [Configuration](#)
-

Normalization

When extracting nonlinguistic entities, the entities encountered are normalized to group like entities according to predefined formats. For example, currency symbols and their equivalent in words are treated as the same. The normalization entries are stored in the Normalization section in the Advanced Resources tab. See the topic [About Advanced Resources](#) for more information. The file is broken up into distinct sections.

Important! This file is for advanced users only. It is highly unlikely that you would need to change this file. If you require additional assistance in this area, please contact IBM® Corp. for help.

Formatting Rules for Normalization

- Add only one normalization entry per line.
- Strictly respect the sections in this file. No new sections can be added.
- To disable an entry, place a # symbol at the beginning of that line. To enable an entry, remove the # character before that line.

English Dates in Normalization

By default dates in an English template are recognized in the American style date format; that is: month, date, year. If you need to change that to the day, month, year format, disable the "format:US" line (by adding # at the beginning of the line) and enable "format:UK" (by removing the # from that line).

Related information

- [Nonlinguistic Entities](#)
 - [Regular Expression Definitions](#)
 - [Configuration](#)
-

Configuration

You can enable and disable the nonlinguistic entity types that you want to extract in the nonlinguistic entity configuration file. By disabling the entities that you do not need, you can decrease the processing time required. This is done in the Configuration section in the Advanced Resources tab. See the topic [About Advanced Resources](#) for more information. If nonlinguistic extraction is enabled, the extraction engine reads this configuration file during the extraction process to determine which nonlinguistic entity types should be extracted.

The syntax for this file is as follows:

```
#name<TAB>Language<TAB>Code
```

Table 1. Syntax for configuration file

Column label	Description
#name	The wording by which nonlinguistic entities will be referenced in the two other required files for nonlinguistic entity extraction. The names used here are case sensitive.

Column label	Description
Language	The language of the documents . It is best to select the specific language; however, an Any option exists. Possible options are: 0 = Any which is used whenever a regexp is not specific to a language and could be used in several templates with different languages, for instance an IP/URL/email addresses; 1 = French; 2 = English; 4 = German; 5 = Spanish; 6 = Dutch; 8 = Portuguese; 10 = Italian.
Code	Part-of-speech code. Most entities take a value of "s" except in a few cases. Possible values are: s = stopword; a = adjective; n = noun. If enabled, nonlinguistic entities are first extracted and the extraction patterns are applied to identify its role in a larger context. For example, percentages are given a value of "a." Suppose that 30% is extracted as an nonlinguistic entity. It would be identified as an adjective. Then if your text contained "30% salary increase," the "30%" nonlinguistic entity fits the part-of-speech pattern "ann" (adjective noun noun).

Order in Defining Entities

The order in which the entities are declared in this file is important and affects how they are extracted. They are applied in the order listed. Changing the order will change the results. The most specific nonlinguistic entities must be defined before more general ones.

For example, the nonlinguistic entity "**Aminoacid**" is defined by:

```
regexp1=($ (AA) -? $ (NUM))
```

where **\$ (AA)** corresponds to "(ala|arg|asn|asp|cys|gln|glu|gly|his|ile|leu|lys|met|phe|pro|ser)", which are specific 3-letter sequences corresponding to particular amino acids.

On the other hand, the nonlinguistic entity "**Gene**" is more general and is defined by:

```
regexp1=p{0-9}{2,3}
regexp2=[a-z]{2,4}-?[0-9]{1,3}-?[r]
regexp3=[a-z]{2,4}-?[0-9]{1,3}-?p?
```

If "**Gene**" is defined before "**Aminoacid**" in the Configuration section, then "**Aminoacid**" will never be matched, since **regexp3** from "**Gene**" will always match first.

Formatting Rules for Configuration

- Use a **TAB** character to separate each entry in a column.
- Do not delete any lines.
- Respect the syntax shown in the preceding table.
- To disable an entry, place a # symbol at the beginning of that line. To enable an entity, remove the # character before that line.

Extraction patterns

When extracting information from your documents , the extraction engine applies a set of parts-of-speech extraction patterns to a "stack" of words in the text to identify candidate terms (words and phrases) for extraction. You can add or modify the extraction patterns.

Parts of speech include grammatical elements, such as nouns, adjectives, past participles, determiners, prepositions, coordinators, first names, initials, and particles. A series of these elements makes up a part-of-speech extraction pattern. In IBM® Corp. text mining products, each part of speech is represented by a single character to make it easier to define your patterns. For instance, an adjective is represented by the lowercase letter *a*. The set of supported codes appears by default at the top of each default extraction patterns section along with a set of patterns and examples of each pattern to help you understand each code that is used.

Formatting rules for extraction patterns

- One pattern per line.
- Use # at the beginning of a line to disable a pattern.

The order in which you list the extraction patterns is very important because a given sequence of words is read only once by the extraction engine and is assigned to the first extraction patterns for which the engine finds a match.

Supported parts of speech codes

Following is a table of all supported parts of speech codes defined in the English compiled dictionary.

All the parts of speech that are used in a particular template are listed at the top of Advanced Resources...> Extraction patterns.

The main difference between the basic resources template and the opinions template is that when minimal determiners ("d") and prepositions ("c") are used in basic, their extended equivalents ("e" and "r") are used in opinions. "0" and "1" have a limited use in all the opinions templates. See Advanced Resources...> Language Handling (English)...> Forced Definitions and Extraction patterns.

Other English templates may use some parts of speech not listed in the dictionary (for instance, "w" and "W", in the Market Intelligence template). But in that case, those parts of speech are assigned to specific words under Advanced Resources...> Forced Definitions.

Table 1. Supported parts of speech codes

Code	Meaning	Example
a	adjective	abdominal, blue...
A	unused	unused
b	adverb	frequently, often, very, ...
B	unused	unused
c	preposition	"of"
C	internal code for misspelled words	
d	determiner	"the"
D	unused	unused
e	extended determiner	the, an, my, your...
E	unused	unused
f	first name	John, Mary...
F	unused	unused
g	unused	unused
G	nationality adjective	french, american...
h	unused	unused
H	unused	unused
i	initial all single letters followed by ":"	"a.", "w." and some single letters such as "w" (used to extract person names such as John W. Doe)
I	unused	unused
j	unused	unused
J	unused	unused
k	unused	unused
K	unused	unused

Code	Meaning	Example
l	unused	unused
L	unused	unused
m	noun or unknown	dog, ibm
M	unused	unused
n	noun	dog
N	a few proper nouns	ibm
o	coordination	"and", "&"
O	unused	unused
p	past participle	abandoned, accessorized...
P	unused	unused
q	unused	unused
Q	qualifier	expensive, small, good, ...
r	extended preposition	of, among, against, from...
R	unused	unused
s	stop word	any word that we do not want to extract
S	unused	unused
t	title	mrs., mrs, captain, brig., ...
T	unused	unused
u	unknown by definition, not in dictionary	
U	unused	unused
v	verb	eat, eats, ate, eating, ...
V	infinitive verb	eat, ...
w	unused	unused
W	unused	unused
x	auxiliary	be
X	unused	unused
y	particle	von, di, de, ... (used to extract person names: John von Doe)
Y	unused	unused
z	unused	unused
Z	unused	unused
0	opinion adverb	Only in Opinions. See Advanced resources > Language Handling (English) > Forced Definitions.
1	"to" in opinions	See Advanced resources > Language Handling (English) > Forced Definitions
2	unused	unused
3	unused	unused
4	unused	unused
5	unused	unused
6	unused	unused
7	unused	unused
8	unused	unused
9	unused	unused

Forced Definitions

When extracting information from your documents , the extraction engine scans the text and identifies the part of speech for every word it encounters. In some cases, a word could fit several different roles depending on the context. If you want to force a word to take a particular part-of-speech role or to exclude the word completely from processing, you can do so in the Forced Definition section of the Advanced Resources tab. See the topic [About Advanced Resources](#) for more information.

To force a part-of-speech role for a given word, you must add a line to this section using the following syntax:

term: code

Table 1. Syntax description

Entry	Description
term	A term name.

Entry	Description
code	A single-character code representing the part-of-speech role. You can list up to six different part-of-speech codes per uniterm. Additionally, you can stop a word from being extracted into compound words/phrases by using the lowercase code s , such as additional:s .

Formatting Rules for Forced Definitions

- One line per word.
- Terms cannot contain a colon.
- Use the lowercase **s** as a part-of-speech code to stop a word from being extracted altogether.
- Use up to six part-of-speech codes per line. Supported part-of-speech codes are shown in the Extraction Patterns section. See the topic [Extraction patterns](#) for more information.
- Use the asterisk character (*) as a wildcard at the end of a string for partial matches. For example, if you enter **add*:s**, words such as **add**, **additional**, **additionally**, **addendum**, and **additive** are never extracted as a term or as part of a compound word term. However, if a word match is explicitly declared as a term in a compiled dictionary or in the forced definitions, it will still be extracted. For example, if you enter both **add*:s** and **addendum:n**, **addendum** will still be extracted if found in the text.

Related information

- [Language Handling](#)
 - [Extraction patterns](#)
 - [Abbreviations](#)
-

Abbreviations

When the extraction engine is processing text, it will generally consider any period it finds as an indication that a sentence has ended. This is typically correct; however, this handling of period characters does not apply when abbreviations are contained in the text.

If you extract terms from your text and find that certain abbreviations were mishandled, you should explicitly declare that abbreviation in this section.

Note: If the abbreviation already appears in a synonym definition or is defined as a term in a type dictionary, there is no need to add the abbreviation entry here.

Formatting Rules for Abbreviations

- Define one abbreviation per line.

Related information

- [Language Handling](#)

About Text Link Rules

Text link analysis (TLA) is a pattern matching technology that is used to extract relationships found in your text using a set of rules. When text link analysis is enabled for extraction, the text data is compared against these rules. When a match is found, the text link analysis pattern is extracted and presented. These rules are defined in the Text Link Rules tab.

For example, extracting concepts representing simple ideas about an organization may not be interesting enough to you, but by using TLA, you could also learn about the links between different organizations or the people associated with the organization. TLA can also be used to extract opinions about topics such as how people feel about a given product or experience.

To benefit from TLA, you must have resources that contain text link (TLA) rules. When you select a template, you can see which templates have TLA rules by whether or not they have an icon in the TLA column.

Text link analysis patterns are found in the text data during the pattern matching phase of the extraction process. During this phase, rules are compared to the text data and when a match is found, this information is extracted as a pattern. There are times when you might want to get more from text link analysis or change how something is matched. In these cases, you can refine the rules to adapt them to your particular needs. This is performed in the Text Link Rules tab.

Note: Starting with version 18.2, Type Reassignment Rules (TRRs) are available. TRRs transform a sequence of types, macros, and/or tokens into a new concept with a specific type. They can be used in Opinions templates to catch opinions with a change in polarity. For more information, see

Type Reassignment Rules.

Where to work on text link rules

You can edit and create rules directly in the Text Link Rules tab in the Template Editor or Resource Editor view. To help you see how rules might match text, you can run a simulation in this tab. During simulation, an extraction is run only on the sample simulation data and the text link rules are applied to see if any patterns match. Any rules that match the text are then shown in the simulation pane. Based on the matches, you can choose to edit rules and macros to change how the text is matched.

Unlike the other advanced resources, TLA rules are library-specific; therefore, you can only use the TLA rules from one library at a time. From within the Template Editor or Resource Editor, go to the Text Link Rules tab. In this tab, you can specify the library in your template that contains the TLA rules you want to use or edit. For this reason, we strongly recommend that you store all your rules in one library unless there is a very specific reason this isn't desired.

Figure 1. Text Link Rules tab

Where to Begin

There are a number of ways to start working in the Text Link Rules tab editor:

- Start by simulating results with some sample text and edit or create matching rules based on how the current set of rules extract patterns from the simulation data. See the topic [Simulating Text Link Analysis Results](#) for more information.
- Create a new rule from scratch or edit an existing rule. See the topic [Working with Text Link Rules](#) for more information.
- Work in source view directly. See the topic [Viewing and working in source mode](#) for more information.

-

When to Edit or Create Rules

While the text link analysis rules delivered with each template are often adequate for extracting many simple or complex relationships from your text, there are times that you may want to make some changes to these rules or create some rules of your own. For example:

- To capture an idea or relation that isn't being extracted with the existing rules by creating a new rule or macro.
- To change the default behavior of a type you added to the resources. This usually requires you to edit a macro such as `mTopic` or `mNonLingEntities`. See the topic [Special Macros: mTopic, mNonLingEntities, SEP](#) for more information.
- To add new types to existing text link analysis rules and macros. For example, if you think the type `<Organization>` is too broad, you could create new types for organizations in several different business sectors such as `<Pharmaceuticals>`, `<Car Manufacturing>`, `<Finance>`, and so on. In this case, you must edit the text link analysis rules and/or create a macro to take these new types into account and process them accordingly.
- To add types to an existing text link analysis rule. For example, let's say you have a rule that captures the following text `john doe called jane doe` but you want this rule that captures phone communications to also capture email exchanges. You could add the nonlinguistic entity type for email to the rule so it would also capture text such as: `johndoe@ibm.com emailed janedoe@ibm.com`.
- To slightly modify an existing rule, instead of creating a new one. For example, let's say you have a rule that matches the following text `xyz is very good` but you want this rule to also capture `xyz is very, very good`.

Simulating Text Link Analysis Results

In order to help define new text link rules or help understand how certain sentences are matched during text link analysis, it is often useful to take a sample piece of text and run a simulation. During simulation, an extraction is run only on the sample simulation data using the current set of linguistic resources and the current extraction settings. The goal is to obtain the simulated results and use these results to improve your rules, create new ones, or better understand how matching occurs. For each piece of text (sentence, word, or clause depending on the context), a simulation output displays the collection of tokens and any TLA rules that uncovered a pattern in that text. A **token** is defined as any word or word phrase identified during the extraction process.

Unlike the other advanced resources, TLA rules are library-specific; therefore, you can only use the TLA rules from one library at a time. From within the Template Editor or Resource Editor, go to the Text Link Rules tab. In this tab, you can specify the library in your template that contains

the TLA rules you want to use or edit. For this reason, we strongly recommend that you store all your rules in one library unless there is a very specific reason this isn't desired.

Important! We strongly recommend that if you use a data file, please ensure that the text it contains is short in order to minimize processing time. The goal of simulation is to see how a piece of text is interpreted and to understand how rules match this text. This information will help you write and edit your rules. Use the text link analysis node or run a stream with interactive session with TLA extraction enabled to obtain results for a more complete data set. This simulation is for testing and rule authoring purposes only.

Defining Data for Simulation

To help you see how rules might match text, you can run a simulation using sample data. The first step is to define the data.

Defining Data

1. Click Define Data in the simulation pane in bottom of the Text Link Rules tab. Alternatively, if no data have been previously defined, choose Tools > Run Simulation from the menus. The Simulation Data wizard opens.
2. Specify the data type by selecting one of the following:
 - Paste or enter text directly A text box is provided for you to paste some text from the clipboard or to manually enter the desired text to be processed. You can enter one sentence per line or use punctuation to break up the sentence such as periods or commas. Once you have entered your text, you can begin the simulation by clicking Run Simulation.
 - Specify a file data source This option indicates that you want to process a file that contains text. Click Next to proceed to the wizard step in which you can define the file to be processed. Once the file has been selected, you can begin the simulation by clicking Run Simulation. The following file types are supported: .txt and .text. The data file you choose is read 'as-is' during the simulation. The entire file is treated in the same manner as if you had connected a File List node to a Text Mining Node.
- Important: We strongly recommend that if you use a data file, ensure that the text it contains is short in order to minimize processing time. The goal of simulation is to see how a piece of text is interpreted and to understand how rules match this text. This information will help you write and edit your rules. Use the text link analysis node or run a stream with interactive session with TLA extraction enabled to obtain results for a more complete data set. This simulation is for testing and rule authoring purposes only.
3. To begin the simulation process, click Run Simulation. A progress dialog appears. If you are in an interactive session, the extraction settings used during simulation are those currently selected in the interactive session (see Tools > Extraction Settings in the Concepts and Categories view). If you are in the Template Editor, the extraction settings used during simulation are the default extraction settings, which are the same as those shown in the Expert tab of a Text Link Analysis node. For more information, see [Understanding Simulation Results](#).

- [Understanding Simulation Results](#)

Understanding Simulation Results

To help you see how rules might match text, you can run a simulation using sample data and review the results. From there you can change your set of rules to better fit your data. When the extraction and simulation process has completed, you will be presented with the results of the simulation.

For each "sentence" identified during extraction, you are presented with several pieces of information including the exact "sentence", the breakdown of the tokens found in this input text sentence, and finally any rules that matched text in that sentence. By "sentence", we mean either a word, sentence, or clause depending on how the extractor broke down the text into readable chunks.

A **token** is defined as any word or word phrase identified during the extraction process. For example, in the sentence *My uncle lives in New York*, the following tokens might be found during extraction: *my*, *uncle*, *lives*, *in*, and *new york*. Additionally, *uncle* could be extracted as a concept and typed as **<Unknown>**, and *new york* could also be extracted as a concept and typed as **<Location>**. All concepts are tokens but not all tokens are concepts. Tokens can also be other macros, literal strings, and word gaps. Only those words or word phrases that are typed can be concepts.

When you are working in the interactive session or resource editor, you are working at the concept level. TLA rules are more granular, and individual tokens in a sentence can be used in the definition of a rule even if they are never extracted and typed. Being able to use tokens which are not concepts offers rules even more flexibility in capturing complex relationships in your text.

If you have more than one sentence in your simulation data, you can move forward and backward through the results by clicking Next and Previous.

In those cases where a sentence does not match any TLA rule in the selected library (see library name above tree in this tab), the results are considered unmatched and the buttons Next Unmatched and Previous Unmatched are enabled to let you know that there is text for which no rule found a match and to allow you to navigate to these instances quickly.

After creating new rules, editing your rules, or changing your resources or extraction settings, you may want to rerun a simulation. To re-run a simulation, click Run Simulation in the simulation pane and the same input data will be used again.

The following fields and tables are shown in the simulation results:

Input text. The actual 'sentence' identified by the extraction process from the simulation data you defined in the wizard. By sentence, we mean either a word, sentence, or clause depending on how the extractor broken down the text into readable chunks.

System View. A collection of tokens that the extraction process has identified.

- **Input Text Token.** Each token found in the input text. Tokens were defined earlier in this topic.
- **Typed As.** If a token was identified as a concept and typed, then the associated type name (such as **<Unknown>**, **<Person>**, **<Location>**) is shown in this column.
- **Matching Macro.** If a token matched an existing macro, then the associated macro name is displayed in this column.

Rules Matched to Input Text. This table shows you any TLA rules that were matched against the input text. For each matched rule, you will see the name of the rule in the Rule Output column and the associated output values for that rule (Concept + Type pairs). You can double-click on the matched rule name to open the rule in the editor pane above the simulation pane.

Generate Rule button. If you click this button in the simulation pane, a new rule will open in the rule editor pane above the simulation pane. It will take the input text as its example. Likewise, any token that was typed or matched to a macro during simulation is automatically inserted in the Elements column in the Rule Values table. If a token was typed and matched a macro, the macro value is the one that will be used in the rule so as to simplify the rule. For example, the sentence "*I like pizza*" could be typed during simulation as **<Unknown>** and matched to macro **mTopic** if you were using the Basic English resources. In this case **mTopic** will be used as the element in the generated rule. See the topic [Working with Text Link Rules](#) for more information.

Navigating Rules and Macros in the Tree

When text link analysis is performed during extraction, the text link rules stored in the library selected in the Text Link Rules tab will be used.

Unlike the other advanced resources, TLA rules are library-specific; therefore, you can only use the TLA rules from one library at a time. From within the Template Editor or Resource Editor, go to the Text Link Rules tab. In this tab, you can specify the library in your template that contains the TLA rules you want to use or edit. For this reason, we strongly recommend that you store all your rules in one library unless there is a strong or specific reason this isn't desired.

You can specify in which library you want to work in the Text Link Rules tab by selecting that library in the Use and store text link analysis rules in dropdown list in this tab. When text link analysis is performed during extraction, the text link rules stored in the library selected in the Text Link Rules tab will be used. Therefore, if you defined text link rules (TLA rules) in more than one library, only the first library in which TLA rules are found will be used for text link analysis. For this reason, we strongly recommend that you store all your rules in one library unless there is a very specific reason this isn't desired.

When you select a macro or rule in the tree, its contents are displayed in the editor pane to the right. If you right-click on any item in the tree, a context menu will open to show you what other tasks are possible, such as:

- Create a new macro in the tree and open it in the editor to the right.
- Create a new rule in the tree and open it in the editor to the right.
- Create a new rule set in the tree.
- Cut, copy, and paste items to simplify editing.
- Delete macros, rules, and rule sets to remove them from the resources.
- Disable macros, rules, and rule sets to indicate that they should be ignored during processing.
- Move rules up or down to affect processing order.

Warnings in the tree

Warnings are displayed with a yellow triangle in the tree and are there to inform you that there may be a problem. Hover the mouse pointer over the faulty macro or rule to display a pop-up explanation. In most cases, you will see something such as: Warning: No example provided; Enter an example so you need to enter an example.

If you're missing an example, or if the example doesn't match the rule, you will not be able to use the Get Tokens feature so we recommend you enter just one example per rule.

When the rule is highlighted in yellow it means that a type or macro is unknown to the TLA editor. The message will be similar to: Warning: Unknown type or macro. This is to inform you that an item that would be defined by \$something in the source view, for instance \$myType, is not a legacy type in your library, nor is it a macro.

To update the syntax checker you need to switch to another rule or macro; there is no need to recompile anything. So, for example, if rule A displays a warning because the example is missing, you need to add an example, click on either an upper or lower rule, and then go back to rule A to check that it is now correct.

Working with Macros

Macros can simplify the appearance of text link analysis rules by allowing you to group types, other macros, and literal (word) strings together with an OR operator (|). The advantage to using macros is that not only can you reuse macros in multiple text link analysis rules to simplify them, but it also enables you to make updates in one macro rather than having to make updates throughout all of your text link analysis rules. Most shipped TLA rules contain predefined macros. Macros appear at the top of the tree in the leftmost pane of the Text Link Rules tab.

The following fields and tables are shown in the simulation results:

Name. A unique name identifying this macro. We recommend that you prefix macro names with a lowercase m to help you identify macros quickly in your rules. When you manually refer to macros in your rules (by inline editing or in the source view) you have to use the \$ character prefix so that the extraction process knows to look for this special name. However, if you drag and drop the macro name or add it through the context menus, the product will automatically recognize it as a macro and no \$ will be added.

Macro Value table.

- A number of rows representing all of the possible values this macro can represent. These values are case-sensitive.
- These values can include one or a combination of types, literal strings, word gaps, or macros. See the topic [Supported Elements for Rules and Macros](#) for more information.
- To enter a value for an element in a macro, double-click the row you want to work in. An editable text box appears in which you can enter a type reference, a macro reference, a literal string, or a word gap. Alternatively, right-click in the cell to display a contextual menu offering lists of common macros, type names, and nonlinguistic type names. To reference a type or a macro you must precede the macro or type

name with a '\$' character such as \$mTopic for the macro mTopic. When combining arguments, you must use parentheses () to group the arguments and the character | to indicate a Boolean OR.

- You can add or remove rows in the Macro Value table using the buttons to its right.
- Enter each element in its own row. For example, if you wanted to create a macro that represents one of 3 literal strings such as am OR was OR is, you would enter each literal string on a separate row in the view, and your Macro table would contain 3 rows.

Creating and Editing Macros

You can create new macros or edit existing ones. Follow the guidelines and descriptions for the macro editor. See the topic [Working with Macros](#) for more information.

Creating New Macros

1. From the menus, choose Tools > New Macro. Alternatively, click the New Macro icon in the tree toolbar to open a new macro in the editor.
2. Enter a unique name and define the macro value elements.
3. Click Apply when finished to check for errors.

Editing Macros

1. Click the macro name in the tree. The macro opens in the editor pane on the right.
2. Make your changes.
3. Click Apply when finished to check for errors.

Disabling and Deleting Macros

Disabling Macros

If you want a macro to be ignored during processing, you can disable it. Doing so may cause warnings or errors in any rules that still reference this disabled macro. Take caution when deleting and disabling macros.

1. Click the macro name in the tree. The macro opens in the editor pane on the right.
2. Right-click on the name.
3. From the context menus, choose Disable. The macro icon becomes gray and the macro itself becomes uneditable.

Deleting Macros

If you want to get rid of a macro, you can delete it. Doing so may cause errors in any rules that still reference this macro. Take caution when deleting and disabling macros.

1. Click the macro name in the tree. The macro opens in the editor pane on the right.
2. Right-click on the name.
3. From the context menus, choose Delete. The macro disappears from the list.

Checking for Errors, Saving, and Cancelling

Applying Macro Changes

If you click outside of the macro editor or if you click Apply, the macro is automatically scanned for errors. If an error is found, you will need to fix it before moving on to another part of the application.

However, if less serious errors are detected, only a warning is given. For example, if your macro contains incomplete or unreferenced definitions to types or other macros, a warning message is displayed. Once you click Apply, any uncorrected warnings cause a warning icon to appear to the left of the macro name in the Rules and Macro Tree in the left pane.

Applying a macro does not mean that your macro is permanently saved. Applying will cause the validation process to check for errors and warnings.

Saving Resources inside an Interactive Workbench Session

1. To save the changes you made to your resources during an interactive workbench session so you can get them next time you run your stream, you must:
 - Update your modeling node to make sure that you can get these same resources next time you execute your stream. See the topic [Updating Modeling Nodes and Saving](#) for more information. Then save your stream. To save your stream, do so in the main IBM® SPSS® Modeler window after updating the modeling node.
2. To save the changes you made to your resources during an interactive workbench session so that you can use them in other streams, you can:

- Update the template you used or make a new one. See the topic [Making and Updating Templates](#) for more information. This will not save the changes for the current node (see previous step)
- Or, update the TAP you used. See the topic [Updating Text Analysis Packages](#) for more information.

Saving Resources inside the Template Editor

1. First, publish the library. See the topic [Publishing Libraries](#) for more information.
2. Then, save the template through File > Save Resource Template in the menus.

Cancelling Macro Changes

1. If you wish to discard the changes, click Cancel.

Special Macros: mTopic, mNonLingEntities, SEP

The Opinions template (and like templates) as well as the Basic Resources templates are shipped with two special macros called **mTopic** and **mNonLingEntities**.

mTopic

By default, the macro **mTopic** groups all the types shipped in the template that are likely to be connected with an opinion, such as the following Core library types: **<Person>**, **<Organization>**, **<Location>**, and so on, as long as the type is not an opinion type (for example, **<Negative>** or **<Positive>**) or a type defined as a nonlinguistic entity in the Advanced Resources.

Whenever you create a new type in an Opinions (or similar) template, the product assumes that unless this type is specified in another macro or in the nonlinguistic entities section of the Advanced Resource tab, it will be treated the same way as the other types defined in the macro **mTopic**.

Let's say you created new types in the resources from an Opinions template: **<Vegetables>** and **<Fruit>**. Without having to make any changes, your new types are treated as **mTopic** types so you can automatically uncover the positive, negative, neutral, and contextual opinions about your new types. During extraction, for example, the sentence "*I enjoy broccoli, but I hate grapefruit*" would produce the following 2 output patterns:

```
broccoli <Vegetables> + like <Positive>
grapefruit <Fruit> + dislike <Negative>
```

However, if you want to process those types differently than the other types in **mTopic**, you can either add the type name to an existing macro such as **mPos**, which groups all positive opinion types, or create a new macro that you can later reference in one or more rules.

Important! If you create a new type such as **<Vegetables>**, this new type will be included as a type in **mTopic**, however, this type name will not be explicitly visible in the macro definition.

mNonLingEntities

Similarly, if you add new nonlinguistic entities in the Nonlinguistic Entities section of the Advanced Resources tab, they will be automatically processed as **mNonLingEntities** unless specified otherwise. See the topic [Nonlinguistic Entities](#) for more information.

Working with Text Link Rules

A text link analysis rule is a Boolean query that is used to perform a match on a sentence. Text link analysis rules contain one or more of the following arguments: types, macros, literal strings, or word gaps. You must have at least one text link analysis rule in order to extract TLA results.

The following areas and fields are displayed in the Text Link Rules tab, Rule Editor:

Name field. The unique name for the text link rule.

Example field. Optionally, you can include an example sentence or word sequence that would be captured by this rule. We recommend using examples. In this editor, you will be able to generate tokens from this example text to see how it matches the rule and how it will be output. A **token** is defined as any word or word phrase identified during the extraction process. For example, in the sentence *My uncle lives in New York*, the following tokens might be found during extraction: *my*, *uncle*, *lives*, *in*, and *new york*. Additionally, *uncle* could be extracted as a concept and typed as **<Unknown>**, and *new york* could also be extracted as a concept and typed as **<Location>**. All concepts are tokens but not all tokens are concepts. Tokens can also be other macros, literal strings, and word gaps. Only those words or word phrases that are typed can be concepts.

Rule Value table. This table contains the elements of the rule that are used for matching a rule to a sentence. You can add or remove rows in the table using the buttons to its right. The table consists of 3 columns:

- Element column. Enter values as one or a combination of types, literal strings, word gaps (**<Any Token>**), or macros. See the topic [Supported Elements for Rules and Macros](#) for more information. Double-click the element cell to enter the information directly. Alternatively, right-click in the cell to display a contextual menu offering lists of common macros, type names, and nonlinguistic type names. Keep in mind that if you enter the information into the cell by typing it in, precede the macro or type name with a '\$' character such as **\$mTopic** for the macro **mTopic**. The order in which you create your element rows is critical to how the rule will be matched to the text. When combining arguments, you must use parentheses () to group the arguments and the character | to indicate a Boolean OR. Keep in mind that values are case-sensitive.
- Quantity column. This indicates the minimum and maximum number of times the element must be found for a match to occur. For example, if you want to define a gap, or a series of words, between two other elements of anywhere from 0 to 3 words, you could choose Between 0 and 3 from the list or enter the numbers directly into the dialog box. The default is 'Exactly 1'. In some cases you will want to make an element optional. If this is the case, then it will have a minimum quantity of 0 and a maximum quantity greater than 0 (i.e. 0 or 1, between 0 and 2). Note that the first element in a rule cannot be optional, meaning it cannot have a quantity of 0.
- Example Token column. If you click Get Tokens, the program breaks the Example text down into tokens and uses those tokens to fill this column with those that match the elements you defined. You can also see these tokens in the output table if you choose to.

Rule Output table Each row in this table defines how the TLA pattern output will appear in the results. Rule output can produce patterns of up to six Concept/Type column pairs, each representing a *slot*. For example, the type pattern **<Location> + <Positive>** is a two slot pattern meaning that it is made up of 2 Concept/Type column pairs.

Note: Terms in the Element column of the Rule Value table, or in any of the Concept columns of the Rule Output table cannot start with any of the following characters: ` , #, %, ^, *, _, :, <, >, /, \, or ".

Just as language gives us the freedom to express the same basic ideas in many different ways, so you might have a number of rules defined to capture the same basic idea. For example, the text "*Paris is a place I love*" and the text "*I really, really like Paris and Florence*" represent the same basic idea -- that Paris is liked -- but are expressed differently and would require two different rules to both be captured. However, it is easier to work with the pattern results if similar ideas are grouped together. For this reason, while you might have 2 different rules to capture these 2 phrases, you could define the same output for both rules, such as the type pattern **<Location> + <Positive>** so that it represents both texts. And in this way, you can see that the output does not always mimic the structure or order of the words found in the original text.

Furthermore, such a type pattern could match other phrases and could produce concept patterns such as: `paris + like` and `tokyo + like`.

To help you define the output quickly with fewer errors, you can use the context menu to choose the element you want to see in the output. Alternatively, you can also drag and drop elements from the Rule Value table into the output. For example, if you have a rule that contains a reference to the `mTopic` macro in row 2 of the Rule Value table, and you want that value to be in your output, you can simply drag/drop the element for `mTopic` to the first column pair in the Rule Output table. Doing so will automatically populate both the Concept and Type for the pair you've selected. Or if you want the output to begin with the type defined by the third element (row 3) of the rule value table, then drag that type from the Rule Value table to the Type 1 cell in the output table. The table will update to show the row reference in parenthesis (3).

Alternatively, you can enter these references manually into the table by double-clicking the cell in each Concept column you want to output and entering the `$` symbol followed by the row number, such as `$2` to refer to the element defined in row 2 of the Rule Value table. When you enter the information manually, you need to also define the Type column, enter the `#` symbol followed by the row number, such as `#2` to refer to the element defined in row 2 of the Rule Value table.

Furthermore, you might even combine methods. Let's say you had the type `<Positive>` in row 4 of your Rule Value table. You could drag it to the `Type` 2 column and then double-click the cell in the `Concept` 2 column and then manually enter the word `'not'` in front of it. The output column would then read `not (4)` in the table, or if you were in the edit mode or source mode `not $4`. Then you could right-click in the Type 1 column and select, for example, the macro called `mTopic`. Then this output could result in a concept pattern such as: `car + bad`.

Most rules have only one output row but there are times when more than one output is possible and desired. In this case, define one output per row in the Rule Output table.

Important: Keep in mind that other linguistic handling operations are performed during the extraction of TLA patterns. So when the output reads `t$3\t#3`, this means that the pattern will ultimately display the final concept for the third element and the final type for the third element after all linguistic processing is applied (synonyms and other groupings).

- Show output as. By default, the option References to row in Rule Value table is selected and the output is shown by using the numerical references to the row as defined in the Rule Value tab. If you previously clicked Get Tokens and have tokens in the Example Tokens column in the Rule Value table, you can choose to see the output for these specific tokens by choosing the option .

Note: If there are not enough concept/type output pairs shown in the output table, you can add another pair by clicking the Add button in the editor toolbar. If 3 pairs are currently shown and you click add, 2 more columns (Concept 4 and Type 4) are added to the table. This means that you will now see 4 pairs in the output table for all rules. You can also remove unused pairs as long as no other rule in the set of rules in this library uses that pair.

Example Rule

Let's suppose your resources contain the following text link analysis rule and that you have enabled the extraction of TLA results:

Figure 1. Text Link Rules tab: Rule Editor

Element	Quantity	Example Token
1 mSupportNeg	Exactly 1	isn't
2	0 or 1	
3 (anything ((any a one) thing. ?))	Exactly 1	anything
4	Between 0 and 2	that i
5 mNeg	Exactly 1	disliked
6 (about with in)	Exactly 1	about
7	0 or 1	
8 mDet	0 or 1	the

Concept 1	Type 1	Concept 2	Type 2	Concept 3	Type 3
product (9)	Products (9)	no dislike (5)	Positive		

Show output as: References to row in Rule Value table Specific token from example

Apply Cancel

Whenever you extract, the extraction engine will read each sentence and will try to match the following sequence:

Table 1. Extraction sequence example

Element (row)	Description of the arguments
1	The concept from one of the types represented by the macros <code>mPos</code> or <code>mNeg</code> or from the type <code><Uncertain></code> .
2	A concept typed as one of the types represented by the macro <code>mTopic</code> .

Element (row)	Description of the arguments
3	One of the words represented by the macro mBe .
4	An optional element, 0 or 1 words, also referred to as a word gap or <Any Token>
5	A concept typed as one of the types represented by the macro mTopic .

The output table shows that all that is wanted from this rule is a pattern where any concept or type corresponding to the **mTopic** macro that was defined in row 5 in the Rule Value table + any concept or type corresponding to the **mPos**, **mNeg**, or **<Uncertain>** as was defined in row 1 in the Rule Value table. This could be **sausage + like** or **<Unknown> + <Positive>**.

- [Creating and Editing Rules](#)
- [Disabling and Deleting Rules](#)
- [Checking for Errors, Saving, and Cancelling](#)

Creating and Editing Rules

You can create new rules or edit existing ones. Follow the guidelines and descriptions for the rule editor. See the topic [Working with Text Link Rules](#) for more information.

Creating New Rules

1. From the menus, choose Tools > New Rule. Alternatively, click the New rule icon in the tree toolbar to open a new rule in the editor.
2. Enter a unique name and define the rule value elements.
3. Click Apply when finished to check for errors.

Editing Rules

1. Click the rule name in the tree. The rule opens in the editor pane on the right.
2. Make your changes.
3. Click Apply when finished to check for errors.

Disabling and Deleting Rules

Disabling Rules

If you want a rule to be ignored during processing, you can disable it. Take caution when deleting and disabling rules.

1. Click the rule name in the tree. The rule opens in the editor pane on the right.
2. Right-click on the name.
3. From the context menus, choose Disable. The rule icon becomes gray and the rule itself becomes uneditable.

Deleting Rules

If you want to get rid of a rule, you can delete it. Take caution when deleting and disabling rules.

1. Click the rule name in the tree. The rule opens in the editor pane on the right.
2. Right-click on the name.
3. From the context menus, choose Delete. The rule disappears from the list.

Checking for Errors, Saving, and Cancelling

Applying Rule Changes

If you click outside of the rule editor or if you click Apply, the rule is automatically scanned for errors. If an error is found, you will need to fix it before moving on to another part of the application.

However, if less serious errors are detected, only a warning is given. For example, if your rule contains incomplete or unreferenced definitions to types or macros, a warning message is displayed. Once you click Apply, any uncorrected warnings cause a warning icon to appear to the left of the rule name in the tree in the left pane.

Applying a rule does not mean that your rule is permanently saved. Applying will cause the validation process to check for errors and warnings.

Saving Resources inside an Interactive Workbench Session

1. To save the changes you made to your resources during an interactive workbench session so you can get them next time you run your stream, you must:
 - Update your modeling node to make sure that you can get these same resources next time you execute your stream. See the topic [Updating Modeling Nodes and Saving](#) for more information. Then save your stream. To save your stream, do so in the main IBM® SPSS® Modeler window after updating the modeling node.
2. To save the changes you made to your resources during an interactive workbench session so that you can use them in other streams, you can:
 - Update the template you used or make a new one. See the topic [Making and Updating Templates](#) for more information. This will not save the changes for the current node (see previous step)
 - Or, update the TAP you used. See the topic [Updating Text Analysis Packages](#) for more information.

Saving Resources inside the Template Editor

1. First, publish the library. See the topic [Publishing Libraries](#) for more information.
2. Then, save the template through File > Save Resource Template in the menus.

Cancelling Rule Changes

1. If you wish to discard the changes, click Cancel in the editor pane.

-

Processing Order for Rules

When text link analysis is performed during extraction, a "sentence" (clause, word, phrase) will be matched against each rule in turn until a match is found or all rules have been exhausted. Position in the tree dictates the order in which rules are tried. Best practice states that you should order your rules from most specific to most generic. The most specific ones should be at the top of the tree. To change the order of a specific rule or rule set, select Move up or Move down from the Rules and Macro Tree context menu or the up and down arrows in the toolbar.

If you are *in the source view*, you cannot change the order of the rules by moving them around in the editor. The higher up the rule appears in the source view, the sooner it is processed. We strongly recommend reordering rules only in the tree to avoid copy/paste issues.

Important! In previous versions of IBM® SPSS® Modeler Text Analytics, you were required to have a unique, numeric rule ID. Starting in version 18.4.0, you can only indicate processing order by moving a rule up or down in the tree, or by their position in the source view.

For example, suppose your text contains the following two sentences:

I love anchovies

I love anchovies and green peppers

In addition, suppose that two text link analysis rules exist with the following values:

Figure 1. 2 Example Rules

A	Element	Quantity	Example Token
1	Positive	Exactly 1	
2	mDet	0 or 1	
3	mTopic	Exactly 1	
4			
5			
6			
7			

B	Element	Quantity	Example Token
1	Positive	Exactly 1	
2	mDet	0 or 1	
3	mTopic	Exactly 1	
4	(SEP and or)	1 or 2	
5	mDet	0 or 1	
6	mTopic	Exactly 1	
7			

In the source view, the rule values might look like the following:

A: value = \$Positive \$mDet? \$mTopic

B: value = \$Positive \$mDet? \$mTopic (\$SEP|and|or){1,2} \$mDet? \$mTopic

If rule **A** is higher up in the tree (closer to the top) than rule **B**, then rule **A** will be processed first and the sentence *I love anchovies and green peppers* will be first matched by **\$Positive \$mDet? \$mTopic**, and it will produce an incomplete pattern output (**anchovies + like**) since it was matched by a rule that wasn't looking for 2 **\$mTopic** matches.

Therefore, to capture the true essence of the text, the most specific rule, in this case **B** must be placed higher in the tree than the more generic one, in this case rule **A**.

Working with Rule Sets (Multiple Pass)

A rule set is a helpful way of grouping a related set of rules together in the Rules and Macro Tree so as to perform multiple pass processing. A rule set has no definition itself other than a name, and is used to organize your rules into meaningful groups. In some contexts, the text is too rich and varied to be processed in a single pass. For example, when working with security intelligence data, the text may contain links between individuals that are uncovered through contact methods (*x called y*), through family relationships (*y's brother-in-law x*), through exchange of money (*x wired \$100 to y*), and so on. In this case, it is helpful to create specialized sets of text link analysis rules, each of which is focused on a certain kind of relationship such as one for uncovering contacts, another for uncovering family members, and so on.

To create a rule set, select "Create Rule Set" from the Rules and Macro Tree context menu, or from the toolbar. You can then create new rules directly under a Rule Set node on the tree, or move existing rules to a Rule Set.

When you run an extraction using resources in which the rules are grouped into rule sets, the extraction engine is forced to make multiple passes through the text in order to match different kinds of patterns in each pass. In this way, a "sentence" can be matched to a rule in each rule set, whereas without a rule set it can only matched to a single rule.

Note: You can add up to 512 rules per rule set.

Creating New Rule Sets

1. From the menus, choose Tools > New Rule Set. Alternatively, click the New Rule Set icon in the tree toolbar. A rule set appears in the rule tree.
2. Add new rules to this rule set or move existing rules into the set.

Disabling Rule Sets

1. Right-click the rule set name in the tree.
2. From the context menus, choose Disable. The rule set icon becomes gray and all of the rules contained within that rule set are also disabled and ignored during processing.

Deleting Rule Sets

1. Right-click the rule set name in the tree.
2. From the context menus, choose Delete. The rule set and all the rules it contains are deleted from the resources.

-

Supported Elements for Rules and Macros

The following arguments are accepted for the value parameters in text link analysis rules and macros:

Macros

You can use a macro directly in a text link analysis rule or within another macro. If you are entering the macro name by hand or from within the source view (as opposed to selecting the macro name from a context menu), make sure to prefix the name with a dollar sign character (\$), such as \$mTopic. The macro name is case sensitive. You can choose from any macro defined in the current Text Link Rules tab when selecting macros through the context menus.

Types

You can use a type directly in a text link analysis rule or macro. If you are entering the type name by hand or in the source view (as opposed to selecting the type from a context menu), make sure to prefix the type name with a dollar sign character (\$), such as \$Person. The type name is case sensitive. If you use the context menus, you can choose from any type from the current set of resources being used.

If you reference an unrecognized type, you will receive a warning message, and the rule will have a warning icon in the Rules and Macro Tree until you correct it.

Literal Strings

To include information that was never extracted, you can define a literal string for which the extraction engine will search. All extracted words or phrases have been assigned to a type and for this reason, they cannot be used in literal strings. If you use a word that was extracted, it will be ignored, even if its type is <Unknown>.

A literal string can be one or more words. The following rules apply when defining a list of literal strings:

- Enclose the list of strings in parentheses such as (his). If there is a choice of literal strings then each string must be separated by the OR operator, such as (a|an|the) or (his|hers|its).
- Use single or compound words.
- Separate each word in the list by the | character, which is like a Boolean OR.
- Enter both singular and plural forms if you want to match both. Inflection is not automatically generated.
- Use lower case only.
- To reuse literal strings, define them as a macro and then use that macro in your other macros and text link analysis rules.
- If a string contains periods (full stops) or hyphens, you must include them. For example, to match a.k.a in the text, enter the periods along with the letters a.k.a as the literal string.

Exclusion Operator

Use ! as an exclusion operator to stop any expression of the negation from occupying a particular slot. You can only add an exclusion operator by hand through inline cell editing (double-click the cell in the Rule Value table or Macro Value table) or in the source view. For example, if you add `$mTopic @{0,2} !($Positive) $Budget` to your text link analysis rule, you are looking for text that contains (1) a term assigned to any of the types in the `mTopic` macro, (2) a word gap of zero to two words long, (3) no instances of a term assigned to the `<Positive>` type, and (4) a term assigned to the `<Budget>` type. This might capture "cars have an inflated price tag" but would ignore "store offers amazing discounts".

To use this operator, you must enter the exclamation point and parenthesis manually into the element cell by double-clicking the cell.

Word Gaps (<Any Token>)

A word gap, also referred to as `<Any Token>`, defines a numeric range of tokens that may be present between two elements. Word gaps are very useful when matching very similar phrases that may differ only slightly due to the presence of additional determiners, prepositional phrases, adjectives, or other such words.

Table 1. Example of the elements in a Rule Value table without a word gap

#	Element
1	Unknown
2	mBeHave
3	Positive

Note: In the source view this value is defined as: `$Unknown $mBeHave $Positive`

This value will match sentences like "*the hotel staff was nice*", where *hotel staff* belongs to type `<Unknown>`, *was* is under the macro `mBeHave` and *nice* is `<Positive>`. But it will not match "*the hotel staff was very nice*".

Table 2. Example of the elements in a Rule Value table with a `<Any Token>` word gap

#	Element
1	Unknown
2	mBeHave
3	
4	Positive

Note: In the source view this value is defined as: `$Unknown $mBeHave @{0,1} $Positive`

If you add a word gap to your rule value, it will match both "*the hotel staff was nice*" and "*the hotel staff was very nice*".

In the source view or with inline editing, the syntax for a word gap is `@{#, #}`, where @ signifies a word gap and the `{#, #}` defines the minimum and maximum of words accepted between the preceding element and following element. For example, `@{1,3}` means that a match can be made between the two defined elements if there is at least one word present but no more than three words appearing between those two elements. `@{0,3}` means that a match can be made between the two defined elements if there is 0, 1, 2 or 3 words present but no more than three words.

Viewing and working in source mode

For each rule and macro the TLA editor generates the underlying source code that is used by the Extractor for matching and producing TLA output. If you prefer to work with the code itself, you can view this source code and edit it directly by clicking the “View Source” button at the top of the Editor. The Source view will jump to and highlight the currently selected rule or macro. However, we recommend using the editor panes to reduce the chance of errors.

When you have finished viewing or editing the source, click Exit Source. If you generate invalid syntax for a rule, you will be required to fix it before you exit the source view.

Important: If you edit in the source view, we strongly recommend that you edit rules and macros one at a time. After editing a macro, please validate the results by extracting. If you are satisfied with the result, we recommend that you save the template before making another change. If you are not satisfied with the result or an error occurs, revert to your saved resources.

Macros in the Source View

```
[macro]
name = macro_name
value = ([type_name|macro_name|literal_string|word_gap])
```

Table 1. Macro entries

[macro]	Each macro must begin with the line marked [macro] to denote the beginning of a macro.
name	The name of the macro definition. Each name must be unique.
value	A combination of one or more types, literal strings, word gaps, or macros. See the topic Supported Elements for Rules and Macros for more information. When combining arguments, you must use parentheses () to group the arguments and the character to indicate a Boolean OR.

In addition to the guidelines and syntax covered in the section on Macros, the source view has a few additional guidelines that aren't required when working in the editor view. Macros must also respect the following when working in source mode:

- Each macro must begin with the line marked [macro] to denote the beginning of a macro.
- To disable an element, place a comment indicator (#) before each line.

Example. This example defines a macro called mTopic. The value for mTopic is the presence of a term matching one of the following types: <Product>, <Person>, <Location>, <Organization>, <Budget>, or <Unknown>.

```
[macro]
name=mTopic
value=($Unknown|$Product|$Person|$Location|$Organization|$Budget|$Currency)
```

Rules in the Source View

```
[pattern(ID)]
name = pattern_name
value = [$type_name|macro_name|word_gaps|literal_strings]
output = $digit[\t]#${digit[\t]}$digit[\t]#${digit[\t]}$digit[\t]
```

Table 2. Rule entries

[pattern(<ID>)]	Indicates the start of a text link analysis rule and provides a unique numerical ID use to determine processing order.
name	Provides a unique name for this text link analysis rule.
value	Provides the syntax and arguments to be matched to the text. See the topic Supported Elements for Rules and Macros for more information.
output	The output format for the resulting matched patterns discovered in the text. The output does not always resemble the exact original position of elements in the source text. Additionally, it is possible to have multiple output lines for a given text link analysis rule by placing each output on a separate line. Syntax for output: <ul style="list-style-type: none">• Separate output with the tab code \t, such as \$1\t#1\t\$3\t#3• \$ and a number calls for the term found matching the argument defined in the value parameter in that position. So \$1 means the term matching the first argument defined for the value.• # and a number calls for the type name of the element in that position. If an item is a list of literal strings, the type <Unknown> will be assigned.• A value of Null\tNull will not create any output.

In addition to the guidelines and syntax covered in the section on Rules, the source view has a few additional guidelines that aren't required when working in the editor view. Rules must also respect the following when working in source mode:

- Whenever two or more elements are defined, they must be enclosed in parentheses whether or not they are optional (for example, `($Negative|$Positive)` or `($mCoord|$SEP)?`). `$SEP` represents a comma.
- The first element in a text link analysis rule cannot be an optional element. For example, you cannot begin with `value = $mTopic?` or `value = @{0,1}.`
- It is possible to associate a quantity (or instance count) to a token. This is useful in writing only one rule that encompasses all cases instead of writing a separate rule for each case. For example, you may use the literal string `($SEP|and)` if you are trying to match either , (comma) or `and`. If you extend this by adding a quantity so that the literal string becomes `($SEP|and){1,2}`, you will now match any of the following instances: " , " `and` " , `and`".
- Spaces are not supported between the macro name and the `$` and `?` characters in the text link analysis rule `value`.
- Spaces are not supported in the text link analysis rule `output`.
- To disable an element, place a comment indicator (#) before each line.

Example. Let's suppose your resources contain the following TLA text link analysis rule and that you have enabled the extraction of TLA results:

```
## Jean Doe was the former HR director of IBM in France
[pattern(201)]
name= 1_201
value = $Person ($SEP|$mDet|$mSupport|as|then){1,2} @{0,1} $Function
        (of|with|for|in|to|at) @{0,1} $Organization @{0,2} $Location
output = $1\t#1\t$4\t#4\t$7\t#7\t$9\t#9
```

Whenever you extract, the extraction engine will read each sentence and will try to match the following sequence:

Table 3. Extraction sequence example

Position	Description of the arguments
1	The name of a person (<code>\$Person</code>),
2	One or two of the following: comma (<code>\$SEP</code>), determiner (<code>\$mDet</code>), auxiliary verb (<code>\$mSupport</code>), the strings “ <code>then</code> ” or “ <code>as</code> ”,
3	0 or 1 word (@{0,1})
4	A function (<code>\$Function</code>)
5	One of the following strings: “ <code>of</code> ”, “ <code>with</code> ”, “ <code>for</code> ”, “ <code>in</code> ”, “ <code>to</code> ”, or “ <code>at</code> ”,
6	0 or 1 word (@{0,1})
7	The name of an organization (<code>\$Organization</code>)
8	0, 1, or 2 words (@{0,2})
9	The name of a location (<code>\$Location</code>)

This sample text link analysis rule would match sentences or phrases like:

Jean Doe, the HR director of IBM in France

Jean Doe was the former HR director of IBM in France

IBM appointed Jean Doe as the HR director of IBM in France

This sample text link analysis rule would produce the following output:

```
jean doe <Person> hr director <Function> ibm <Organization> france <Location>
```

Where:

- `jean doe` is the term corresponding to `$1` (the first element in the text link analysis rule) and `<Person>` is the type for `jean doe` (#1),
- `hr director` is the term corresponding to `$4` (the 4th element in the text link analysis rule) and `<Function>` is the type for `hr director` (#4),
- `ibm` is the term corresponding to `$7` (the 7th element in the text link analysis rule) and `<Organization>` is the type for `ibm`. (#7),
- `france` is the term corresponding to `$9` (the 9th element in the text link analysis rule) and `<Location>` is the type for `france` (#9)

Rule Sets in the Source View

```
[set(<ID>)]
```

Where `[set (<ID>)]` indicates the start of a rule set and provides a unique numerical ID use to determine processing order of the sets.

Example. The following sentence contains information about individuals, their function within a company, and also the merge/acquisition activities of that company.

```
Org1 Inc has entered into a definitive merger agreement with Org2 Ltd, said John Doe, CEO of Org2 Ltd.
```

You could write one rule with several outputs to handle all possible output such as:

```
## Org1 Inc entered into a definitive merger agreement with Org2 Ltd, said
John Doe, CEO of Org2 Ltd.
```

```
[pattern(020)]
name=020
value = $Organization @{0,4} $ActionNouns @{0,6} $mOrg @{1,2}
$Person @{0,2} $Function @{0,1} $Organization
output = $1\t#1\t$3\t#3\t$5\t#5
output = $7\t#7\t$9\t#9\t$11\t#11
```

which would produce the following 2 output patterns:

- org1 inc<Organization> + merges with <ActiveVerb> + org2
ltd<Organization>
- john doe <Person> + ceo <Function> + org2 ltd<Organization>

Important! Keep in mind that other linguistic handling operations are performed during the extraction of TLA patterns. In this case, `merges` is grouped under `merges`

`with` during the synonym grouping phase of the extraction process. And since `merges` belongs to `<ActiveVerb>` type, this type name is what appears in the final TLA pattern output. So when the output reads `t$3\t#3`, this means that the pattern will ultimately display the final concept for the third element and the final type for the third element after all linguistic processing is applied (synonyms and other groupings).

Instead of writing complex rules like the preceding, it can be easier to manage and work with two rules. The first is specialized in finding out mergers/acquisitions between companies:

```
[set(1)]
## Org1 Inc has entered into a definitive merger agreement with Org2 Ltd
[pattern(44)]
name=firm + action + firm_0044
value=$mOrg @{0,20} $ActionNouns @{0,6} $mOrg
output(1)=$1\t#1\t$3\t#3\t$5\t#5
```

which would produce `org1 inc<Organization> + merges with <ActiveVerb> + org2 ltd <Organization>`

The second is specialized in individual/function/company:

```
[set(2)]
## said John Doe, CEO of Org2 Ltd
[pattern(52)]
name=individual + role + firm_0007
value=$Person @{0,3} $mFunction (at|of)? ($mOrg|$Media|$Unknown)
output(1)=$1\t#1\t$3\tFunction\t$5\t#5
```

which would produce `john doe <Person> + ceo <Function> + org2 ltd <Organization>`

About IBM SPSS Modeler

IBM® SPSS® Modeler is a set of data mining tools that enable you to quickly develop predictive models using business expertise and deploy them into business operations to improve decision making. Designed around the industry-standard CRISP-DM model, IBM SPSS Modeler supports the entire data mining process, from data to better business results.

IBM SPSS Modeler offers a variety of modeling methods taken from machine learning, artificial intelligence, and statistics. The methods available on the Modeling palette allow you to derive new information from your data and to develop predictive models. Each method has certain strengths and is best suited for particular types of problems.

SPSS Modeler can be purchased as a standalone product, or used as a client in combination with SPSS Modeler Server. A number of additional options are also available, as summarized in the following sections. For more information, see <https://www.ibm.com/analytics/us/en/technology/spss/>.

- [IBM SPSS Modeler Products](#)
- [IBM SPSS Modeler Editions](#)
- [Documentation](#)
- [Application examples](#)
- [Demos Folder](#)

IBM SPSS Modeler Products

The IBM® SPSS® Modeler family of products and associated software comprises the following.

- IBM SPSS Modeler
 - IBM SPSS Modeler Server
 - IBM SPSS Modeler Administration Console (included with IBM SPSS Deployment Manager)
 - IBM SPSS Modeler Batch
 - IBM SPSS Modeler Solution Publisher
 - IBM SPSS Modeler Server adapters for IBM SPSS Collaboration and Deployment Services
- [IBM SPSS Modeler](#)**
[IBM SPSS Modeler Server](#)
[IBM SPSS Modeler Administration Console](#)
[IBM SPSS Modeler Batch](#)
[IBM SPSS Modeler Solution Publisher](#)
[IBM SPSS Modeler Server Adapters for IBM SPSS Collaboration and Deployment Services](#)
-

IBM SPSS Modeler

SPSS® Modeler is a functionally complete version of the product that you install and run on your personal computer. You can run SPSS Modeler in local mode as a standalone product, or use it in distributed mode along with IBM® SPSS Modeler Server for improved performance on large data sets.

With SPSS Modeler, you can build accurate predictive models quickly and intuitively, without programming. Using the unique visual interface, you can easily visualize the data mining process. With the support of the advanced analytics embedded in the product, you can discover previously hidden patterns and trends in your data. You can model outcomes and understand the factors that influence them, enabling you to take advantage of business opportunities and mitigate risks.

SPSS Modeler is available in two editions: SPSS Modeler Professional and SPSS Modeler Premium. See the topic [IBM SPSS Modeler Editions](#) for more information.

IBM SPSS Modeler Server

SPSS® Modeler uses a client/server architecture to distribute requests for resource-intensive operations to powerful server software, resulting in faster performance on larger data sets.

SPSS Modeler Server is a separately-licensed product that runs continually in distributed analysis mode on a server host in conjunction with one or more IBM® SPSS Modeler installations. In this way, SPSS Modeler Server provides superior performance on large data sets because memory-intensive operations can be done on the server without downloading data to the client computer. IBM SPSS Modeler Server also provides support for SQL optimization and in-database modeling capabilities, delivering further benefits in performance and automation.

IBM SPSS Modeler Administration Console

The Modeler Administration Console is a graphical user interface for managing many of the SPSS® Modeler Server configuration options, which are also configurable by means of an options file. The console is included in IBM® SPSS Deployment Manager, can be used to monitor and configure your SPSS Modeler Server installations, and is available free-of-charge to current SPSS Modeler Server customers. The application can be installed only on Windows computers; however, it can administer a server installed on any supported platform.

IBM® SPSS Modeler Batch

While data mining is usually an interactive process, it is also possible to run SPSS® Modeler from a command line, without the need for the graphical user interface. For example, you might have long-running or repetitive tasks that you want to perform with no user intervention. SPSS Modeler Batch is a special version of the product that provides support for the complete analytical capabilities of SPSS Modeler without access to the regular user interface. SPSS Modeler Server is required to use SPSS Modeler Batch.

IBM SPSS Modeler Solution Publisher

SPSS® Modeler Solution Publisher is a tool that enables you to create a packaged version of an SPSS Modeler stream that can be run by an external runtime engine or embedded in an external application. In this way, you can publish and deploy complete SPSS Modeler streams for use

in environments that do not have SPSS Modeler installed. SPSS Modeler Solution Publisher is distributed as part of the IBM® SPSS Collaboration and Deployment Services - Scoring service, for which a separate license is required. With this license, you receive SPSS Modeler Solution Publisher Runtime, which enables you to execute the published streams.

For more information about SPSS Modeler Solution Publisher, see the IBM SPSS Collaboration and Deployment Services documentation. The IBM SPSS Collaboration and Deployment Services IBM Documentation contains sections called "IBM SPSS Modeler Solution Publisher" and "IBM SPSS Analytics Toolkit."

IBM SPSS Modeler Server Adapters for IBM SPSS Collaboration and Deployment Services

A number of adapters for IBM® SPSS® Collaboration and Deployment Services are available that enable SPSS Modeler and SPSS Modeler Server to interact with an IBM SPSS Collaboration and Deployment Services repository. In this way, an SPSS Modeler stream deployed to the repository can be shared by multiple users, or accessed from the thin-client application IBM SPSS Modeler Advantage. You install the adapter on the system that hosts the repository.

IBM SPSS Modeler Editions

SPSS® Modeler is available in the following editions.

SPSS Modeler Professional

SPSS Modeler Professional provides all the tools you need to work with most types of structured data, such as behaviors and interactions tracked in CRM systems, demographics, purchasing behavior and sales data.

SPSS Modeler Premium

SPSS Modeler Premium is a separately-licensed product that extends SPSS Modeler Professional to work with specialized data and with unstructured text data. SPSS Modeler Premium includes IBM® SPSS Modeler Text Analytics:

IBM SPSS Modeler Text Analytics uses advanced linguistic technologies and Natural Language Processing (NLP) to rapidly process a large variety of unstructured text data, extract and organize the key concepts, and group these concepts into categories. Extracted concepts and categories can be combined with existing structured data, such as demographics, and applied to modeling using the full suite of IBM SPSS Modeler data mining tools to yield better and more focused decisions.

IBM SPSS Modeler Subscription

IBM SPSS Modeler Subscription provides all the same predictive analytics capabilities as the traditional IBM SPSS Modeler client. With the Subscription edition, you can download product updates regularly.

Documentation

Documentation is available from the Help menu in SPSS® Modeler. This opens the online IBM Documentation, which is always available outside the product.

Complete documentation for each product (including installation instructions) is also available in PDF format at <https://www.ibm.com/support/pages/spss-modeler-184-documentation>.

- [SPSS Modeler Professional documentation](#)
- [SPSS Modeler Premium Documentation](#)

SPSS Modeler Professional documentation

The SPSS® Modeler Professional documentation suite (excluding installation instructions) is as follows.

- **IBM® SPSS Modeler User's Guide.** General introduction to using SPSS Modeler, including how to build data streams, handle missing values, build CLEM expressions, work with projects and reports, and package streams for deployment to IBM SPSS Collaboration and Deployment Services or IBM SPSS Modeler Advantage.
- **IBM SPSS Modeler Source, Process, and Output Nodes.** Descriptions of all the nodes used to read, process, and output data in different formats. Effectively this means all nodes other than modeling nodes.
- **IBM SPSS Modeler Modeling Nodes.** Descriptions of all the nodes used to create data mining models. IBM SPSS Modeler offers a variety of modeling methods taken from machine learning, artificial intelligence, and statistics.
- **IBM SPSS Modeler Algorithms Guide.** Descriptions of the mathematical foundations of the modeling methods used in IBM SPSS Modeler. This guide is available in PDF format only.

SPSS Modeler Premium Documentation

The SPSS® Modeler Premium documentation suite (excluding installation instructions) is as follows.

- **SPSS Modeler Text Analytics User's Guide.** Information on using text analytics with SPSS Modeler, covering the text mining nodes, interactive workbench, templates, and other resources.

Application examples

While the data mining tools in SPSS® Modeler can help solve a wide variety of business and organizational problems, the application examples provide brief, targeted introductions to specific modeling methods and techniques. The data sets used here are much smaller than the enormous data stores managed by some data miners, but the concepts and methods that are involved are scalable to real-world applications.

To access the examples, click Application Examples on the Help menu in SPSS Modeler.

The data files and sample streams are installed in the Demos folder under the product installation directory. For more information, see [Demos Folder](#).

After you open an example, click the Next button in the lower left corner of the tutorial page to move forward through the example.

A PDF version of the Applications Guide is also available. For more information, see [Documentation](#).

Demos Folder

The data files and sample streams that are used with the application examples are installed in the Demos folder under the product installation directory (for example: C:\Program Files\IBM\SPSS\Modeler\<version>\Demos). This folder can also be accessed from the IBM SPSS® Modeler program group on the Windows Start menu, or by clicking Demos on the list of recent directories in the File->Open Stream dialog box.

License tracking

When you use SPSS® Modeler, license usage is tracked and logged at regular intervals. The license metrics that are logged are AUTHORIZED_USER and CONCURRENT_USER, and the type of metric that is logged depends on the type of license that you have for SPSS Modeler.

The log files that are produced can be processed by the IBM License Metric Tool, from which you can generate license usage reports.

The license log files are created in the same directory where SPSS Modeler Client log files are recorded (by default, %ALLUSERSPROFILE%\IBM\SPSS\Modeler\<version>/log).

Product overview

- [Getting started](#)
- [Starting IBM SPSS Modeler](#)
- [IBM SPSS Modeler Interface at a Glance](#)

Getting started

As a data mining application, IBM® SPSS® Modeler offers a strategic approach to finding useful relationships in large data sets. In contrast to more traditional statistical methods, you do not necessarily need to know what you are looking for when you start. You can explore your data, fitting different models and investigating different relationships, until you find useful information.

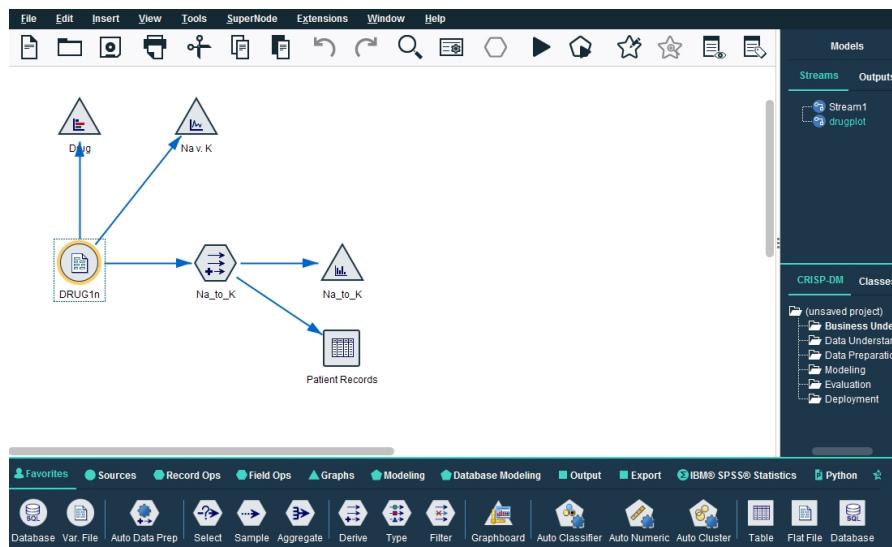

Starting IBM® SPSS® Modeler

To start the application, click:

Start->[All] Programs->IBM SPSS Modeler <version>->IBM SPSS Modeler <version>

The main window is displayed after a few seconds.

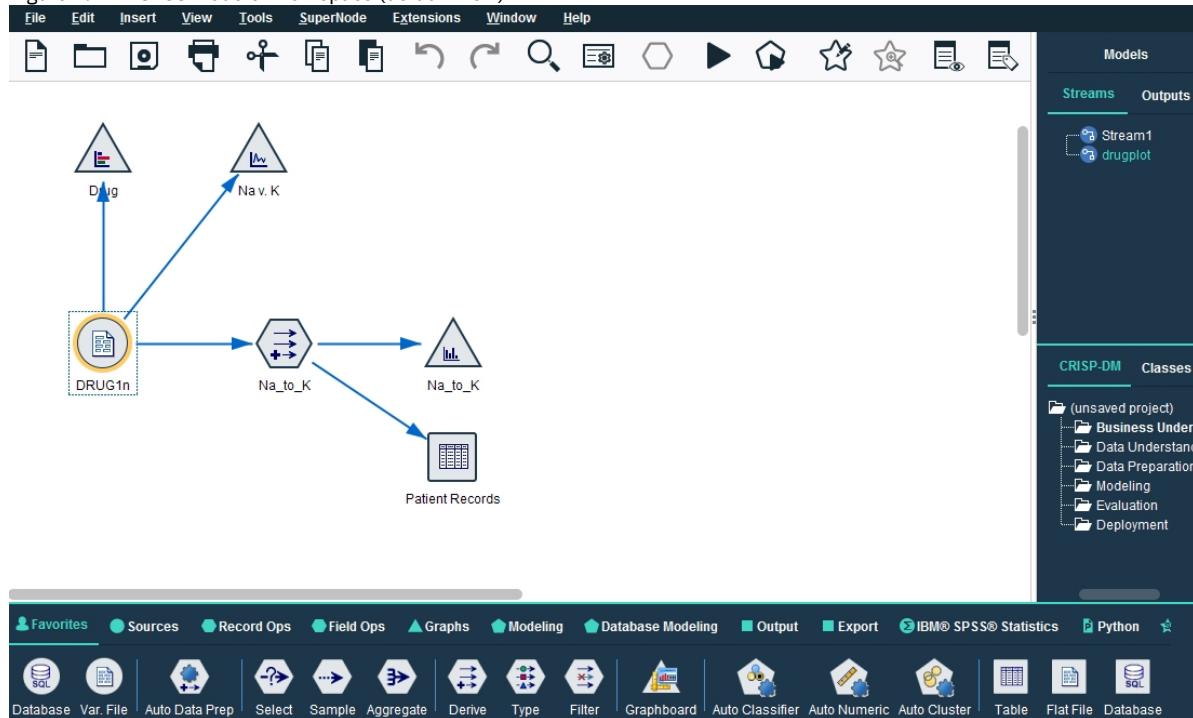

Figure 1. IBM SPSS Modeler main application window

IBM SPSS Modeler Interface at a Glance

At each point in the data mining process, the easy-to-use IBM® SPSS® Modeler interface invites your specific business expertise. Modeling algorithms, such as prediction, classification, segmentation, and association detection, ensure powerful and accurate models. Model results can easily be deployed and read into databases, IBM SPSS Statistics, and a wide variety of other applications.

Figure 1. IBM SPSS Modeler workspace (default view)

Working with IBM SPSS Modeler is a three-step process of working with data.

- First, you read data into IBM SPSS Modeler.
- Next, you run the data through a series of manipulations.
- Finally, you send the data to a destination.

This sequence of operations is known as a **data stream** because the data flows record by record from the source through each manipulation and, finally, to the destination--either a model or type of data output.

Figure 2. A simple stream

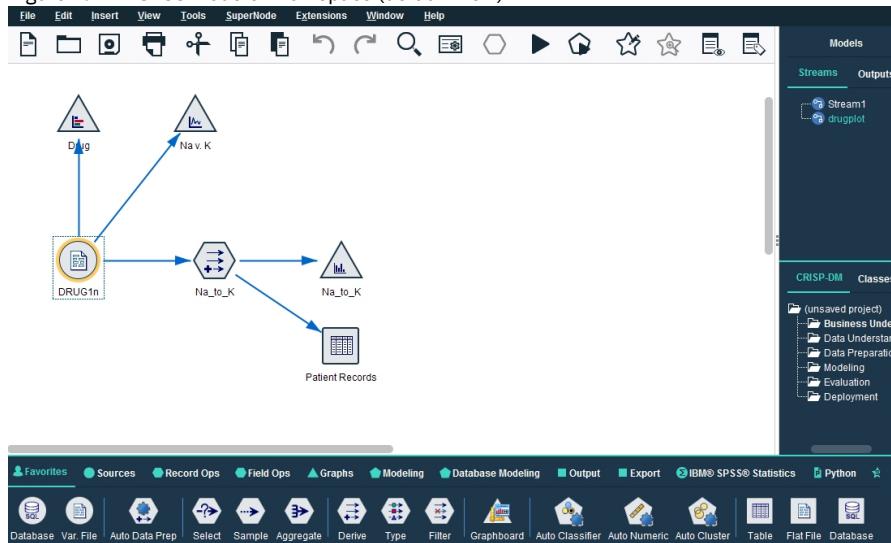

- [IBM SPSS Modeler Stream Canvas](#)
- [Nodes palette](#)
- [IBM SPSS Modeler Managers](#)
- [IBM SPSS Modeler Projects](#)
- [Using the Mouse in IBM SPSS Modeler](#)

IBM SPSS Modeler Stream Canvas

The stream canvas is the largest area of the IBM® SPSS® Modeler window and is where you will build and manipulate data streams.

Figure 1. IBM SPSS Modeler workspace (default view)

Streams are created by drawing diagrams of data operations relevant to your business on the main canvas in the interface. Each operation is represented by an icon or **node**, and the nodes are linked together in a **stream** representing the flow of data through each operation.

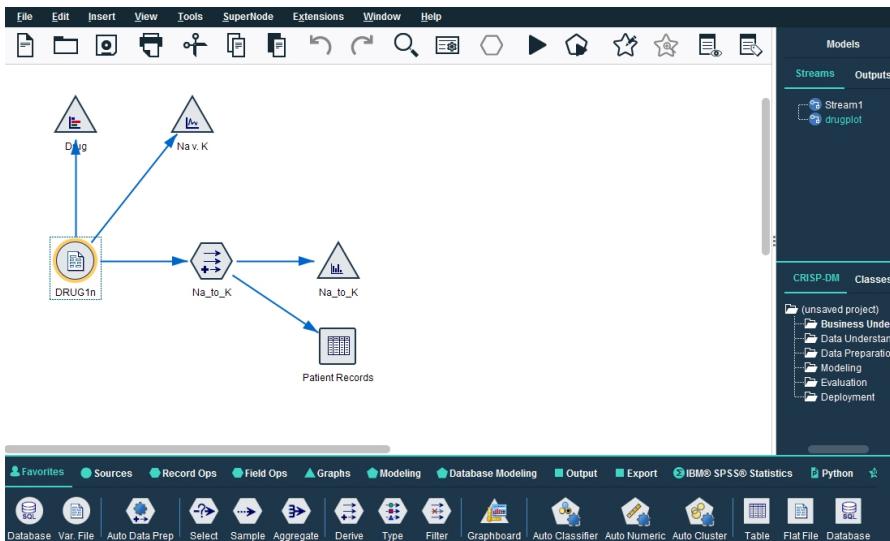

You can work with multiple streams at one time in IBM SPSS Modeler, either in the same stream canvas or by opening a new stream canvas. During a session, streams are stored in the Streams manager, at the upper right of the IBM SPSS Modeler window.

Note: If using a MacBook with the built-in trackpad's Force Click and haptic feedback setting enabled, dragging and dropping nodes from the nodes palette to the stream canvas can result in duplicate nodes being added to the canvas. To avoid this issue, we recommend disabling the Force Click and haptic feedback trackpad system preference.

Nodes palette

Most of the data and modeling tools in SPSS® Modeler are available from the *Nodes Palette*, across the bottom of the window below the stream canvas.

Figure 1. SPSS Modeler workspace (default view)

For example, the Record Ops palette tab contains nodes that you can use to perform operations on the data *records*, such as selecting, merging, and appending.

To add nodes to the canvas, double-click icons from the Nodes Palette or drag them onto the canvas. You then connect them to create a *stream*, representing the flow of data.

Each palette tab contains a collection of related nodes used for different phases of stream operations, such as:

- Sources nodes bring data into SPSS Modeler.
- Record Ops nodes perform operations on data *records*, such as selecting, merging, and appending.
- Field Ops nodes perform operations on data *fields*, such as filtering, deriving new fields, and determining the measurement level for given fields.
- Graphs nodes graphically display data before and after modeling. Graphs include plots, histograms, web nodes, and evaluation charts.
- Modeling nodes use the modeling algorithms available in SPSS Modeler, such as neural nets, decision trees, clustering algorithms, and data sequencing.
- Database Modeling nodes use the modeling algorithms available in Microsoft SQL Server, IBM Db2, and Oracle and Netezza databases.
- Output nodes produce various output for data, charts, and model results that can be viewed in SPSS Modeler.
- Export nodes produce various output that can be viewed in external applications, such as IBM® SPSS Data Collection or Excel.
- **IBM SPSS Statistics** nodes import data from, or export data to, IBM SPSS Statistics, as well as running IBM SPSS Statistics procedures.
- Python nodes can be used to run Python algorithms.
- Spark nodes can be used to run Spark algorithms.

As you become more familiar with SPSS Modeler, you can customize the palette contents for your own use.

On the left side of the Nodes Palette, you can filter the nodes that display by selecting Supervised, Association, or Segmentation.

Located below the Nodes Palette, a report pane provides feedback on the progress of various operations, such as when data is being read into the data stream. Also located below the Nodes Palette, a status pane provides information on what the application is currently doing, as well as indications of when user feedback is required.

Note: If using a MacBook with the built-in trackpad's Force Click and haptic feedback setting enabled, dragging and dropping nodes from the nodes palette to the stream canvas can result in duplicate nodes being added to the canvas. To avoid this issue, we recommend disabling the Force Click and haptic feedback trackpad system preference.

IBM SPSS Modeler Managers

At the top right of the window is the managers pane. This has three tabs, which are used to manage streams, output and models.

You can use the Streams tab to open, rename, save, and delete the streams created in a session.

Figure 1. Streams tab

Figure 2. Outputs tab

The Outputs tab contains a variety of files, such as graphs and tables, produced by stream operations in IBM® SPSS® Modeler. You can display, save, rename, and close the tables, graphs, and reports listed on this tab.

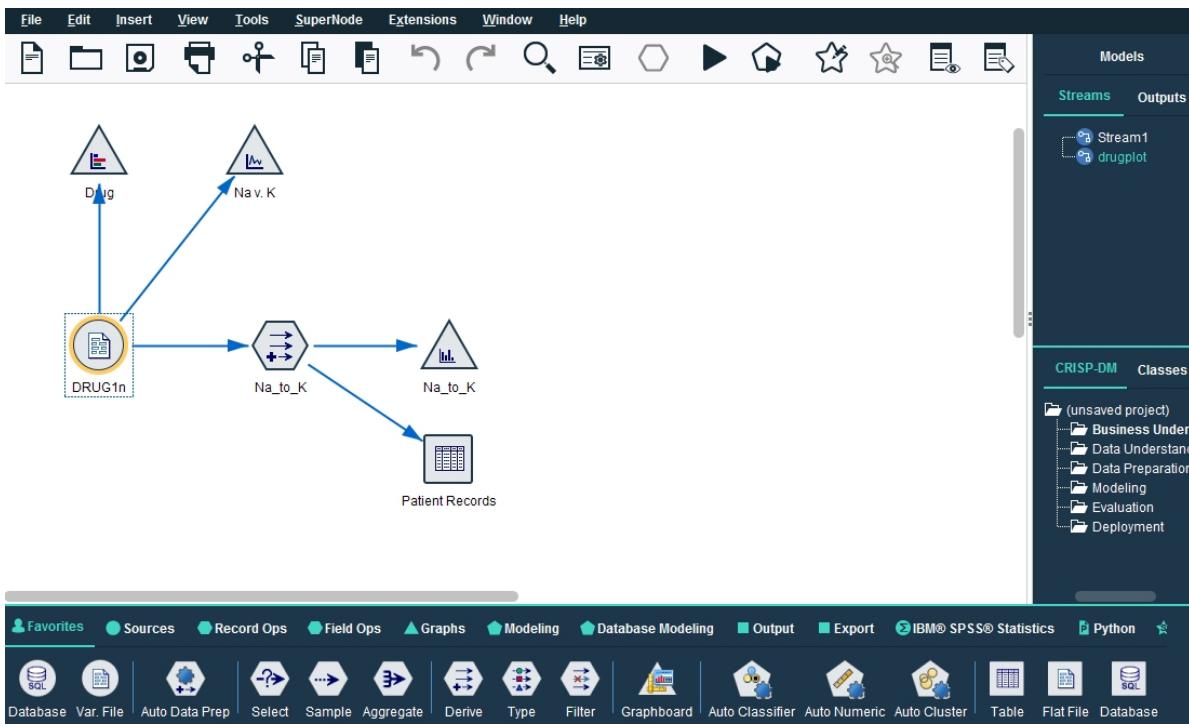

Figure 3. Models tab containing model nuggets

The Models tab is the most powerful of the manager tabs. This tab contains all model **nuggets**, which contain the models generated in IBM SPSS Modeler, for the current session. These models can be browsed directly from the Models tab or added to the stream in the canvas.

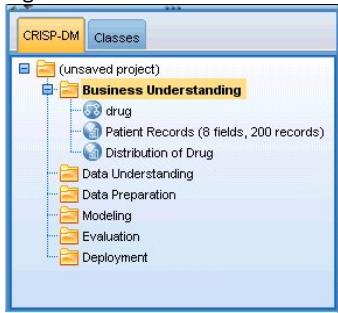

IBM SPSS Modeler Projects

Figure 1. IBM SPSS Modeler workspace (default view)

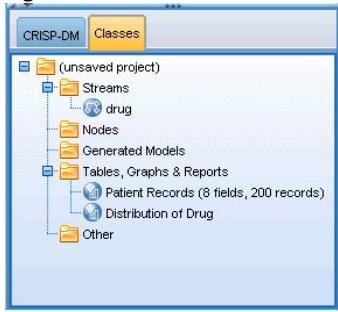

On the lower right side of the window is the project pane, used to create and manage data mining **projects** (groups of files related to a data mining task). There are two ways to view projects you create in IBM® SPSS® Modeler—in the **Classes** view and the **CRISP-DM** view.

Figure 2. CRISP-DM view

The CRISP-DM tab provides a way to organize projects according to the Cross-Industry Standard Process for Data Mining, an industry-proven, nonproprietary methodology. For both experienced and first-time data miners, using the CRISP-DM tool will help you to better organize and communicate your efforts.

Figure 3. Classes view

The Classes tab provides a way to organize your work in IBM SPSS Modeler categorically—by the types of objects you create. This view is useful when taking inventory of data, streams, and models.

Using the Mouse in IBM SPSS Modeler

The most common uses of the mouse in IBM® SPSS® Modeler include the following:

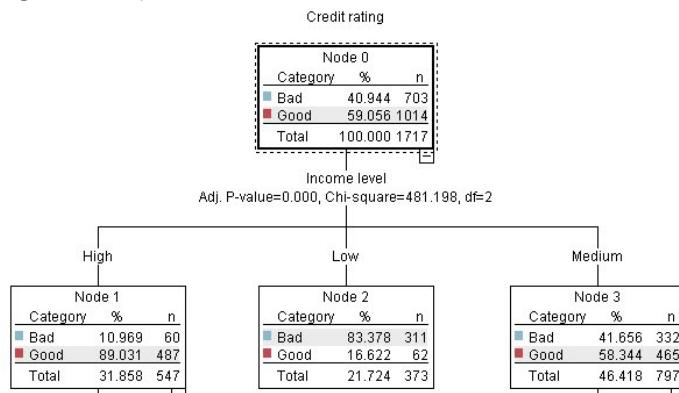

- **Single-click.** Use either the right or left mouse button to select options from menus, open pop-up menus, and access various other standard controls and options. Click and hold the button to move and drag nodes.
- **Double-click.** Double-click using the left mouse button to place nodes on the stream canvas and edit existing nodes.
- **Middle-click.** Click the middle mouse button and drag the cursor to connect nodes on the stream canvas. Double-click the middle mouse button to disconnect a node. If you do not have a three-button mouse, you can simulate this feature by pressing the Alt key while clicking and dragging the mouse.

Introduction to Modeling

A model is a set of rules, formulas, or equations that can be used to predict an outcome based on a set of input fields or variables. For example, a financial institution might use a model to predict whether loan applicants are likely to be good or bad risks, based on information that is already known about past applicants.

The ability to predict an outcome is the central goal of predictive analytics, and understanding the modeling process is the key to using IBM® SPSS® Modeler.

Figure 1. A simple decision tree model

This example uses a **decision tree** model, which classifies records (and predicts a response) using a series of decision rules, for example:

```
IF income = Medium
AND cards < 5
THEN -> 'Good'
```

While this example uses a CHAID (Chi-squared Automatic Interaction Detection) model, it is intended as a general introduction, and most of the concepts apply broadly to other modeling types in IBM SPSS Modeler.

To understand any model, you first need to understand the data that go into it. The data in this example contain information about the customers of a bank. The following fields are used:

Field name	Description
Credit_rating	Credit rating: 0=Bad, 1=Good, 9=missing values
Age	Age in years
Income	Income level: 1=Low, 2=Medium, 3=High
Credit_cards	Number of credit cards held: 1=Less than five, 2=Five or more
Education	Level of education: 1=High school, 2=College
Car_loans	Number of car loans taken out: 1=None or one, 2=More than two

The bank maintains a database of historical information on customers who have taken out loans with the bank, including whether or not they repaid the loans (Credit rating = Good) or defaulted (Credit rating = Bad). Using this existing data, the bank wants to build a model that will enable them to predict how likely future loan applicants are to default on the loan.

Using a decision tree model, you can analyze the characteristics of the two groups of customers and predict the likelihood of loan defaults.

This example uses the stream named *modelingintro.str*, available in the *Demos* folder under the *streams* subfolder. The data file is *tree_credit.sav*. See the topic [Demos Folder](#) for more information.

Let's take a look at the stream.

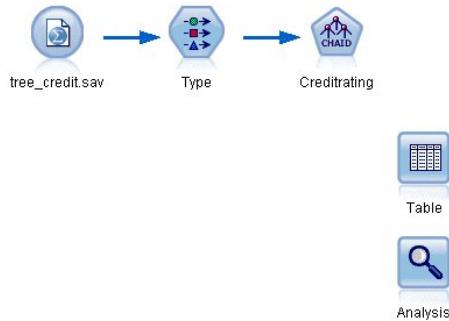

1. Choose the following from the main menu:
File->Open Stream
2. Click the gold nugget icon on the toolbar of the Open dialog box and choose the Demos folder.
3. Double-click the *streams* folder.
4. Double-click the file named *modelingintro.str*.

[Next](#)

- [Building the Stream](#)
- [Browsing the Model](#)
- [Evaluating the Model](#)
- [Scoring records](#)
- [Summary](#)

Building the Stream

Figure 1. Modeling stream

To build a stream that will create a model, we need at least three elements:

- A source node that reads in data from some external source, in this case an IBM® SPSS® Statistics data file.
- A source or Type node that specifies field properties, such as measurement level (the type of data that the field contains), and the role of each field as a target or input in modeling.
- A modeling node that generates a model nugget when the stream is run.

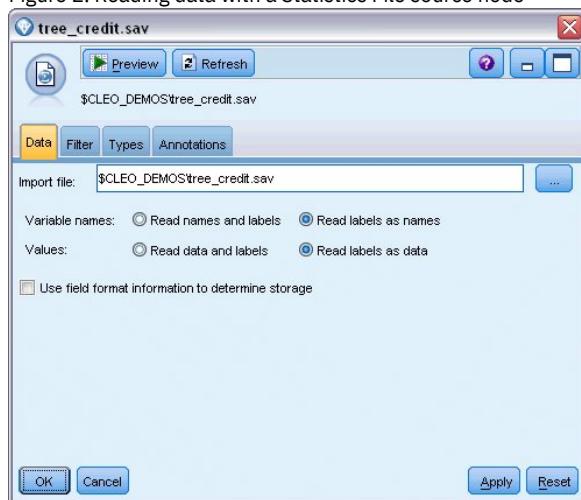

In this example, we're using a CHAID modeling node. CHAID, or Chi-squared Automatic Interaction Detection, is a classification method that builds decision trees by using a particular type of statistics known as chi-square statistics to work out the best places to make the splits in the decision tree.

If measurement levels are specified in the source node, the separate Type node can be eliminated. Functionally, the result is the same.

This stream also has Table and Analysis nodes that will be used to view the scoring results after the model nugget has been created and added to the stream.

The Statistics File source node reads data in IBM SPSS Statistics format from the *tree_credit.sav* data file, which is installed in the *Demos* folder. (A special variable named \$CLEO_DEMOS is used to reference this folder under the current IBM SPSS Modeler installation. This ensures the path will be valid regardless of the current installation folder or version.)

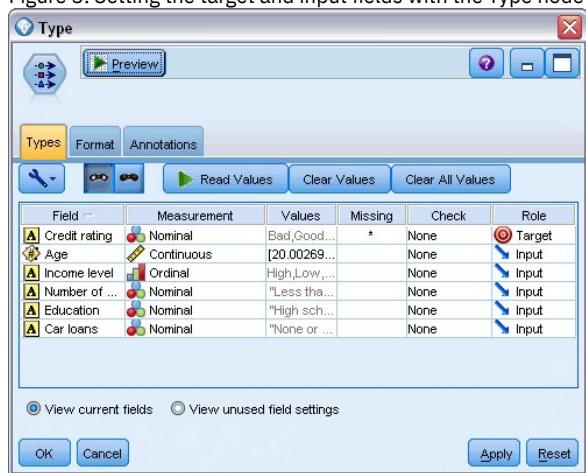

Figure 2. Reading data with a Statistics File source node

The Type node specifies the **measurement level** for each field. The measurement level is a category that indicates the type of data in the field. Our source data file uses three different measurement levels.

A **Continuous** field (such as the *Age* field) contains continuous numeric values, while a **Nominal** field (such as the *Credit rating* field) has two or more distinct values, for example *Bad*, *Good*, or *No credit history*. An **Ordinal** field (such as the *Income level* field) describes data with multiple distinct values that have an inherent order—in this case *Low*, *Medium* and *High*.

Figure 3. Setting the target and input fields with the Type node

For each field, the Type node also specifies a **role**, to indicate the part that each field plays in modeling. The role is set to *Target* for the field *Credit rating*, which is the field that indicates whether or not a given customer defaulted on the loan. This is the **target**, or the field for which we want to predict the value.

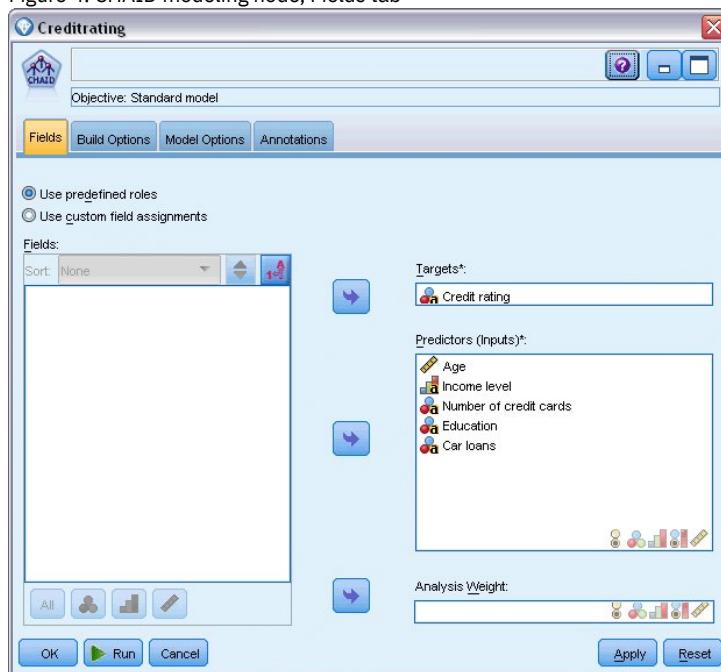

Role is set to *Input* for the other fields. Input fields are sometimes known as **predictors**, or fields whose values are used by the modeling algorithm to predict the value of the target field.

The CHAID modeling node generates the model.

On the Fields tab in the modeling node, the option *Use predefined roles* is selected, which means the target and inputs will be used as specified in the Type node. We could change the field roles at this point, but for this example we'll use them as they are.

1. Click the Build Options tab.

Figure 4. CHAID modeling node, Fields tab

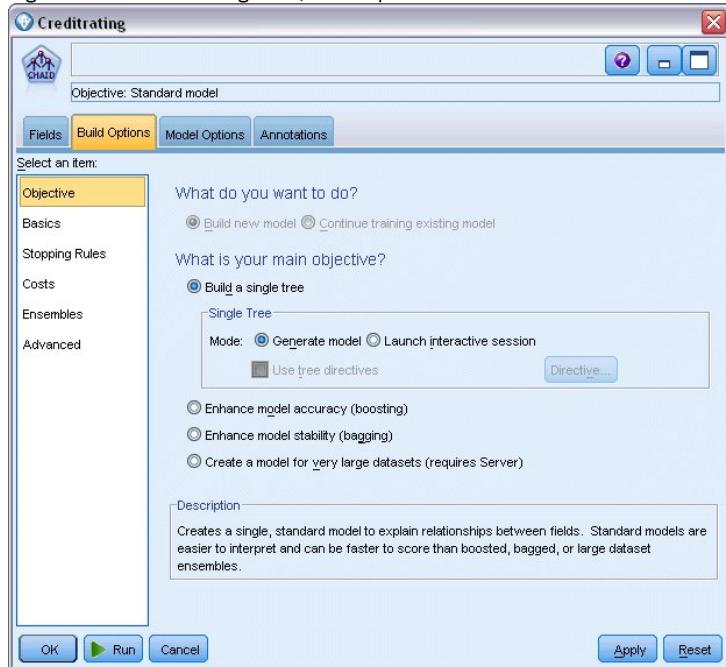

Here there are several options where we could specify the kind of model we want to build.

We want a brand-new model, so we'll use the default option *Build new model*.

We also just want a single, standard decision tree model without any enhancements, so we'll also leave the default objective option *Build a single tree*.

While we can optionally launch an interactive modeling session that allows us to fine-tune the model, this example simply generates a model using the default mode setting Generate model.

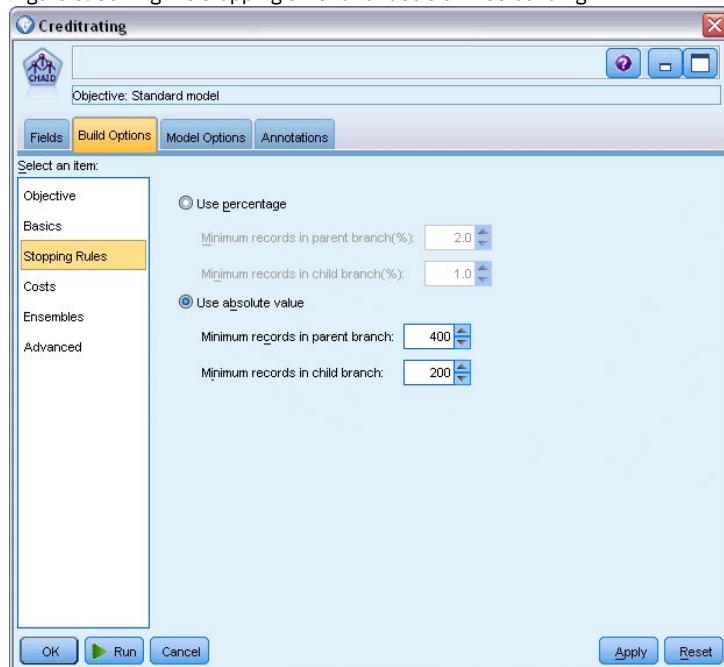

Figure 5. CHAID modeling node, Build Options tab

For this example, we want to keep the tree fairly simple, so we'll limit the tree growth by raising the minimum number of cases for parent and child nodes.

2. On the Build Options tab, select Stopping Rules from the navigator pane on the left.
3. Select the Use absolute value option.
4. Set Minimum records in parent branch to 400.
5. Set Minimum records in child branch to 200.

Figure 6. Setting the stopping criteria for decision tree building

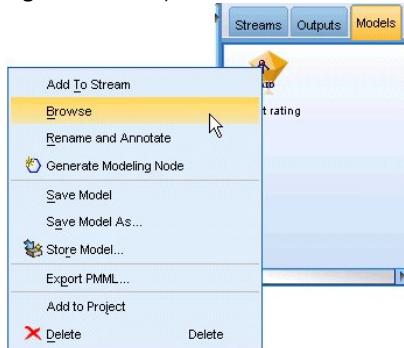

We can use all the other default options for this example, so click Run to create the model. (Alternatively, right-click on the node and choose Run from the context menu, or select the node and choose Run from the Tools menu.)

[Next](#)

Browsing the Model

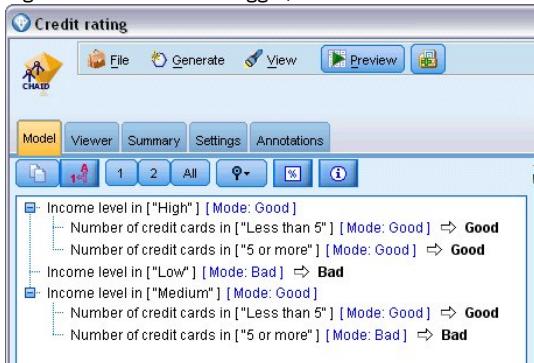

When execution completes, the model nugget is added to the Models palette in the upper right corner of the application window, and is also placed on the stream canvas with a link to the modeling node from which it was created. To view the model details, right-click on the model nugget and choose Browse (on the models palette) or Edit (on the canvas).

Figure 1. Models palette

In the case of the CHAID nugget, the Model tab displays the details in the form of a rule set--essentially a series of rules that can be used to assign individual records to child nodes based on the values of different input fields.

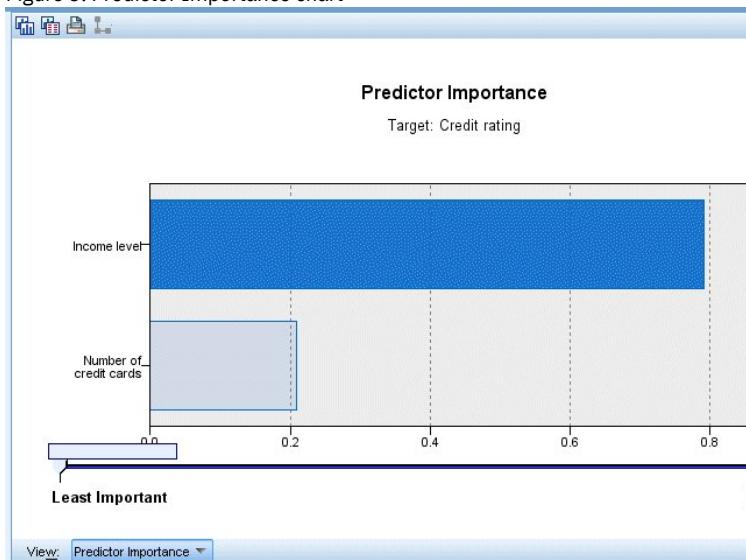

Figure 2. CHAID model nugget, rule set

For each decision tree terminal node--meaning those tree nodes that are not split further--a prediction of *Good* or *Bad* is returned. In each case the prediction is determined by the **mode**, or most common response, for records that fall within that node.

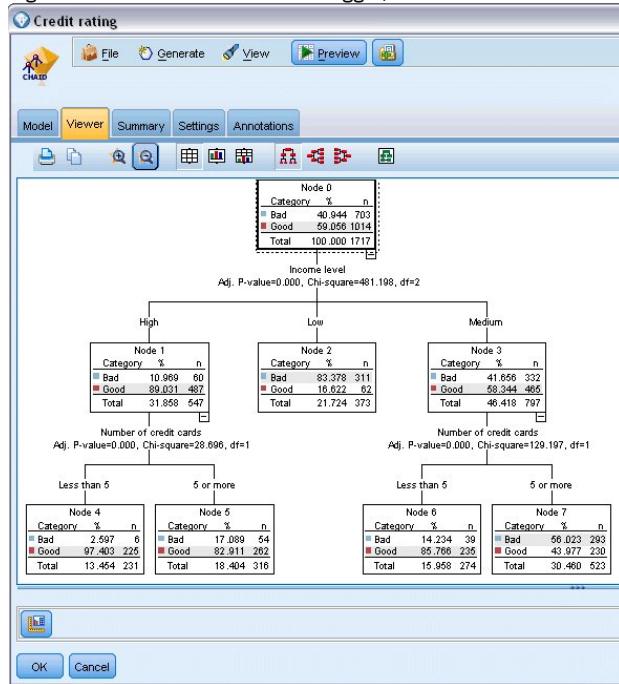

To the right of the rule set, the Model tab displays the Predictor Importance chart, which shows the relative importance of each predictor in estimating the model. From this we can see that *Income level* is easily the most significant in this case, and that the only other significant factor is *Number of credit cards*.

Figure 3. Predictor Importance chart

The Viewer tab in the model nugget displays the same model in the form of a tree, with a node at each decision point. Use the Zoom controls on the toolbar to zoom in on a specific node or zoom out to see the more of the tree.

Figure 4. Viewer tab in the model nugget, with zoom out selected

Looking at the upper part of the tree, the first node (Node 0) gives us a summary for all the records in the data set. Just over 40% of the cases in the data set are classified as a bad risk. This is quite a high proportion, so let's see if the tree can give us any clues as to what factors might be responsible.

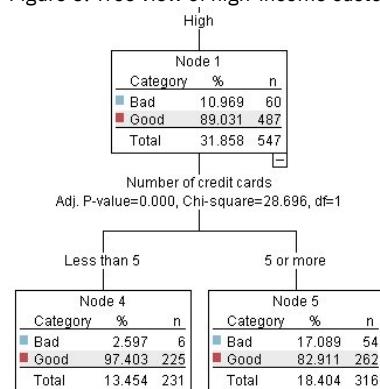

We can see that the first split is by *Income level*. Records where the income level is in the *Low* category are assigned to Node 2, and it's no surprise to see that this category contains the highest percentage of loan defaulters. Clearly lending to customers in this category carries a high risk.

However, 16% of the customers in this category actually *didn't* default, so the prediction won't always be correct. No model can feasibly predict every response, but a good model should allow us to predict the *most likely* response for each record based on the available data.

In the same way, if we look at the high income customers (Node 1), we see that the vast majority (89%) are a good risk. But more than 1 in 10 of these customers has also defaulted. Can we refine our lending criteria to minimize the risk here?

Notice how the model has divided these customers into two sub-categories (Nodes 4 and 5), based on the number of credit cards held. For high-income customers, if we lend only to those with fewer than 5 credit cards, we can increase our success rate from 89% to 97%--an even more satisfactory outcome.

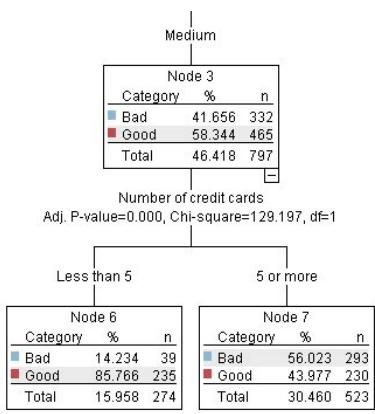

Figure 5. Tree view of high-income customers

But what about those customers in the *Medium* income category (Node 3)? They're much more evenly divided between Good and Bad ratings.

Again, the sub-categories (Nodes 6 and 7 in this case) can help us. This time, lending only to those medium-income customers with fewer than 5 credit cards increases the percentage of Good ratings from 58% to 85%, a significant improvement.

Figure 6. Tree view of medium-income customers

So, we've learnt that every record that is input to this model will be assigned to a specific node, and assigned a prediction of *Good* or *Bad* based on the most common response for that node.

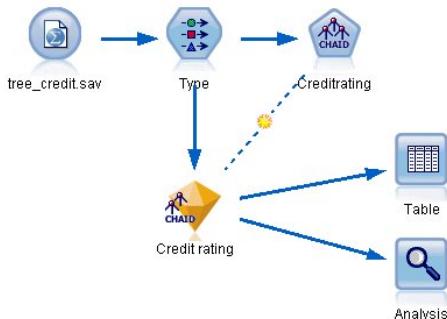

This process of assigning predictions to individual records is known as **scoring**. By scoring the same records used to estimate the model, we can evaluate how accurately it performs on the training data—the data for which we know the outcome. Let's look at how to do this.

[Next](#)

Evaluating the Model

We've been browsing the model to understand how scoring works. But to evaluate *how accurately* it works, we need to score some records and compare the responses predicted by the model to the actual results. We're going to score the same records that were used to estimate the model, allowing us to compare the observed and predicted responses.

Figure 1. Attaching the model nugget to output nodes for model evaluation

1. To see the scores or predictions, attach the Table node to the model nugget, double-click the Table node and click Run. The table displays the predicted scores in a field named *\$R-Credit rating*, which was created by the model. We can compare these values to the original *Credit rating* field that contains the actual responses.

By convention, the names of the fields generated during scoring are based on the target field, but with a standard prefix. Prefixes *\$G* and *\$GE* are generated by the Generalized Linear Model, *\$R* is the prefix used for the prediction generated by the CHAID model in this case, *\$RC* is for confidence values, *\$X* is typically generated by using an ensemble, and *\$XR*, *\$XS*, and *\$XF* are used as prefixes in cases where the target field is a Continuous, Categorical, Set, or Flag field, respectively. Different model types use different sets of prefixes. A **confidence value** is the model's own estimation, on a scale from 0.0 to 1.0, of how accurate each predicted value is.

Figure 2. Table showing generated scores and confidence values

Number of credit cards	Education	Car loans	\$R-Credit rating	\$RC-Credit rating
5 or more	College	More than 2	Bad	0.560
5 or more	College	More than 2	Bad	0.560
5 or more	High school	More than 2	Bad	0.832
5 or more	College	None or 1	Bad	0.832
5 or more	College	More than 2	Bad	0.560
5 or more	College	More than 2	Bad	0.560
5 or more	College	More than 2	Bad	0.560
5 or more	High school	More than 2	Bad	0.832
5 or more	High school	More than 2	Bad	0.832
5 or more	College	More than 2	Bad	0.560
5 or more	College	More than 2	Bad	0.832
5 or more	High school	More than 2	Bad	0.832
5 or more	High school	More than 2	Bad	0.560
5 or more	College	None or 1	Bad	0.832
5 or more	High school	More than 2	Bad	0.832
5 or more	College	More than 2	Bad	0.832
5 or more	College	More than 2	Bad	0.560
5 or more	College	More than 2	Bad	0.560
5 or more	College	More than 2	Good	0.827

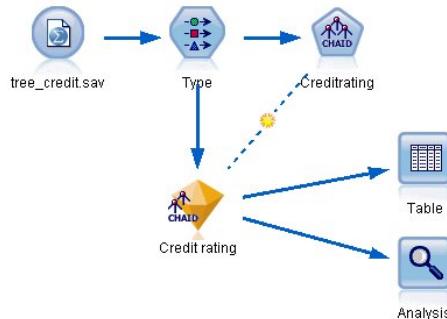

As expected, the predicted value matches the actual responses for many records but not all. The reason for this is that each CHAID terminal node has a mix of responses. The prediction matches the *most common* one, but will be wrong for all the others in that node. (Recall the 16% minority of low-income customers who did not default.)

To avoid this, we could continue splitting the tree into smaller and smaller branches, until every node was 100% pure—all *Good* or *Bad* with no mixed responses. But such a model would be extremely complicated and would probably not generalize well to other datasets.

To find out exactly how many predictions are correct, we could read through the table and tally the number of records where the value of the predicted field *\$R-Credit rating* matches the value of *Credit rating*. Fortunately, there's a much easier way—we can use an Analysis node, which does this automatically.

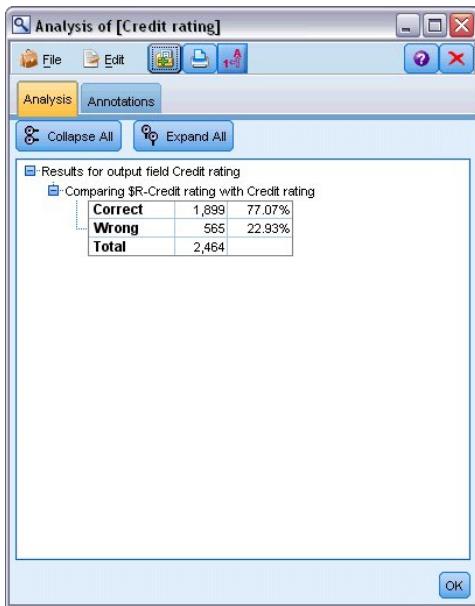

2. Connect the model nugget to the Analysis node.
3. Double-click the Analysis node and click Run.

Figure 3. Attaching an Analysis node

The analysis shows that for 1899 out of 2464 records--over 77%--the value predicted by the model matched the actual response.

Figure 4. Analysis results comparing observed and predicted responses

This result is limited by the fact that the records being scored are the same ones used to estimate the model. In a real situation, you could use a Partition node to split the data into separate samples for training and evaluation.

By using one sample partition to generate the model and another sample to test it, you can get a much better indication of how well it will generalize to other datasets.

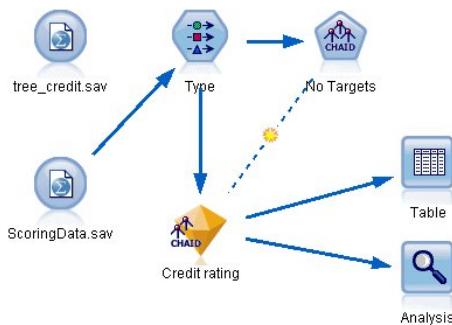

The Analysis node allows us to test the model against records for which we already know the actual result. The next stage illustrates how we can use the model to score records for which we don't know the outcome. For example, this might include people who are not currently customers of the bank, but who are prospective targets for a promotional mailing.

[Next](#)

Scoring records

Earlier, we scored the same records used to estimate the model in order to evaluate how accurate the model was. Now we're going to see how to score a different set of records from the ones used to create the model. This is the goal of modeling with a target field: Study records for which you know the outcome, to identify patterns that will allow you to predict outcomes you don't yet know.

Figure 1. Attaching new data for scoring

You could update the Statistics File source node to point to a different data file, or you could add a new source node that reads in the data you want to score. Either way, the new dataset must contain the same input fields used by the model (*Age*, *Income level*, *Education* and so on) but not the target field *Credit rating*.

Alternatively, you could add the model nugget to any stream that includes the expected input fields. Whether read from a file or a database, the source type doesn't matter as long as the field names and types match those used by the model.

You could also save the model nugget as a separate file, or export the model in PMML format for use with other applications that support this format, or store the model in an IBM® SPSS® Collaboration and Deployment Services repository, which offers enterprise-wide deployment, scoring, and management of models.

Regardless of the infrastructure used, the model itself works in the same way.

Summary

This example demonstrates the basic steps for creating, evaluating, and scoring a model.

- The modeling node estimates the model by studying records for which the outcome is known, and creates a model nugget. This is sometimes referred to as training the model.
- The model nugget can be added to any stream with the expected fields to score records. By scoring the records for which you already know the outcome (such as existing customers), you can evaluate how well it performs.
- Once you are satisfied that the model performs acceptably well, you can score new data (such as prospective customers) to predict how they will respond.
- The data used to train or estimate the model may be referred to as the analytical or historical data; the scoring data may also be referred to as the operational data.

Automated Modeling for a Flag Target

- [Modeling Customer Response \(Auto Classifier\)](#)
- [Historical Data](#)
- [Building the Stream](#)
- [Generating and Comparing Models](#)
- [Summary](#)

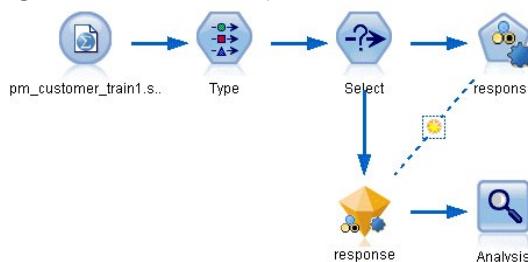

Modeling Customer Response (Auto Classifier)

The Auto Classifier node enables you to automatically create and compare a number of different models for either flag (such as whether or not a given customer is likely to default on a loan or respond to a particular offer) or nominal (set) targets. In this example we'll search for a flag (yes or no) outcome. Within a relatively simple stream, the node generates and ranks a set of candidate models, chooses the ones that perform the best, and combines them into a single aggregated (Ensembled) model. This approach combines the ease of automation with the benefits of combining multiple models, which often yield more accurate predictions than can be gained from any one model.

This example is based on a fictional company that wants to achieve more profitable results by matching the right offer to each customer.

This approach stresses the benefits of automation. For a similar example that uses a continuous (numeric range) target, see [Property Values \(Auto Numeric\)](#).

Figure 1. Auto Classifier sample stream

This example uses the stream *pm_binaryclassifier.str*, installed in the Demo folder under *streams*. The data file used is *pm_customer_train1.sav*. See the topic [Historical Data](#) for more information.

[Next](#)

Historical Data

The file *pm_customer_train1.sav* has historical data tracking the offers made to specific customers in past campaigns, as indicated by the value of the *campaign* field. The largest number of records fall under the *Premium account* campaign.

The values of the *campaign* field are actually coded as integers in the data (for example 2 = *Premium account*). Later, you'll define labels for these values that you can use to give more meaningful output.

Figure 1. Data about previous promotions

The screenshot shows a software interface titled "Table (31 fields, 21,927 records)". The window has a toolbar with icons for File, Edit, Generate, and various data manipulation tools. Below the toolbar is a menu bar with "Table" and "Annotations". The main area is a grid of data rows. The first few rows are:

	customer_id	campaign	response	response_date	purchase	purchase_date	product_id	Rowid
1	7	2	0	\$null\$	0	\$null\$	\$null\$	1
2	13	2	0	\$null\$	0	\$null\$	\$null\$	2
3	15	2	0	\$null\$	0	\$null\$	\$null\$	3
4	16	2	1	2006-07-05 00:00:00	0	\$null\$	183	761
5	23	2	0	\$null\$	0	\$null\$	\$null\$	4
6	24	2	0	\$null\$	0	\$null\$	\$null\$	5
7	30	2	0	\$null\$	0	\$null\$	\$null\$	6
8	30	3	0	\$null\$	0	\$null\$	\$null\$	7
9	33	2	0	\$null\$	0	\$null\$	\$null\$	8
10	42	3	0	\$null\$	0	\$null\$	\$null\$	9
11	42	2	0	\$null\$	0	\$null\$	\$null\$	10
12	52	2	0	\$null\$	0	\$null\$	\$null\$	11
13	57	2	0	\$null\$	0	\$null\$	\$null\$	12
14	63	2	1	2006-07-14 00:00:00	0	\$null\$	183	1501
15	74	2	0	\$null\$	0	\$null\$	\$null\$	13
16	74	3	0	\$null\$	0	\$null\$	\$null\$	14
17	75	2	0	\$null\$	0	\$null\$	\$null\$	15
18	82	2	0	\$null\$	0	\$null\$	\$null\$	16
19	89	3	0	\$null\$	0	\$null\$	\$null\$	17
20	89	2	0	\$null\$	0	\$null\$	\$null\$	18

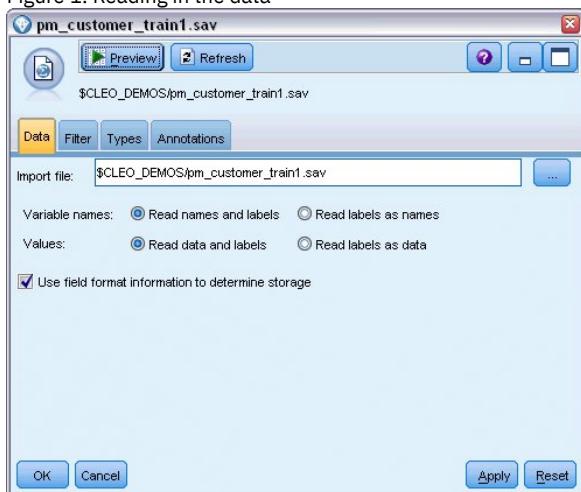

The file also includes a *response* field that indicates whether the offer was accepted (0 = no, and 1 = yes). This will be the **target field**, or value, that you want to predict. A number of fields containing demographic and financial information about each customer are also included. These can be used to build or "train" a model that predicts response rates for individuals or groups based on characteristics such as income, age, or number of transactions per month.

[Next](#)

Building the Stream

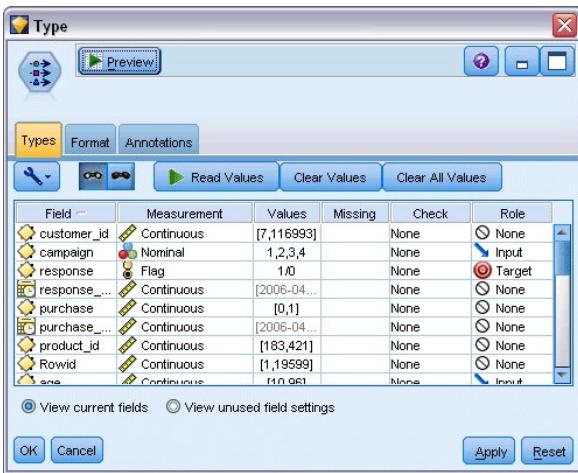

1. Add a Statistics File source node pointing to *pm_customer_train1.sav*, located in the *Demos* folder of your IBM® SPSS® Modeler installation. (You can specify **\$CLEO_DEMOS/** in the file path as a shortcut to reference this folder. Note that a forward slash—rather than a backslash—must be used in the path, as shown.)

Figure 1. Reading in the data

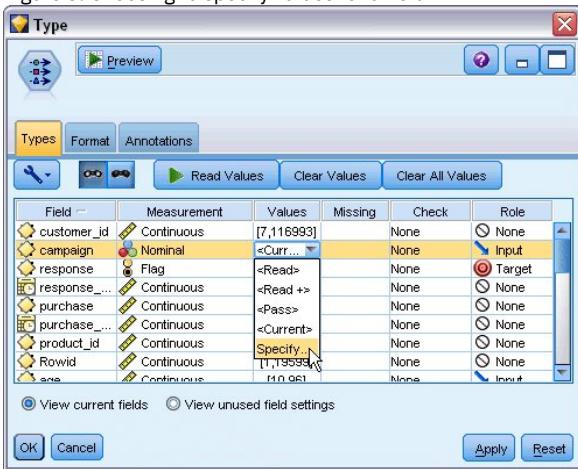

2. Add a Type node, and select *response* as the target field (Role = Target). Set the Measurement for this field to Flag.

Figure 2. Setting the measurement level and role

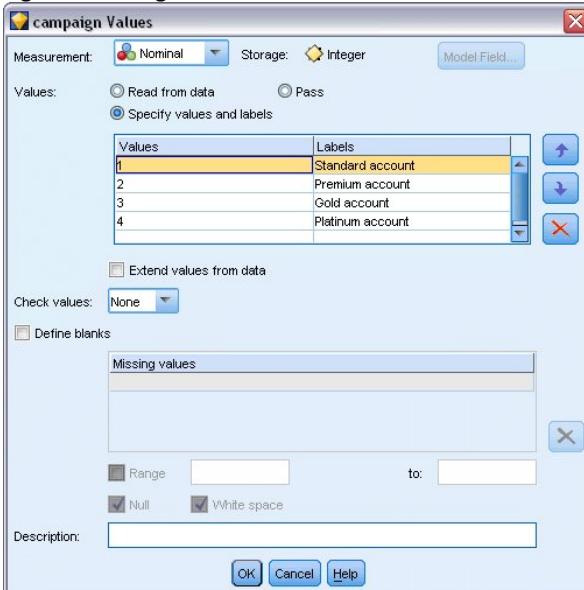

- Set the role to None for the following fields: *customer_id*, *campaign*, *response_date*, *purchase*, *purchase_date*, *product_id*, *Rowid*, and *X_random*. These fields will be ignored when you are building the model.
 - Click the Read Values button in the Type node to make sure that values are instantiated.
- As we saw earlier, our source data includes information about four different campaigns, each targeted to a different type of customer account. These campaigns are coded as integers in the data, so to make it easier to remember which account type each integer represents, let's define labels for each one.

Figure 3. Choosing to specify values for a field

- On the row for the campaign field, click the entry in the Values column.
- Choose Specify from the drop-down list.

Figure 4. Defining labels for the field values

- In the Labels column, type the labels as shown for each of the four values of the campaign field.
- Click OK.

Now you can display the labels in output windows instead of the integers.

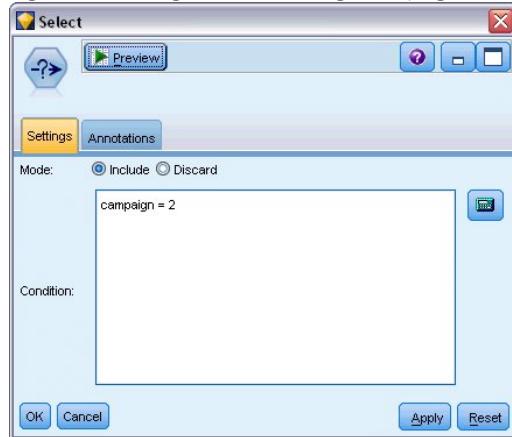

Figure 5. Displaying the field value labels

	customer_id	campaign	response	response_date	purchase	purchase_date	product_id
1	7	Premium account	0	\$null\$	0	\$null\$	1
2	13	Premium account	0	\$null\$	0	\$null\$	2
3	15	Premium account	0	\$null\$	0	\$null\$	3
4	16	Premium account	1	2006-07-05 00:00:00	0	\$null\$	183
5	23	Premium account	0	\$null\$	0	\$null\$	4
6	24	Premium account	0	\$null\$	0	\$null\$	5
7	30	Premium account	0	\$null\$	0	\$null\$	6
8	30	Gold account	0	\$null\$	0	\$null\$	7
9	33	Premium account	0	\$null\$	0	\$null\$	8
10	42	Gold account	0	\$null\$	0	\$null\$	9
11	42	Premium account	0	\$null\$	0	\$null\$	10
12	52	Premium account	0	\$null\$	0	\$null\$	11
13	57	Premium account	0	\$null\$	0	\$null\$	12
14	63	Premium account	1	2006-07-14 00:00:00	0	\$null\$	183
15	74	Premium account	0	\$null\$	0	\$null\$	13
16	74	Gold account	0	\$null\$	0	\$null\$	14
17	75	Premium account	0	\$null\$	0	\$null\$	15
18	82	Premium account	0	\$null\$	0	\$null\$	16
19	89	Gold account	0	\$null\$	0	\$null\$	17
20	89	Premium account	0	\$null\$	0	\$null\$	18

- Attach a Table node to the Type node.
- Open the Table node and click Run.
- On the output window, click the Display field and value labels toolbar button to display the labels.
- Click OK to close the output window.

Although the data includes information about four different campaigns, you will focus the analysis on one campaign at a time. Since the largest number of records fall under the Premium account campaign (coded *campaign*=2 in the data), you can use a Select node to include only these records in the stream.

Figure 6. Selecting records for a single campaign

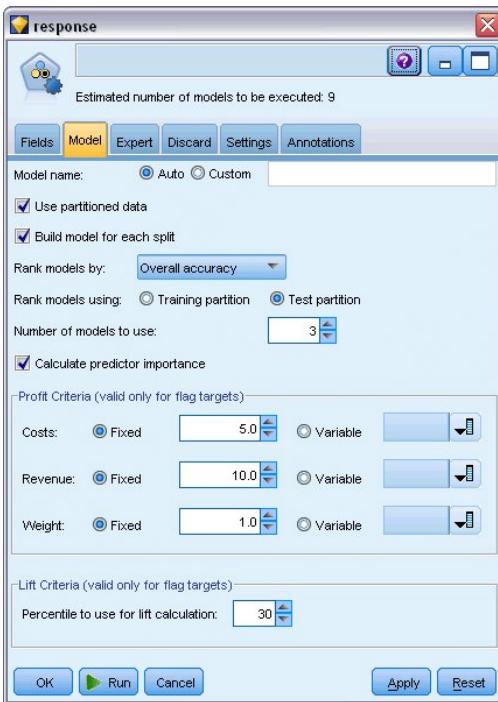

[Next](#)

Generating and Comparing Models

- Attach an Auto Classifier node, and select Overall Accuracy as the metric used to rank models.
- Set the Number of models to use to 3. This means that the three best models will be built when you execute the node.

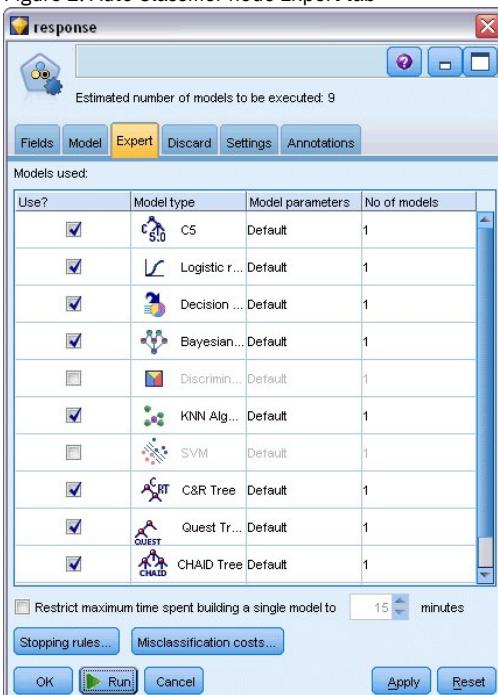

Figure 1. Auto Classifier node Model tab

On the Expert tab you can choose from up to 11 different model algorithms.

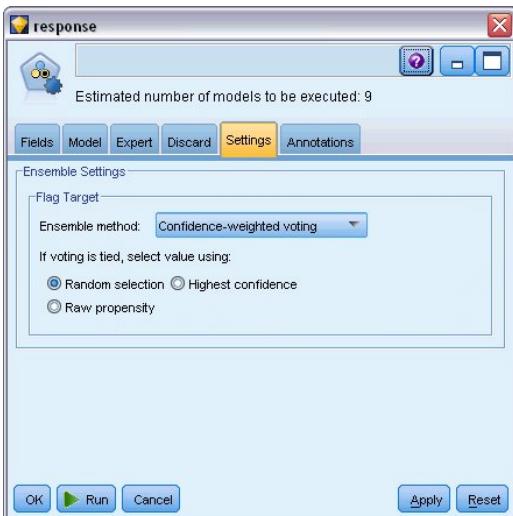

3. Deselect the Discriminant and SVM model types. (These models take longer to train on these data, so deselecting them will speed up the example. If you don't mind waiting, feel free to leave them selected.)
- Because you set Number of models to use to 3 on the Model tab, the node will calculate the accuracy of the remaining nine algorithms and build a single model nugget containing the three most accurate.

Figure 2. Auto Classifier node Expert tab

4. On the Settings tab, for the ensemble method, select Confidence-weighted voting. This determines how a single aggregated score is produced for each record.
- With simple voting, if two out of three models predict yes, then yes wins by a vote of 2 to 1. In the case of confidence-weighted voting, the votes are weighted based on the confidence value for each prediction. Thus, if one model predicts no with a higher confidence than the two yes predictions combined, then no wins.

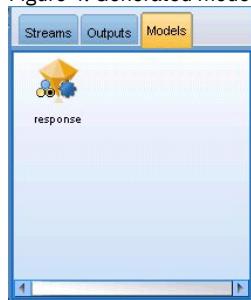

Figure 3. Auto Classifier node: Settings tab

5. Click Run.

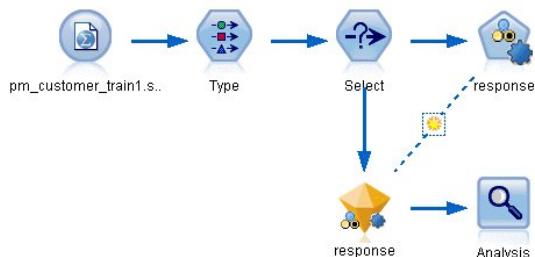

After a few minutes, the generated model nugget is built and placed on the canvas, and on the Models palette in the upper right corner of the window. You can browse the model nugget, or save or deploy it in a number of other ways.

Figure 4. Generated model displayed in the palette

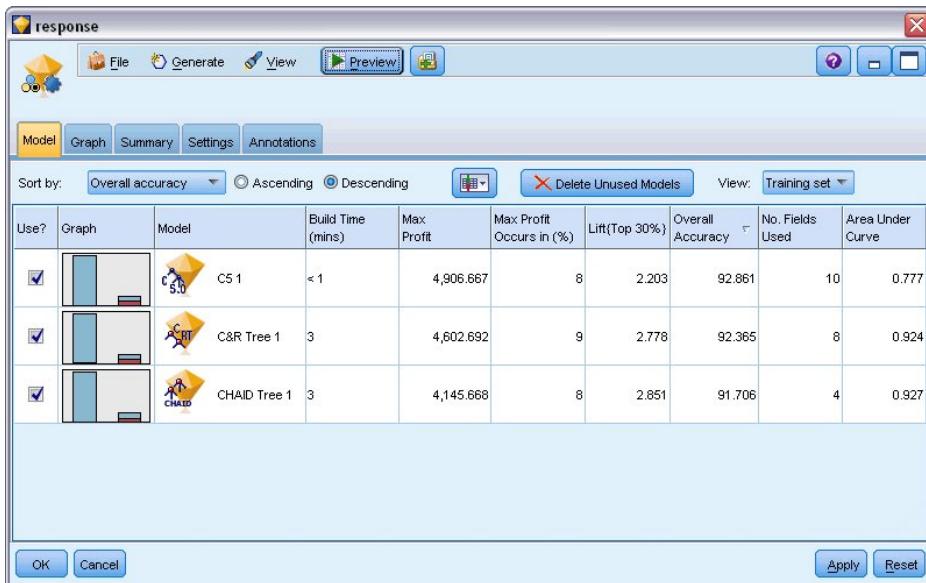

Open the model nugget; it lists details about each of the models created during the run. (In a real situation, in which hundreds of models may be created on a large dataset, this could take many hours.)

Figure 5. Auto Classifier stream with model nugget

If you want to explore any of the individual models further, you can double-click on a model nugget icon in the Model column to drill down and browse the individual model results; from there you can generate modeling nodes, model nuggets, or evaluation charts. In the Graph column, you can double-click on a thumbnail to generate a full-sized graph.

Figure 6. Auto Classifier results

By default, models are sorted based on overall accuracy, because this was the measure you selected on the Auto Classifier node Model tab. The C51 model ranks best by this measure, but the C&R Tree and CHAID models are nearly as accurate.

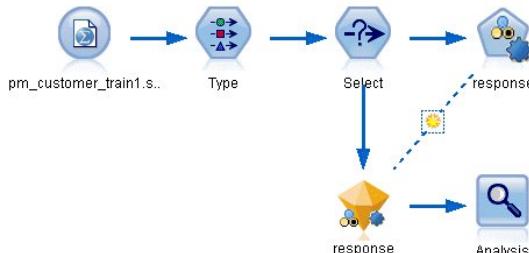

You can sort on a different column by clicking the header for that column, or you can choose the desired measure from the Sort by drop-down list on the toolbar.

Based on these results, you decide to use all three of these most accurate models. By combining predictions from multiple models, limitations in individual models may be avoided, resulting in a higher overall accuracy.

In the Use? column, select the C51, C&R Tree, and CHAID models.

Attach an Analysis node (Output palette) after the model nugget. Right-click on the Analysis node and choose Run to run the stream.

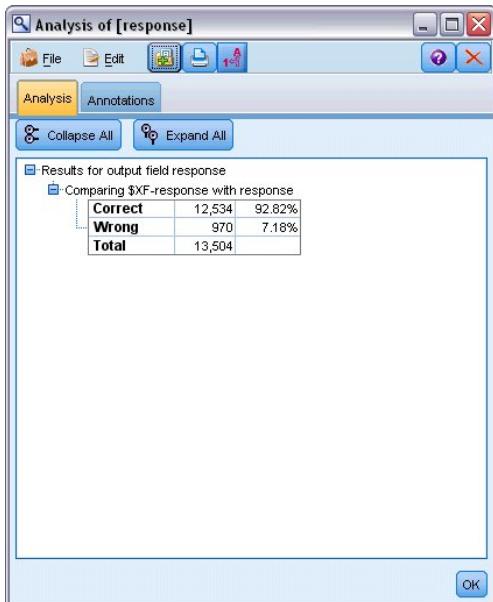

Figure 7. Auto Classifier sample stream

The aggregated score generated by the ensembled model is shown in a field named `$XF-response`. When measured against the training data, the predicted value matches the actual response (as recorded in the original `response` field) with an overall accuracy of 92.82%.

While not quite as accurate as the best of the three individual models in this case (92.86% for C51), the difference is too small to be meaningful. In general terms, an ensembled model will typically be more likely to perform well when applied to datasets other than the training data.

Figure 8. Analysis of the three ensembled models

Summary

To sum up, you used the Auto Classifier node to compare a number of different models, used the three most accurate models and added them to the stream within an ensembled Auto Classifier model nugget.

- Based on overall accuracy, the C51, C&R Tree, and CHAID models performed best on the training data.
- The ensembled model performed nearly as well as the best of the individual models and may perform better when applied to other datasets. If your goal is to automate the process as much as possible, this approach allows you to obtain a robust model under most circumstances without having to dig deeply into the specifics of any one model.

Automated Modeling for a Continuous Target

- [Property Values \(Auto Numeric\)](#)
- [Training Data](#)
- [Building the Stream](#)
- [Comparing the Models](#)
- [Summary](#)

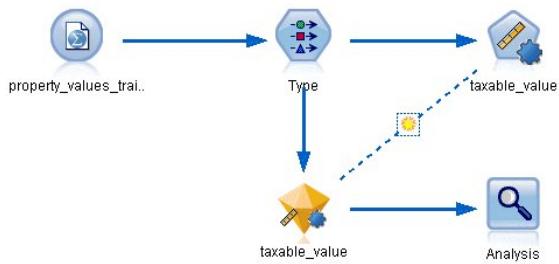

Property Values (Auto Numeric)

The Auto Numeric node enables you to automatically create and compare different models for continuous (numeric range) outcomes, such as predicting the taxable value of a property. With a single node, you can estimate and compare a set of candidate models and generate a subset of models for further analysis. The node works in the same manner as the Auto Classifier node, but for continuous rather than flag or nominal targets.

The node combines the best of the candidate models into a single aggregated (Ensembled) model nugget. This approach combines the ease of automation with the benefits of combining multiple models, which often yield more accurate predictions than can be gained from any one model.

This example focuses on a fictional municipality responsible for adjusting and assessing real estate taxes. To do this more accurately, they will build a model that predicts property values based on building type, neighborhood, size, and other known factors.

Figure 1. Auto Numeric sample stream

This example uses the stream *property_values_numericpredictor.str*, installed in the Demos folder under streams. The data file used is *property_values_train.sav*. See the topic [Demos Folder](#) for more information.

[Next](#)

Training Data

The data file includes a field named *taxable_value*, which is the **target field**, or value, that you want to predict. The other fields contain information such as neighborhood, building type, and interior volume and may be used as predictors.

Field name	Label
<i>property_id</i>	Property ID
<i>neighborhood</i>	Area within the city
<i>building_type</i>	Type of building
<i>year_built</i>	Year built
<i>volume_interior</i>	Volume of interior
<i>volume_other</i>	Volume of garage and extra buildings
<i>lot_size</i>	Lot size
<i>taxable_value</i>	Taxable value

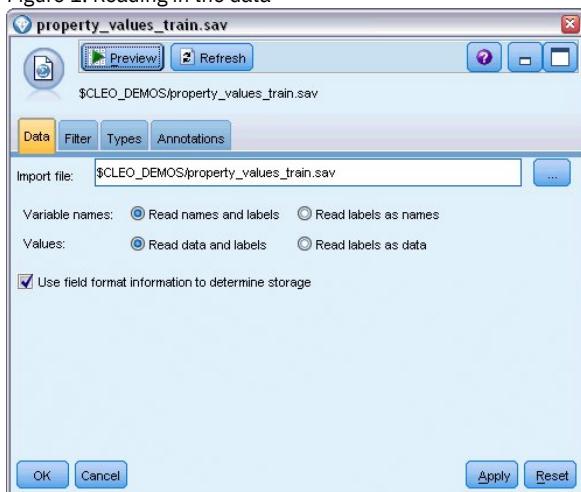

A scoring data file named *property_values_score.sav* is also included in the Demos folder. It contains the same fields but without the *taxable_value* field. After training models using a dataset where the taxable value is known, you can score records where this value is not yet known.

[Next](#)

Building the Stream

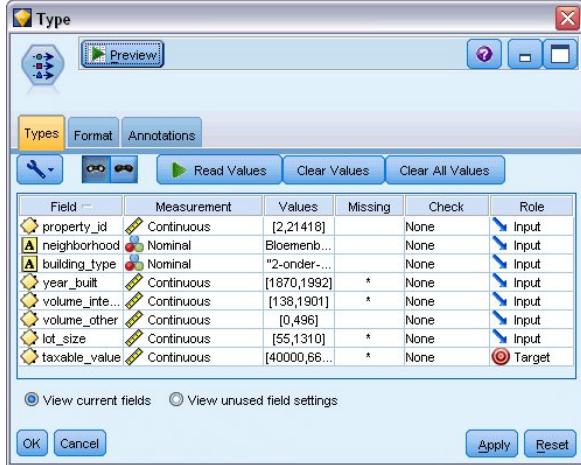

1. Add a Statistics File source node pointing to *property_values_train.sav*, located in the Demos folder of your IBM® SPSS® Modeler installation. (You can specify **\$CLEO_DEMOS/** in the file path as a shortcut to reference this folder. Note that a forward slash—rather than a backslash—must be used in the path, as shown.)

Figure 1. Reading in the data

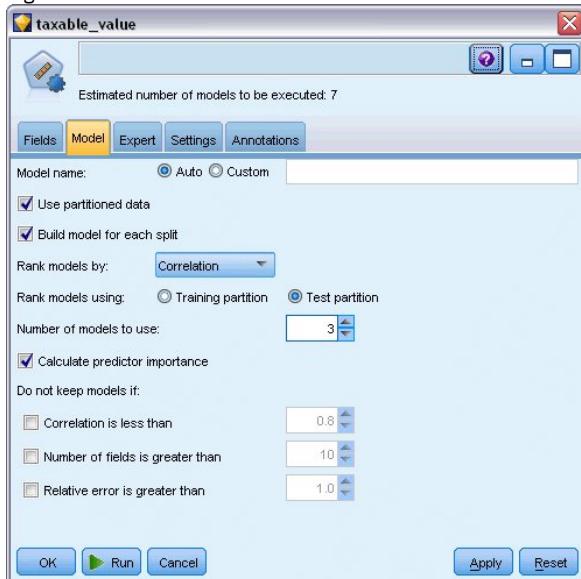

2. Add a Type node, and select *taxable_value* as the target field (Role = Target). Role should be set to Input for all other fields, indicating that they will be used as predictors.

Figure 2. Setting the target field

3. Attach an Auto Numeric node, and select Correlation as the metric used to rank models.
4. Set the Number of models to use to 3. This means that the three best models will be built when you execute the node.

Figure 3. Auto Numeric node Model tab

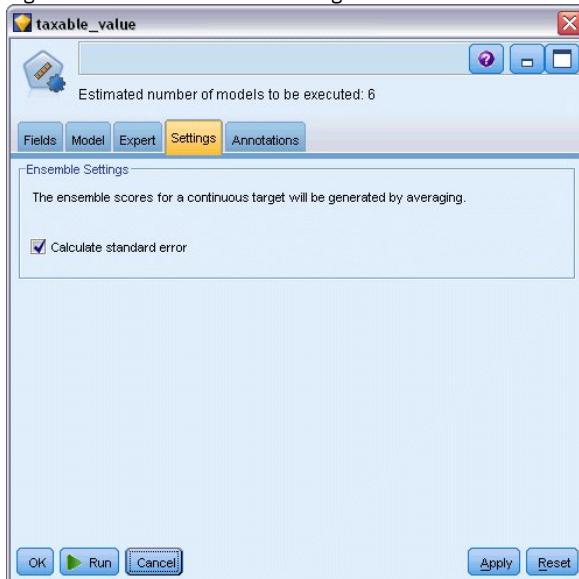

5. On the Expert tab, leave the default settings in place; the node will estimate a single model for each algorithm, for a total of seven models. (Alternatively, you can modify these settings to compare multiple variants for each model type.)
- Because you set Number of models to use to 3 on the Model tab, the node will calculate the accuracy of the seven algorithms and build a single model nugget containing the three most accurate.

Figure 4. Auto Numeric node Expert tab

6. On the Settings tab, leave the default settings in place. Since this is a continuous target, the ensemble score is generated by averaging the scores for the individual models.

Figure 5. Auto Numeric node Settings tab

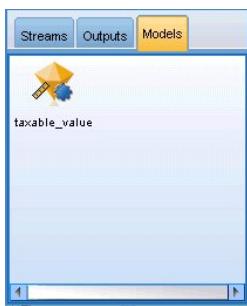

[Next](#)

Comparing the Models

1. Click the Run button.

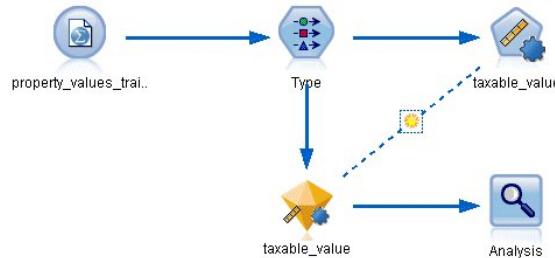

The model nugget is built and placed on the canvas, and also on the Models palette in the upper right corner of the window. You can browse the nugget, or save or deploy it in a number of other ways.

Figure 1. Model displayed in the Models palette

Open the model nugget; it lists details about each of the models created during the run. (In a real situation, in which hundreds of models are estimated on a large dataset, this could take many hours.)

Figure 2. Auto Numeric sample stream with model nugget

If you want to explore any of the individual models further, you can double-click on a model nugget icon in the Model column to drill down and browse the individual model results; from there you can generate modeling nodes, model nuggets, or evaluation charts.

Figure 3. Auto Numeric results

Use?	Graph	Model	Build Time (mins)	Correlation r	No. Fields Used	Relative Error
<input checked="" type="checkbox"/>		Generalized Linear 1	< 1	0.915	7	0.162
<input checked="" type="checkbox"/>		Regression 1	< 1	0.9	5	0.19
<input checked="" type="checkbox"/>		CHAID Tree 1	< 1	0.892	5	0.204

By default, models are sorted by correlation because this was the measure you selected in the Auto Numeric node. For purposes of ranking, the absolute value of the correlation is used, with values closer to 1 indicating a stronger relationship. The Generalized Linear model ranks best on this measure, but several others are nearly as accurate. The Generalized Linear model also has the lowest relative error.

You can sort on a different column by clicking the header for that column, or you can choose the desired measure from the Sort by list on the toolbar.

Each graph displays a plot of observed values against predicted values for the model, providing a quick visual indication of the correlation between them. For a good model, points should cluster along the diagonal, which is true for all the models in this example.

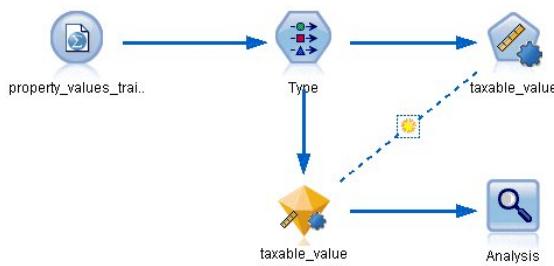

In the Graph column, you can double-click on a thumbnail to generate a full-sized graph.

Based on these results, you decide to use all three of these most accurate models. By combining predictions from multiple models, limitations in individual models may be avoided, resulting in a higher overall accuracy.

In the Use? column, ensure that all three models are selected.

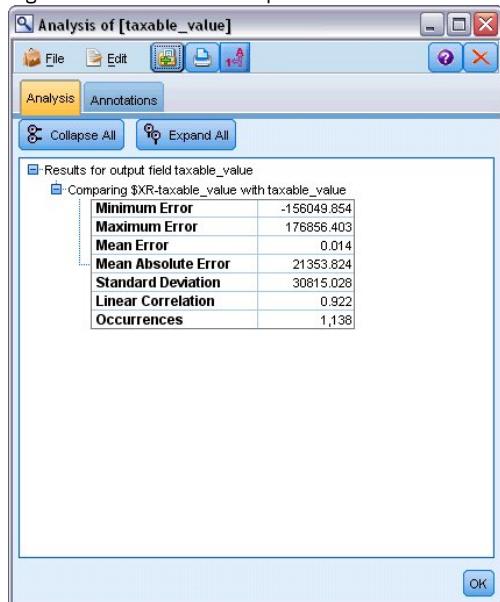

Attach an Analysis node (Output palette) after the model nugget. Right-click on the Analysis node and choose Run to run the stream.

Figure 4. Auto Numeric sample stream

The averaged score generated by the ensembled model is added in a field named \$XR-taxable_value, with a correlation of 0.922, which is higher than those of the three individual models. The ensemble scores also show a low mean absolute error and may perform better than any of the individual models when applied to other datasets.

Figure 5. Auto Numeric sample stream

[Next](#)

Summary

To sum up, you used the Auto Numeric node to compare a number of different models, selected the three most accurate models and added them to the stream within an ensembled Auto Numeric model nugget.

- Based on overall accuracy, the Generalized Linear, Regression, and CHAID models performed best on the training data.
- The ensembled model showed performance that was better than two of the individual models and may perform better when applied to other datasets. If your goal is to automate the process as much as possible, this approach allows you to obtain a robust model under most circumstances without having to dig deeply into the specifics of any one model.

Automated Data Preparation (ADP)

Preparing data for analysis is one of the most important steps in any data-mining project—and traditionally, one of the most time consuming. The Automated Data Preparation (ADP) node handles the task for you, analyzing your data and identifying fixes, screening out fields that are problematic or not likely to be useful, deriving new attributes when appropriate, and improving performance through intelligent screening techniques. You can use the node in fully automated fashion, allowing the node to choose and apply fixes, or you can preview the changes before they are made and accept or reject them as desired.

Using the ADP node enables you to make your data ready for data mining quickly and easily, without needing to have prior knowledge of the statistical concepts involved. If you run the node with the default settings, models will tend to build and score more quickly.

This example uses the stream named *ADP_basic_demo.str*, which references the data file named *telco.sav* to demonstrate the increased accuracy that may be found by using the default ADP node settings when building models. These files are available from the *Demos* directory of any IBM® SPSS® Modeler installation. This can be accessed from the IBM SPSS Modeler program group on the Windows Start menu. The *ADP_basic_demo.str* file is in the *streams* directory.

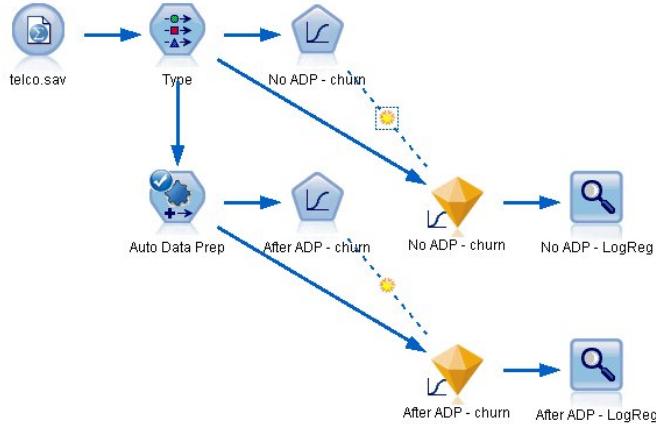

[Next](#)

- [Building the stream](#)
- [Comparing Model Accuracy](#)

Building the stream

1. To build the stream, add a Statistics File source node pointing to telco.sav located in the Demos directory of your IBM® SPSS® Modeler installation.

Figure 1. Building the stream

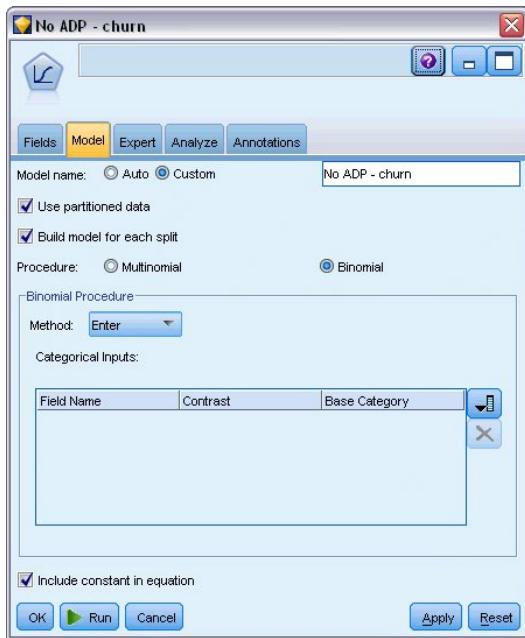

2. Attach a Type node to the source node, set the measurement level for the *churn* field to Flag, and set the role to Target. All other fields should have their role set to Input.

Figure 2. Selecting the target

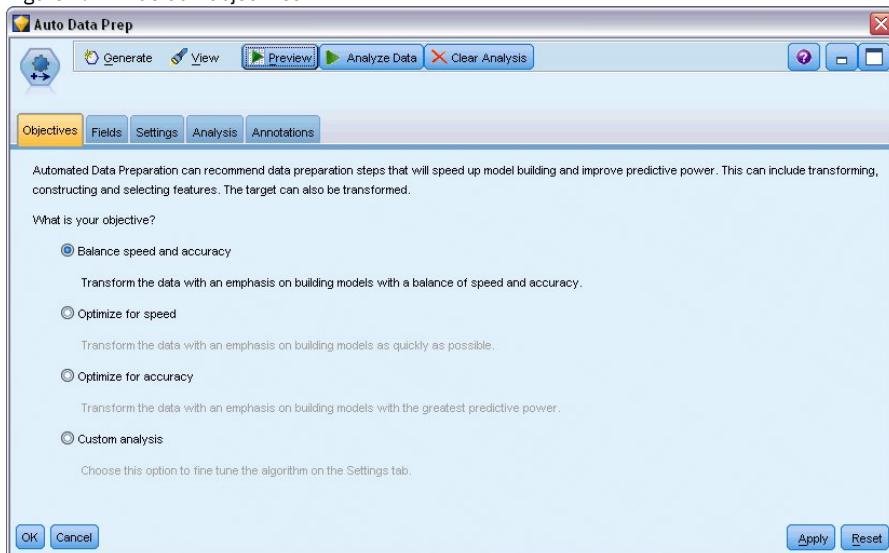

3. Attach a Logistic node to the Type node.
4. In the Logistic node, click the Model tab and select the Binomial procedure. In the *Model name* field, select Custom and enter *No ADP - churn*.

Figure 3. Choosing model options

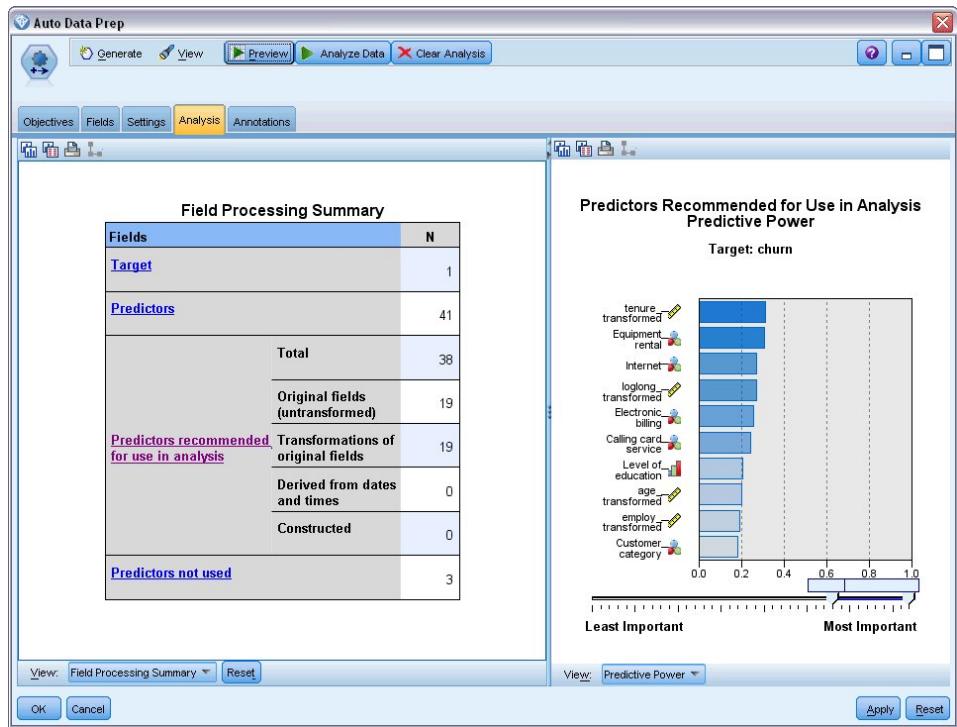

5. Attach an ADP node to the Type node. On the Objectives tab, leave the default settings in place to analyze and prepare your data by balancing both speed and accuracy.
6. At the top of the Objectives tab, click Analyze Data to analyze and process your data. Other options on the ADP node enable you to specify that you want to concentrate more on accuracy, more on the speed of processing, or to fine tune many of the data preparation processing steps.

Figure 4. ADP default objectives

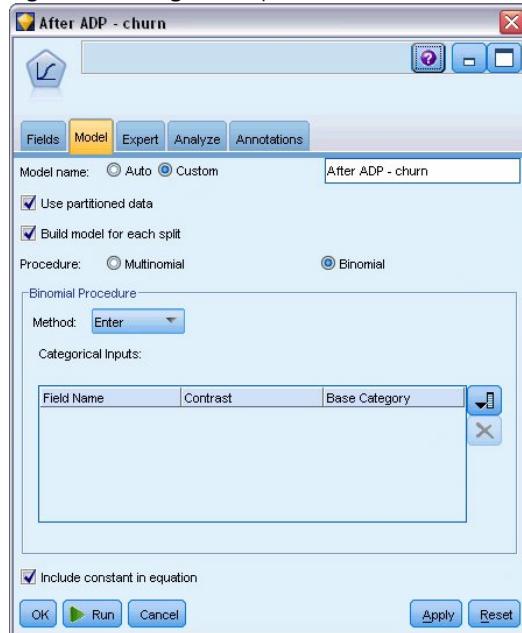

The results of the data processing are displayed on the Analysis tab. The Field Processing Summary shows that of the 41 data features brought in to the ADP node, 19 have been transformed to aid processing, and 3 have been discarded as unused.

Figure 5. Summary of data processing

7. Attach a Logistic node to the ADP node.
8. In the Logistic node, click the Model tab and select the Binomial procedure. In the *Modeling name* field, select Custom and enter *After ADP - churn*.

Figure 6. Choosing model options

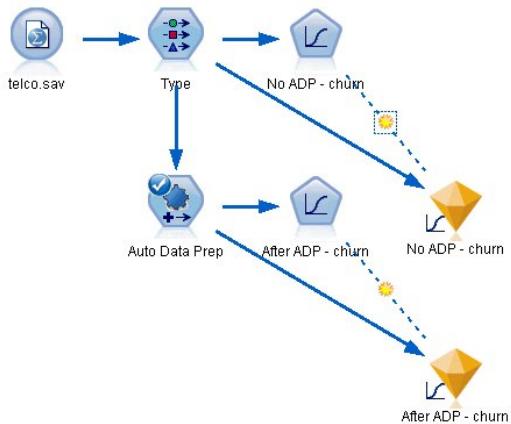

[Next](#)

Comparing Model Accuracy

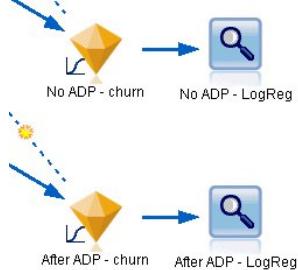

1. Run both Logistic nodes to create the model nuggets, which are added to the stream and to the Models palette in the upper-right corner.

Figure 1. Attaching the model nuggets

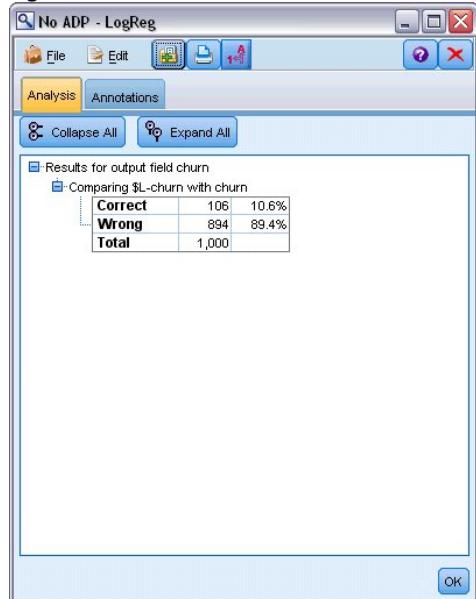

2. Attach Analysis nodes to the model nuggets and run the Analysis nodes using their default settings.

Figure 2. Attaching the Analysis nodes

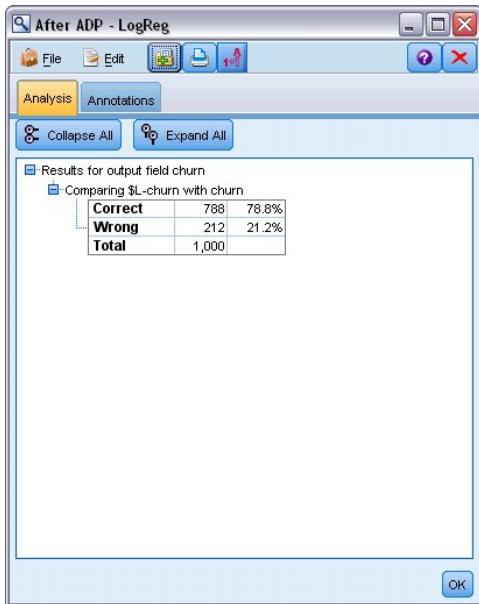

The Analysis of the non ADP-derived model shows that just running the data through the Logistic Regression node with its default settings gives a model with low accuracy - just 10.6%.

Figure 3. Non ADP-derived model results

The Analysis of the ADP-derived model shows that running the data through the default ADP settings, you have built a much more accurate model that is 78.8% correct.

Figure 4. ADP-derived model results

In summary, by just running the ADP node to fine tune the processing of your data, you were able to build a more accurate model with little direct data manipulation.

Obviously, if you are interested in proving or disproving a certain theory, or want to build specific models, you may find it beneficial to work directly with the model settings; however, for those with a reduced amount of time, or with a large amount of data to prepare, the ADP node may give you an advantage.

Explanations of the mathematical foundations of the modeling methods used in IBM® SPSS® Modeler are listed in the *IBM SPSS Modeler Algorithms Guide*, available from the *|Documentation* directory of the installation disk.

Note that the results in this example are based on the training data only. To assess how well models generalize to other data in the real world, you would use a Partition node to hold out a subset of records for purposes of testing and validation.

Preparing Data for Analysis (Data Audit)

The Data Audit node provides a comprehensive first look at the data you bring into IBM® SPSS® Modeler. Often used during the initial data exploration, the data audit report shows summary statistics as well as histograms and distribution graphs for each data field, and it allows you to specify treatments for missing values, outliers, and extreme values.

This example uses the stream named *telco_dataaudit.str*, which references the data file named *telco.sav*. These files are available from the *Demos* directory of any IBM SPSS Modeler installation. This can be accessed from the IBM SPSS Modeler program group on the Windows Start menu. The *telco_dataaudit.str* file is in the *streams* directory.

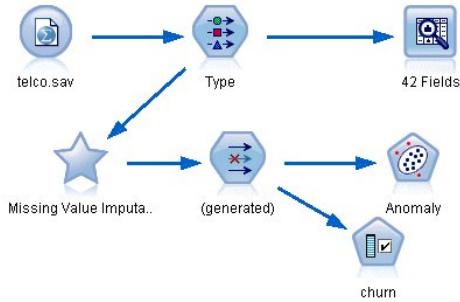

[Next](#)

- [Building the Stream](#)
- [Browsing Statistics and Charts](#)
- [Handling Outliers and Missing Values](#)

Building the Stream

1. To build the stream, add a Statistics File source node pointing to *telco.sav* located in the *Demos* directory of your IBM® SPSS® Modeler installation.

Figure 1. Building the stream

2. Add a Type node to define fields, and specify *churn* as the target field (Role = Target). Role should be set to Input for all of the other fields so that this is the only target.

Figure 2. Setting the target

3. Confirm that field measurement levels are defined correctly. For example, most fields with values 0 and 1 can be regarded as flags, but certain fields, such as gender, are more accurately viewed as a nominal field with two values.

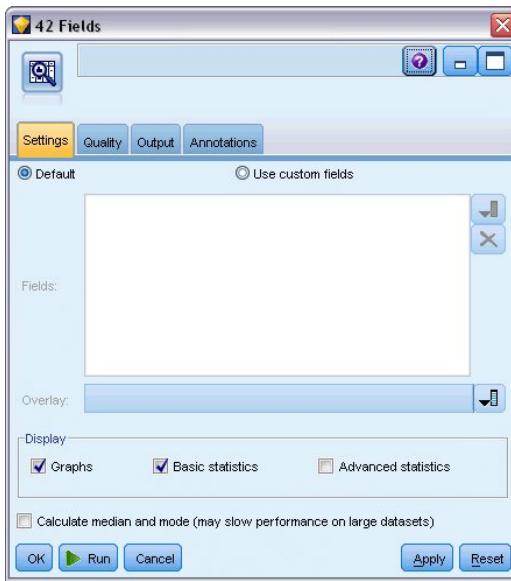

Figure 3. Setting measurement levels

Tip: To change properties for multiple fields with similar values (such as 0/1), click the *Values* column header to sort fields by that column, and use the Shift key to select all of the fields you want to change. You can then right-click on the selection to change the measurement level or other attributes for all selected fields.

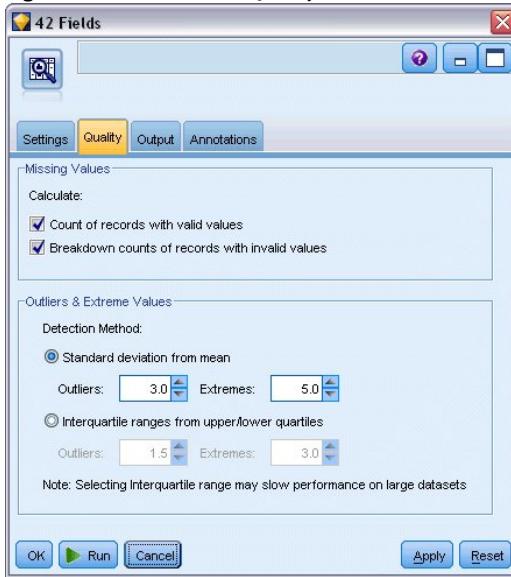

4. Attach a Data Audit node to the stream. On the Settings tab, leave the default settings in place to include all fields in the report. Since *churn* is the only target field defined in the Type node, it will automatically be used as an overlay.

Figure 4. Data Audit node, Settings tab

On the Quality tab, leave the default settings for detecting missing values, outliers, and extreme values in place, and click Run.

Figure 5. Data Audit node, Quality tab

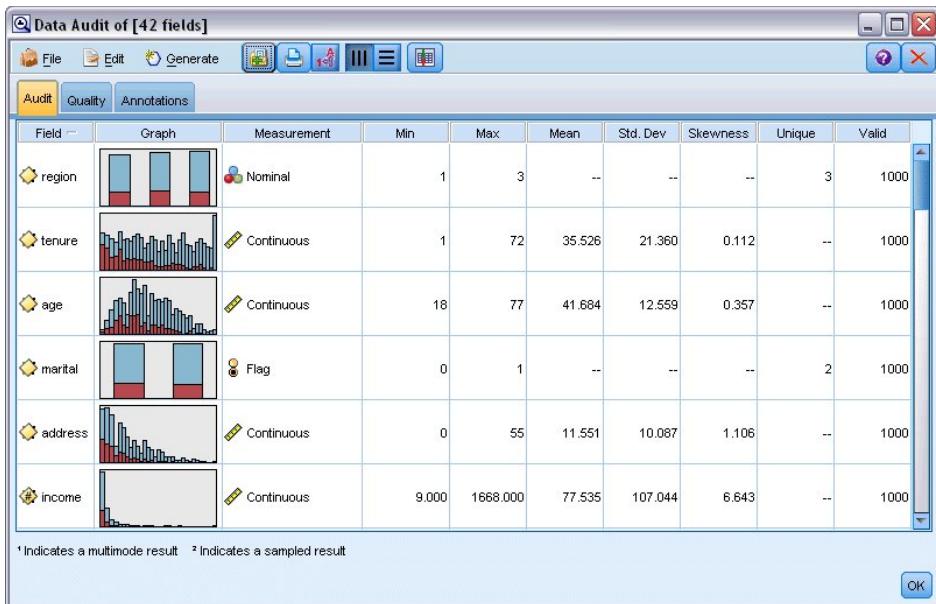

[Next](#)

Browsing Statistics and Charts

The Data Audit browser is displayed, with thumbnail graphs and descriptive statistics for each field.

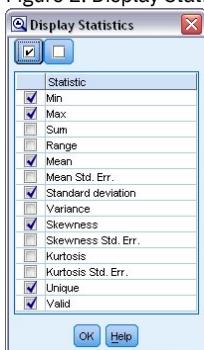

Figure 1. Data Audit browser

Use the toolbar to display field and value labels, and to toggle the alignment of charts from horizontal to vertical (for categorical fields only).

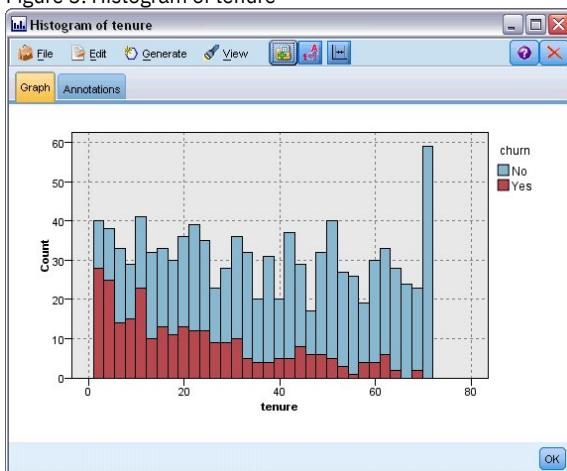

1. You can also use the toolbar or Edit menu to choose the statistics to display.

Figure 2. Display Statistics

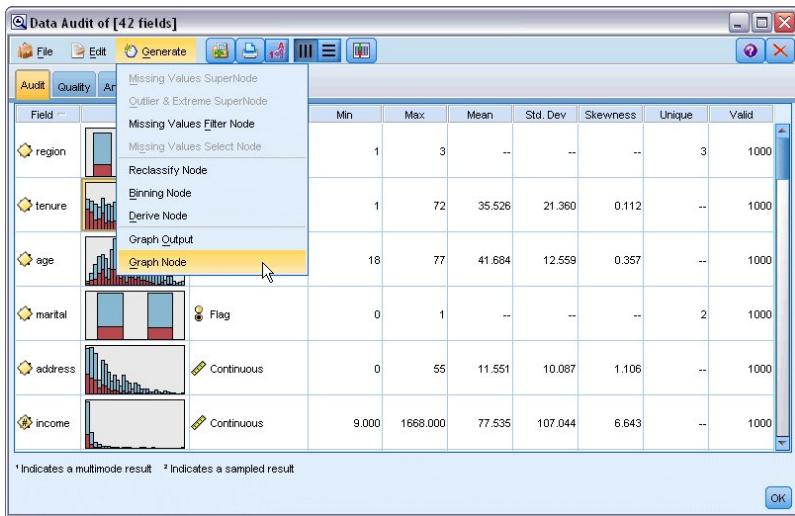

Double-click on any thumbnail graph in the audit report to view a full-sized version of that chart. Because *churn* is the only target field in the stream, it is automatically used as an overlay. You can toggle the display of field and value labels using the graph window toolbar, or click the Edit mode button to further customize the chart.

Figure 3. Histogram of tenure

Alternatively, you can select one or more thumbnails and generate a Graph node for each. The generated nodes are placed on the stream canvas and can be added to the stream to re-create that particular graph.

Figure 4. Generating a Graph node

[Next](#)

Handling Outliers and Missing Values

The Quality tab in the audit report displays information about outliers, extremes, and missing values.

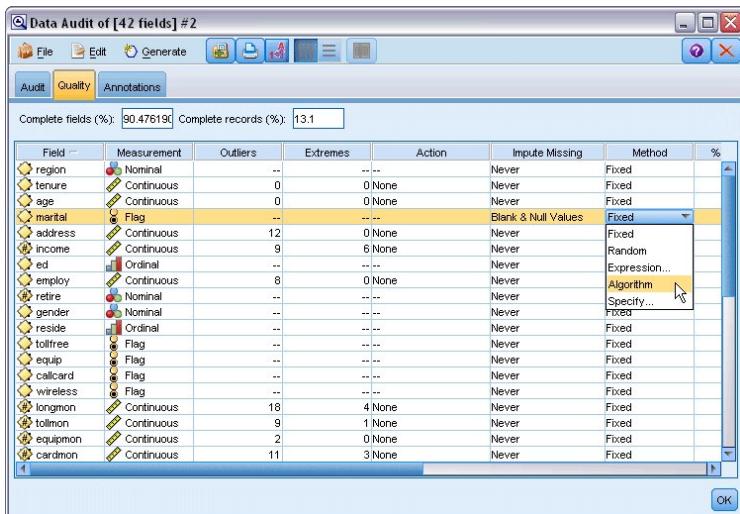

Figure 1. Data Audit browser, Quality tab

The screenshot shows the Data Audit browser window with the Quality tab selected. The top bar shows 'Complete fields (%)' at 90.47619 and 'Complete records (%)' at 13.1. The main table has columns: Field, Measurement, Outliers, Extremes, Action, Impute Missing, and Method. The table lists numerous fields with their respective settings for handling missing values.

Field	Measurement	Outliers	Extremes	Action	Impute Missing	Method
region	Nominal	--	--	Never	Fixed	
tenure	Continuous	0	0 None	Never	Fixed	
age	Continuous	0	0 None	Never	Fixed	
marital	Flag	--	--	Never	Fixed	
address	Continuous	12	0 None	Never	Fixed	
income	Continuous	9	6 None	Never	Fixed	
ed	Ordinal	--	--	Never	Fixed	
employ	Continuous	8	0 None	Never	Fixed	
retire	Nominal	--	--	Never	Fixed	
gender	Nominal	--	--	Never	Fixed	
reside	Ordinal	--	--	Never	Fixed	
tollfree	Flag	--	--	Never	Fixed	
equip	Flag	--	--	Never	Fixed	
callcard	Flag	--	--	Never	Fixed	
wireless	Flag	--	--	Never	Fixed	
longmon	Continuous	18	4 None	Never	Fixed	
tolmon	Continuous	9	1 None	Never	Fixed	
equimon	Continuous	2	0 None	Never	Fixed	
cardmon	Continuous	11	3 None	Never	Fixed	

You can also specify methods for handling these values and generate SuperNodes to automatically apply the transformations. For example you can select one or more fields and choose to impute or replace missing values for these fields using a number of methods, including the C&RT algorithm.

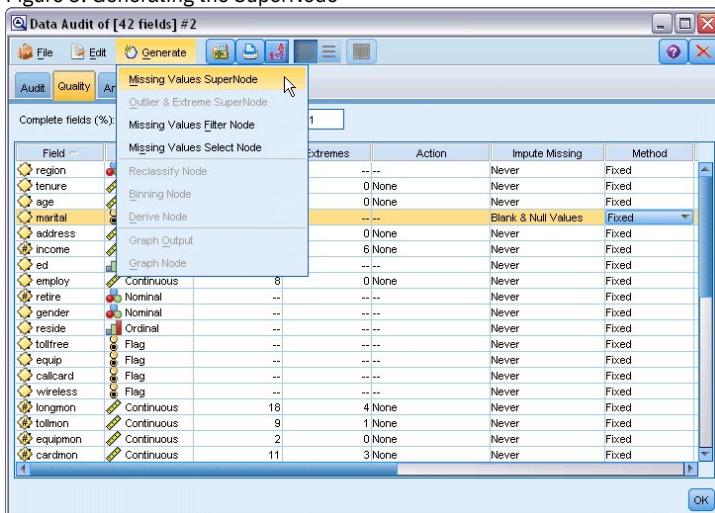

Figure 2. Choosing an impute method

After specifying an impute method for one or more fields, to generate a Missing Values SuperNode, from the menus choose:

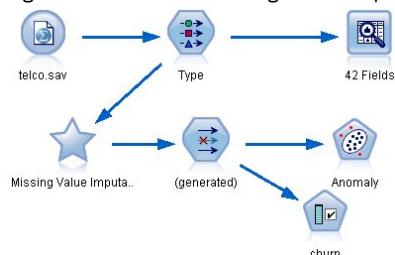

Generate > Missing Values SuperNode

Figure 3. Generating the SuperNode

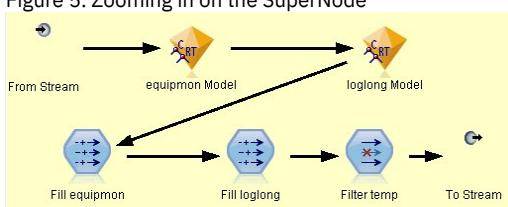

The generated SuperNode is added to the stream canvas, where you can attach it to the stream to apply the transformations.

Figure 4. Stream with Missing Values SuperNode

The SuperNode actually contains a series of nodes that perform the requested transformations. To understand how it works, you can edit the SuperNode and click Zoom In.

Figure 5. Zooming in on the SuperNode

For each field imputed using the algorithm method, for example, there will be a separate C&RT model, along with a Filler node that replaces blanks and nulls with the value predicted by the model. You can add, edit, or remove specific nodes within the SuperNode to further customize the behavior.

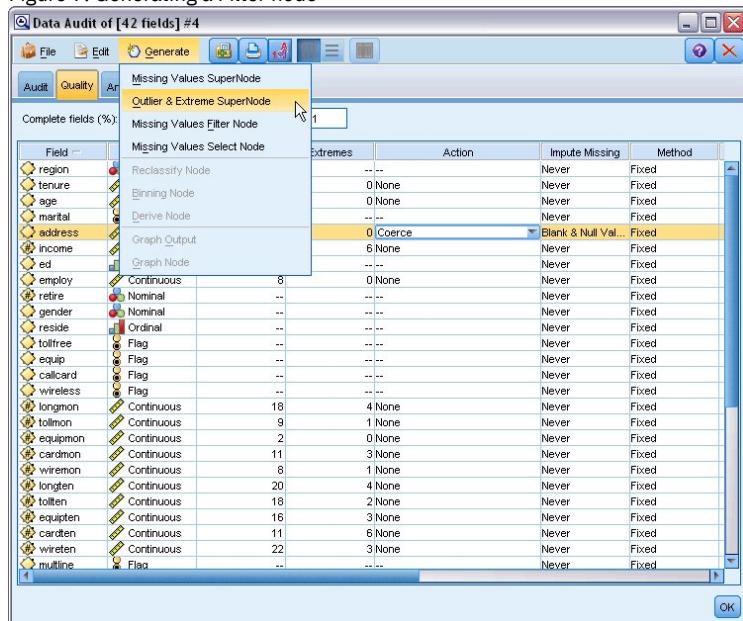

Alternatively, you can generate a Select or Filter node to remove fields or records with missing values. For example, you can filter any fields with a quality percentage below a specified threshold.

Figure 6. Generating a Filter node

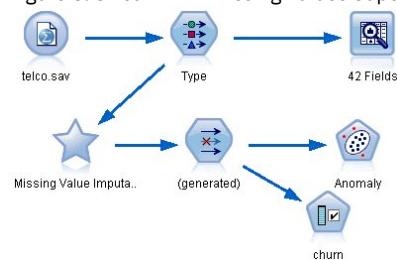

Outliers and extreme values can be handled in a similar manner. Specify the action you want to take for each field—either coerce, discard, or nullify—and generate a SuperNode to apply the transformations.

Figure 7. Generating a Filter node

After completing the audit and adding the generated nodes to the stream, you can proceed with your analysis. Optionally, you may want to further screen your data using Anomaly Detection, Feature Selection, or a number of other methods.

Figure 8. Stream with Missing Values SuperNode

Drug Treatments (Exploratory Graphs/C5.0)

For this section, imagine that you are a medical researcher compiling data for a study. You have collected data about a set of patients, all of whom suffered from the same illness. During their course of treatment, each patient responded to one of five medications. Part of your job is to use data mining to find out which drug might be appropriate for a future patient with the same illness.

This example uses the stream named *druglearn.str*, which references the data file named *DRUG1n*. These files are available from the *Demos* directory of any IBM® SPSS® Modeler installation. This can be accessed from the IBM SPSS Modeler program group on the Windows Start menu. The *druglearn.str* file is in the *streams* directory.

The data fields used in the demo are:

Data field	Description
Age	(Number)
Sex	M or F
BP	Blood pressure: HIGH, NORMAL, or LOW
Cholesterol	Blood cholesterol: NORMAL or HIGH
Na	Blood sodium concentration
K	Blood potassium concentration
Drug	Prescription drug to which a patient responded

Reading in Text Data

Figure 1. Adding a Variable File node

You can read in delimited text data using a **Variable File node**. You can add a Variable File node from the palettes--either click the Sources tab to find the node or use the Favorites tab, which includes this node by default. Next, double-click the newly placed node to open its dialog box.

Click the button just to the right of the File box marked with an ellipsis (...) to browse to the directory in which IBM® SPSS® Modeler is installed on your system. Open the *Demos* directory and select the file called *DRUG1n*.

Ensuring that Read field names from file is selected, notice the fields and values that have just been loaded into the dialog box.

Figure 2. Variable File dialog box

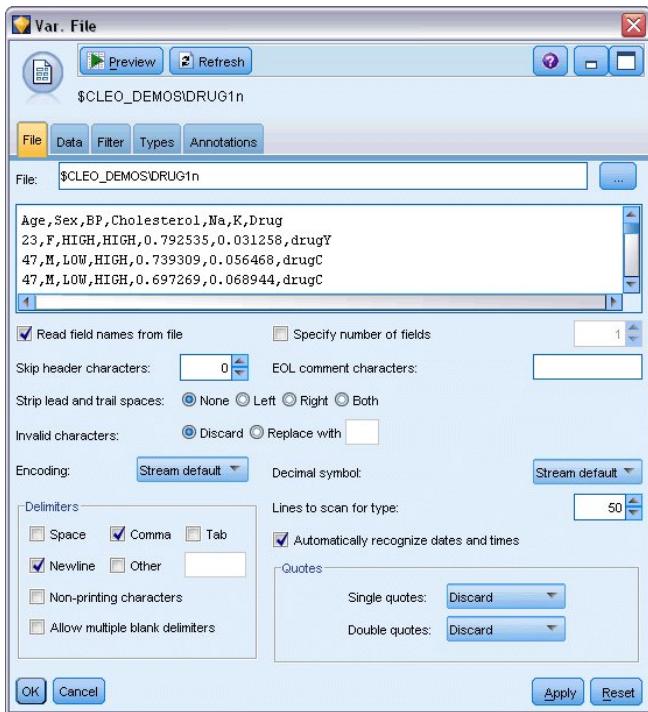

Figure 3. Changing the storage type for a field

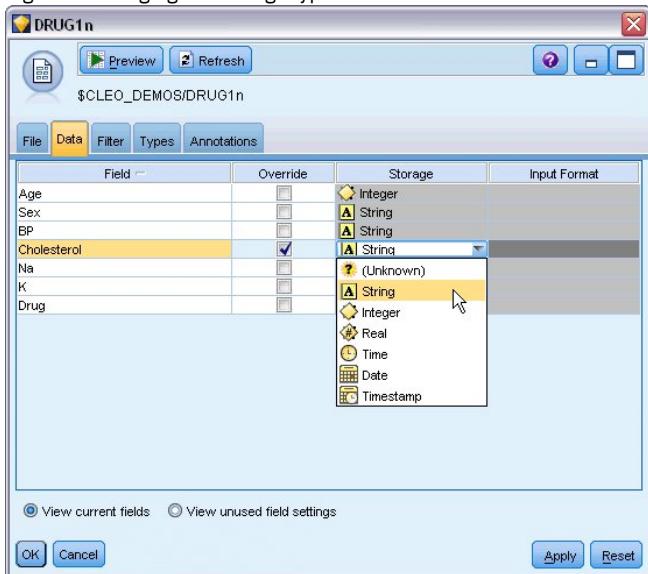

Figure 4. Selecting Value options on the Types tab

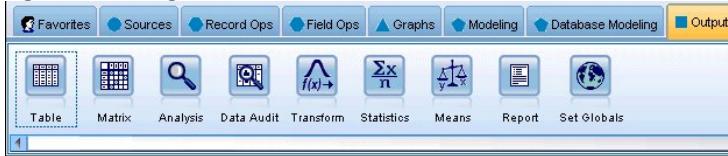

Click the Data tab to override and change **Storage** for a field. Note that storage is different from **Measurement**, that is, the measurement level (or usage type) of the data field. The Types tab helps you learn more about the type of fields in your data. You can also choose Read Values to view the actual values for each field based on the selections that you make from the *Values* column. This process is known as **instantiation**.

[Next](#)

Adding a Table

Figure 1. Selecting the Table node

Now that you have loaded the data file, you may want to glance at the values for some of the records. One way to do this is by building a stream that includes a Table node. To place a Table node in the stream, either double-click the icon in the palette or drag and drop it on to the canvas.

Figure 2. Table node connected to the data source

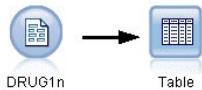

Figure 3. Running a stream from the toolbar

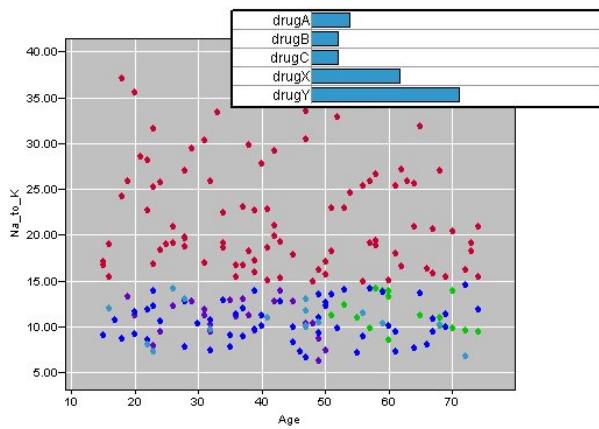

Double-clicking a node from the palette will automatically connect it to the selected node in the stream canvas. Alternatively, if the nodes are not already connected, you can use your middle mouse button to connect the Source node to the Table node. To simulate a middle mouse button, hold down the Alt key while using the mouse. To view the table, click the green arrow button on the toolbar to run the stream, or right-click the Table node and choose Run.

[Next](#)

Creating a Distribution Graph

During data mining, it is often useful to explore the data by creating visual summaries. IBM® SPSS® Modeler offers several different types of graphs to choose from, depending on the kind of data that you want to summarize. For example, to find out what proportion of the patients responded to each drug, use a Distribution node.

Figure 1. Sample of available graphs

Add a Distribution node to the stream and connect it to the Source node, then double-click the node to edit options for display.

Select *Drug* as the target field whose distribution you want to show. Then, click Run from the dialog box.

Figure 2. Selecting drug as the target field

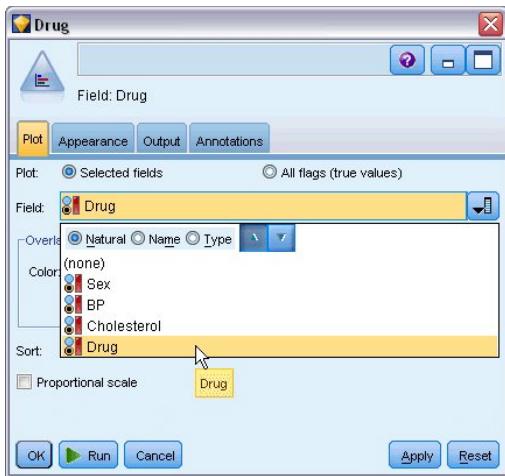

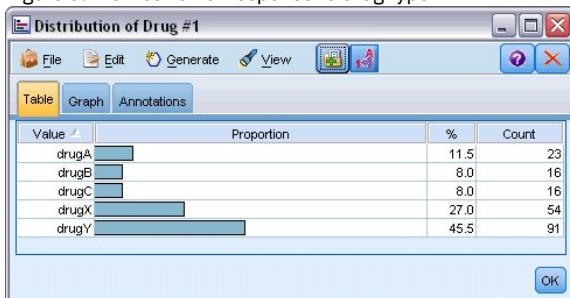

Figure 3. Distribution of response to drug type

The resulting graph helps you see the "shape" of the data. It shows that patients responded to drug Y most often and to drugs B and C least often.

Figure 4. Results of a data audit

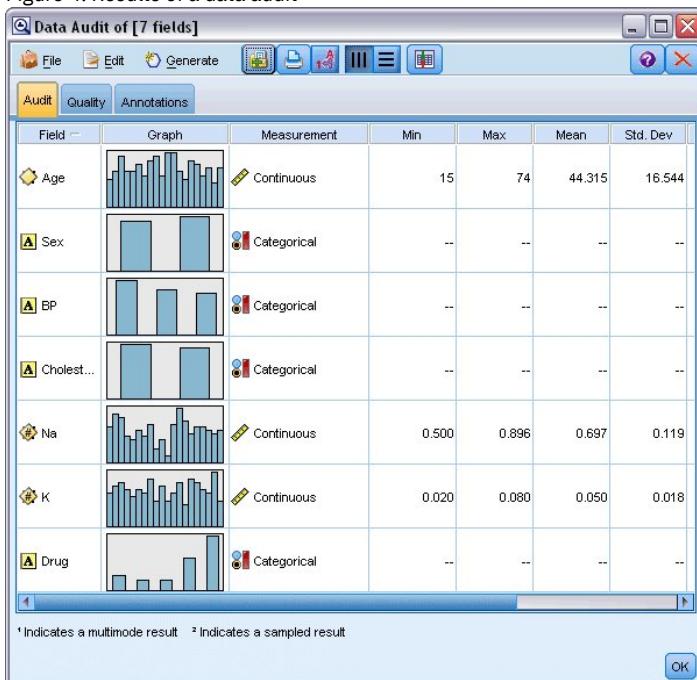

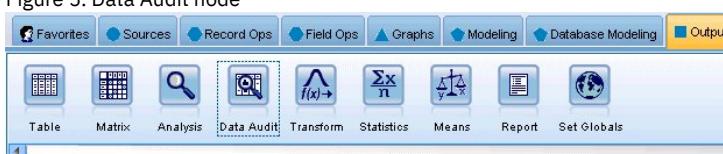

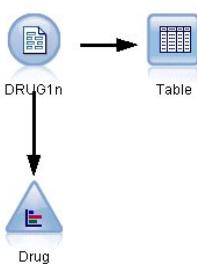

Figure 5. Data Audit node

Alternatively, you can attach and execute a Data Audit node for a quick glance at distributions and histograms for all fields at once. The Data Audit node is available on the Output tab.

Creating a Scatterplot

Now let's take a look at what factors might influence *Drug*, the target variable. As a researcher, you know that the concentrations of sodium and potassium in the blood are important factors. Since these are both numeric values, you can create a scatterplot of sodium versus potassium, using the drug categories as a color overlay.

Place a Plot node in the workspace and connect it to the Source node, and double-click to edit the node.

Figure 1. Stream with plot node

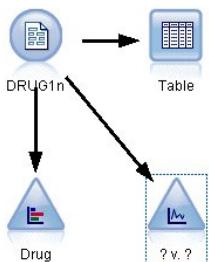

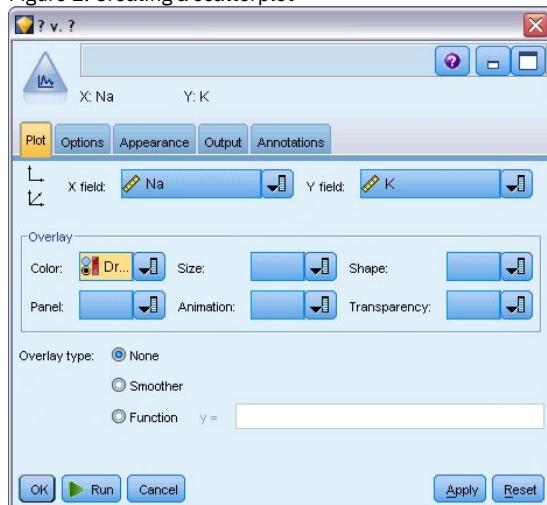

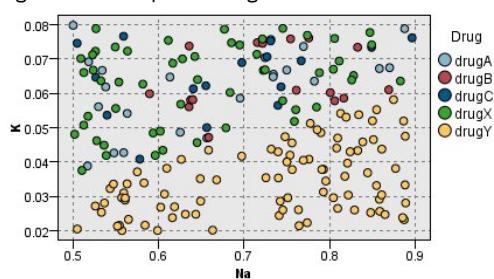

Figure 2. Creating a scatterplot

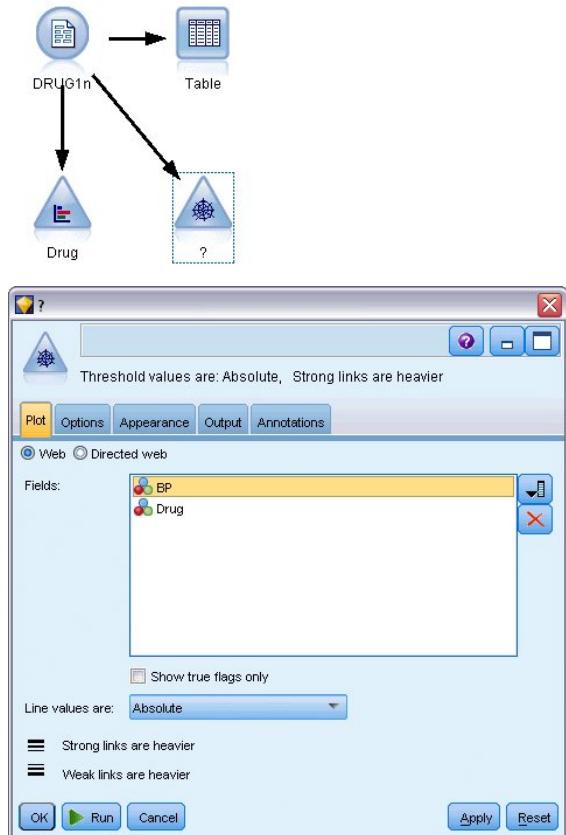

On the Plot tab, select *Na* as the X field, *K* as the Y field, and *Drug* as the overlay field. Then, click Run.

The plot clearly shows a threshold above which the correct drug is always drug Y and below which the correct drug is never drug Y. This threshold is a ratio--the ratio of sodium (*Na*) to potassium (*K*).

Figure 3. Scatterplot of drug distribution

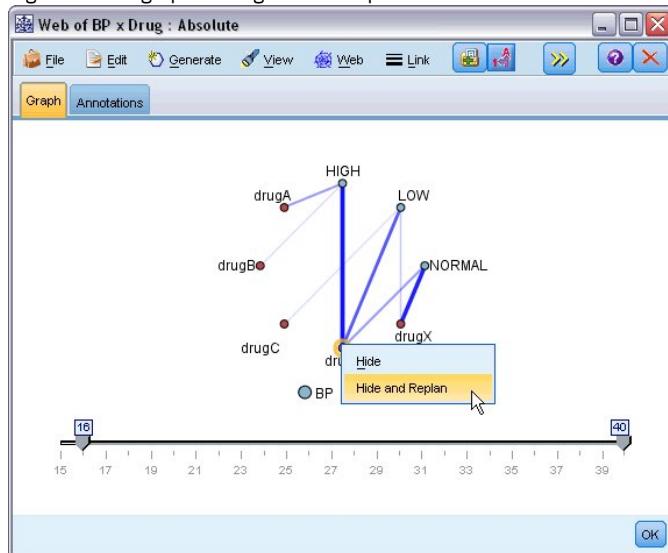

Creating a Web Graph

Since many of the data fields are categorical, you can also try plotting a web graph, which maps associations between different categories. Start by connecting a Web node to the Source node in your workspace. In the Web node dialog box, select *BP* (for blood pressure) and *Drug*. Then, click Run.

Figure 1. Web graph of drugs vs. blood pressure

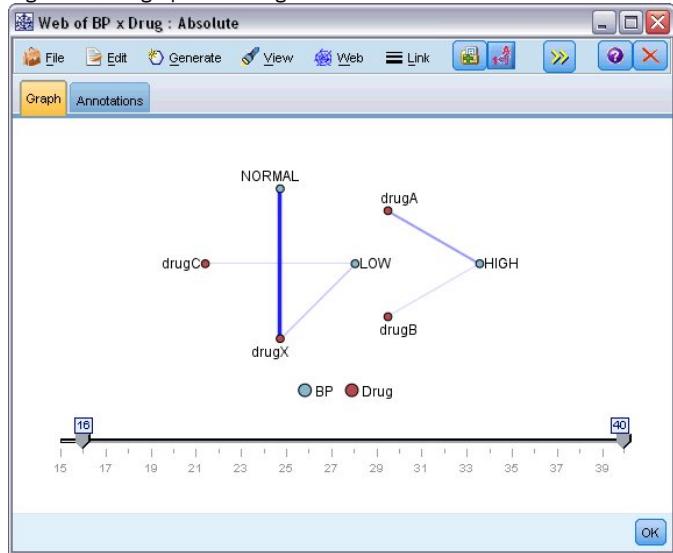

From the plot, it appears that drug Y is associated with all three levels of blood pressure. This is no surprise--you have already determined the situation in which drug Y is best. To focus on the other drugs, you can hide drug Y. On the View menu, choose Edit Mode, then right-click over the drug Y point and choose Hide and Replan.

In the simplified plot, drug Y and all of its links are hidden. Now, you can clearly see that only drugs A and B are associated with high blood pressure. Only drugs C and X are associated with low blood pressure. And normal blood pressure is associated only with drug X. At this point,

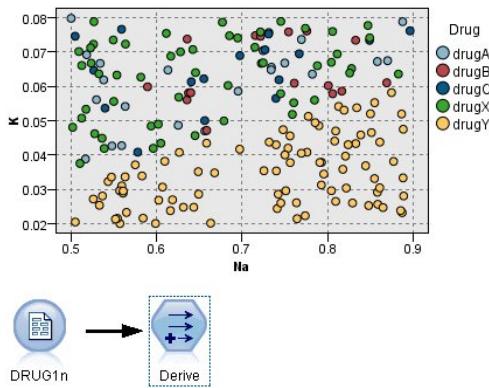

though, you still don't know how to choose between drugs *A* and *B* or between drugs *C* and *X*, for a given patient. This is where modeling can help.

Figure 2. Web graph with drug Y and its links hidden

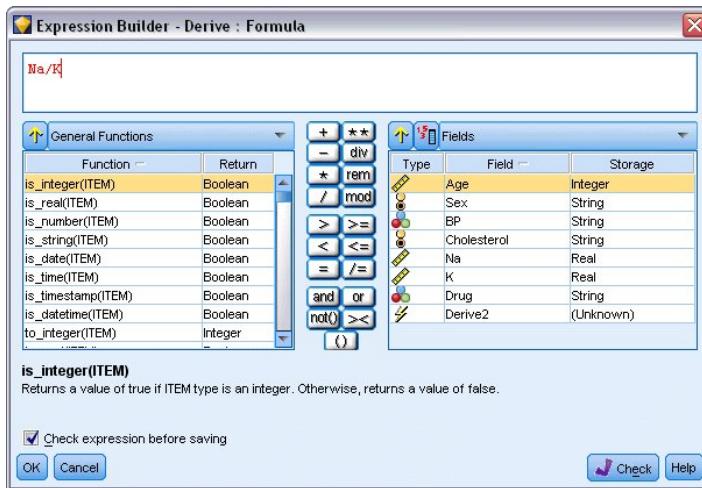

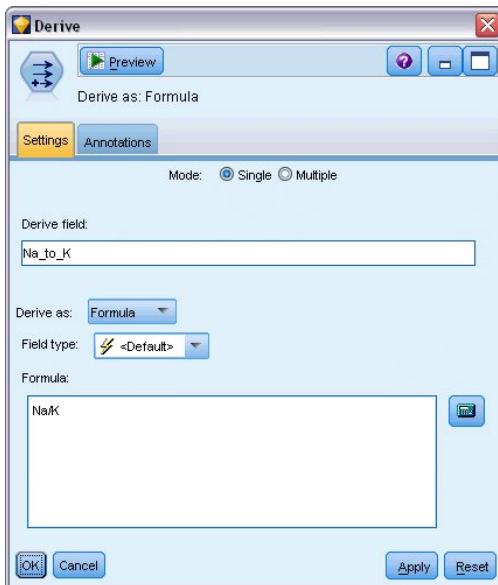

[Next](#)

Deriving a New Field

Since the ratio of sodium to potassium seems to predict when to use drug *Y*, you can derive a field that contains the value of this ratio for each record. This field might be useful later when you build a model to predict when to use each of the five drugs. To simplify the stream layout, start by deleting all the nodes except the DRUG1n source node. Attach a Derive node (Field Ops tab) to DRUG1n, then double-click the Derive node to edit it.

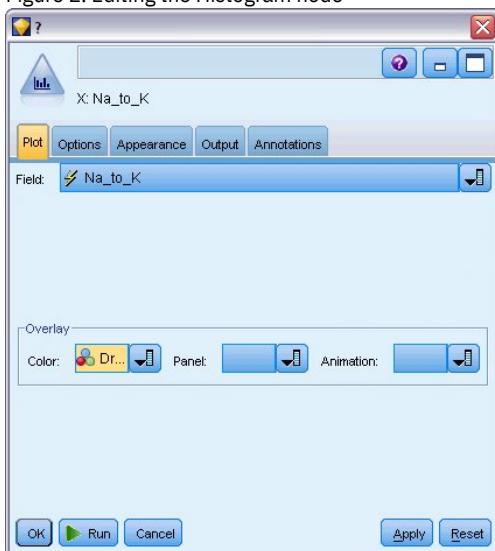

Figure 1. Editing the Derive node

Name the new field *Na_to_K*. Since you obtain the new field by dividing the sodium value by the potassium value, enter *Na/K* for the formula. You can also create a formula by clicking the icon just to the right of the field. This opens the Expression Builder, a way to interactively create expressions using built-in lists of functions, operands, and fields and their values.

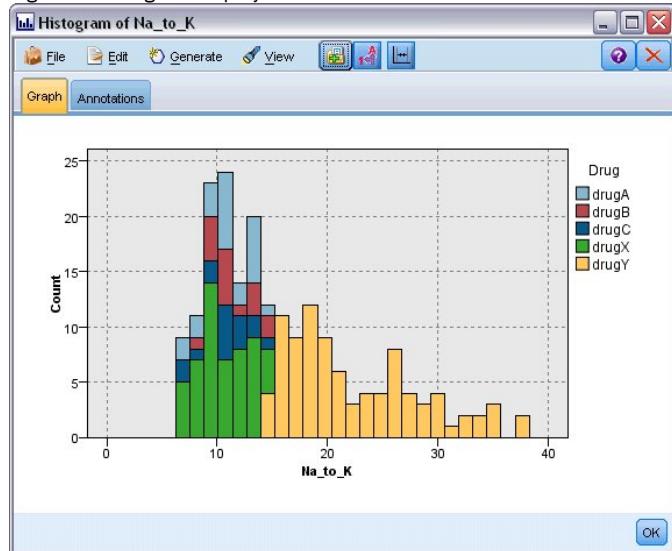

You can check the distribution of your new field by attaching a Histogram node to the Derive node. In the Histogram node dialog box, specify *Na_to_K* as the field to be plotted and *Drug* as the overlay field.

Figure 2. Editing the Histogram node

When you run the stream, you get the graph shown here. Based on the display, you can conclude that when the *Na_to_K* value is about 15 or above, drug Y is the drug of choice.

Figure 3. Histogram display

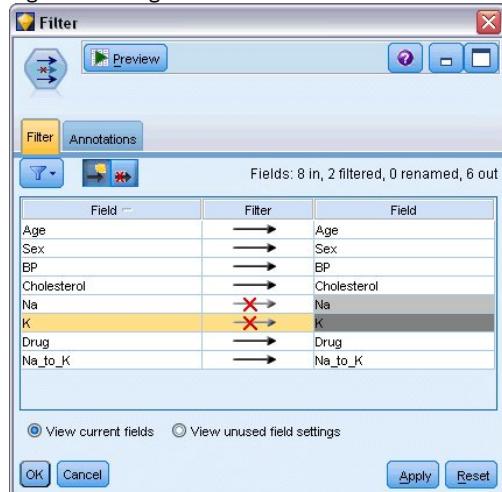

[Next](#)

Building a Model

By exploring and manipulating the data, you have been able to form some hypotheses. The ratio of sodium to potassium in the blood seems to affect the choice of drug, as does blood pressure. But you cannot fully explain all of the relationships yet. This is where modeling will likely provide some answers. In this case, you will use try to fit the data using a rule-building model, C5.0.

Since you are using a derived field, *Na_to_K*, you can filter out the original fields, *Na* and *K*, so that they are not used twice in the modeling algorithm. You can do this using a Filter node.

Figure 1. Editing the Filter node

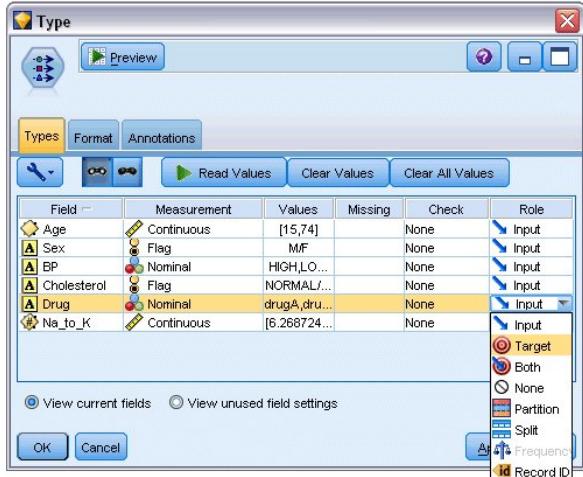

On the Filter tab, click the arrows next to *Na* and *K*. Red Xs appear over the arrows to indicate that the fields are now filtered out.

Next, attach a Type node connected to the Filter node. The Type node allows you to indicate the types of fields that you are using and how they are used to predict the outcomes.

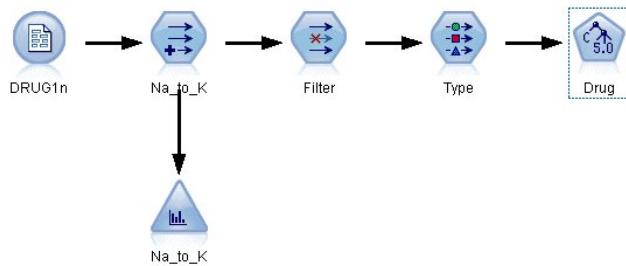

On the Types tab, set the role for the *Drug* field to Target, indicating that *Drug* is the field you want to predict. Leave the role for the other fields set to Input so they will be used as predictors.

Figure 2. Editing the Type node

To estimate the model, place a C5.0 node in the workspace and attach it to the end of the stream as shown. Then click the green Run toolbar button to run the stream.

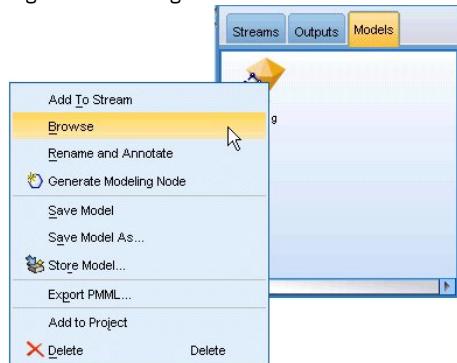

Figure 3. Adding a C5.0 node

[Next](#)

Browsing the model

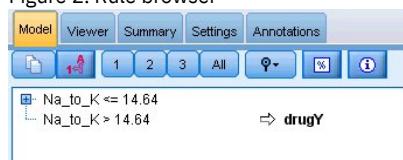

Figure 1. Browsing the model

When the C5.0 node is executed, the model nugget is added to the stream, and also to the Models palette in the upper-right corner of the window. To browse the model, right-click either of the icons and choose Edit or Browse from the context menu.

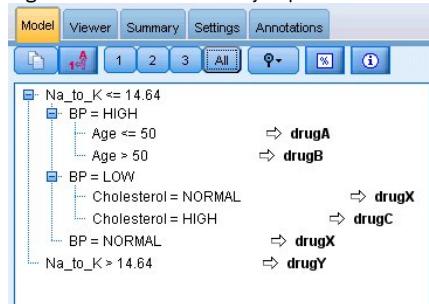

The Rule browser displays the set of rules generated by the C5.0 node in a decision tree format. Initially, the tree is collapsed. To expand it, click the All button to show all levels.

Figure 2. Rule browser

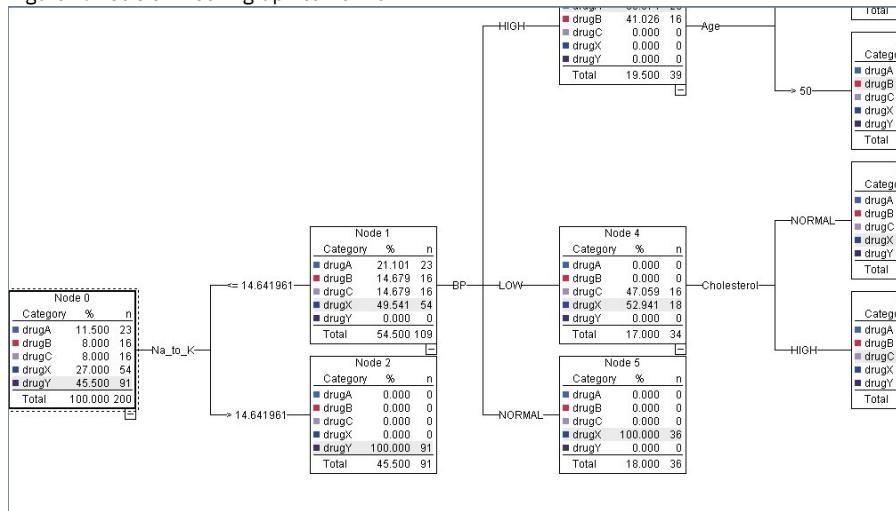

Now you can see the missing pieces of the puzzle. For people with an Na-to-K ratio less than 14.64 and high blood pressure, age determines the choice of drug. For people with low blood pressure, cholesterol level seems to be the best predictor.

Figure 3. Rule browser fully expanded

The same decision tree can be viewed in a more sophisticated graphical format by clicking the Viewer tab. Here, you can see more easily the number of cases for each blood pressure category, as well as the percentage of cases.

Figure 4. Decision tree in graphical format

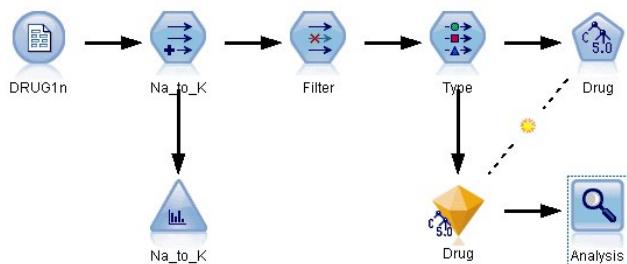

[Next](#)

Using an Analysis Node

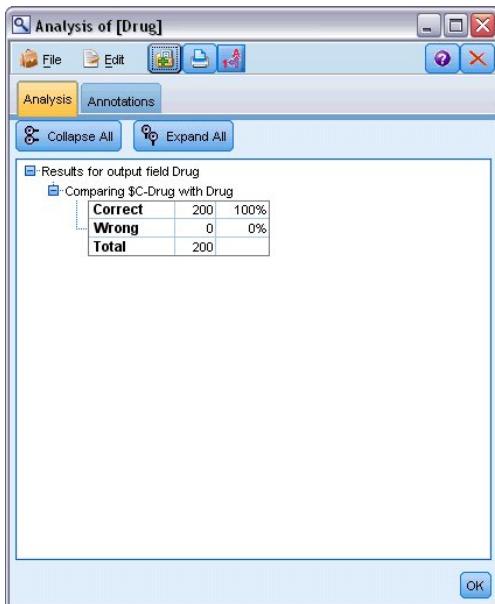

You can assess the accuracy of the model using an analysis node. Attach an Analysis node (from the Output node palette) to the model nugget, open the Analysis node and click Run.

Figure 1. Adding an Analysis node

The Analysis node output shows that with this artificial dataset, the model correctly predicted the choice of drug for every record in the dataset. With a real dataset you are unlikely to see 100% accuracy, but you can use the Analysis node to help determine whether the model is acceptably accurate for your particular application.

Figure 2. Analysis node output

Screening Predictors (Feature Selection)

The Feature Selection node helps you to identify the fields that are most important in predicting a certain outcome. From a set of hundreds or even thousands of predictors, the Feature Selection node screens, ranks, and selects the predictors that may be most important. Ultimately, you may end up with a quicker, more efficient model—one that uses fewer predictors, executes more quickly, and may be easier to understand.

The data used in this example represent a data warehouse for a hypothetical telephone company and contain information about responses to a special promotion by 5,000 of the company's customers. The data include a large number of fields containing customers' age, employment, income, and telephone usage statistics. Three "target" fields show whether or not the customer responded to each of three offers. The company wants to use this data to help predict which customers are most likely to respond to similar offers in the future.

This example uses the stream named *featureselection.str*, which references the data file named *customer_dbase.sav*. These files are available from the *Demos* directory of any IBM® SPSS® Modeler installation. This can be accessed from the IBM SPSS Modeler program group on the Windows Start menu. The *featureselection.str* file is in the *streams* directory.

This example focuses on only one of the offers as a target. It uses the CHAID tree-building node to develop a model to describe which customers are most likely to respond to the promotion. It contrasts two approaches:

- Without feature selection. All predictor fields in the dataset are used as inputs to the CHAID tree.
- With feature selection. The Feature Selection node is used to select the top 10 predictors. These are then input into the CHAID tree.

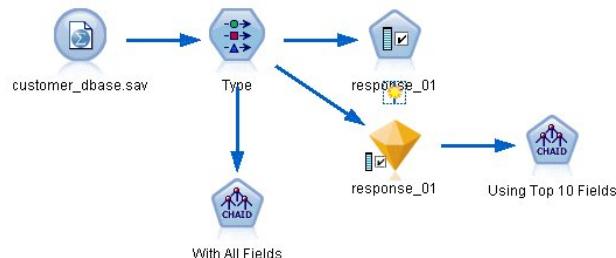

By comparing the two resulting tree models, we can see how feature selection produces effective results.

- [Building the Stream](#)
- [Building the Models](#)
- [Comparing the Results](#)
- [Summary](#)

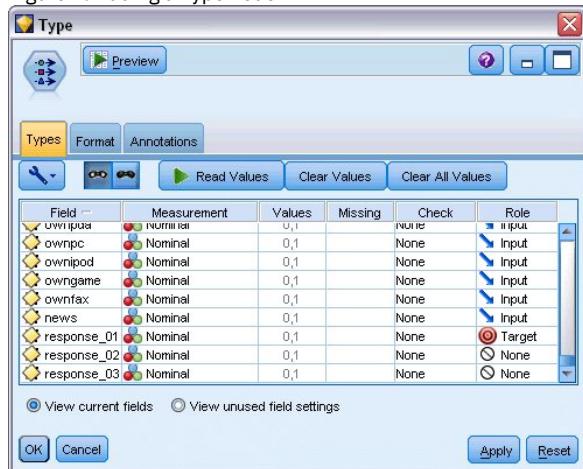

Building the Stream

Figure 1. Feature Selection example stream

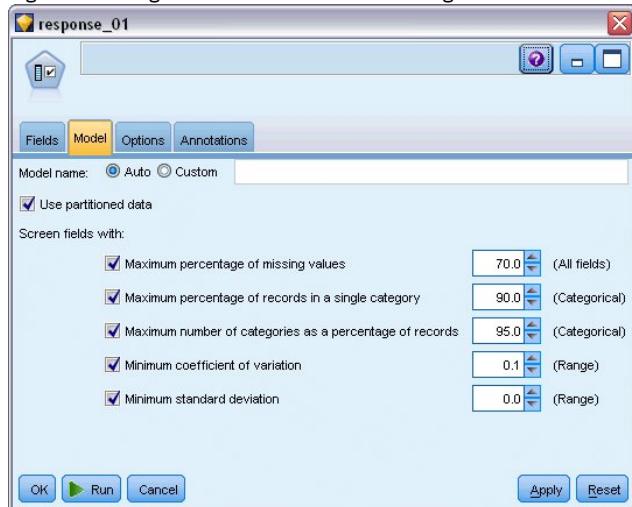

1. Place a Statistics File source node onto a blank stream canvas. Point this node to the example data file *customer_dbase.sav*, available in the *Demos* directory under your IBM® SPSS® Modeler installation. (Alternatively, open the example stream file *featureselection.str* in the *streams* directory.)
2. Add a Type node. On the Types tab, scroll down to the bottom and change the role for *response_01* to *Target*. Change the role to *None* for the other response fields (*response_02* and *response_03*) as well as for the customer ID (*custid*) at the top of the list. Leave the role set to *Input* for all other fields, and click the Read Values button, then click OK.

Figure 2. Adding a Type node

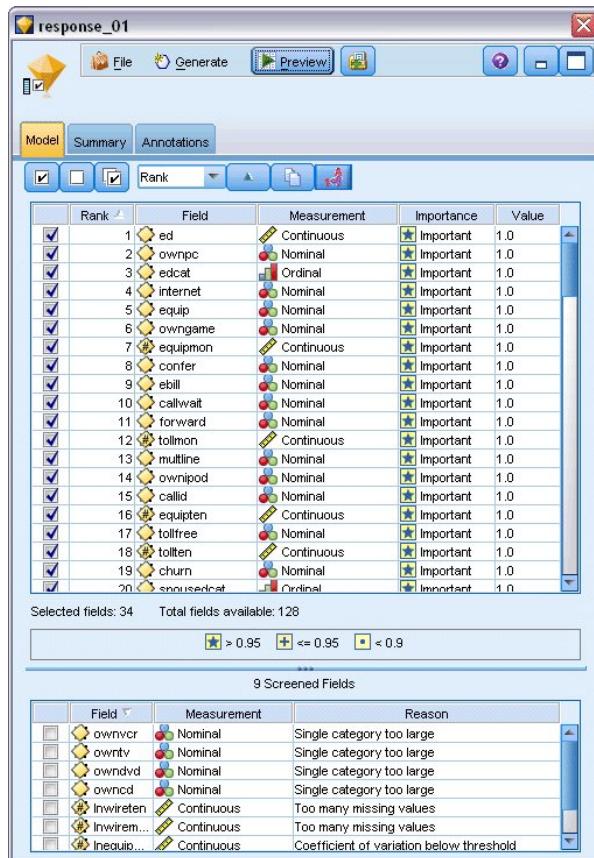

3. Add a Feature Selection modeling node to the stream. On this node, you can specify the rules and criteria for screening, or disqualifying, fields.

Figure 3. Adding the Feature Selection modeling node

4. Run the stream to create the Feature Selection model nugget.
5. Right-click the model nugget on the stream or in the Models palette and choose Edit or Browse to look at the results.

Figure 4. Model tab in Feature Selection model nugget

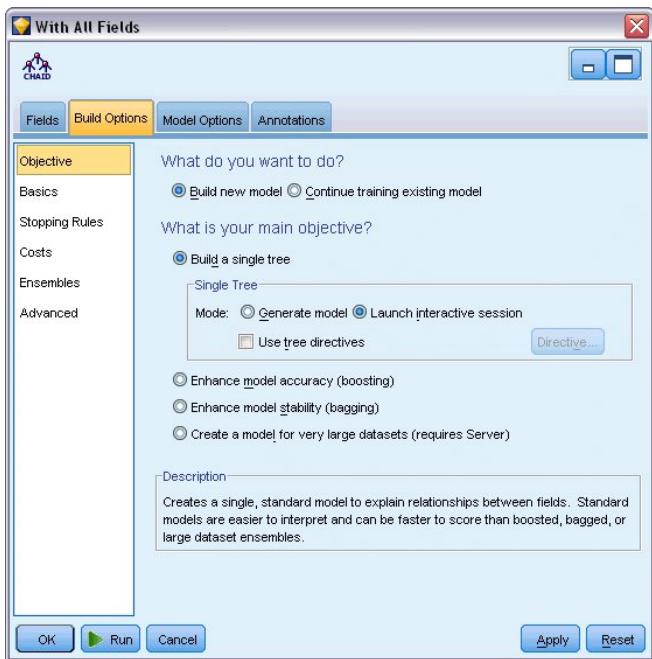

The top panel shows the fields found to be useful in the prediction. These are ranked based on importance. The bottom panel shows which fields were screened from the analysis and why. By examining the fields in the top panel, you can decide which ones to use in subsequent modeling sessions.

6. Now we can select the fields to use downstream. Although 34 fields were originally identified as important, we want to reduce the set of predictors even further.
7. Select only the top 10 predictors using the check marks in the first column to deselect the unwanted predictors. (Click the check mark in row 11, hold down the Shift key and click the check mark in row 34.) Close the model nugget.
8. To compare results without feature selection, you must add two CHAID modeling nodes to the stream: one that uses feature selection and one that does not.
9. Connect one CHAID node to the Type node, and the other one to the Feature Selection model nugget.
10. Open each CHAID node, select the Build Options tab and ensure that the options Build new model, Build a single tree and Launch interactive session are selected in the Objectives pane.

On the Basics pane, make sure that Maximum Tree Depth is set to 5.

Figure 5. Objectives settings for CHAID modeling node for all predictor fields

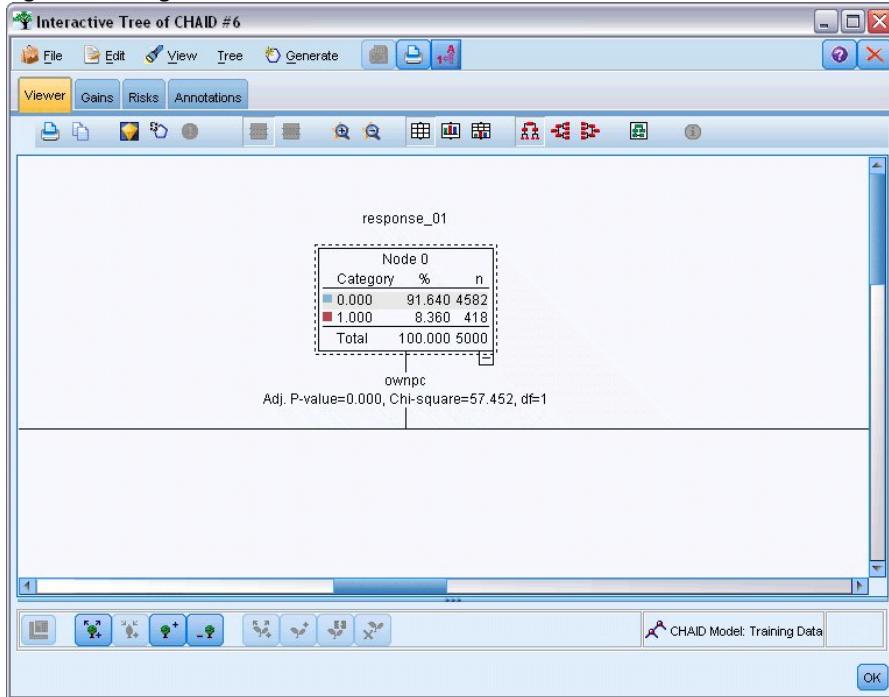

[Next](#)

Building the Models

1. Execute the CHAID node that uses all of the predictors in the dataset (the one connected to the Type node). As it runs, notice how long it takes to execute. The results window displays a table.
2. From the menus, choose Tree > Grow Tree to grow and display the expanded tree.

Figure 1. Growing the tree in the Tree Builder

3. Now do the same for the other CHAID node, which uses only 10 predictors. Again, grow the tree when the Tree Builder opens.

The second model should have executed faster than the first one. Because this dataset is fairly small, the difference in execution times is probably a few seconds; but for larger real-world datasets, the difference may be very noticeable—minutes or even hours. Using feature selection may speed up your processing times dramatically.

The second tree also contains fewer tree nodes than the first. It is easier to comprehend. But before you decide to use it, you need to find out whether it is effective and how it compares to the model that uses all predictors.

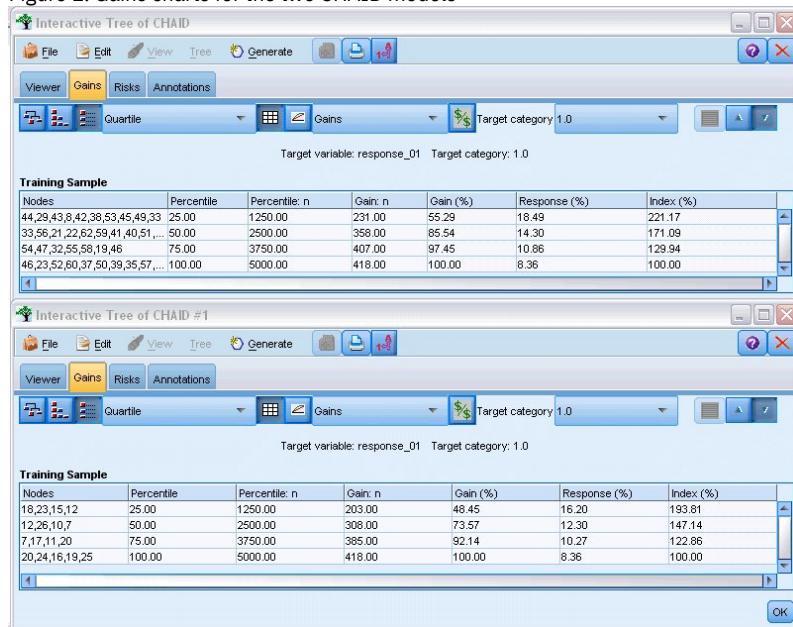

[Next](#)

Comparing the Results

To compare the two results, we need a measure of effectiveness. For this, we will use the Gains tab in the Tree Builder. We will look at **lift**, which measures how much more likely the records in a node are to fall under the target category when compared to all records in the dataset. For example, a lift value of 148% indicates that records in the node are 1.48 times more likely to fall under the target category than all records in the dataset. Lift is indicated in the *Index* column on the Gains tab.

1. In the Tree Builder for the full set of predictors, click the Gains tab. Change the target category to 1.0. Change the display to quartiles by first clicking the Quantiles toolbar button. Then select Quartile from the drop-down list to the right of this button.
2. Repeat this procedure in the Tree Builder for the set of 10 predictors so that you have two similar Gains tables to compare, as shown in the following figures.

Figure 1. Gains charts for the two CHAID models

Each Gains table groups the terminal nodes for its tree into quartiles. To compare the effectiveness of the two models, look at the lift (*Index* value) for the top quartile in each table.

When all predictors are included, the model shows a lift of 221%. That is, cases with the characteristics in these nodes are 2.2 times more likely to respond to the target promotion. To see what those characteristics are, click to select the top row. Then switch to the Viewer tab, where the corresponding nodes are now outlined in black. Follow the tree down to each highlighted terminal node to see how the predictors were split. The top quartile alone includes 10 nodes. When translated into real-world scoring models, 10 different customer profiles can be difficult to manage.

With only the top 10 predictors (as identified by feature selection) included, the lift is nearly 194%. Although this model is not quite as good as the model that uses all predictors, it is certainly useful. Here, the top quartile includes only four nodes, so it is simpler. Therefore, we can determine that the feature selection model is preferable to the one with all predictors.

[Next](#)

Summary

Let's review the advantages of feature selection. Using fewer predictors is less expensive. It means that you have less data to collect, process, and feed into your models. Computing time is improved. In this example, even with the extra feature selection step, model building was noticeably faster with the smaller set of predictors. With a larger real-world dataset, the time savings should be greatly amplified.

Using fewer predictors results in simpler scoring. As the example shows, you might identify only four profiles of customers who are likely to respond to the promotion. Note that with larger numbers of predictors, you run the risk of overfitting your model. The simpler model may generalize better to other datasets (although you would need to test this to be sure).

You could have used a tree-building algorithm to do the feature selection work, allowing the tree to identify the most important predictors for you. In fact, the CHAID algorithm is often used for this purpose, and it is even possible to grow the tree level-by-level to control its depth and complexity. However, the Feature Selection node is faster and easier to use. It ranks all of the predictors in one fast step, allowing you to identify the most important fields quickly. It also allows you to vary the number of predictors to include. You could easily run this example again using the top 15 or 20 predictors instead of 10, comparing the results to determine the optimal model.

Reducing Input Data String Length (Reclassify Node)

- #### **• Reducing Input Data String Length (Reclassify)**

Reducing Input Data String Length (Reclassify)

For binomial logistic regression, and auto classifier models that include a binomial logistic regression model, string fields are limited to a maximum of eight characters. Where strings are more than eight characters, they can be recoded using a Reclassify node.

This example uses the stream named *reclassify_strings.str*, which references the data file named *drug_long_name*. These files are available from the *Demos* directory of any IBM® SPSS® Modeler installation. This can be accessed from the IBM SPSS Modeler program group on the Windows Start menu. The *reclassify_strings.str* file is in the *streams* directory.

This example focuses on a small part of a stream to show the sort of errors that may be generated with overlong strings and explains how to use the Reclassify node to change the string details to an acceptable length. Although the example uses a binomial Logistic Regression node, it is equally applicable when using the Auto Classifier node to generate a binomial Logistic Regression model.

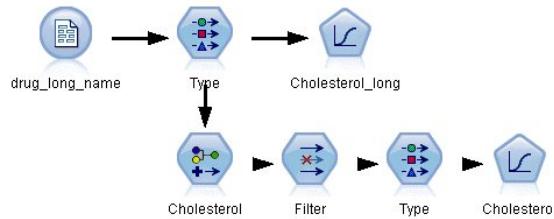

Next

- Reclassifying the Data

Reclassifying the Data

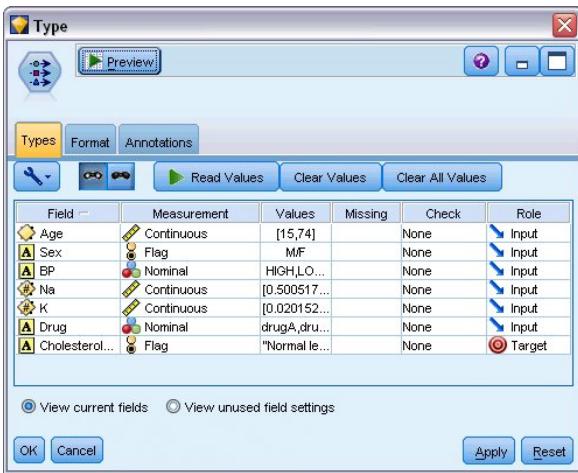

1. Using a Variable File source node, connect to the dataset *drug_long_name* in the *Demos* folder.

Figure 1. Sample stream showing string reclassification for binomial logistic regression

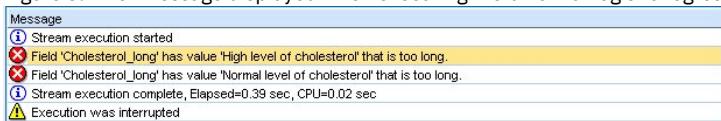

2. Add a Type node to the Source node and select Cholesterol_long as the target.
 3. Add a Logistic Regression node to the Type node.
 4. In the Logistic Regression node, click the Model tab and select the Binomial procedure.

Figure 2. Long string details in the "Cholesterol_long" field

5. When you execute the Logistic Regression node in *reclassify_strings.str*, an error message is displayed warning that the Cholesterol_long string values are too long.
If you encounter this type of error message, follow the procedure explained in the rest of this example to modify your data.

Figure 3. Error message displayed when executing the binomial logistic regression node

6. Add a Reclassify node to the Type node.
7. In the Reclassify field, select Cholesterol_long.
8. Type Cholesterol as the new field name.
9. Click the Get button to add the Cholesterol_long values to the original value column.
10. In the new value column, type High next to the original value of High level of cholesterol and Normal next to the original value of Normal level of cholesterol.

Figure 4. Reclassifying the long strings

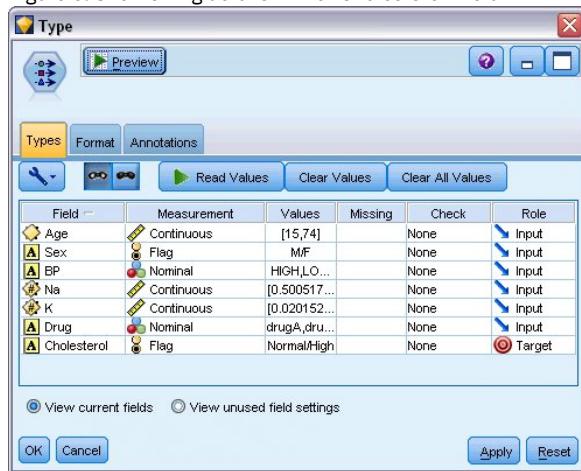

11. Add a Filter node to the Reclassify node.
12. In the Filter column, click to remove Cholesterol_long.

Figure 5. Filtering the "Cholesterol_long" field from the data

13. Add a Type node to the Filter node and select Cholesterol as the target.

Figure 6. Short string details in the "Cholesterol" field

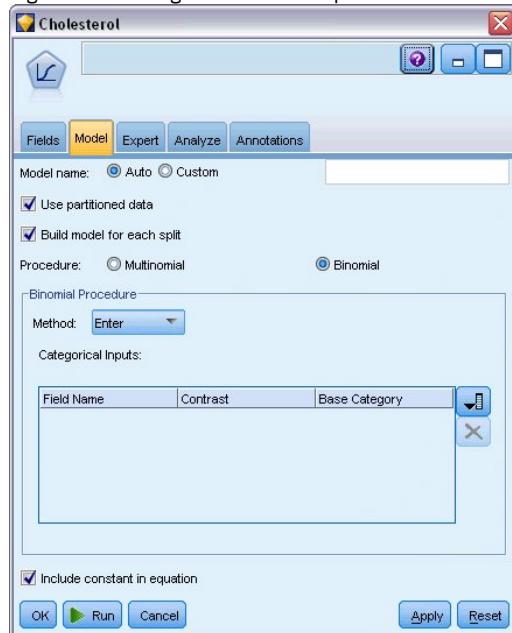

14. Add a Logistic Node to the Type node.

15. In the Logistic node, click the Model tab and select the Binomial procedure.

16. You can now execute the Binomial Logistic node and generate a model without displaying an error message.

Figure 7. Choosing Binomial as the procedure

This example only shows part of a stream. If you require further information about the types of streams in which you may need to reclassify long strings, the following examples are available:

- Auto Classifier node. See the topic [Modeling Customer Response \(Auto Classifier\)](#) for more information.
- Binomial Logistic Regression node. See the topic [Telecommunications Churn \(Binomial Logistic Regression\)](#) for more information.

More information on how to use IBM® SPSS® Modeler, such as a user's guide, node reference, and algorithms guide, are available from the *|Documentation* directory of the installation disk.

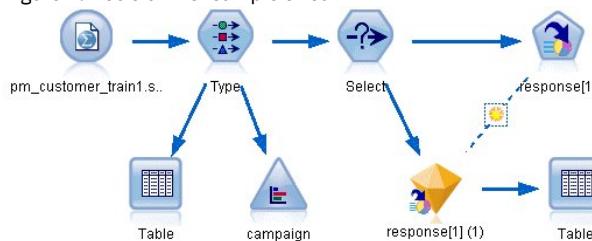

Modeling Customer Response (Decision List)

The Decision List algorithm generates rules that indicate a higher or lower likelihood of a given binary (yes or no) outcome. Decision List models are widely used in customer relationship management, such as call center or marketing applications.

This example is based on a fictional company that wants to achieve more profitable results in future marketing campaigns by matching the right offer to each customer. Specifically, the example uses a Decision List model to identify the characteristics of customers who are most likely to respond favorably, based on previous promotions, and to generate a mailing list based on the results.

Decision List models are particularly well suited to interactive modeling, allowing you to adjust parameters in the model and immediately see the results. For a different approach that allows you to automatically create a number of different models and rank the results, the Auto Classifier node can be used instead.

Figure 1. Decision List sample stream

This example uses the stream *pm_decisionlist.str*, which references the data file *pm_customer_train1.sav*. These files are available from the *Demos* directory of any IBM® SPSS® Modeler installation. This can be accessed from the IBM SPSS Modeler program group on the Windows Start menu. The *pm_decisionlist.str* file is in the *streams* directory.

- [Historical Data](#)
- [Building the Stream](#)
- [Creating the model](#)
- [Calculating custom measures using Excel](#)
- [Saving the Results](#)

Historical Data

The file *pm_customer_train1.sav* has historical data tracking the offers made to specific customers in past campaigns, as indicated by the value of the *campaign* field. The largest number of records fall under the *Premium account* campaign.

Figure 1. Data about previous promotions

Table (31 fields, 21,927 records)

The screenshot shows a window titled "Table (31 fields, 21,927 records)". The toolbar includes icons for File, Edit, Generate, and various data manipulation tools. Below the toolbar is a tab bar with "Table" and "Annotations". The main area is a grid showing data from a CSV file. The columns include "customer_id", "campaign", "response", "response_date", "purchase", "purchase_date", "product_id", and others. Row 1 shows "customer_id" 7 with "campaign" "Premium account" and "response" 0. Row 2 shows "customer_id" 13 with "campaign" "Premium account" and "response" 0. Row 3 shows "customer_id" 15 with "campaign" "Premium account" and "response" 0. Row 4 shows "customer_id" 16 with "campaign" "Premium account" and "response" 1. Row 5 shows "customer_id" 23 with "campaign" "Premium account" and "response" 0. Row 6 shows "customer_id" 24 with "campaign" "Premium account" and "response" 0. Row 7 shows "customer_id" 30 with "campaign" "Gold card" and "response" 0. Row 8 shows "customer_id" 30 with "campaign" "Gold card" and "response" 0. Row 9 shows "customer_id" 33 with "campaign" "Premium account" and "response" 0. Row 10 shows "customer_id" 42 with "campaign" "Gold card" and "response" 0. Row 11 shows "customer_id" 42 with "campaign" "Premium account" and "response" 0. Row 12 shows "customer_id" 52 with "campaign" "Premium account" and "response" 0. Row 13 shows "customer_id" 57 with "campaign" "Premium account" and "response" 0. Row 14 shows "customer_id" 63 with "campaign" "Premium account" and "response" 1. Row 15 shows "customer_id" 74 with "campaign" "Premium account" and "response" 0. Row 16 shows "customer_id" 74 with "campaign" "Gold card" and "response" 0. Row 17 shows "customer_id" 75 with "campaign" "Premium account" and "response" 0. Row 18 shows "customer_id" 82 with "campaign" "Premium account" and "response" 0. Row 19 shows "customer_id" 89 with "campaign" "Gold card" and "response" 0. Row 20 shows "customer_id" 89 with "campaign" "Premium account" and "response" 0.

The values of the *campaign* field are actually coded as integers in the data, with labels defined in the Type node (for example, 2 = *Premium account*). You can toggle display of value labels in the table using the toolbar.

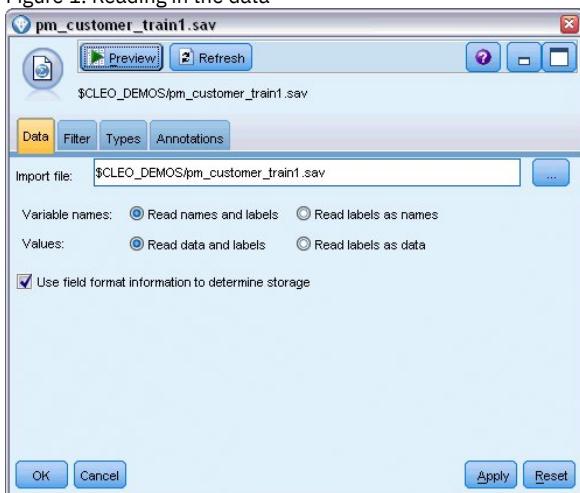

The file also includes a number of fields containing demographic and financial information about each customer that can be used to build or "train" a model that predicts response rates for different groups based on specific characteristics.

[Next](#)

Building the Stream

- Add a Statistics File node pointing to *pm_customer_train1.sav*, located in the *Demos* folder of your IBM® SPSS® Modeler installation. (You can specify **\$CLEO_DEMOS/** in the file path as a shortcut to reference this folder.)

Figure 1. Reading in the data

- Add a Type node, and select *response* as the target field (Role = Target). Set the measurement level for this field to Flag.

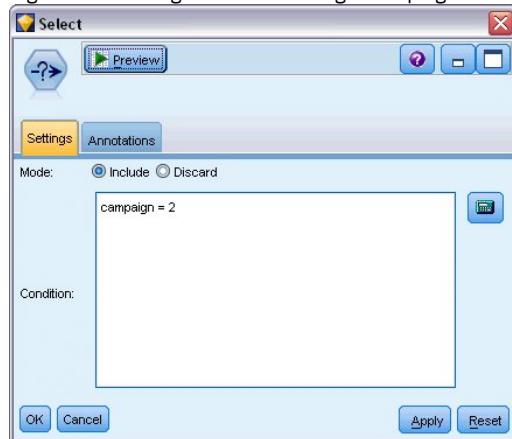

Figure 2. Setting the measurement level and role

3. Set the role to None for the following fields: *customer_id*, *campaign*, *response_date*, *purchase*, *purchase_date*, *product_id*, *Rowid*, and *X_random*. These fields all have uses in the data but will not be used in building the actual model.
4. Click the Read Values button in the Type node to make sure that values are instantiated.

Although the data includes information about four different campaigns, you will focus the analysis on one campaign at a time. Since the largest number of records fall under the Premium campaign (coded *campaign* = 2 in the data), you can use a Select node to include only these records in the stream.

Figure 3. Selecting records for a single campaign

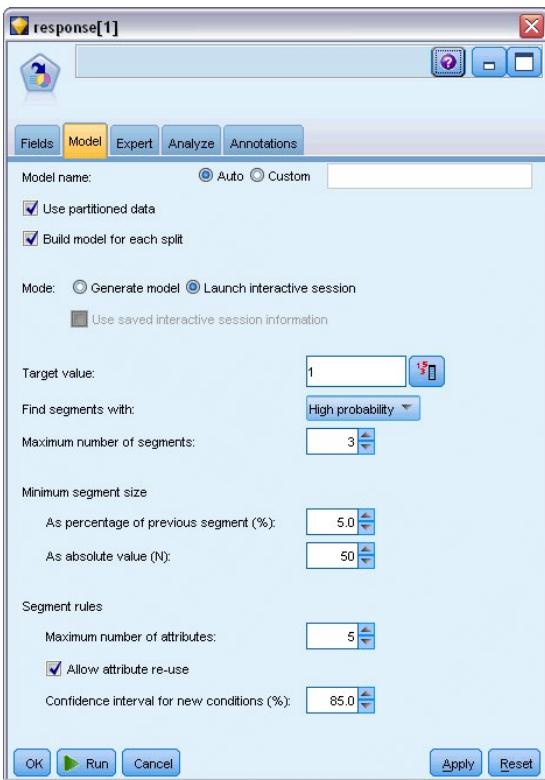

[Next](#)

Creating the model

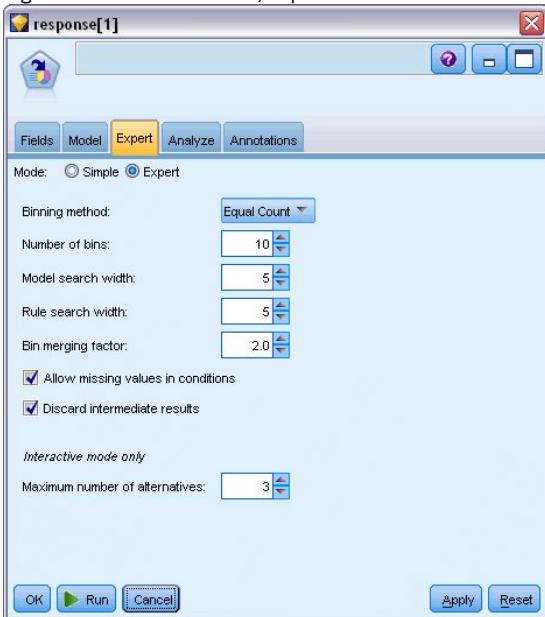

1. Attach a Decision List node to the stream. On the Model tab, set the Target value to 1 to indicate the outcome you want to search for. In this case, you are looking for customers who responded Yes to a previous offer.

Figure 1. Decision List node, Model tab

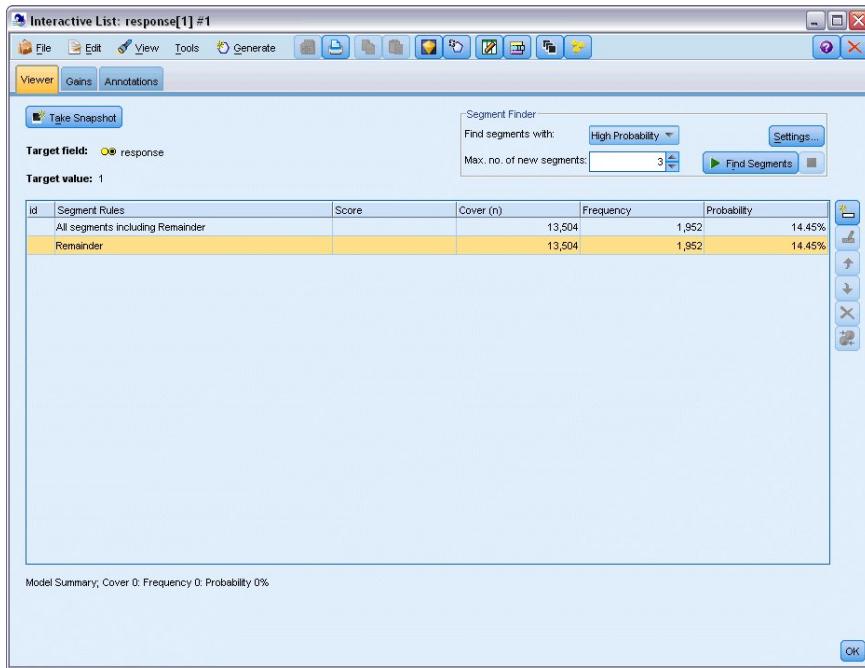

2. Select Launch interactive session.
3. To keep the model simple for purposes of this example, set the maximum number of segments to 3.
4. Change the confidence interval for new conditions to 85%.
5. On the Expert tab, set the Mode to Expert.

Figure 2. Decision List node, Expert tab

6. Increase the Maximum number of alternatives to 3. This option works in conjunction with the Launch interactive session setting that you selected on the Model tab.
7. Click Run to display the Interactive List viewer.

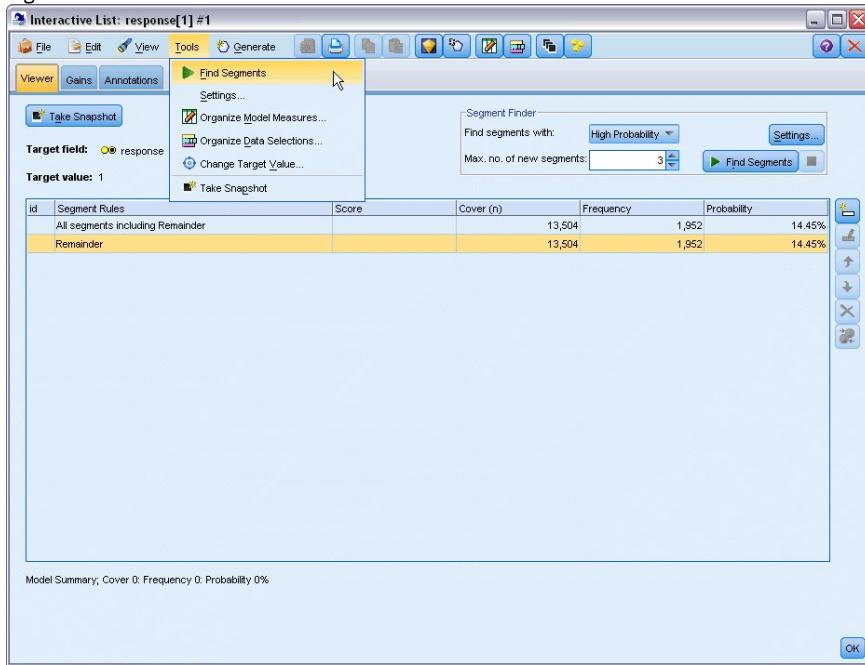

Figure 3. Interactive List viewer

Since no segments have yet been defined, all records fall under the remainder. Out of 13,504 records in the sample, 1,952 said Yes, for an overall hit rate of 14.45%. You want to improve on this rate by identifying segments of customers more (or less) likely to give a favorable response.

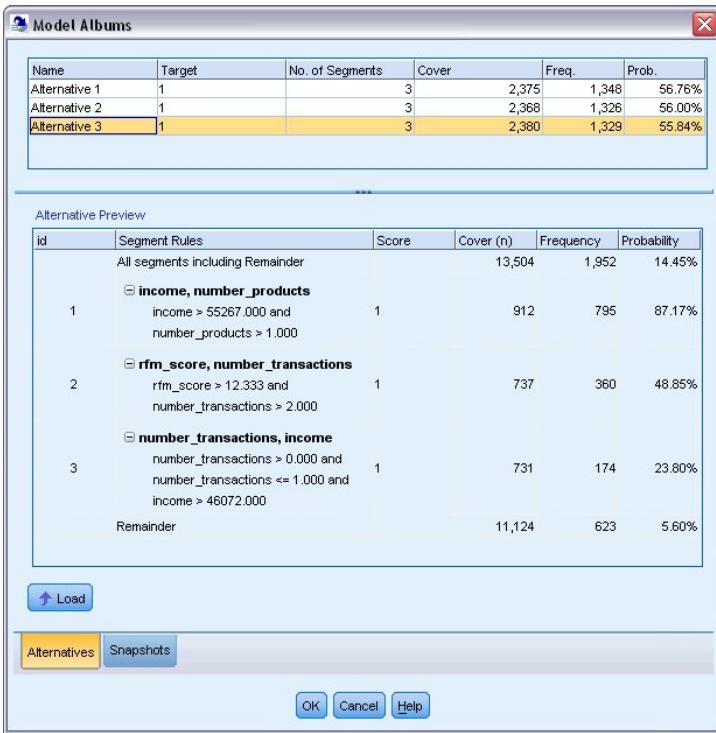

8. In the Interactive List viewer, from the menus choose:
Tools > Find Segments

Figure 4. Interactive List viewer

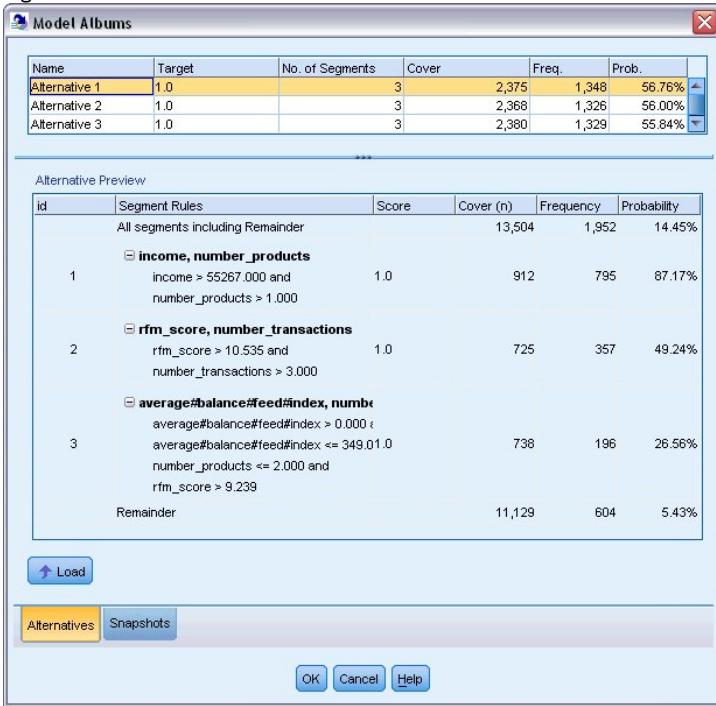

This runs the default mining task based on the settings you specified in the Decision List node. The completed task returns three alternative models, which are listed in the Alternatives tab of the Model Albums dialog box.

Figure 5. Available alternative models

9. Select the first alternative from the list; its details are shown in the Alternative Preview panel.

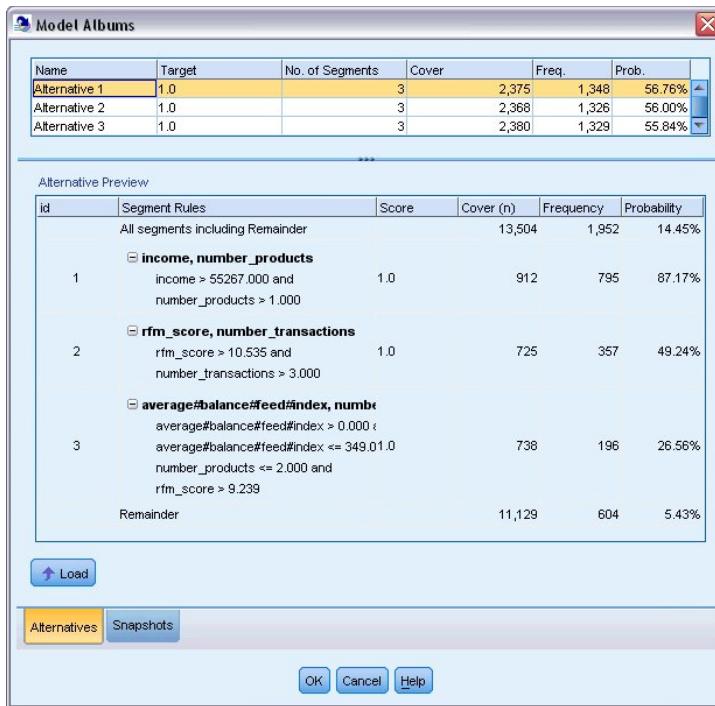

Figure 6. Alternative model selected

The Alternative Preview panel allows you to quickly browse any number of alternatives without changing the working model, making it easy to experiment with different approaches.

Note: To get a better look at the model, you may want to maximize the Alternative Preview panel within the dialog, as shown here. You can do this by dragging the panel border.

Figure 7. Alternative model selected

Using rules based on predictors, such as income, number of transactions per month, and RFM score, the model identifies segments with response rates that are higher than those for the sample overall. When the segments are combined, this model suggests that you could improve your hit rate to 56.76%. However, the model covers only a small portion of the overall sample, leaving over 11,000 records—with several hundred hits among them—to fall under the remainder. You want a model that will capture more of these hits while still excluding the low-performing segments.

10. To try a different modeling approach, from the menus choose:

Tools>Settings

Figure 8. Create/Edit Mining Task dialog box

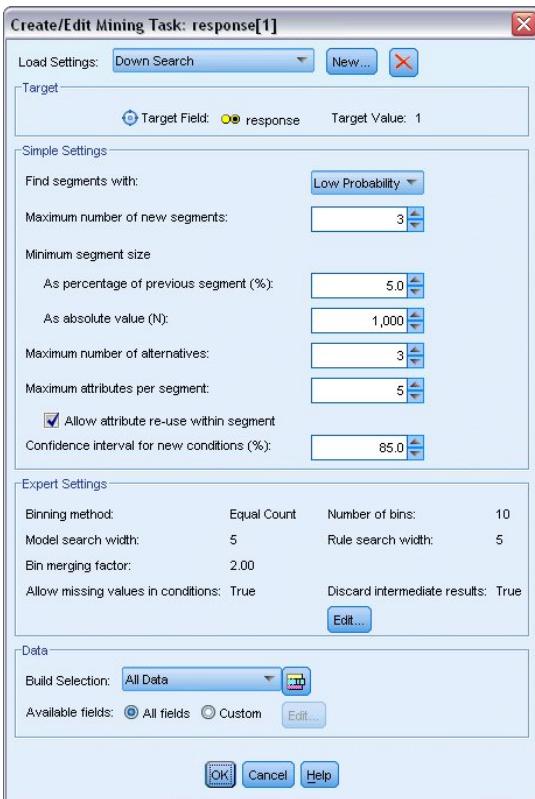

The screenshot shows the 'Create/Edit Mining Task: response[1]' dialog box. It has several sections:

- Load Settings:** dropdown set to 'response[1]', 'New...', and 'X' button.
- Target:** section with 'Target Field:' set to 'response' and 'Target Value:' set to '1'.
- Simple Settings:**
 - 'Find segments with:' dropdown set to 'High Probability'.
 - 'Maximum number of new segments:' dropdown set to '3'.
 - 'Minimum segment size' section with two options: 'As percentage of previous segment (%)' set to '5.0' and 'As absolute value (N)' set to '50'.
 - 'Maximum number of alternatives:' dropdown set to '3'.
 - 'Maximum attributes per segment:' dropdown set to '5'.
 - 'Allow attribute re-use within segment' checkbox.
 - 'Confidence interval for new conditions (%):' dropdown set to '85.0'.
- Expert Settings:**
 - 'Binning method:' dropdown set to 'Equal Count', 'Number of bins:' dropdown set to '10'.
 - 'Model search width:' dropdown set to '5', 'Rule search width:' dropdown set to '5'.
 - 'Bin merging factor:' dropdown set to '2.00'.
 - 'Allow missing values in conditions:' checkbox set to 'True'.
 - 'Discard intermediate results:' checkbox set to 'True'.
 - 'Edit...' button.
- Data:**
 - 'Build Selection:' dropdown set to 'All Data'.
 - 'Available fields:' section with 'All fields' radio button selected.
 - 'Edit...' button.

At the bottom are 'OK', 'Cancel', and 'Help' buttons.

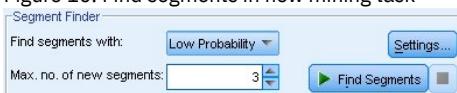

11. Click the New button (upper right corner) to create a second mining task, and specify Down Search as the task name in the New Settings dialog box.

Figure 9. Create/Edit Mining Task dialog box

12. Change the search direction to Low probability for the task. This will cause the algorithm to search for segments with the *lowest* response rates rather than the highest.
13. Increase the minimum segment size to 1,000. Click OK to return to the Interactive List viewer.
14. In Interactive List viewer, make sure that the *Segment Finder* panel is displaying the new task details and click Find Segments.

Figure 10. Find segments in new mining task

The task returns a new set of alternatives, which are displayed in the Alternatives tab of the Model Albums dialog box and can be previewed in the same manner as previous results.

Figure 11. Down Search model results

Alternatives Solutions

This time each model identifies segments with low response probabilities rather than high. Looking at the first alternative, simply excluding these segments will increase the hit rate for the remainder to 39.81%. This is lower than the model you looked at earlier but with higher coverage (meaning more total hits).

By combining the two approaches—using a Low Probability search to weed out uninteresting records, followed by a High Probability search—you may be able to improve this result.

- Click Load to make this (the first Down Search alternative) the working model and click OK to close the Model Albums dialog box.

Figure 12. Excluding a segment

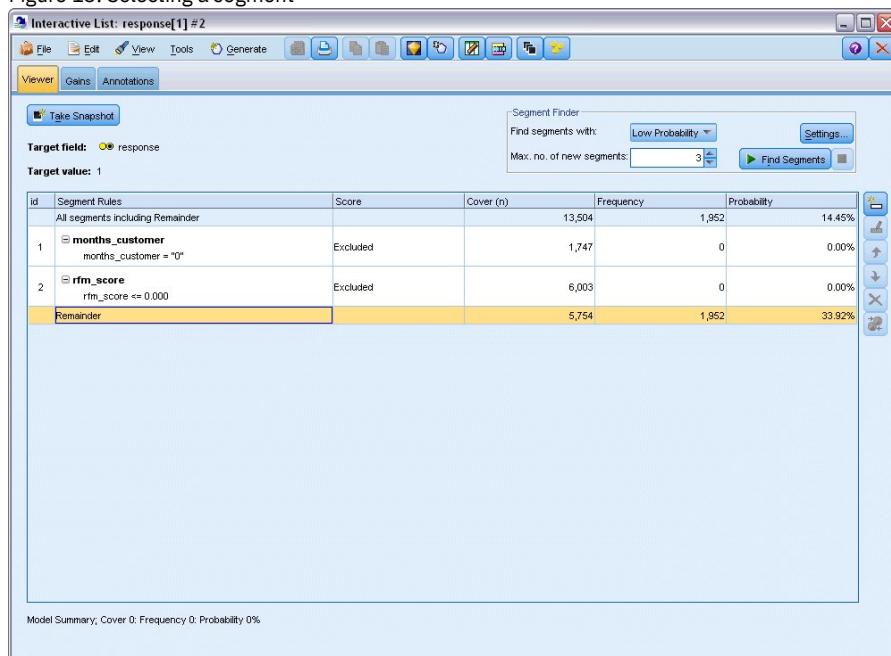

- Right-click on each of the first two segments and select Exclude Segment. Together, these segments capture almost 8,000 records with zero hits between them, so it makes sense to exclude them from future offers. (Excluded segments will be scored as null to indicate this.)
 - Right-click on the third segment and select Delete Segment. At 16.19%, the hit rate for this segment is not that different than the baseline rate of 14.45%, so it doesn't add enough information to justify keeping it in place.
- Note:* Deleting a segment is not the same as excluding it. Excluding a segment simply changes how it is scored, while deleting it removes it from the model entirely.

Having excluded the lowest-performing segments, you can now search for high-performing segments in the remainder.

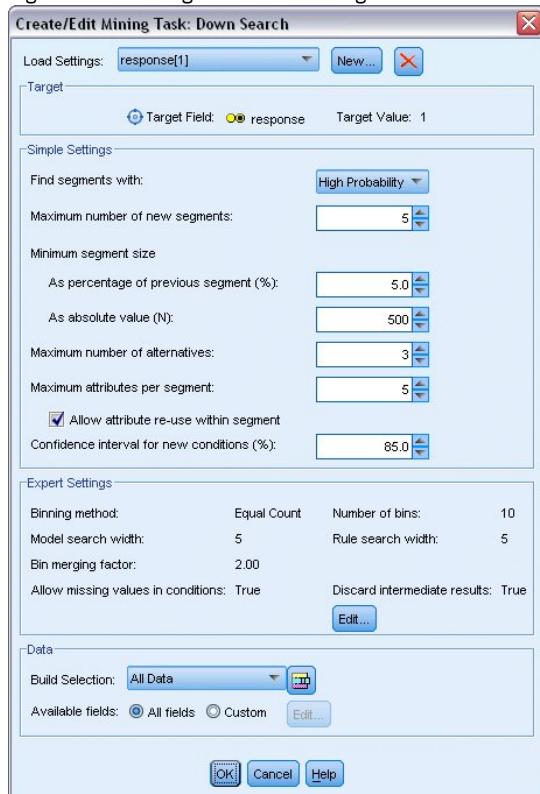

- Click on the remainder row in the table to select it, so that the next mining task will apply to the remainder only.

Figure 13. Selecting a segment

19. With the remainder selected, click Settings to reopen the Create/Edit Mining Task dialog box.
20. At the top, in Load Settings, select the default mining task: response[1].
21. Edit the Simple Settings to increase the number of new segments to 5 and the minimum segment size to 500.
22. Click OK to return to the Interactive List viewer.

Figure 14. Selecting the default mining task

23. Click Find Segments.

This displays yet another set of alternative models. By feeding the results of one mining task into another, these latest models contain a mix of high- and low-performing segments. Segments with low response rates are excluded, which means that they will be scored as null, while included segments will be scored as 1. The overall statistics reflect these exclusions, with the first alternative model showing a hit rate of 45.63%, with higher coverage (1,577 hits out of 3,456 records) than any of the previous models.

Figure 15. Alternatives for combined model

Name	Target	No. of Segments	Cover	Freq.	Prob.
Alternative 1	1	7	3,456	1,577	45.63%
Alternative 2	1	7	3,456	1,577	45.63%
Alternative 3	1	7	3,456	1,577	45.63%

ID	Segment Rules	Score	Cover (n)	Frequency	Probability
1	All segments including Remainder	13,504	1,952	14.45%	
2	months_customer = "0"	Excluded	1,747	0	0.00%
3	rfm_score <= 0.000	Excluded	6,003	0	0.00%
4	rfm_score > 12.333 and income > 52213.000	1	555	456	82.16%
5	income > 55267.000	1	643	551	85.69%
6	number_transactions, rfm_score > 2.000 and rfm_score > 12.333	1	533	206	38.65%

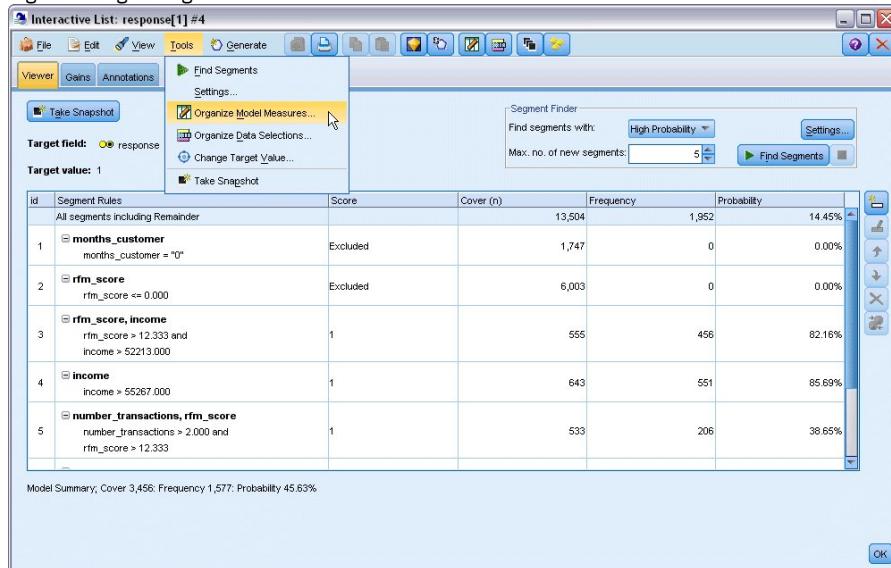

24. Preview the first alternative and then click Load to make it the working model.

[Next](#)

Calculating custom measures using Excel

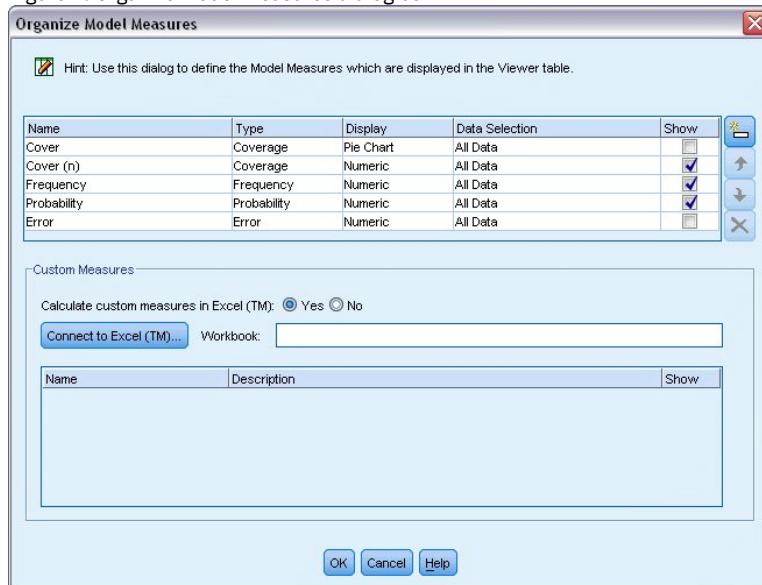

1. To gain a bit more insight as to how the model performs in practical terms, choose Organize Model Measures from the Tools menu.

Figure 1. Organizing model measures

The Organize Model Measures dialog box allows you to choose the measures (or columns) to show in the Interactive List viewer. You can also specify whether measures are computed against all records or a selected subset, and you can choose to display a pie chart rather than a number, where applicable.

Figure 2. Organize Model Measures dialog box

In addition, if you have Microsoft Excel installed, you can link to an Excel template that will calculate custom measures and add them to the interactive display.

2. In the Organize Model Measures dialog box, set Calculate custom measures in Excel (TM) to Yes.
3. Click Connect to Excel (TM)
4. Select the *template_profit.xlt* workbook, located under *streams* in the *Demos* folder of your IBM® SPSS® Modeler installation, and click Open to launch the spreadsheet.

Figure 3. Excel Model Measures worksheet

	#	Use	Metric: Frequency	Imported Metric: Cover	Calculated Metric: Profit Margin	Calculated Metric: Cumulative Profit	Target
	4	1				-2,500.00	
	5	2					

Model Measures / Settings / Configuration / Ready NUM

The Excel template contains three worksheets:

- Model Measures displays model measures imported from the model and calculates custom measures for export back to the model.
- Settings contains parameters to be used in calculating custom measures.
- Configuration defines the measures to be imported from and exported to the model.

The metrics exported back to the model are:

- **Profit Margin.** Net revenue from the segment
- **Cumulative Profit.** Total profit from campaign

As defined by the following formulas:

```
Profit Margin = Frequency * Revenue per respondent - Cover * Variable cost

Cumulative Profit = Total Profit Margin - Fixed cost
```

Note that Frequency and Cover are imported from the model.

The cost and revenue parameters are specified by the user on the Settings worksheet.

Figure 4. Excel Settings worksheet

12	Costs and revenue	
13	- Fixed costs	2,500.00
14	- Variable cost	0.50
15	- Revenue per respondent	100.00

Model Measures / Settings / Configuration / Ready NUM

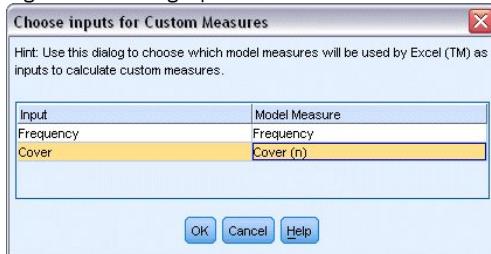

Fixed cost is the setup cost for the campaign, such as design and planning.

Variable cost is the cost of extending the offer to each customer, such as envelopes and stamps.

Revenue per respondent is the net revenue from a customer who responds to the offer.

5. To complete the link back to the model, use the Windows taskbar (or press Alt+Tab) to navigate back to the Interactive List viewer.

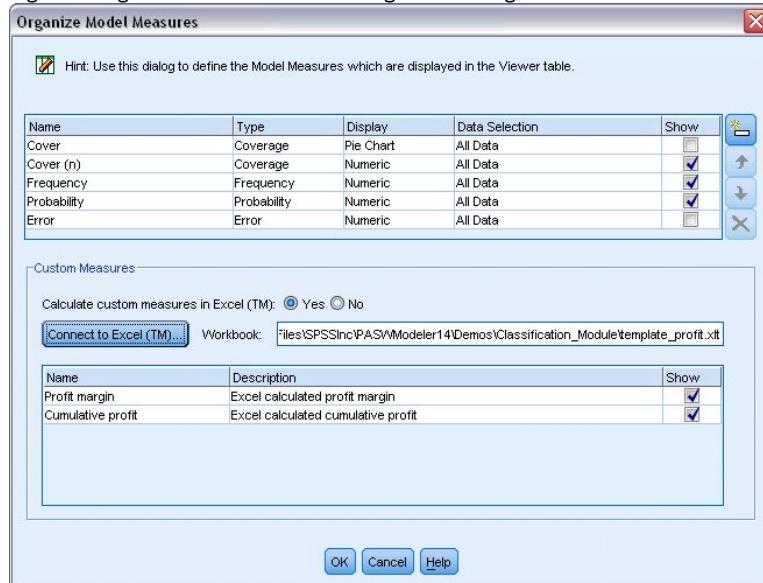

Figure 5. Choosing inputs for custom measures

The Choose Inputs for Custom Measures dialog box is displayed, allowing you to map inputs from the model to specific parameters defined in the template. The left column lists the available measures, and the right column maps these to spreadsheet parameters as defined in the Configuration worksheet.

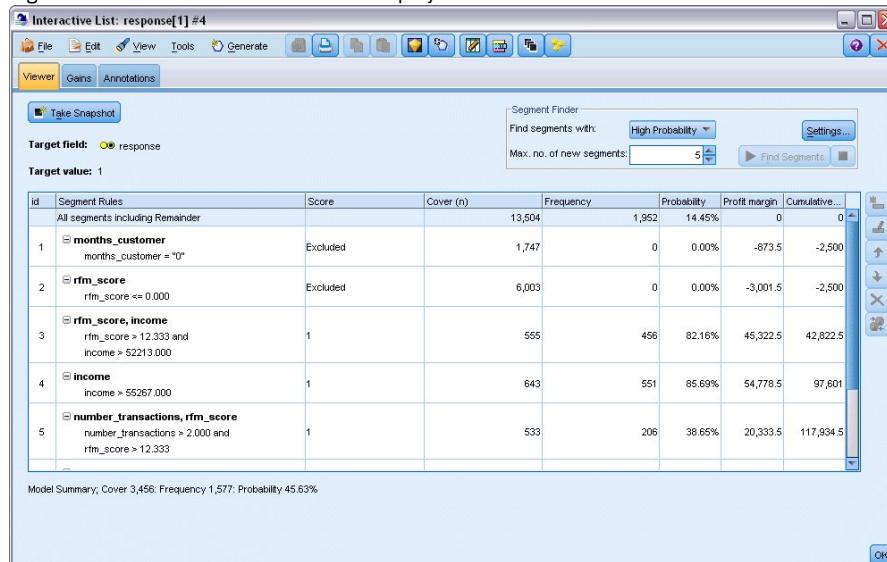

6. In the Model Measures column, select Frequency and Cover (n) against the respective inputs and click OK.
In this case, the parameter names in the template—Frequency and Cover (n)—happen to match the inputs, but different names could also be used.
7. Click OK in the Organize Model Measures dialog box to update the Interactive List viewer.

Figure 6. Organize Model Measures dialog box showing custom measures from Excel

The new measures are now added as new columns in the window and will be recalculated each time the model is updated.

Figure 7. Custom measures from Excel displayed in the Interactive List viewer

By editing the Excel template, any number of custom measures can be created.

[Next](#)

- [Modifying the Excel template](#)

Modifying the Excel template

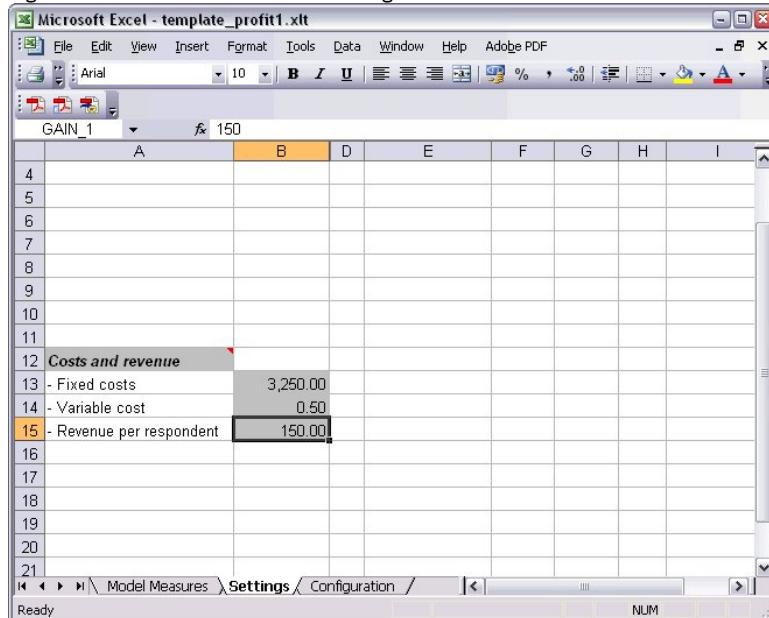

Although IBM® SPSS® Modeler is supplied with a default Excel template to use with the Interactive List viewer, you may want to change the settings or add your own. For example, the costs in the template may be incorrect for your organization and need amending.

Note: If you do modify an existing template, or create your own, remember to save the file with an Excel 2003 .xlt suffix.

To modify the default template with new cost and revenue details and update the Interactive List viewer with the new figures:

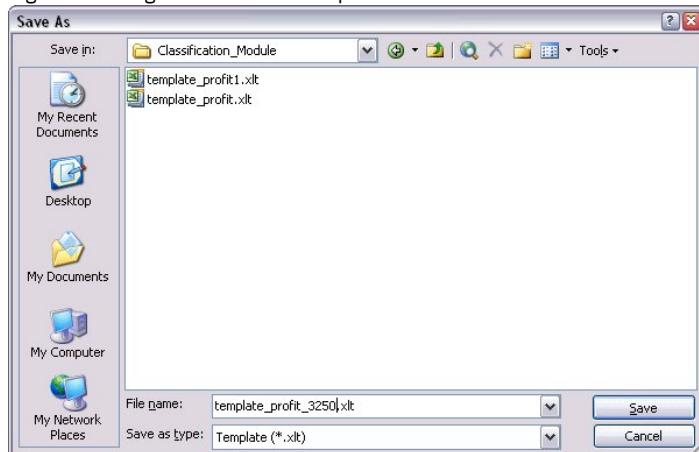

1. In the Interactive List viewer, choose Organize Model Measures from the Tools menu.
2. In the Organize Model Measures dialog box, click Connect to Excel™.
3. Select the *template_profit.xlt* workbook, and click Open to launch the spreadsheet.
4. Select the Settings worksheet.
5. Edit the Fixed costs to be 3,250.00, and the Revenue per respondent to be 150.00.

Figure 1. Modified values on Excel Settings worksheet

6. Save the modified template with a unique, relevant filename. Ensure it has an Excel 2003 .xlt extension.

Figure 2. Saving modified Excel template

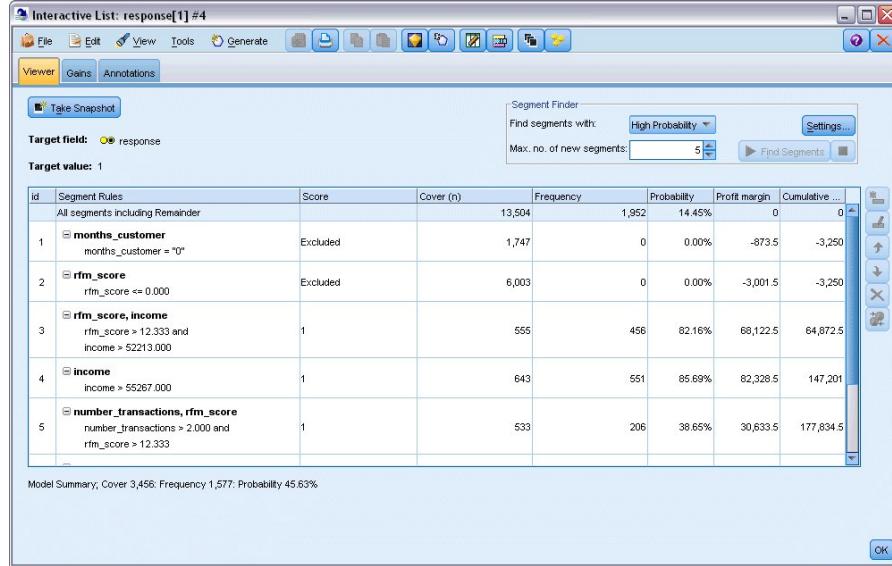

7. Use the Windows taskbar (or press Alt+Tab) to navigate back to the Interactive List viewer.
In the Choose Inputs for Custom Measures dialog box, select the measures you want to display and click OK.

8. In the Organize Model Measures dialog box, click OK to update the Interactive List viewer.

Obviously, this example has only shown one simple way of modifying the Excel template; you can make further changes that pull data from, and pass data to, the Interactive List viewer, or work within Excel to produce other output, such as graphs.

Figure 3. Modified custom measures from Excel displayed in the Interactive List viewer

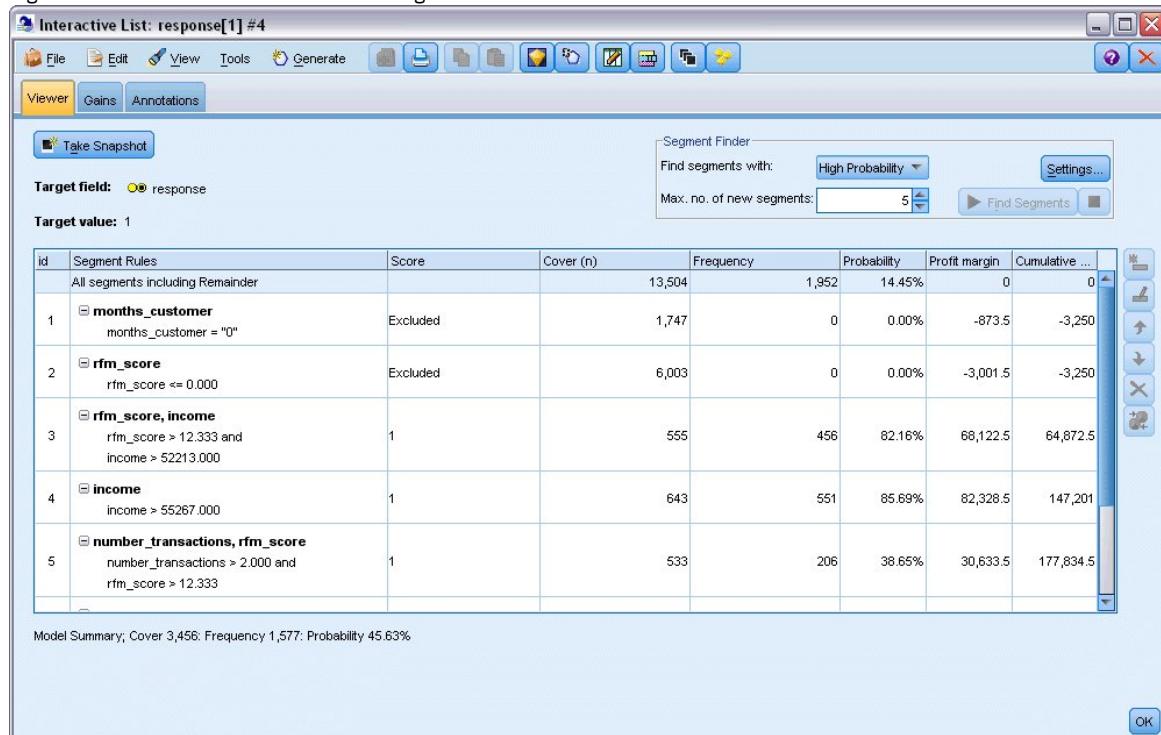

[Next](#)

Saving the Results

To save a model for later use during your interactive session, you can take a snapshot of the model, which will be listed on the Snapshots tab. You can return to any saved snapshot at any time during the interactive session.

Figure 1. Combined model with excluded segments

Continuing in this manner, you can experiment with additional mining tasks to search for additional segments. You can also edit existing segments, insert custom segments based on your own business rules, create data selections to optimize the model for specific groups, and customize the model in a number of other ways. Finally, you can explicitly include or exclude each segment as appropriate to specify how each will be scored.

When you are satisfied with your results, you can use the Generate menu to generate a model that can be added to streams or deployed for purposes of scoring.

Alternatively, to save the current state of your interactive session for another day, choose Update Modeling Node from the File menu. This will update the Decision List modeling node with the current settings, including mining tasks, model snapshots, data selections, and custom measures. The next time you run the stream, just make sure that Use saved session information is selected in the Decision List modeling node to restore the session to its current state.

Classifying Telecommunications Customers (Multinomial Logistic Regression)

Logistic regression is a statistical technique for classifying records based on values of input fields. It is analogous to linear regression but takes a categorical target field instead of a numeric one.

For example, suppose a telecommunications provider has segmented its customer base by service usage patterns, categorizing the customers into four groups. If demographic data can be used to predict group membership, you can customize offers for individual prospective customers.

This example uses the stream named *telco_custcat.str*, which references the data file named *telco.sav*. These files are available from the *Demos* directory of any IBM® SPSS® Modeler installation. This can be accessed from the IBM SPSS Modeler program group on the Windows Start menu. The *telco_custcat.str* file is in the *streams* directory.

The example focuses on using demographic data to predict usage patterns. The target field *custcat* has four possible values that correspond to the four customer groups, as follows:

Value	Label
1	Basic Service
2	E-Service
3	Plus Service
4	Total Service

Because the target has multiple categories, a multinomial model is used. In the case of a target with two distinct categories, such as yes/no, true/false, or churn/don't churn, a binomial model could be created instead. See the topic [Telecommunications Churn \(Binomial Logistic Regression\)](#) for more information.

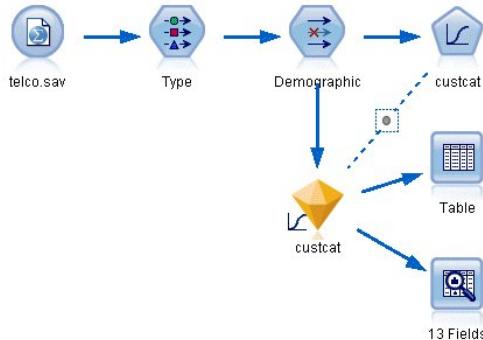

[Next](#)

- [Building the Stream](#)
- [Browsing the Model](#)

Building the Stream

1. Add a Statistics File source node pointing to *telco.sav* in the *Demos* folder.

Figure 1. Sample stream to classify customers using multinomial logistic regression

- a. Add a Type node and click Read Values, making sure that all measurement levels are set correctly. For example, most fields with values 0 and 1 can be regarded as flags.

Figure 2. Setting the measurement level for multiple fields

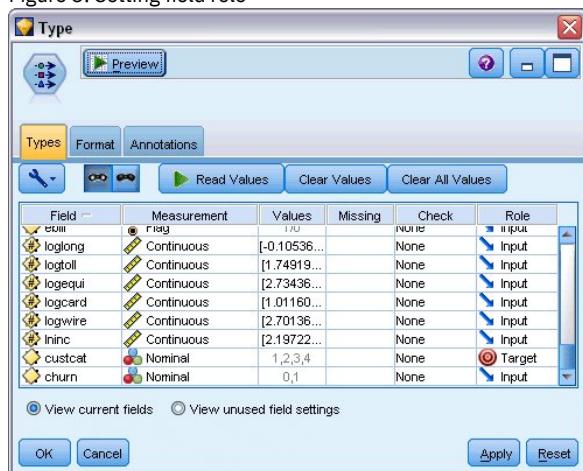

Tip: To change properties for multiple fields with similar values (such as 0/1), click the *Values* column header to sort fields by value, and then hold down the shift key while using the mouse or arrow keys to select all the fields you want to change. You can then right-click on the selection to change the measurement level or other attributes of the selected fields.

Notice that *gender* is more correctly considered as a field with a set of two values, instead of a flag, so leave its Measurement value as Nominal.

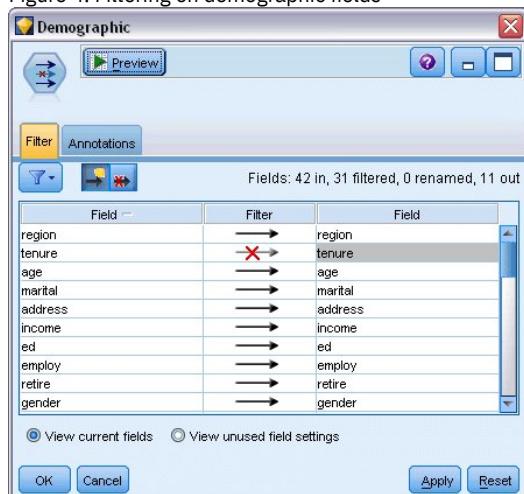

- Set the role for the *custcat* field to Target. All other fields should have their role set to Input.

Figure 3. Setting field role

Since this example focuses on demographics, use a Filter node to include only the relevant fields (*region*, *age*, *marital*, *address*, *income*, *ed*, *employ*, *retire*, *gender*, *reside*, and *custcat*). Other fields can be excluded for the purpose of this analysis.

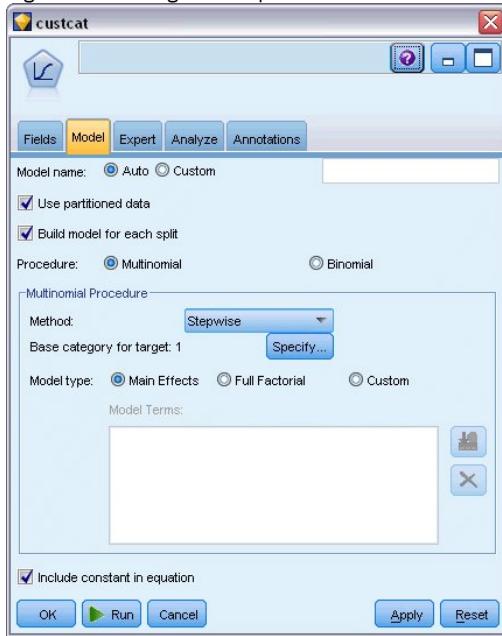

Figure 4. Filtering on demographic fields

(Alternatively, you could change the role to None for these fields rather than exclude them, or select the fields you want to use in the modeling node.)

2. In the Logistic node, click the Model tab and select the Stepwise method. Select Multinomial, Main Effects, and Include constant in equation as well.

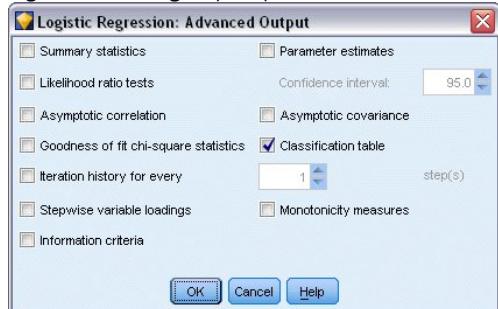

Figure 5. Choosing model options

Leave the Base category for target as 1. The model will compare other customers to those who subscribe to the Basic Service.

3. On the Expert tab, select the Expert mode, select Output, and, in the Advanced Output dialog box, select Classification table.

Figure 6. Choosing output options

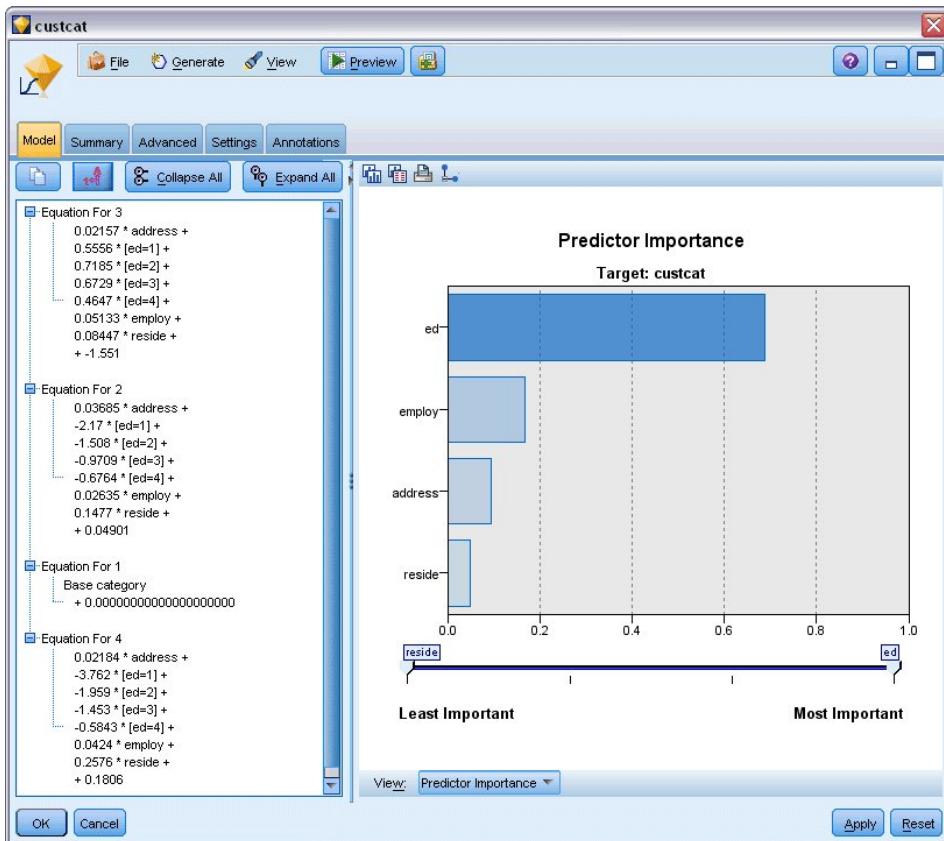

Browsing the Model

1. Execute the node to generate the model, which is added to the Models palette in the upper-right corner. To view its details, right-click on the generated model node and choose Browse.

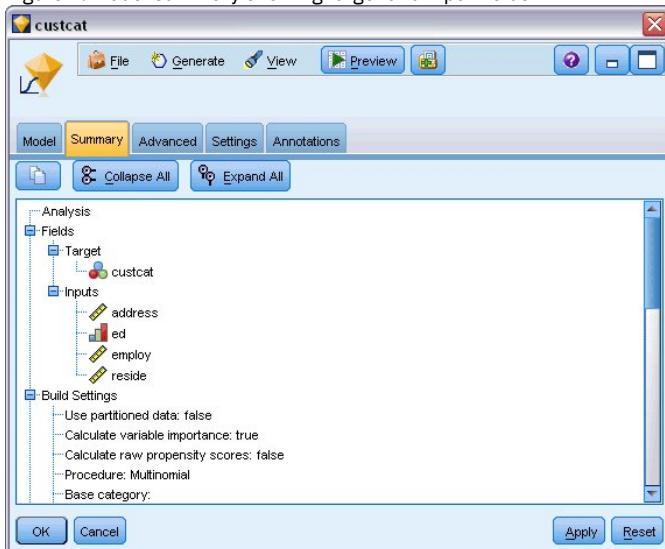

The model tab displays the equations used to assign records to each category of the target field. There are four possible categories, one of which is the base category for which no equation details are shown. Details are shown for the remaining three equations, where category 3 represents Plus Service, and so on.

Figure 1. Browsing the model results

The Summary tab shows (among other things) the target and inputs (predictor fields) used by the model. Note that these are the fields that were actually chosen based on the Stepwise method, not the complete list submitted for consideration.

Figure 2. Model summary showing target and input fields

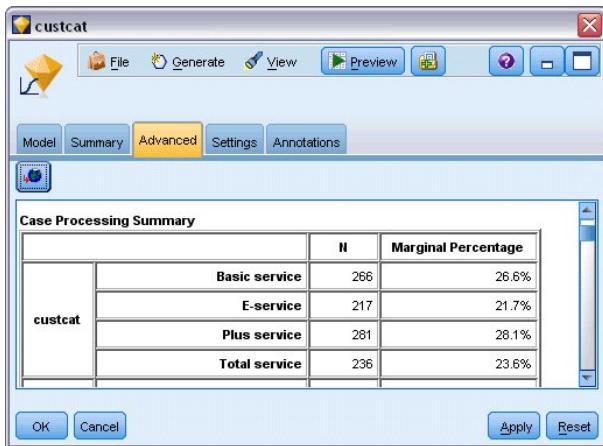

The items shown on the Advanced tab depend on the options selected on the Advanced Output dialog box in the modeling node.

One item that is always shown is the Case Processing Summary, which shows the percentage of records that falls into each category of the target field. This gives you a null model to use as a basis for comparison.

Without building a model that used predictors, your best guess would be to assign all customers to the most common group, which is the one for Plus service.

Figure 3. Case processing summary

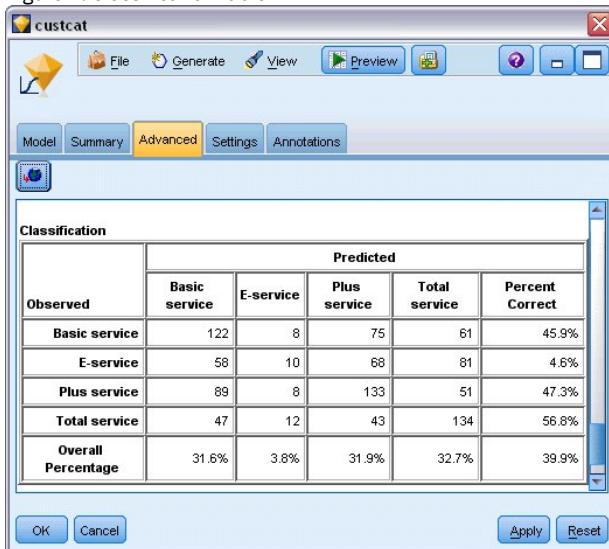

Based on the training data, if you assigned all customers to the null model, you would be correct $281/1000 = 28.1\%$ of the time. The Advanced tab contains further information that enables you to examine the model's predictions. You can then compare the predictions with the null model's results to see how well the model works with your data.

At the bottom of the Advanced tab, the Classification table shows the results for your model, which is correct 39.9% of the time.

In particular, your model excels at identifying Total Service customers (category 4) but does a very poor job of identifying E-service customers (category 2). If you want better accuracy for customers in category 2, you may need to find another predictor to identify them.

Figure 4. Classification table

Depending on what you want to predict, the model may be perfectly adequate for your needs. For example, if you are not concerned with identifying customers in category 2, the model may be accurate enough for you. This may be the case where the E-service is a loss-leader that brings in little profit.

If, for example, your highest return on investment comes from customers who fall into category 3 or 4, the model may give you the information you need.

To assess how well the model actually fits the data, a number of diagnostics are available in the Advanced Output dialog box when you are building the model. Explanations of the mathematical foundations of the modeling methods used in IBM® SPSS® Modeler are listed in the *IBM SPSS Modeler Algorithms Guide*, available from the |Documentation directory of the installation disk.

Note also that these results are based on the training data only. To assess how well the model generalizes to other data in the real world, you can use a Partition node to hold out a subset of records for purposes of testing and validation.

Telecommunications Churn (Binomial Logistic Regression)

Logistic regression is a statistical technique for classifying records based on values of input fields. It is analogous to linear regression but takes a categorical target field instead of a numeric one.

This example uses the stream named `telco_churn.str`, which references the data file named `telco.sav`. These files are available from the *Demos* directory of any IBM® SPSS® Modeler installation. This can be accessed from the IBM SPSS Modeler program group on the Windows Start menu. The `telco_churn.str` file is in the *streams* directory.

For example, suppose a telecommunications provider is concerned about the number of customers it is losing to competitors. If service usage data can be used to predict which customers are liable to transfer to another provider, offers can be customized to retain as many customers as possible.

This example focuses on using usage data to predict customer loss (churn). Because the target has two distinct categories, a binomial model is used. In the case of a target with multiple categories, a multinomial model could be created instead. See the topic [Classifying Telecommunications Customers \(Multinomial Logistic Regression\)](#) for more information.

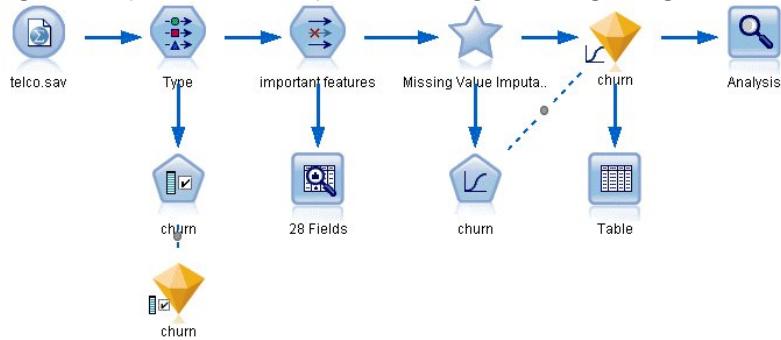

[Next](#)

- [Building the Stream](#)
- [Browsing the Model](#)

Building the Stream

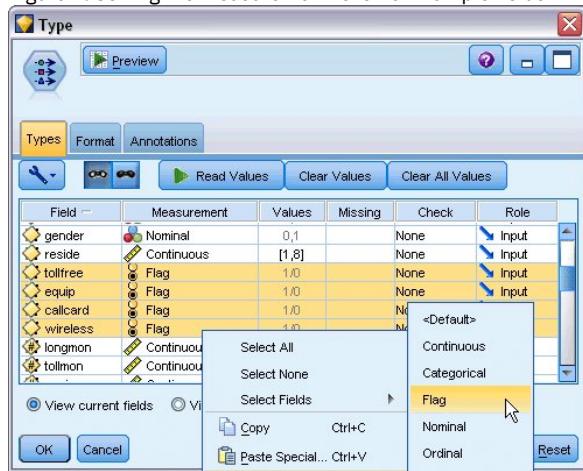

1. Add a Statistics File source node pointing to `telco.sav` in the *Demos* folder.

Figure 1. Sample stream to classify customers using binomial logistic regression

2. Add a Type node to define fields, making sure that all measurement levels are set correctly. For example, most fields with values 0 and 1 can be regarded as flags, but certain fields, such as gender, are more accurately viewed as a nominal field with two values.

Figure 2. Setting the measurement level for multiple fields

Tip: To change properties for multiple fields with similar values (such as 0/1), click the *Values* column header to sort fields by value, and then hold down the Shift key while using the mouse or arrow keys to select all of the fields that you want to change. You can then right-click on the selection to change the measurement level or other attributes of the selected fields.

3. Set the measurement level for the `churn` field to Flag, and set the role to Target. All other fields should have their role set to Input.

Figure 3. Setting the measurement level and role for the `churn` field

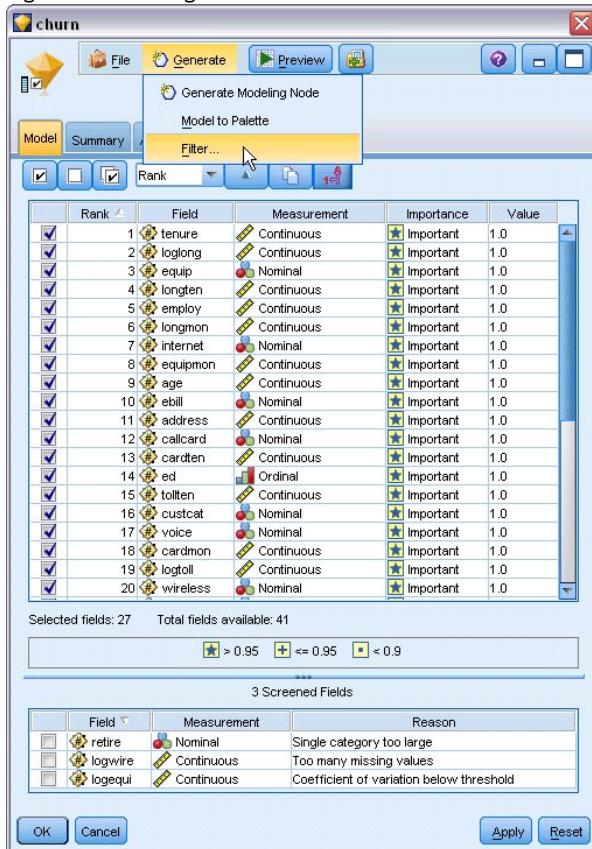

4. Add a Feature Selection modeling node to the Type node.

Using a Feature Selection node enables you to remove predictors or data that do not add any useful information with respect to the predictor/target relationship.

5. Run the stream.

6. Open the resulting model nugget, and from the Generate menu, choose Filter to create a Filter node.

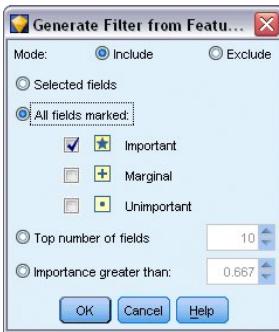

Figure 4. Generating a Filter node from a Feature Selection node

Not all of the data in the *telco.sav* file will be useful in predicting churn. You can use the filter to only select data considered to be important for use as a predictor.

7. In the Generate Filter dialog box, select All fields marked: Important and click OK.
8. Attach the generated Filter node to the Type node.

Figure 5. Selecting important fields

9. Attach a Data Audit node to the generated Filter node.

Open the Data Audit node and click Run.

10. On the Quality tab of the Data Audit browser, click the % Complete column to sort the column by ascending numerical order. This lets you identify any fields with large amounts of missing data; in this case the only field you need to amend is *logtoll*, which is less than 50% complete.

11. In the *Impute Missing* column for *logtoll*, click Specify.

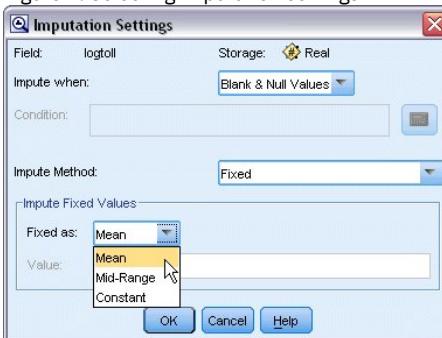

Figure 6. Imputing missing values for logtoll

Field	Measurement	Outliers	Extremes	Action	Impute Missing	Method	% Complete	Valid
logtoll	Continuous	2	0 None	Never	Fixed	47.5	96.43%	100
tenure	Continuous	0	0 None	Never	Fixed	100		
age	Continuous	0	0 None	Blank Values	Fixed	100		
address	Continuous	12	0 None	Null Values	Fixed	100		
income	Continuous	9	6 None	Blank & Null Value	Fixed	100		
ed	Ordinal	--	--	Condition...	Fixed	100		
employ	Continuous	8	0 None	Condition...	Fixed	100		
equip	Flag	--	--	Specify...	Never	100		
callcard	Flag	--	--	Never	Fixed	100		
wireless	Flag	--	--	Never	Fixed	100		
longmon	Continuous	18	4 None	Never	Fixed	100		
tollmon	Continuous	9	1 None	Never	Fixed	100		
equipment	Continuous	2	0 None	Never	Fixed	100		
cardmon	Continuous	11	3 None	Never	Fixed	100		
wiremon	Continuous	8	1 None	Never	Fixed	100		
longten	Continuous	20	4 None	Never	Fixed	100		
tolten	Continuous	18	2 None	Never	Fixed	100		
cardten	Continuous	11	6 None	Never	Fixed	100		
voice	Flag	--	--	Never	Fixed	100		

12. For Impute when, select Blank and Null values. For Fixed As, select Mean and click OK.

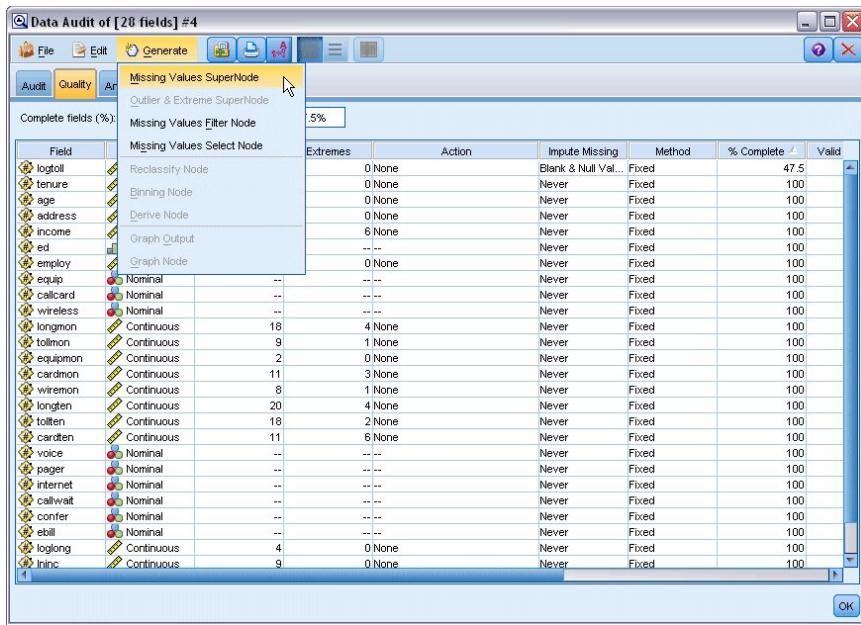

Selecting Mean ensures that the imputed values do not adversely affect the mean of all values in the overall data.

Figure 7. Selecting imputation settings

13. On the Data Audit browser Quality tab, generate the Missing Values SuperNode. To do this, from the menus choose: Generate > Missing Values SuperNode

Figure 8. Generating a missing values SuperNode

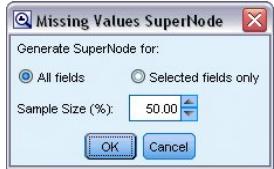

In the Missing Values SuperNode dialog box, increase the Sample Size to 50% and click OK.

The SuperNode is displayed on the stream canvas, with the title: *Missing Value Imputation*.

14. Attach the SuperNode to the Filter node.

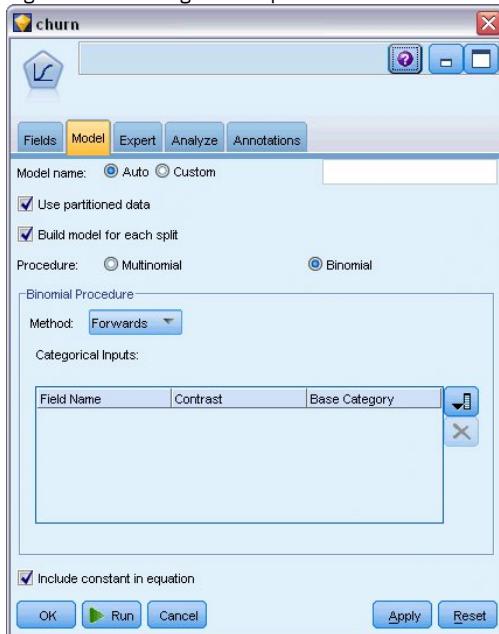

Figure 9. Specifying sample size

15. Add a Logistic node to the SuperNode.

16. In the Logistic node, click the Model tab and select the Binomial procedure. In the *Binomial Procedure* area, select the Forwards method.

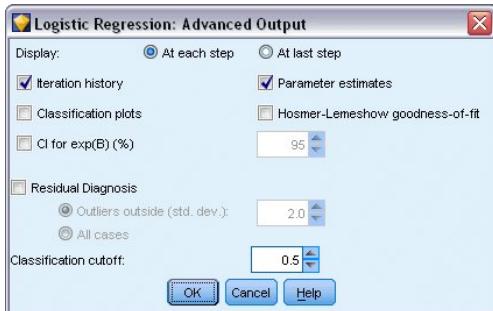

Figure 10. Choosing model options

17. On the Expert tab, select the Expert mode and then click Output. The Advanced Output dialog box is displayed.

18. In the Advanced Output dialog, select At each step as the *Display* type. Select Iteration history and Parameter estimates and click OK.

Figure 11. Choosing output options

[Next](#)

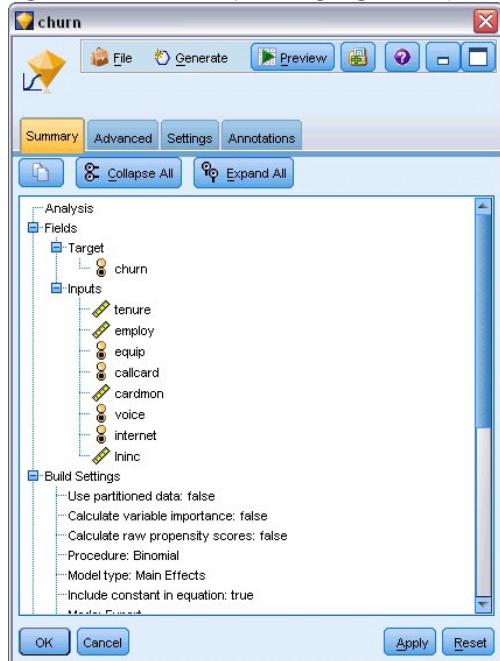

Browsing the Model

1. On the Logistic node, click Run to create the model.

The model nugget is added to the stream canvas, and also to the Models palette in the upper-right corner. To view its details, right-click on the model nugget and select Edit or Browse.

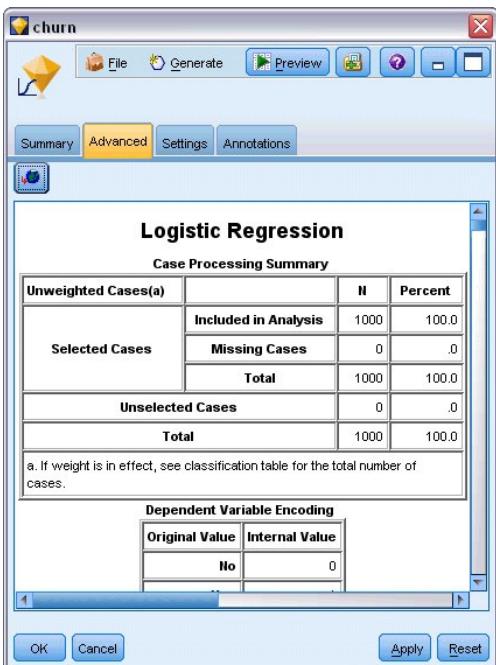

The Summary tab shows (among other things) the target and inputs (predictor fields) used by the model. Note that these are the fields that were actually chosen based on the Forwards method, not the complete list submitted for consideration.

Figure 1. Model summary showing target and input fields

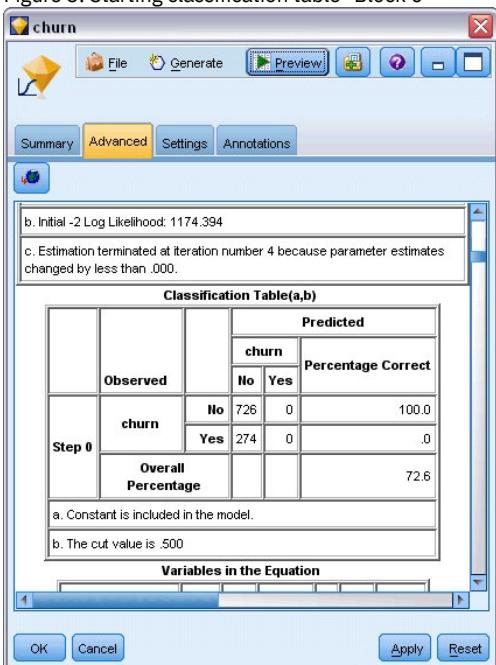

The items shown on the Advanced tab depend on the options selected on the Advanced Output dialog box in the Logistic node. One item that is always shown is the Case Processing Summary, which shows the number and percentage of records included in the analysis. In addition, it lists the number of missing cases (if any) where one or more of the input fields are unavailable and any cases that were not selected.

Figure 2. Case processing summary

2. Scroll down from the Case Processing Summary to display the Classification Table under Block 0: Beginning Block. The Forward Stepwise method starts with a null model - that is, a model with no predictors - that can be used as a basis for comparison with the final built model. The null model, by convention, predicts everything as a 0, so the null model is 72.6% accurate simply because the 726 customers who didn't churn are predicted correctly. However, the customers who did churn aren't predicted correctly at all.

Figure 3. Starting classification table- Block 0

3. Now scroll down to display the Classification Table under Block 1: Method = Forward Stepwise. This Classification Table shows the results for your model as a predictor is added in at each of the steps. Already, in the first step - after just one predictor has been used - the model has increased the accuracy of the churn prediction from 0.0% to 29.9%

Figure 4. Classification table - Block 1

Classification Table(a)

Observed		Predicted		Percentage Correct	
		churn			
		No	Yes		
Step 1	churn	668	58	92.0	
	Yes	192	82	29.9	
	Overall Percentage			75.0	
Step 2	churn	657	69	90.5	
	Yes	160	114	41.6	
	Overall Percentage			77.1	
Step 3	churn	661	65	91.0	
	Yes	153	121	44.2	
	Overall Percentage			79.1	

OK Cancel Apply Reset

4. Scroll down to the bottom of this Classification Table.

The Classification Table shows that the last step is step 8. At this stage the algorithm has decided that it no longer needs to add any further predictors into the model. Although the accuracy of the non-churning customers has decreased a little to 91.2%, the accuracy of the prediction for those who did churn has risen from the original 0% to 47.1%. This is a significant improvement over the original null model that used no predictors.

Figure 5. Classification table - Block 1

Step 7

Overall Percentage				
churn	No	657	69	90.5
Yes	144	130		47.4
Overall Percentage				78.7

Step 8

Overall Percentage				
churn	No	662	64	91.2
Yes	145	129		47.1
Overall Percentage				79.1

a. The cut value is .500

Variables in the Equation

	B	S.E.	Wald	df	Sig.	Exp(B)	
Step 1(a)	tenure	-.046	.004	123.346	1	.000	.955
Step 1(a)	Constant	462	136	11.574	1	.001	1.587

OK Cancel Apply Reset

For a customer who wants to reduce churn, being able to reduce it by nearly half would be a major step in protecting their income streams.

Note: This example also shows how taking the Overall Percentage as a guide to a model's accuracy may, in some cases, be misleading. The original null model was 72.6% accurate overall, whereas the final predicted model has an overall accuracy of 79.1%; however, as we have seen, the accuracy of the actual individual category predictions were vastly different.

To assess how well the model actually fits the data, a number of diagnostics are available in the Advanced Output dialog box when you are building the model. Explanations of the mathematical foundations of the modeling methods used in IBM® SPSS® Modeler are listed in the *IBM SPSS Modeler Algorithms Guide*, available from the |Documentation directory of the installation disk.

Note also that these results are based on the training data only. To assess how well the model generalizes to other data in the real world, you would use a Partition node to hold out a subset of records for purposes of testing and validation.

Forecasting Bandwidth Utilization (Time Series)

- [Forecasting with the Time Series Node](#)
- [Reapplying a Time Series Model](#)

Forecasting with the Time Series Node

An analyst for a national broadband provider is required to produce forecasts of user subscriptions in order to predict utilization of bandwidth. Forecasts are needed for each of the local markets that make up the national subscriber base. You will use time series modeling to produce forecasts for the next three months for a number of local markets. A second example shows how you can convert source data if it is not in the correct format for input to the Time Series node.

These examples use the stream named *broadband_create_models.str*, which references the data file named *broadband_1.sav*. These files are available from the *Demos* folder of any IBM® SPSS® Modeler installation. This can be accessed from the IBM SPSS Modeler program group on the Windows Start menu. The *broadband_create_models.str* file is in the *streams* folder.

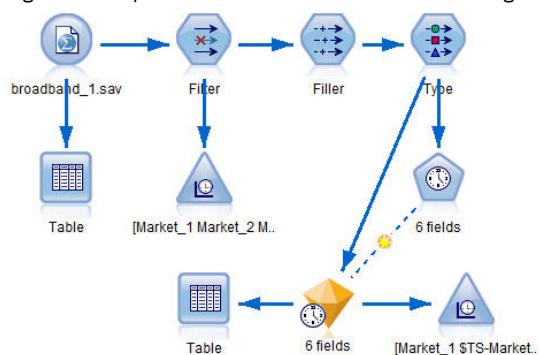

The last example demonstrates how to apply the saved models to an updated dataset in order to extend the forecasts by another three months.

In IBM SPSS Modeler, you can produce multiple time series models in a single operation. The source file you'll be using has time series data for 85 different markets, although for the sake of simplicity you will only model five of these markets, plus the total for all markets.

The *broadband_1.sav* data file has monthly usage data for each of 85 local markets. For the purposes of this example, only the first five series will be used; a separate model will be created for each of these five series, plus a total.

The file also includes a date field that indicates the month and year for each record. This field will be used to label records. The date field reads into IBM SPSS Modeler as a string, but in order to use the field in IBM SPSS Modeler you will convert the storage type to numeric Date format using a Filler node.

Figure 1. Sample stream to show Time Series modeling

The Time Series node requires that each series be in a separate column, with a row for each interval. IBM SPSS Modeler provides methods for transforming data to match this format if necessary.

Figure 2. Monthly subscription data for broadband local markets

A screenshot of the SPSS Modeler interface showing a table window titled "Table (89 fields, 60 records)". The table contains 60 rows of data with 89 fields each. The first row is highlighted in yellow. The columns are labeled Market_1, Market_2, Market_3, Market_4, Market_5, Market_6, Market_7, Market_8, and Mar.

[Next](#)

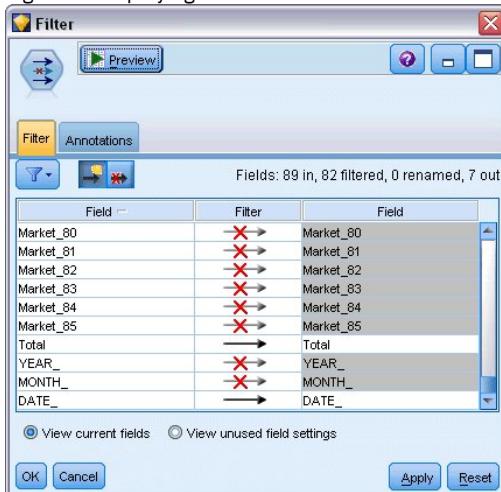

- [Creating the Stream](#)
- [Examining the Data](#)
- [Defining the Dates](#)
- [Defining the Targets](#)
- [Setting the Time Intervals](#)
- [Creating the Model](#)
- [Examining the model](#)
- [Summary](#)

Creating the Stream

1. Create a new stream and add a Statistics File source node pointing to *broadband_1.sav*.
2. Use a Filter node to filter out the *Market_6* to *Market_85* fields and the *MONTH_* and *YEAR_* fields to simplify the model.

Tip: To select multiple adjacent fields in a single operation, click the *Market_6* field, hold down the left mouse button and drag the mouse down to the *Market_85* field. Selected fields are highlighted in blue. To add the other fields, hold down the Ctrl key and click the *MONTH_* and *YEAR_* fields.

Figure 1. Simplifying the model

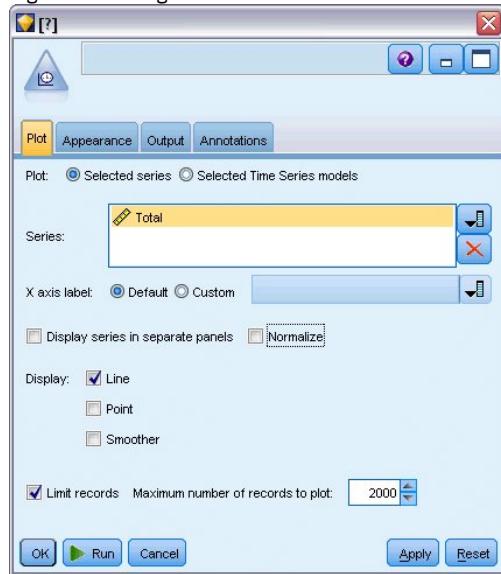

[Next](#)

Examining the Data

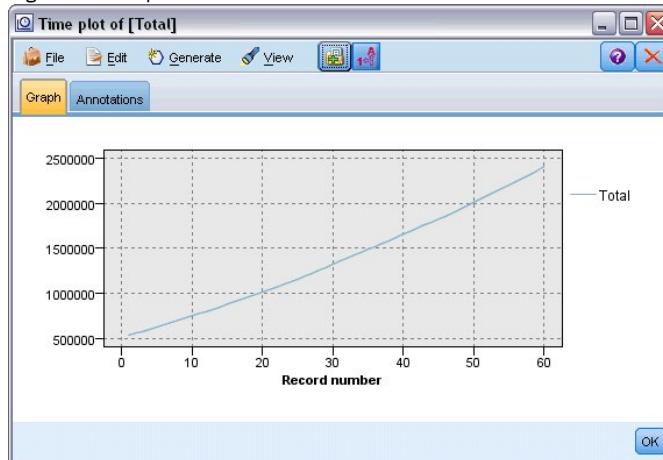

It is always a good idea to have a feel for the nature of your data before building a model. Do the data exhibit seasonal variations? Although the Expert Modeler can automatically find the best seasonal or nonseasonal model for each series, you can often obtain faster results by limiting the search to nonseasonal models when seasonality is not present in your data. Without examining the data for each of the local markets, we can get a rough picture of the presence or absence of seasonality by plotting the total number of subscribers over all five markets.

Figure 1. Plotting the total number of subscribers

1. From the Graphs palette, attach a Time Plot node to the Filter node.
2. Add the *Total* field to the Series list.
3. Deselect the Display series in separate panels and Normalize check boxes.
4. Click Run.

Figure 2. Time plot of Total field

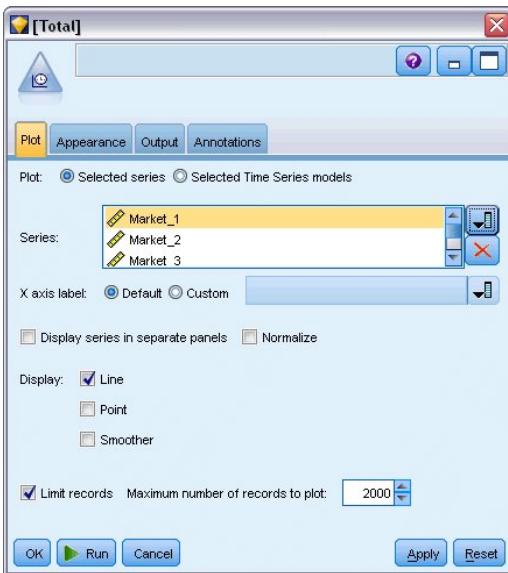

The series exhibits a very smooth upward trend with no hint of seasonal variations. There might be individual series with seasonality, but it appears that seasonality is not a prominent feature of the data in general.

Of course you should inspect each of the series before ruling out seasonal models. You can then separate out series exhibiting seasonality and model them separately.

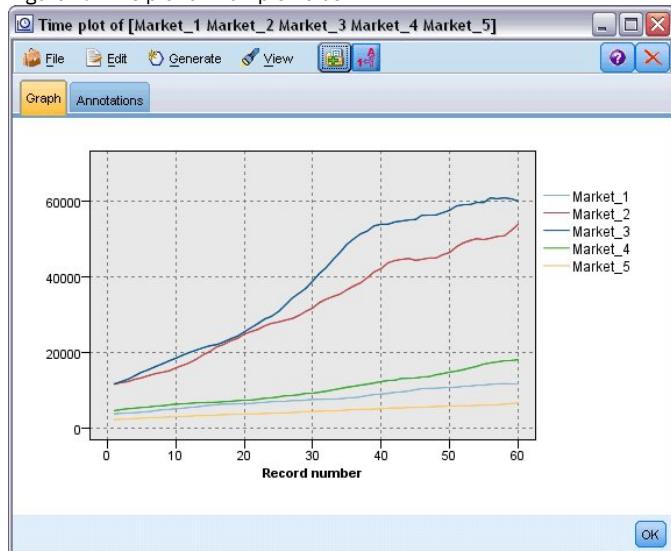

IBM® SPSS® Modeler makes it easy to plot multiple time series together.

Figure 3. Plotting multiple time series

5. Reopen the Time Plot node.
6. Remove the *Total* field from the Series list (select it and click the red X button).
7. Add the *Market_1* through *Market_5* fields to the list.
8. Click Run.

Figure 4. Time plot of multiple fields

Inspection of each of the markets reveals a steady upward trend in each case. Although some markets are a little more erratic than others, there is no evidence of seasonality to be seen.

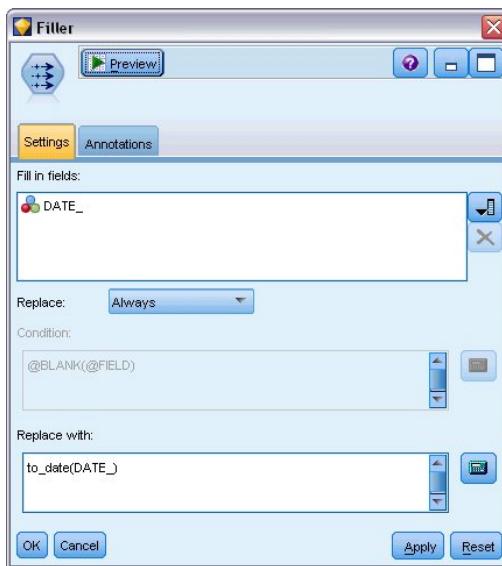

[Next](#)

Defining the Dates

Now you need to change the storage type of the *DATE_* field to Date format.

1. Attach a Filler node to the Filter node.
2. Open the Filler node and click the field selector button.
3. Select *DATE_* to add it to Fill in fields.
4. Set the Replace condition to Always.
5. Set the value of Replace with to `to_date(DATE_)`.

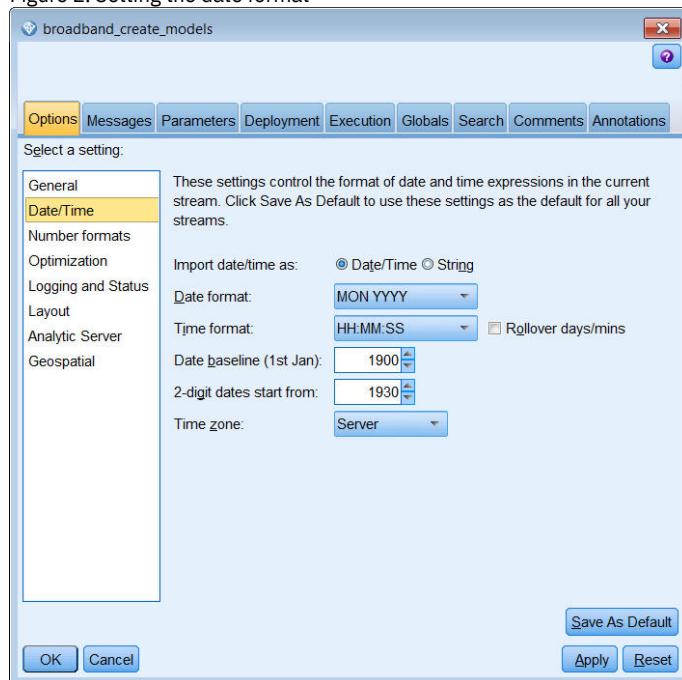

Figure 1. Setting the date storage type

Change the default date format to match the format of the Date field. This is necessary for the conversion of the Date field to work as expected.

6. On the menu, choose Tools > Stream Properties > Options to display the Stream Options dialog box.
7. Select the Date/Time pane and set the default Date format to MON YYYY .

Figure 2. Setting the date format

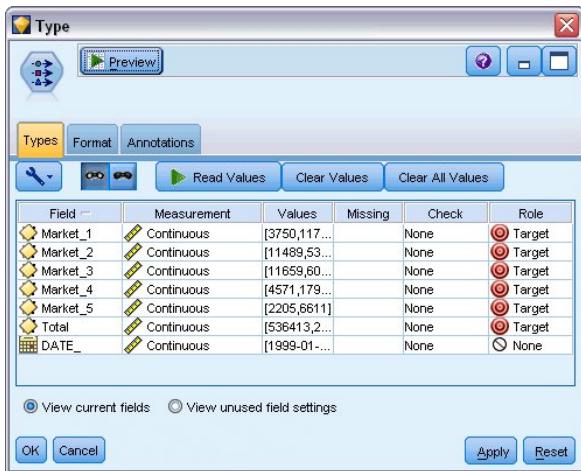

[Next](#)

Defining the Targets

1. Add a Type node and set the role to None for the *DATE_* field. Set the role to Target for all others (the *Market_n* fields plus the *Total* field).
2. Click the Read Values button to populate the Values column.

Figure 1. Setting the role for multiple fields

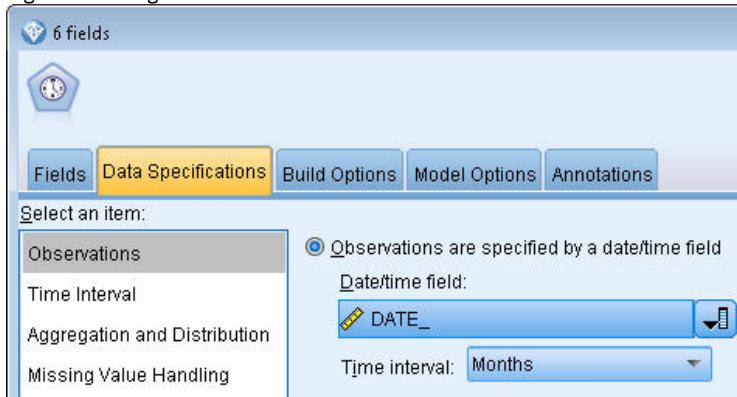

[Next](#)

Setting the Time Intervals

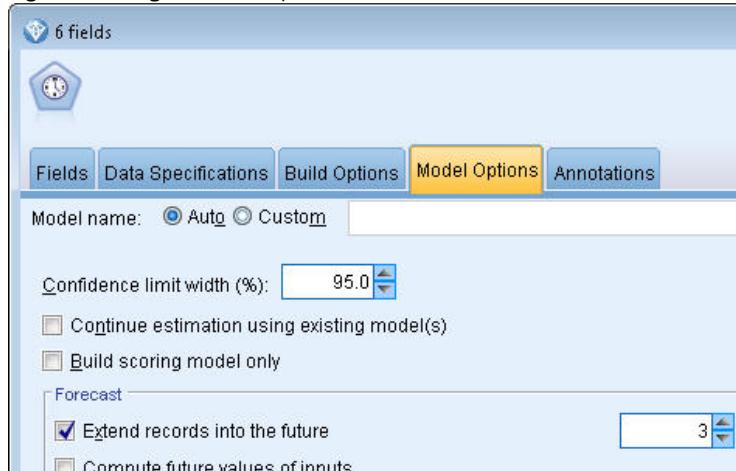

1. From the Modeling palette, add a Time Series node to the stream and attach it to the Type node.
2. On the Data Specifications tab, in the Observations pane, select **DATE_** as the Date/time field.
3. Select **Months** as the Time interval.

Figure 1. Setting the time interval

4. On the Model Options tab, select the Extend records into the future check box.
5. Set the value to 3.

Figure 2. Setting the forecast period

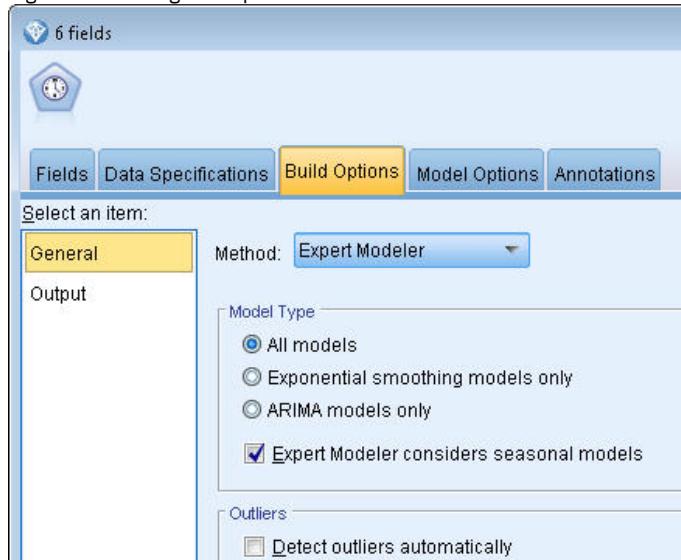

[Next](#)

Creating the Model

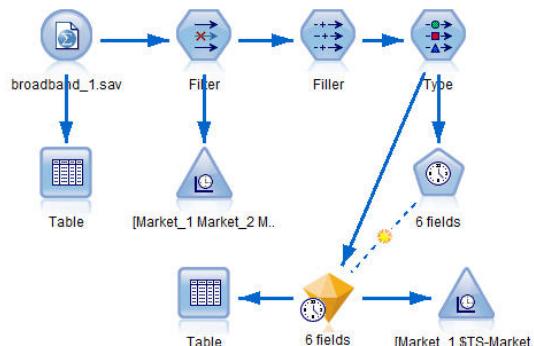

1. On the Time Series node, choose the Fields tab. In the Fields list, select all 5 of the markets and copy them to both the Targets and Candidate inputs lists. In addition, select and copy the Total field to the Targets list.
2. Choose the Build Options tab and, on the General pane, ensure the Expert Modeler Method is selected using all default settings. Doing so enables the Expert Modeler to decide the most appropriate model to use for each time series. Click Run.

Figure 1. Choosing the Expert Modeler for Time Series

3. Attach the Time Series model nugget to the Time Series node.
4. Attach a Table node to the Time Series model nugget and click Run.

Figure 2. Sample stream to show Time Series modeling

There are now three new rows (61 through 63) appended to the original data. These are the rows for the forecast period, in this case January to March 2004.

Several new columns are also present now; the `$TS-` columns are added by the Time Series node. The columns indicate the following for each row (that is, for each interval in the time series data):

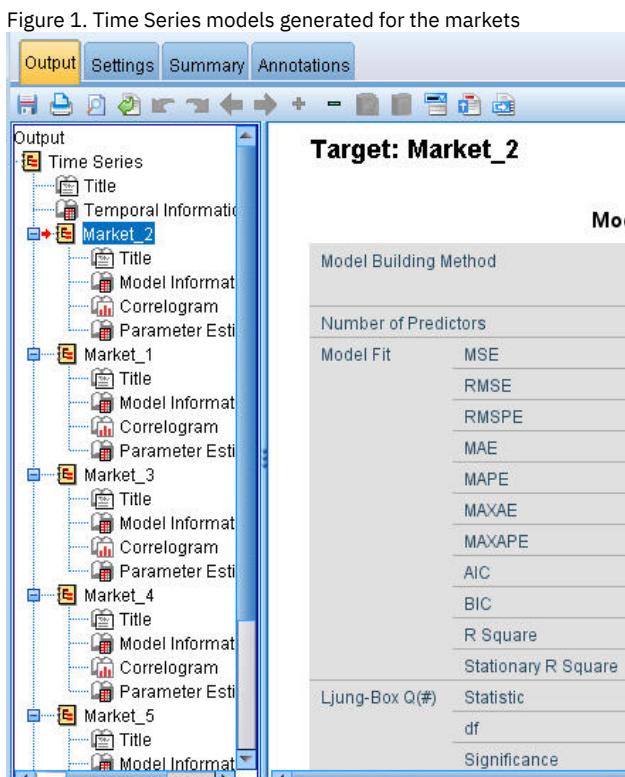

Column	Description
<code>\$TS-colname</code>	The generated model data for each column of the original data.
<code>\$TSLCI-colname</code>	The lower confidence interval value for each column of the generated model data.
<code>\$TSUCI-colname</code>	The upper confidence interval value for each column of the generated model data.
<code>\$TS-Total</code>	The total of the <code>\$TS-colname</code> values for this row.
<code>\$TSLCI-Total</code>	The total of the <code>\$TSLCI-colname</code> values for this row.
<code>\$TSUCI-Total</code>	The total of the <code>\$TSUCI-colname</code> values for this row.

The most significant columns for the forecast operation are the `$TS-Market_n`, `$TSLCI-Market_n`, and `$TSUCI-Market_n` columns. In particular, these columns in rows 61 through 63 contain the user subscription forecast data and confidence intervals for each of the local markets.

[Next](#)

Examining the model

1. Double-click the Time Series model nugget, and select the Output tab to display data about the models generated for each of the markets.

In the left Output column, select the Model Information for any of the Markets. The Number of Predictors line shows how many fields were used as predictors for each target; in this case, none.

The remaining lines in the Model Information tables show various goodness-of-fit measures for each model. The Stationary R Square value provides an estimate of the proportion of the total variation in the series that is explained by the model. The higher the value (to a maximum of 1.0), the better the fit of the model.

The Q(#) Statistic, df, and Significance lines relate to the Ljung-Box statistic, a test of the randomness of the residual errors in the model; the more random the errors, the better the model is likely to be. Q(#) is the Ljung-Box statistic itself, while df (degrees of freedom) indicates the number of model parameters that are free to vary when estimating a particular target.

The Significance line gives the significance value of the Ljung-Box statistic, providing another indication of whether the model is correctly specified. A significance value less than 0.05 indicates that the residual errors are not random, implying that there is structure in the observed series that is not accounted for by the model.

Taking both the Stationary R Square and Significance values into account, the models that the Expert Modeler has chosen for *Market_3*, and *Market_4* are quite acceptable. The Significance values for *Market_1*, *Market_2*, and *Market_5* are all less than 0.05, indicating that some experimentation with better-fitting models for these markets might be necessary.

The display shows a number of additional goodness-of-fit measures. The R Square value gives an estimation of the total variation in the time series that can be explained by the model. As the maximum value for this statistic is 1.0, our models are fine in this respect.

RMSE is the root mean square error, a measure of how much the actual values of a series differ from the values predicted by the model, and is expressed in the same units as those used for the series itself. As this is a measurement of an error, we want this value to be as low as possible. At first sight it appears that the models for *Market_2* and *Market_3*, while still acceptable according to the statistics we have seen so far, are less successful than those for the other three markets.

These additional goodness-of-fit measures include the mean absolute percentage errors (MAPE) and its maximum value (MAXAPE). Absolute percentage error is a measure of how much a target series varies from its model-predicted level, expressed as a percentage value. By examining the mean and maximum across all models, you can get an indication of the uncertainty in your predictions.

The MAPE value shows that all models display a mean uncertainty of around 1%, which is very low. The MAXAPE value displays the maximum absolute percentage error and is useful for imagining a worst-case scenario for your forecasts. It shows that the largest percentage error for most of the models falls in the range of roughly 1.8 to 3.7%, again a very low set of figures, with only *Market_4* being higher at nearer 7%.

The MAE (mean absolute error) value shows the mean of the absolute values of the forecast errors. Like the RMSE value, this is expressed in the same units as those used for the series itself. MAXAE shows the largest forecast error in the same units and indicates worst-case scenario for the forecasts.

Interesting though these absolute values are, it is the values of the percentage errors (MAPE and MAXAPE) that are more useful in this case, as the target series represent subscriber numbers for markets of varying sizes.

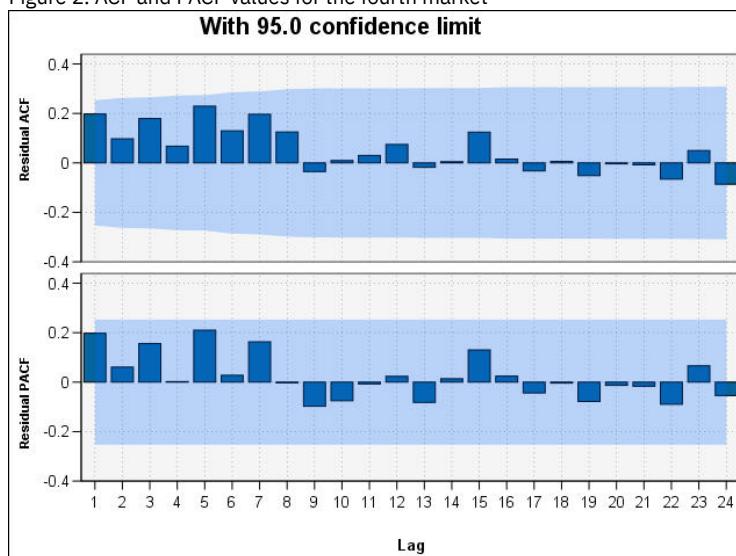

Do the MAPE and MAXAPE values represent an acceptable amount of uncertainty with the models? They are certainly very low. This is a situation in which business sense comes into play, because acceptable risk will change from problem to problem. We'll assume that the goodness-of-fit statistics fall within acceptable bounds and go on to look at the residual errors.

Examining the values of the autocorrelation function (ACF) and partial autocorrelation function (PACF) for the model residuals provides more quantitative insight into the models than simply viewing goodness-of-fit statistics.

A well-specified time series model will capture all of the nonrandom variation, including seasonality, trend, and cyclic and other factors that are important. If this is the case, any error should not be correlated with itself (autocorrelated) over time. A significant structure in either of the autocorrelation functions would imply that the underlying model is incomplete.

2. For the fourth market, in the left column, click Correlogram to display the values of the autocorrelation function (ACF) and partial autocorrelation function (PACF) for the residual errors in the model.

Figure 2. ACF and PACF values for the fourth market

In these plots, the original values of the error variable have been lagged by up to 24 time periods and compared with the original value to see if there is any correlation over time. For the model to be acceptable, none of the bars in the upper (ACF) plot should extend outside the shaded area, in either a positive (up) or negative (down) direction.

Should this occur, you would need to check the lower (PACF) plot to see whether the structure is confirmed there. The PACF plot looks at correlations after controlling for the series values at the intervening time points.

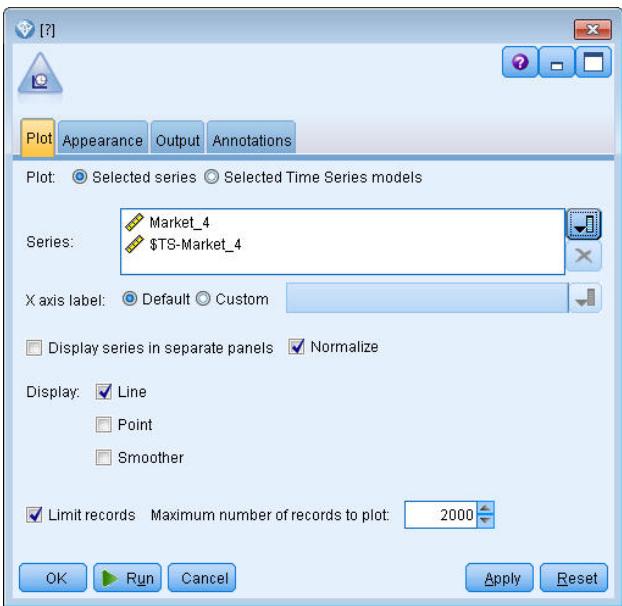

The values for *Market_4* are all within the shaded area, so we can continue and check the values for the other markets.

3. Click the Correlogram for each of the other markets and the totals.

The values for the other markets all show some values outside the shaded area, confirming what we suspected earlier from their Significance values. We'll need to experiment with some different models for those markets at some point to see if we can get a better fit, but for the rest of this example, we'll concentrate on what else we can learn from the *Market_4* model.

4. From the Graphs palette, attach a Time Plot node to the Time Series model nugget.
5. On the Plot tab, clear the Display series in separate panels check box.
6. At the Series list, click the field selector button, select the *Market_4* and *\$TS-Market_4* fields, and click OK to add them to the list.
7. Click Run to display a line graph of the actual and forecast data for the first of the local markets.

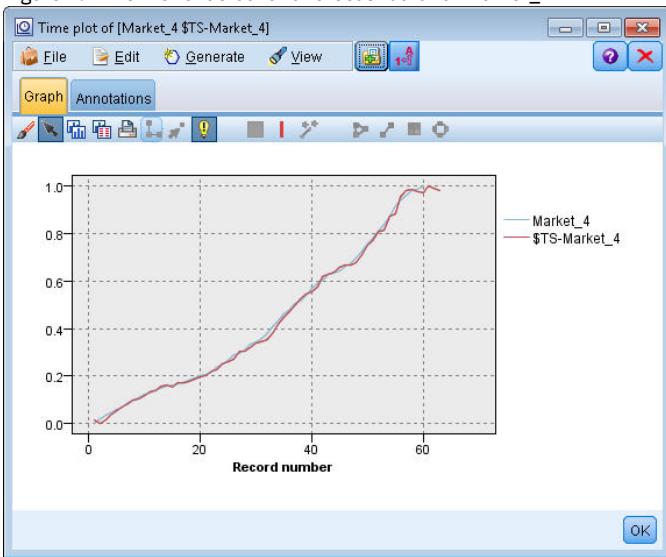

Figure 3. Selecting the fields to plot

Notice how the forecast (\$TS-Market_4) line extends past the end of the actual data. You now have a forecast of expected demand for the next three months in this market.

The lines for actual and forecast data over the entire time series are very close together on the graph, indicating that this is a reliable model for this particular time series.

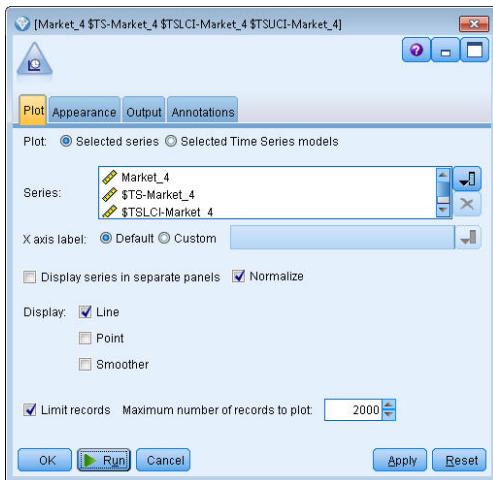

Figure 4. Time Plot of actual and forecast data for Market_4

Save the model in a file for use in a future example:

8. Click OK to close the current graph.
 9. Open the Time Series model nugget.
 10. Choose File > Save Node and specify the file location.
 11. Click Save.
- You have a reliable model for this particular market, but what margin of error does the forecast have? You can get an indication of this by examining the confidence interval.
12. Double-click the last Time Plot node in the stream (the one labeled Market_4 \$TS-Market_4) to open its dialog box again.
 13. Click the field selector button and add the \$TSLCI-Market_4 and \$TSUCI-Market_4 fields to the Series list.
 14. Click Run.

Figure 5. Adding more fields to plot

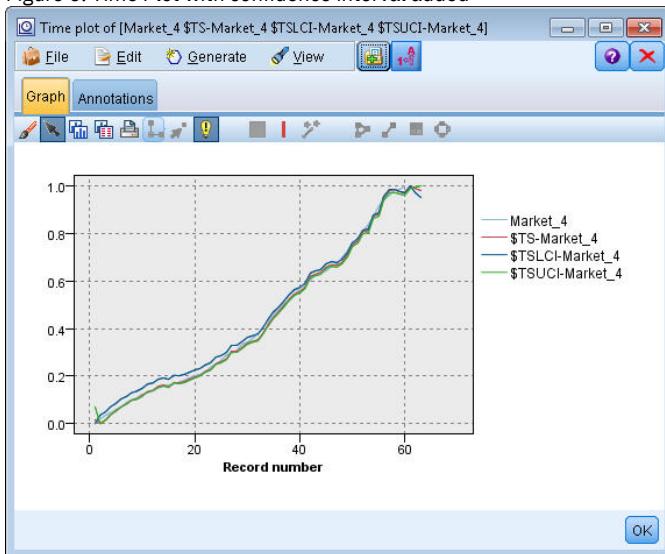

Now you have the same graph as before, but with the upper ($\$TSLCI$) and lower ($\$TSLCI$) limits of the confidence interval added.

Notice how the boundaries of the confidence interval diverge over the forecast period, indicating increasing uncertainty as you forecast further into the future.

However, as each time period goes by, you will have another (in this case) month's worth of actual usage data on which to base your forecast. You can read the new data into the stream and reapply your model now that you know it is reliable. See the topic [Reapplying a Time Series Model](#) for more information.

Figure 6. Time Plot with confidence interval added

[Next](#)

Summary

You have learned how to use the Expert Modeler to produce forecasts for multiple time series, and you have saved the resulting models to an external file.

In the next example, you will see how to transform nonstandard time series data into a format suitable for input to a Time Series node.

[Next](#)

Reapplying a Time Series Model

This example applies the time series models from the first time series example but can also be used independently. See the topic [Forecasting with the Time Series Node](#) for more information.

As in the original scenario, an analyst for a national broadband provider is required to produce monthly forecasts of user subscriptions for each of a number of local markets, in order to predict bandwidth requirements. You have already used the Expert Modeler to create models and to forecast three months into the future.

Your data warehouse has now been updated with the actual data for the original forecast period, so you would like to use that data to extend the forecast horizon by another three months.

This example uses the stream named *broadband_apply_models.str*, which references the data file named *broadband_2.sav*. These files are available from the *Demos* folder of any IBM® SPSS® Modeler installation. This can be accessed from the IBM SPSS Modeler program group on the Windows Start menu. The *broadband_apply_models.str* file is in the *streams* folder.

[Next](#)

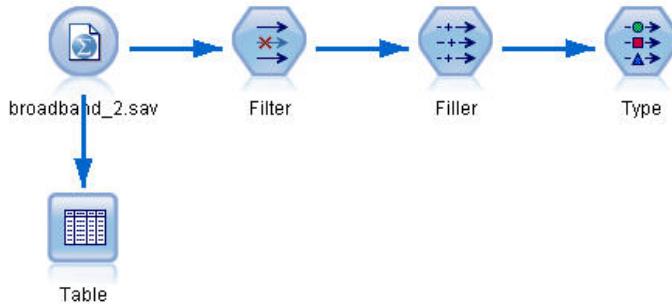

- [Retrieving the Stream](#)
- [Retrieving the saved model](#)
- [Generating a Modeling Node](#)
- [Generating a New Model](#)
- [Examining the New Model](#)
- [Summary](#)

Retrieving the Stream

In this example, you'll be recreating a Time Series node from the Time Series model saved in the first example. Don't worry if you don't have a model saved, we've provided one in the *Demos* folder.

1. Open the stream *broadband_apply_models.str* from the *streams* folder under *Demos*.

Figure 1. Opening the stream

The updated monthly data is collected in *broadband_2.sav*.

2. Attach a Table node to the IBM® SPSS® Statistics File source node, open the Table node and click Run.

Note: The data file has been updated with the actual sales data for January through March 2004, in rows 61 to 63.

Figure 2. Updated sales data

A screenshot of the SPSS Modeler Table node interface. The title bar says "Table (89 fields, 63 records)". The main area shows a data grid with columns labeled: #1, Market_82, Market_83, Market_84, Market_85, Total, YEAR_, MONTH_, DATE_. The data starts at row 44 and continues to row 63. The first few rows of data are:

#1	Market_82	Market_83	Market_84	Market_85	Total	YEAR_	MONTH_	DATE_

[Next](#)

Retrieving the saved model

1. On the IBM® SPSS® Modeler menu, choose Insert > Node From File and select the *TSmodel.nod* file from the *Demos* folder (or use the Time Series model you saved in the first time series example).

This file contains the time series models from the previous example. The insert operation places the corresponding Time Series model nugget on the canvas.

Figure 1. Adding the model nugget

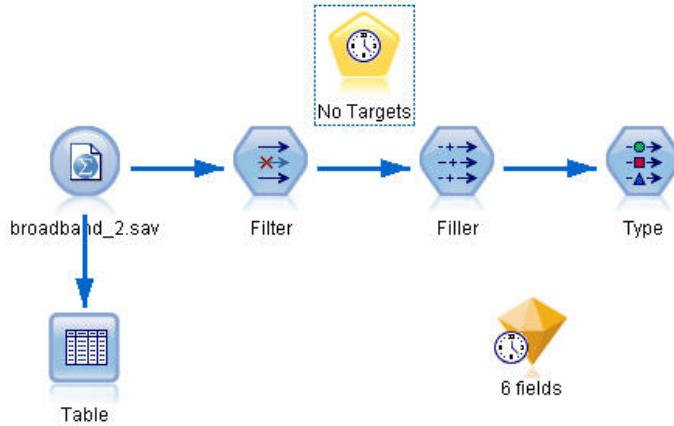

[Next](#)

Generating a Modeling Node

1. Open the Time Series model nugget and choose Generate > Generate Modeling Node.

This places a Time Series modeling node on the canvas.

Figure 1. Generating a modeling node from the model nugget

[Next](#)

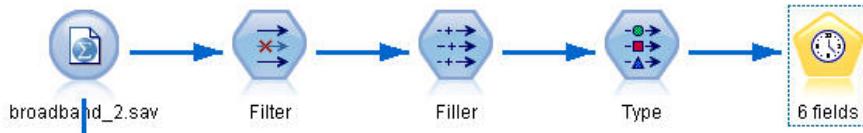

Generating a New Model

1. Close the Time Series model nugget and delete it from the canvas.

The old model was built on 60 rows of data. You need to generate a new model based on the updated sales data (63 rows).

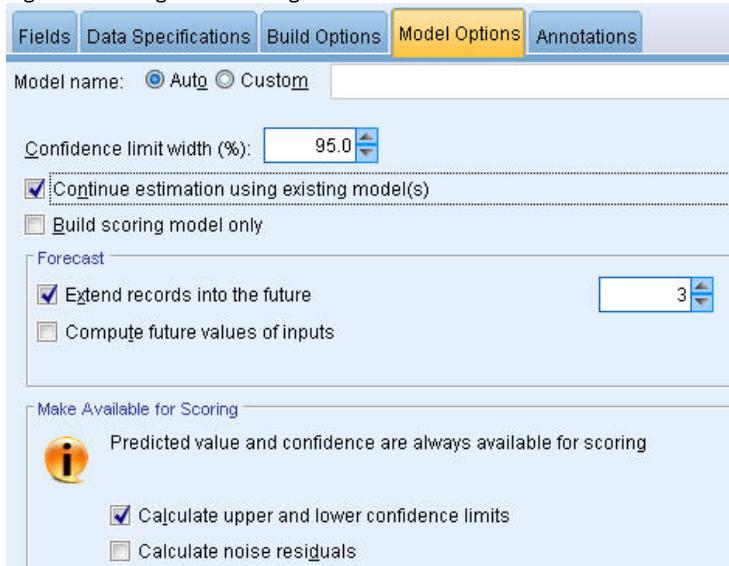

2. Attach the newly generated Time Series build node to the stream.

Figure 1. Attaching the modeling node to the stream

3. Open the Time Series node.
4. On the Model Options tab, ensure that Continue estimation using existing models is checked.

Figure 2. Reusing stored settings for the time series model

5. Ensure that Extend records into the future is set to 3.
6. Click Run to place a new model nugget on the canvas and in the Models palette.

[Next](#)

Examining the New Model

1. Attach a Table node to the new Time Series model nugget on the canvas.
2. Open the Table node and click Run.

The new model still forecasts three months ahead because you're reusing the stored settings. However, this time it forecasts April through June (on lines 64 to 66) because the estimation period now ends in March instead of January.

Figure 1. Table showing new forecast

Table (26 fields, 66 records)

OK

3. Attach a Time Plot graph node to the Time Series model nugget.

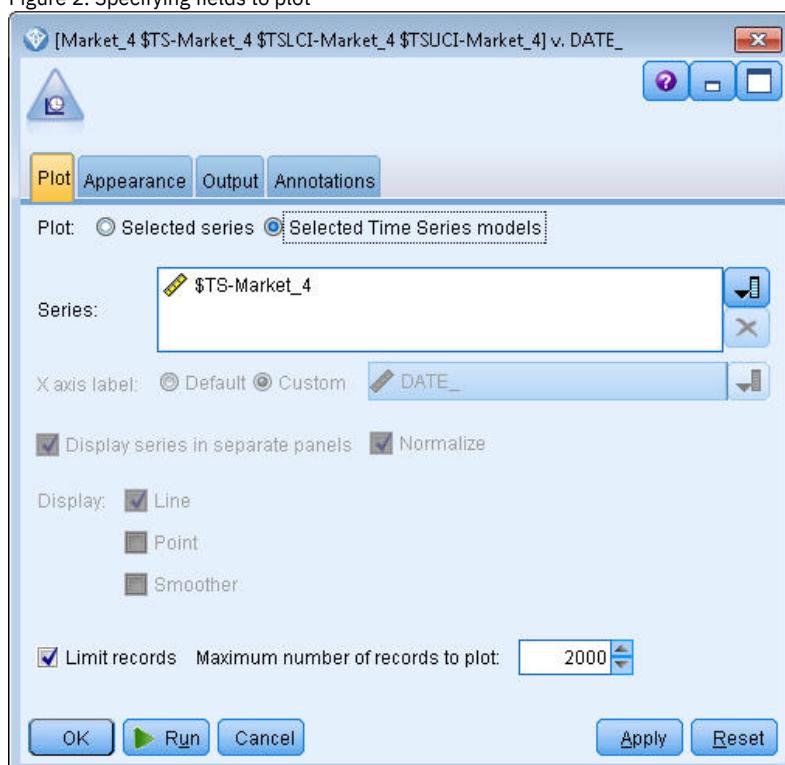

This time we'll use the time plot display designed especially for time series models.

4. On the Plot tab, set the X axis label to Custom, and select **Date_**.

5. For the Plot, choose the Selected Time Series models option.

6. From the Series list, click the field selector button, select the **\$TS-Market_4** field, and click OK to add it to the list.

Figure 2. Specifying fields to plot

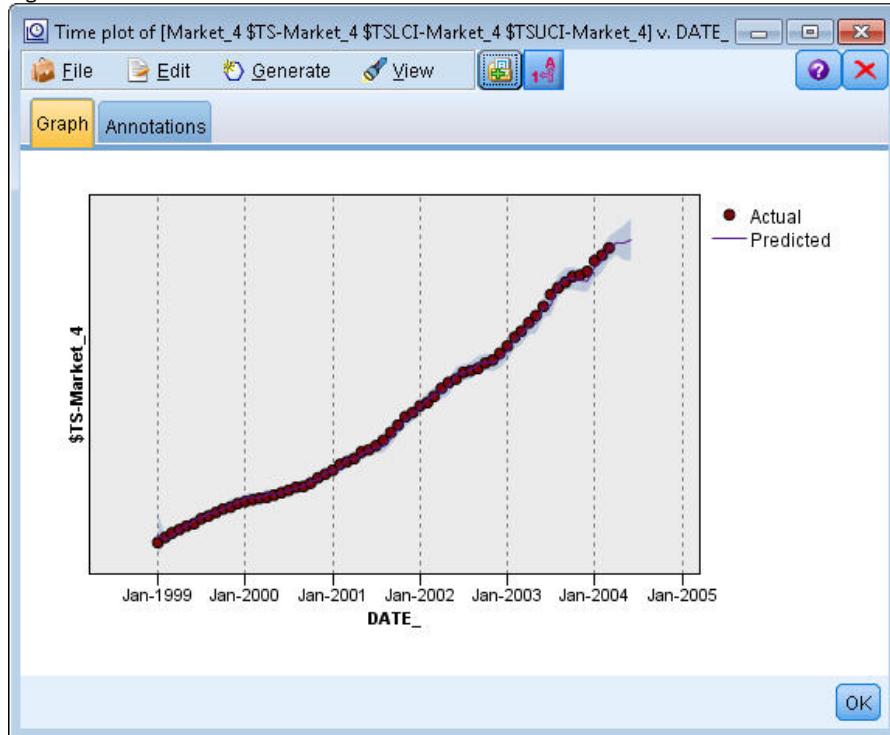

7. Click Run.

Now you have a graph that shows the actual sales for Market_4 up to March 2004, together with the forecast (Predicted) sales and the confidence interval (indicated by the blue shaded area) up to June 2004.

As in the first example, the forecast values follow the actual data closely throughout the time period, indicating once again that you have a good model.

Figure 3. Forecast extended to June

[Next](#)

Summary

You have learned how to apply saved models to extend your previous forecasts when more current data becomes available, and you have done this without rebuilding your models. Of course, if there is reason to think that a model has changed, you should rebuild it.

Forecasting Catalog Sales (Time Series)

A catalog company is interested in forecasting monthly sales of its men's clothing line, based on their sales data for the last 10 years.

This example uses the stream named *catalog_forecast.str*, which references the data file named *catalog_seasfac.sav*. These files are available from the *Demos* directory of any IBM® SPSS® Modeler installation. This can be accessed from the IBM SPSS Modeler program group on the Windows Start menu. The *catalog_forecast.str* file is in the *streams* directory.

We've seen in an earlier example how you can let the Expert Modeler decide which is the most appropriate model for your time series. Now it's time to take a closer look at the two methods that are available when choosing a model yourself--exponential smoothing and ARIMA.

To help you decide on an appropriate model, it's a good idea to plot the time series first. Visual inspection of a time series can often be a powerful guide in helping you choose. In particular, you need to ask yourself:

- Does the series have an overall trend? If so, does the trend appear constant or does it appear to be dying out with time?
- Does the series show seasonality? If so, do the seasonal fluctuations seem to grow with time or do they appear constant over successive periods?

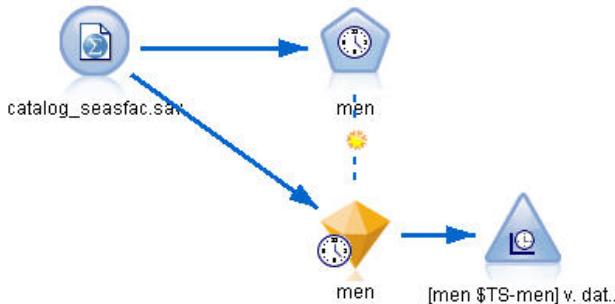

[Next](#)

- [Creating the Stream](#)
- [Examining the Data](#)
- [Exponential Smoothing](#)
- [ARIMA](#)
- [Summary](#)

Creating the Stream

1. Create a new stream and add a Statistics File source node pointing to *catalog_seasfac.sav*.

Figure 1. Forecasting catalog sales

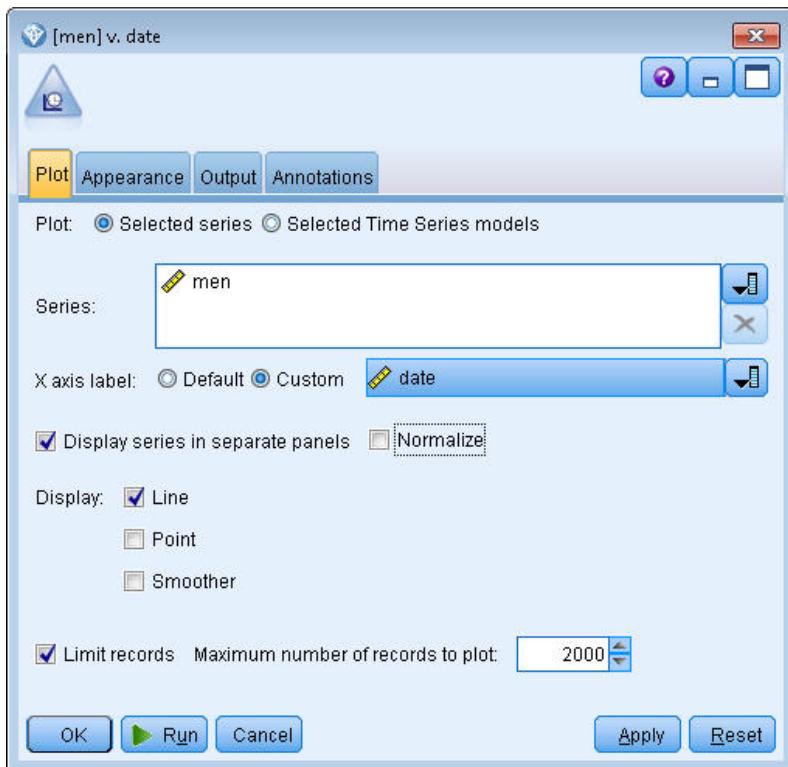

2. Open the IBM® SPSS® Statistics File source node and select the Types tab.
3. Click Read Values, then OK.
4. Click the Role column for the **men** field and set the role to Target.

Figure 2. Specifying the target field

5. Set the role for all the other fields to None, and click OK.
6. Attach a Time Plot graph node to the IBM SPSS Statistics File source node.
7. Open the Time Plot node and, on the Plot tab, add **men** to the Series list.
8. Set the X axis label to Custom, and select **date**.
9. Clear the Normalize check box.

Figure 3. Plotting the time series

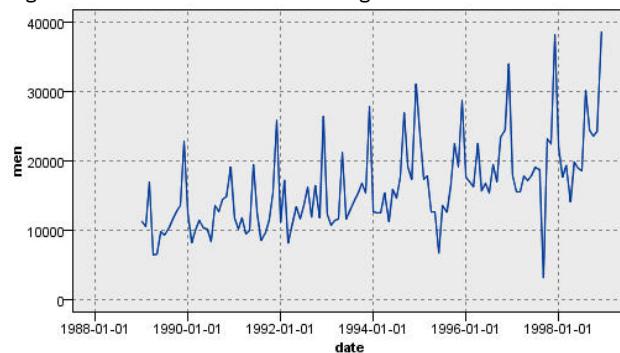

10. Click Run.

[Next](#)

Examining the Data

Figure 1. Actual sales of men's clothing

The series shows a general upward trend; that is, the series values tend to increase over time. The upward trend is seemingly constant, which indicates a linear trend.

The series also has a distinct seasonal pattern with annual highs in December, as indicated by the vertical lines on the graph. The seasonal variations appear to grow with the upward series trend, which suggests multiplicative rather than additive seasonality.

1. Click OK to close the plot.

Now that you've identified the characteristics of the series, you're ready to try modeling it. The exponential smoothing method is useful for forecasting series that exhibit trend, seasonality, or both. As we've seen, your data exhibit both characteristics.

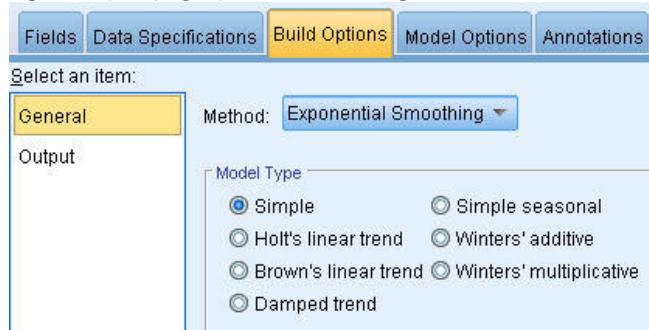

[Next](#)

Exponential Smoothing

Building a best-fit exponential smoothing model involves determining the model type (whether the model needs to include trend, seasonality, or both) and then obtaining the best-fit parameters for the chosen model.

The plot of men's clothing sales over time suggested a model with both a linear trend component and a multiplicative seasonality component. This implies a Winters' model. First, however, we will explore a simple model (no trend and no seasonality) and then a Holt's model (incorporates linear trend but no seasonality). This will give you practice in identifying when a model is not a good fit to the data, an essential skill in successful model building.

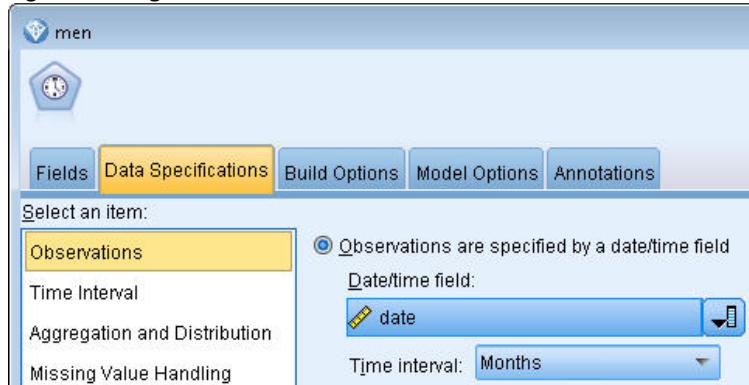

Figure 1. Specifying exponential smoothing

We'll start with a simple exponential smoothing model.

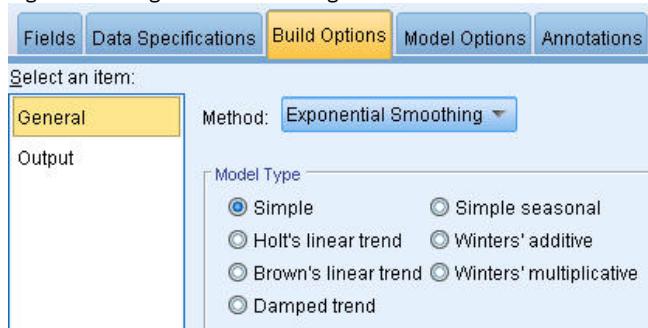

1. Add a Time Series node to the stream and attach it to the source node.
2. On the Data Specifications tab, in the Observations pane, select date as the Date/time field.
3. Select Months as the Time interval.

Figure 2. Setting the time interval

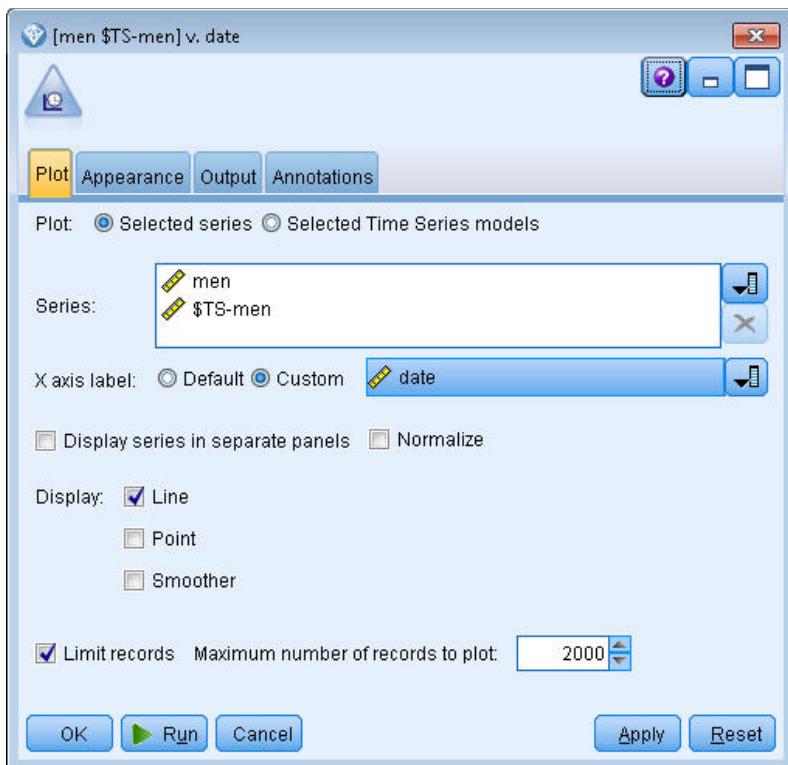

4. On the Build Options tab, in the General pane, set Method to Exponential Smoothing.
5. Set Model Type to Simple.

Figure 3. Setting the model building method

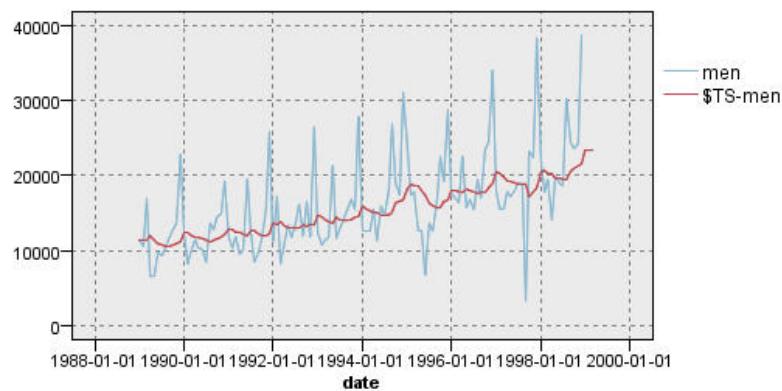

6. Click Run to create the model nugget.

Figure 4. Plotting the Time Series model

7. Attach a Time Plot node to the model nugget.
8. On the Plot tab, add men and \$TS-men to the Series list.
9. Set the X axis label to Custom, and select date.
10. Clear the Display series in separate panels and Normalize check boxes.
11. Click Run.

Figure 5. Simple exponential smoothing model

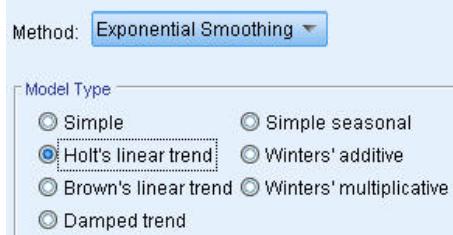

The men plot represents the actual data, while \$TS-men denotes the time series model.

Although the simple model does, in fact, exhibit a gradual (and rather ponderous) upward trend, it takes no account of seasonality. You can safely reject this model.

12. Click OK to close the time plot window.

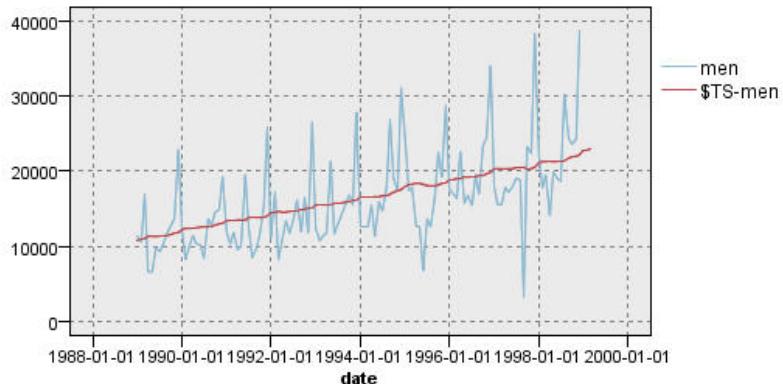

Figure 6. Selecting Holt's model

Let's try Holt's linear model. This should at least model the trend better than the simple model, although it too is unlikely to capture the seasonality.

13. Reopen the Time Series node.
14. On the Build Options tab, in the General pane, with Exponential Smoothing still selected as the Method, select Holts linear trend as the Model Type.
15. Click Run to re-create the model nugget.
16. Re-open the Time Plot node and click Run.

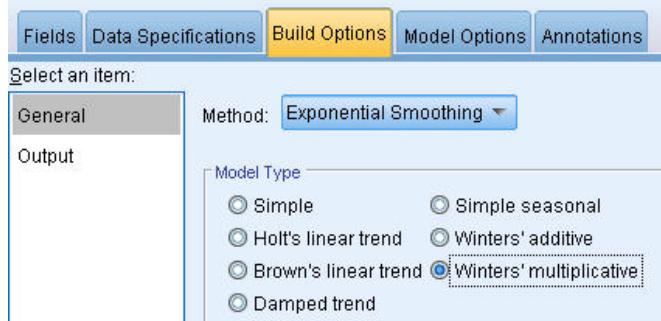

Figure 7. Holt's linear trend model

Holt's model displays a smoother upward trend than the simple model but it still takes no account of the seasonality, so you can discard this one too.

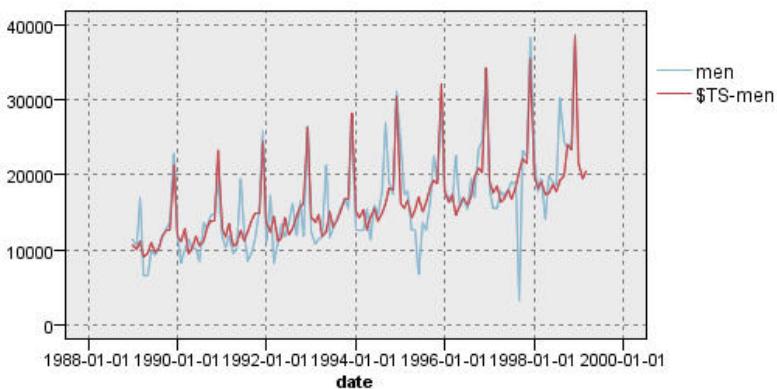

17. Close the time plot window.
- You may recall that the initial plot of men's clothing sales over time suggested a model incorporating a linear trend and multiplicative seasonality. A more suitable candidate, therefore, might be Winters' model.

Figure 8. Selecting Winters' model

18. Reopen the Time Series node.
19. On the Build Options tab, in the General pane, with Exponential Smoothing still selected as the Method, select Winters' multiplicative as the Model Type.
20. Click Run to re-create the model nugget.
21. Open the Time Plot node and click Run.

Figure 9. Winters' multiplicative model

This looks better; the model reflects both the trend and the seasonality of the data.

The dataset covers a period of 10 years and includes 10 seasonal peaks occurring in December of each year. The 10 peaks present in the predicted results match up well with the 10 annual peaks in the real data.

However, the results also underscore the limitations of the Exponential Smoothing procedure. Looking at both the upward and downward spikes, there is significant structure that is not accounted for.

If you are primarily interested in modeling a long-term trend with seasonal variation, then exponential smoothing may be a good choice. To model a more complex structure such as this one, we need to consider using the ARIMA procedure.

[Next](#)

ARIMA

With the ARIMA procedure you can create an autoregressive integrated moving-average (ARIMA) model that is suitable for finely tuned modeling of time series. ARIMA models provide more sophisticated methods for modeling trend and seasonal components than do exponential smoothing models, and they have the added benefit of being able to include predictor variables in the model.

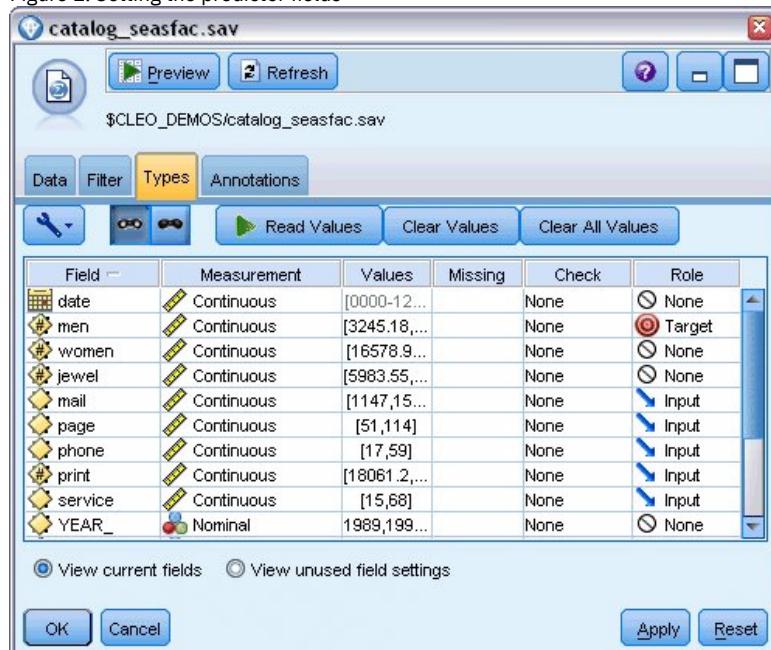

Continuing the example of the catalog company that wants to develop a forecasting model, we have seen how the company has collected data on monthly sales of men's clothing along with several series that might be used to explain some of the variation in sales. Possible predictors include the number of catalogs mailed and the number of pages in the catalog, the number of phone lines open for ordering, the amount spent on print advertising, and the number of customer service representatives.

Are any of these predictors useful for forecasting? Is a model with predictors really better than one without? Using the ARIMA procedure, we can create a forecasting model with predictors, and see if there is a significant difference in predictive ability over the exponential smoothing model with no predictors.

With the ARIMA method, you can fine-tune the model by specifying orders of autoregression, differencing, and moving average, as well as seasonal counterparts to these components. Determining the best values for these components manually can be a time-consuming process involving a good deal of trial and error so, for this example, we'll let the Expert Modeler choose an ARIMA model for us.

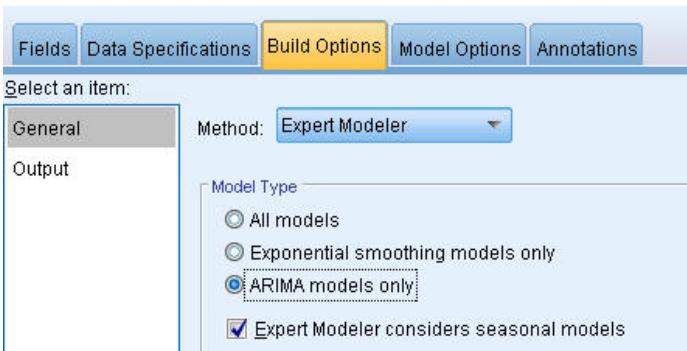

We'll try to build a better model by treating some of the other variables in the dataset as predictor variables. The ones that seem most useful to include as predictors are the number of catalogs mailed (`mail`), the number of pages in the catalog (`page`), the number of phone lines open for ordering (`phone`), the amount spent on print advertising (`print`), and the number of customer service representatives (`service`).

Figure 1. Setting the predictor fields

1. Open the IBM® SPSS® Statistics File source node.
2. On the Types tab, set the Role for `mail`, `page`, `phone`, `print`, and `service` to Input.
3. Ensure that the role for `men` is set to Target and that all the remaining fields are set to None.
4. Click OK.
5. Open the Time Series node.
6. On the Build Options tab, in the General pane, set Method to Expert Modeler.
7. Select the ARIMA models only option and ensure that Expert Modeler considers seasonal models is checked.

Figure 2. Choosing only ARIMA models

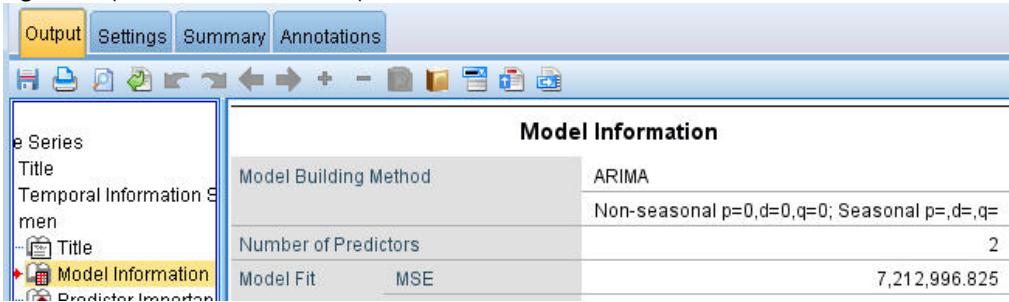

8. Click Run to re-create the model nugget.

9. Open the model nugget.

On the Output tab, in the left column, select the Model information. Notice how the Expert Modeler has chosen only two of the five specified predictors as being significant to the model.

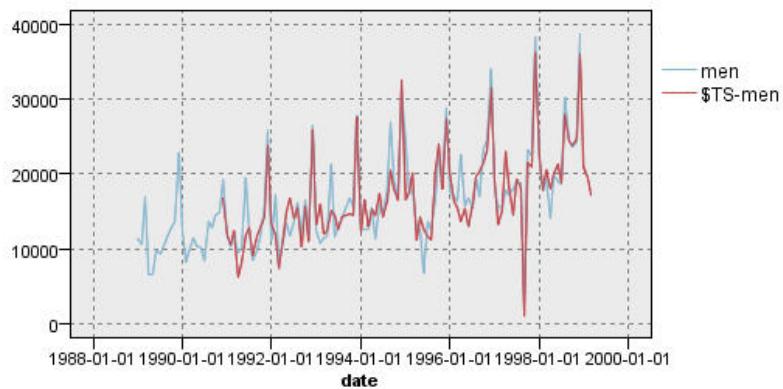

Figure 3. Expert Modeler chooses two predictors

10. Click OK to close the model nugget.

11. Open the Time Plot node and click Run.

Figure 4. ARIMA model with predictors specified

This model improves on the previous one by capturing the large downward spike as well, making it the best fit so far.

We could try refining the model even further, but any improvements from this point on are likely to be minimal. We've established that the ARIMA model with predictors is preferable, so let's use the model we have just built. For the purposes of this example, we'll forecast sales for the coming year.

12. Click OK to close the time plot window.

13. Open the Time Series node and select the Model Options tab.

14. Select the Extend records into the future checkbox and set its value to 12.

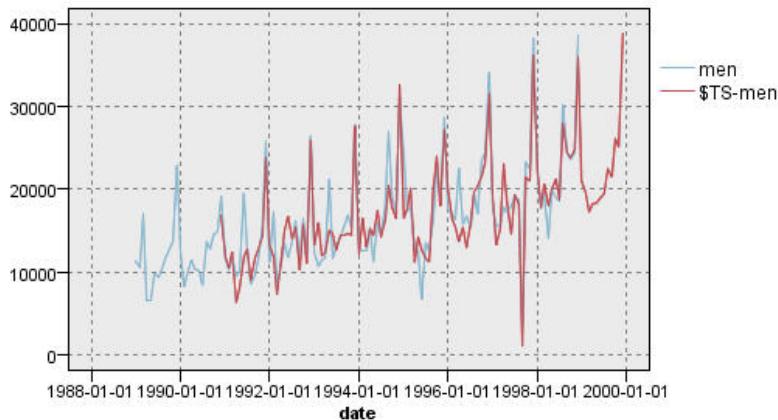

15. Select the Compute future values of inputs checkbox.

16. Click Run to re-create the model nugget.

17. Open the Time Plot node and click Run.

The forecast for 1999 looks good; as expected, there's a return to normal sales levels following the December peak, and a steady upward trend in the second half of the year, with sales in general above those for the previous year.

Figure 5. Sales forecast extended by 12 months

[Next](#)

Summary

You have successfully modeled a complex time series, incorporating not only an upward trend but also seasonal and other variations. You have also seen how, through trial and error, you can get closer and closer to an accurate model, which you have then used to forecast future sales.

In practice, you would need to reapply the model as your actual sales data are updated--for example, every month or every quarter--and produce updated forecasts. See the topic [Reapplying a Time Series Model](#) for more information.

Making Offers to Customers (Self-Learning)

The Self-Learning Response Model (SLRM) node generates and enables the updating of a model that allows you to predict which offers are most appropriate for customers and the probability of the offers being accepted. These sorts of models are most beneficial in customer relationship management, such as marketing applications or call centers.

This example is based on a fictional banking company. The marketing department wants to achieve more profitable results in future campaigns by matching the right offer of financial services to each customer. Specifically, the example uses a Self-Learning Response Model to identify the characteristics of customers who are most likely to respond favorably based on previous offers and responses and to promote the best current offer based on the results.

This example uses the stream *pm_selflearn.str*, which references the data files *pm_customer_train1.sav*, *pm_customer_train2.sav*, and *pm_customer_train3.sav*. These files are available from the *Demos* folder of any IBM® SPSS® Modeler installation. This can be accessed from the IBM SPSS Modeler program group on the Windows Start menu. The *pm_selflearn.str* file is in the *streams* folder.

Existing Data

The company has historical data tracking the offers made to customers in past campaigns, along with the responses to those offers. These data also include demographic and financial information that can be used to predict response rates for different customers.

Figure 1. Responses to previous offers

Table (31 fields, 21,927 records)

	customer_id	campaign	response	response_date	purchase	purchase_date	product_id	Rowid
1	7	2	0	\$null\$	0	\$null\$	\$null\$	1
2	13	2	0	\$null\$	0	\$null\$	\$null\$	2
3	15	2	0	\$null\$	0	\$null\$	\$null\$	3
4	16	2	1	2006-07-05 00:00:00	0	\$null\$	183	761
5	23	2	0	\$null\$	0	\$null\$	\$null\$	4
6	24	2	0	\$null\$	0	\$null\$	\$null\$	5

- [Building the Stream](#)
- [Browsing the model](#)

Building the Stream

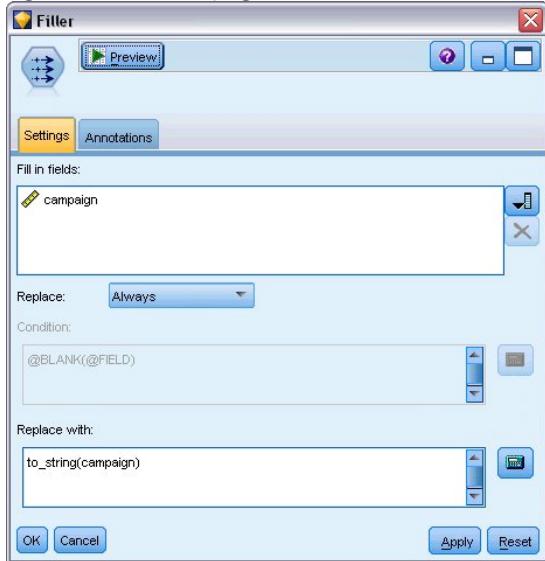

1. Add a Statistics File source node pointing to *pm_customer_train1.sav*, located in the *Demos* folder of your IBM® SPSS® Modeler installation.

Figure 1. SLM sample stream

2. Add a Filler node and select *campaign* as the Fill in field.
3. Select a Replace type of Always.
4. In the Replace with text box, enter *to_string(campaign)* and click OK.

Figure 2. Derive a campaign field

5. Add a Type node, and set the Role to None for the *customer_id*, *response_date*, *purchase_date*, *product_id*, *Rowid*, and *X_random* fields.

Figure 3. Changing the Type node settings

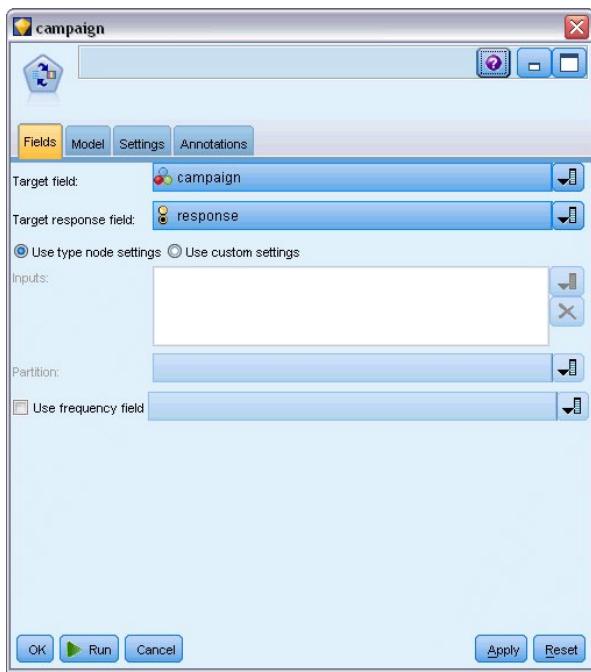

6. Set the *Role* to Target for the *campaign* and *response* fields. These are the fields on which you want to base your predictions.
Set the Measurement to Flag for the *response* field.
7. Click Read Values, then OK.
Because the campaign field data show as a list of numbers (1, 2, 3, and 4), you can reclassify the fields to have more meaningful titles.
8. Add a Reclassify node to the Type node.
9. In the Reclassify into field, select Existing field.
10. In the Reclassify field list, select campaign.
11. Click the Get button; the campaign values are added to the *Original value* column.
12. In the *New value* column, enter the following campaign names in the first four rows:
 - Mortgage
 - Car loan
 - Savings
 - Pension
13. Click OK.

Figure 4. Reclassify the campaign names

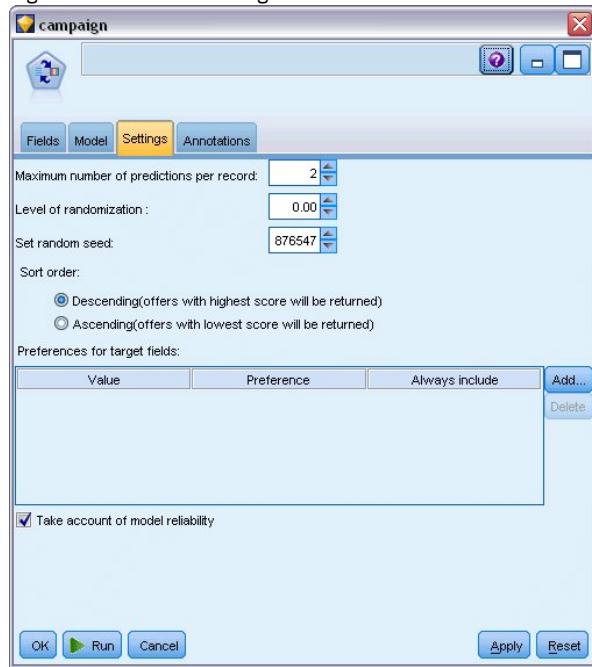

14. Attach an SLRM modeling node to the Reclassify node. On the Fields tab, select campaign for the Target field, and response for the Target response field.

Figure 5. Select the target and target response

15. On the Settings tab, in the Maximum number of predictions per record field, reduce the number to 2.
This means that for each customer, there will be two offers identified that have the highest probability of being accepted.
16. Ensure that Take account of model reliability is selected, and click Run.

Figure 6. SLM node settings

[Next](#)

Browsing the model

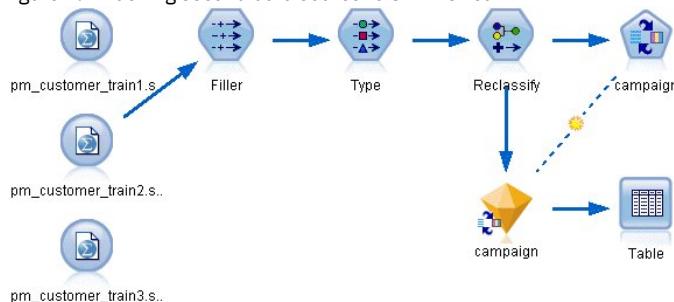

1. Open the model nugget. The Model tab initially shows the estimated the accuracy of the predictions for each offer and the relative importance of each predictor in estimating the model.
To display the correlation of each predictor with the target variable, choose Association with Response from the View list in the right-hand pane.
2. To switch between each of the four offers for which there are predictions, select the required offer from the View list in the left-hand pane.

Figure 1. SLM model nugget

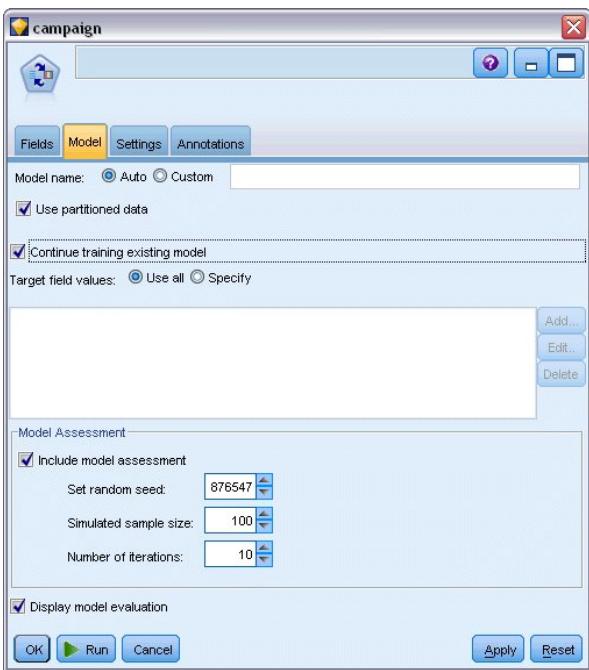

3. Close the model nugget window.
4. On the stream canvas, disconnect the IBM® SPSS® Statistics File source node pointing to *pm_customer_train1.sav*.
5. Add a Statistics File source node pointing to *pm_customer_train2.sav*, located in the *Demos* folder of your IBM SPSS Modeler installation, and connect it to the Filler node.

Figure 2. Attaching second data source to SLM stream

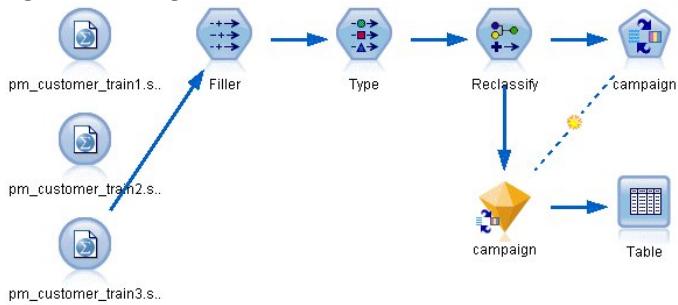

6. On the Model tab of the SLM node, select Continue training existing model.

Figure 3. Continue training model

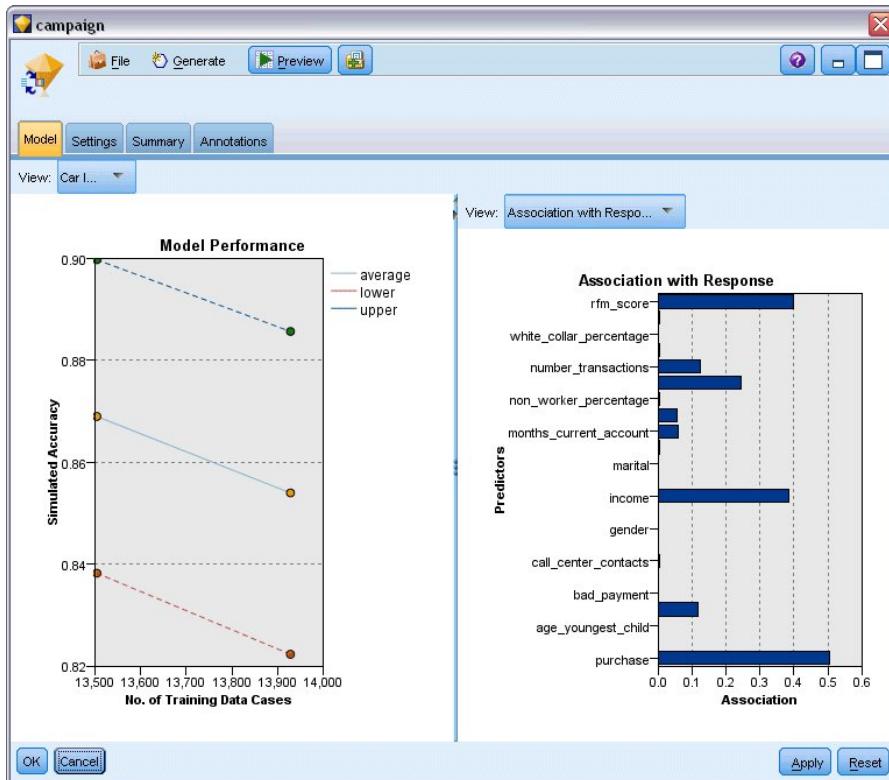

7. Click Run to re-create the model nugget. To view its details, double-click the nugget on the canvas. The Model tab now shows the revised estimates of the accuracy of the predictions for each offer.
8. Add a Statistics File source node pointing to *pm_customer_train3.sav*, located in the *Demos* folder of your IBM SPSS Modeler installation, and connect it to the Filler node.

Figure 4. Attaching third data source to SLM stream

9. Click Run to re-create the model nugget once more. To view its details, double-click the nugget on the canvas.
 10. The Model tab now shows the final estimated accuracy of the predictions for each offer.
- As you can see, the average accuracy fell slightly (from 86.9% to 85.4%) as you added the additional data sources; however, this fluctuation is a minimal amount and may be attributed to slight anomalies within the available data.

Figure 5. Updated SLM model nugget

11. Attach a Table node to the last (third) generated model and execute the Table node.
12. Scroll across to the right of the table. The predictions show which offers a customer is most likely to accept and the confidence that they will accept, depending on each customer's details.

For example, in the first line of the table shown, there is only a 13.2% confidence rating (denoted by the value 0.132 in the \$SC-campaign-1 column) that a customer who previously took out a car loan will accept a pension if offered one. However, the second and third lines show two more customers who also took out a car loan; in their cases, there is a 95.7% confidence that they, and other customers with similar histories, would open a savings account if offered one, and over 80% confidence that they would accept a pension.

Figure 6. Model output - predicted offers and confidences

Table (35 fields, 27 records)					
	X_random	\$S-campaign-1	\$SC-campaign-1	\$S-campaign-2	\$SC-campaign-2
1	1	Pension	0.132	Mortgage	0.107
2	1	Savings	0.957	Pension	0.844
3	1	Savings	0.957	Pension	0.802
4	3	Pension	0.132	Mortgage	0.107
5	1	Pension	0.805	Savings	0.284
6	3	Pension	0.132	Mortgage	0.107
7	2	Pension	0.132	Mortgage	0.107
8	3	Pension	0.132	Mortgage	0.107
9	1	Pension	0.132	Mortgage	0.107
10	1	Pension	0.132	Mortgage	0.107
11	2	Pension	0.132	Mortgage	0.107
12	2	Pension	0.132	Mortgage	0.107
13	2	Savings	0.957	Mortgage	0.829
14	2	Savings	0.164	Pension	0.132
15	2	Savings	0.957	Pension	0.868
16	2	Pension	0.132	Mortgage	0.107
17	3	Pension	0.132	Mortgage	0.107
18	3	Pension	0.132	Mortgage	0.107
19	3	Savings	0.289	Pension	0.132
20	2	Pension	0.132	Mortgage	0.107

Explanations of the mathematical foundations of the modeling methods used in IBM SPSS Modeler are listed in the *IBM SPSS Modeler Algorithms Guide*, available as a PDF file as part of your product download.

Note also that these results are based on the training data only. To assess how well the model generalizes to other data in the real world, you would use a Partition node to hold out a subset of records for purposes of testing and validation.

Predicting Loan Defaulters (Bayesian Network)

Bayesian networks enable you to build a probability model by combining observed and recorded evidence with "common-sense" real-world knowledge to establish the likelihood of occurrences by using seemingly unlinked attributes.

This example uses the stream named *bayes_bankloan.str*, which references the data file named *bankloan.sav*. These files are available from the *Demos* directory of any IBM® SPSS® Modeler installation and can be accessed from the IBM SPSS Modeler program group on the Windows Start menu. The *bayes_bankloan.str* file is in the *streams* directory.

For example, suppose a bank is concerned about the potential for loans not to be repaid. If previous loan default data can be used to predict which potential customers are liable to have problems repaying loans, these "bad risk" customers can either be declined a loan or offered alternative products.

This example focuses on using existing loan default data to predict potential future defaulters, and looks at three different Bayesian network model types to establish which is better at predicting in this situation.

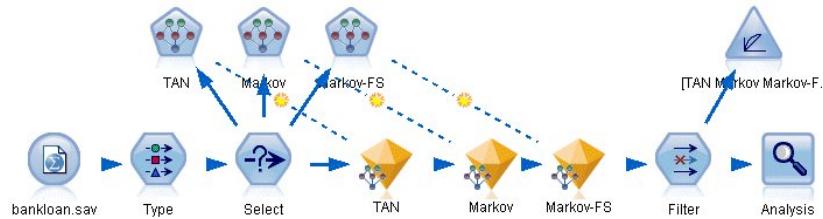

[Next](#)

- [Building the Stream](#)
- [Browsing the model](#)

Building the Stream

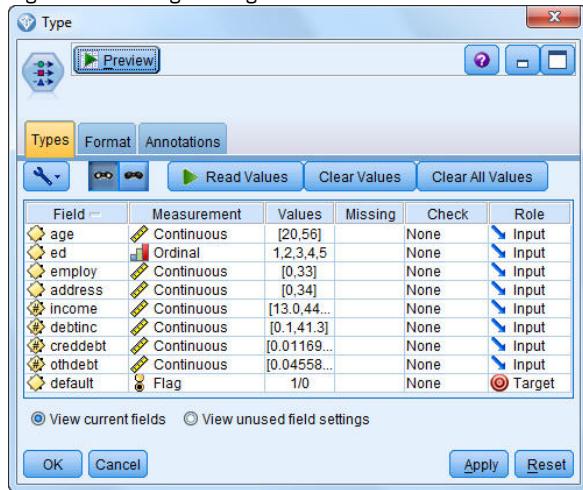

1. Add a Statistics File source node pointing to *bankloan.sav* in the *Demos* folder.

Figure 1. Bayesian Network sample stream

2. Add a Type node to the source node and set the role of the default field to Target. All other fields should have their role set to Input.
3. Click the Read Values button to populate the *Values* column.

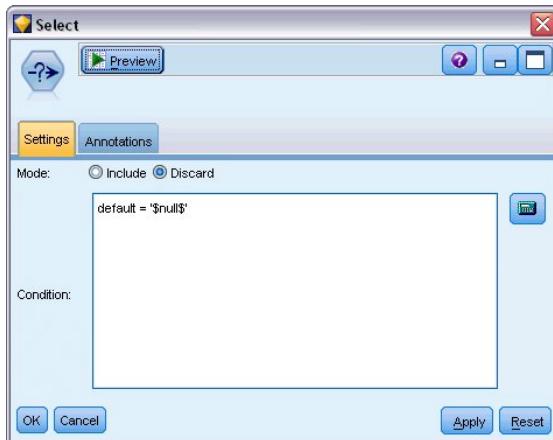

Figure 2. Selecting the target field

Cases where the target has a null value are of no use when building the model. You can exclude those cases to prevent them from being used in model evaluation.

4. Add a Select node to the Type node.
5. For Mode, select Discard.
6. In the Condition box, enter default = '\$null\$'.

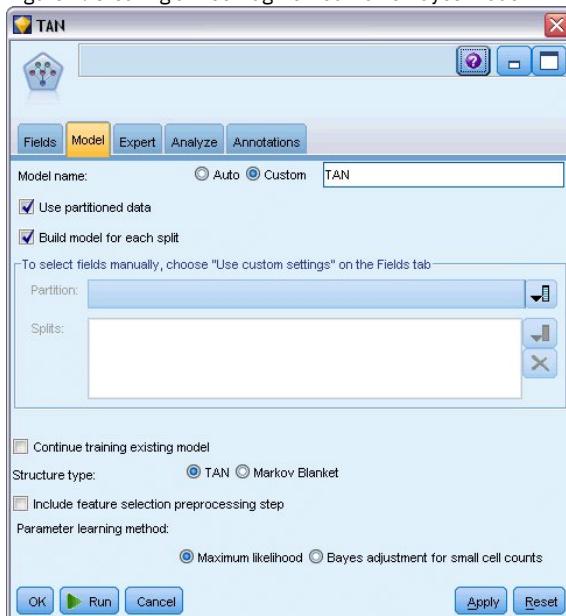

Figure 3. Discarding null targets

Because you can build several different types of Bayesian networks, it is worth comparing several to see which model provides the best predictions. The first one to create is a Tree Augmented Naïve Bayes (TAN) model.

7. Attach a Bayesian Network node to the Select node.
8. On the Model tab, for Model name, select Custom and enter TAN in the text box.
9. For Structure type, select TAN and click OK.

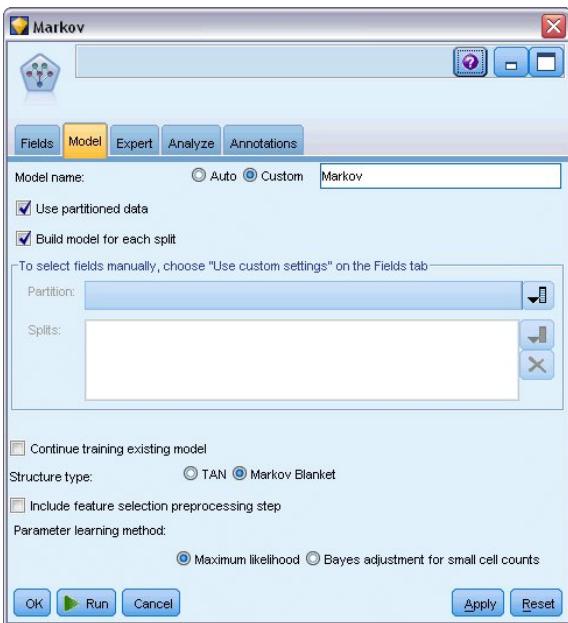

Figure 4. Creating a Tree Augmented Naïve Bayes model

The second model type to build has a Markov Blanket structure.

10. Attach a second Bayesian Network node to the Select node.
11. On the Model tab, for Model name, select Custom and enter Markov in the text box.
12. For Structure type, select Markov Blanket and click OK.

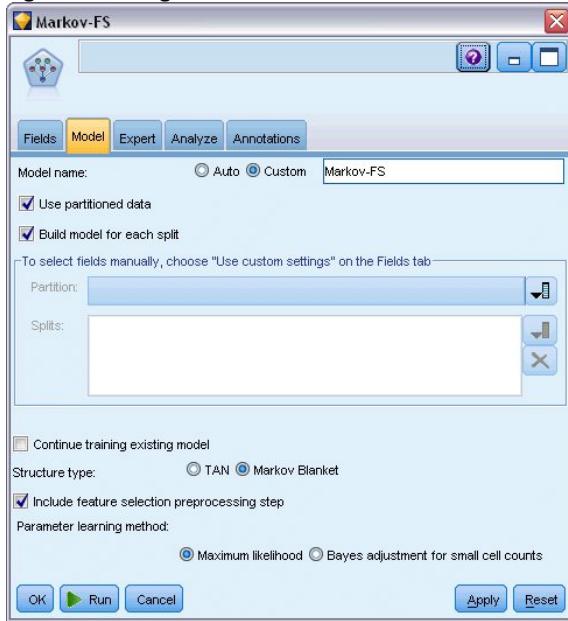

Figure 5. Creating a Markov Blanket model

The third model type to build has a Markov Blanket structure and also uses feature selection preprocessing to select the inputs that are significantly related to the target variable.

13. Attach a third Bayesian Network node to the Select node.
14. On the Model tab, for Model name, select Custom and enter Markov-FS in the text box.
15. For Structure type, select Markov Blanket.
16. Select Include feature selection preprocessing step and click OK.

Figure 6. Creating a Markov Blanket model with Feature Selection preprocessing

[Next](#)

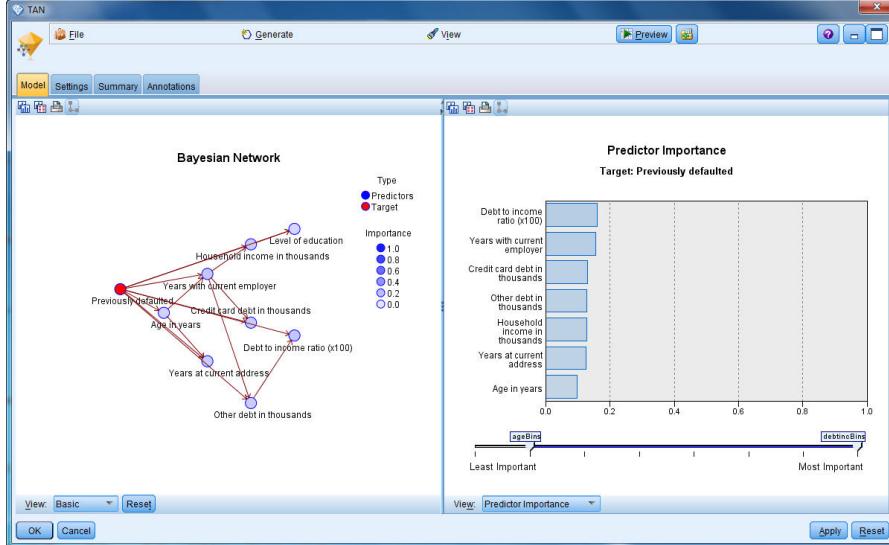

Browsing the model

1. Run the stream to create the model nuggets, which are added to the stream and to the Models palette in the upper-right corner. To view their details, double-click on any of the model nuggets in the stream.

The model nugget Model tab is split into two panes. The left pane contains a network graph of nodes that displays the relationship between the target and its most important predictors, as well as the relationship between the predictors.

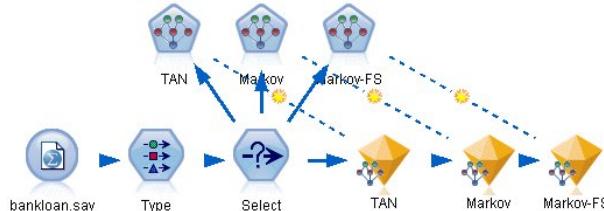

The right pane shows either *Predictor Importance*, which indicates the relative importance of each predictor in estimating the model, or *Conditional Probabilities*, which contains the conditional probability value for each node value and each combination of values in its parent nodes.

Figure 1. Viewing a Tree Augmented Naïve Bayes model

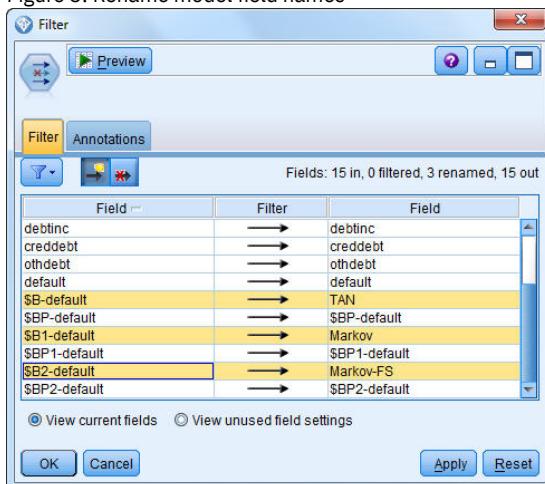

2. Connect the TAN model nugget to the Markov nugget (choose Replace on the warning dialog).
3. Connect the Markov nugget to the Markov-FS nugget (choose Replace on the warning dialog).
4. Align the three nuggets with the Select node for ease of viewing.

Figure 2. Aligning the nuggets in the stream

5. To rename the model outputs for clarity on the Evaluation graph that you'll be creating, attach a Filter node to the Markov-FS model nugget.
6. In the right Field column, rename \$B-default as TAN, \$B1-default as Markov, and \$B2-default as Markov-FS.

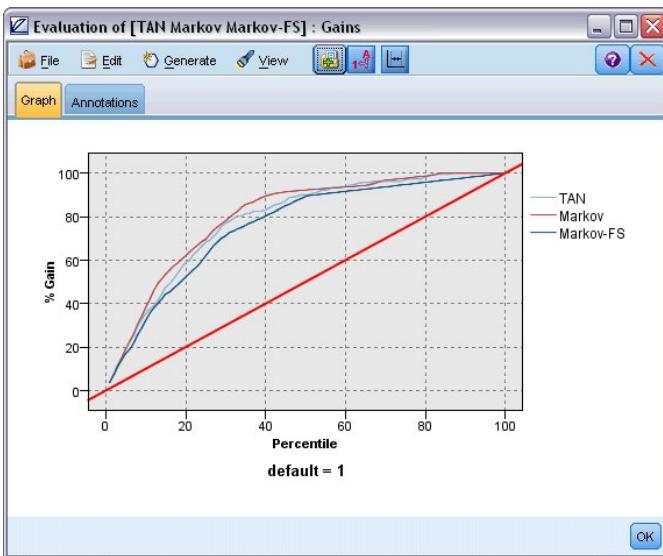

Figure 3. Rename model field names

To compare the models' predicted accuracy, you can build a gains chart.

7. Attach an Evaluation graph node to the Filter node and execute the graph node using its default settings. The graph shows that each model type produces similar results; however, the Markov model is slightly better.

Figure 4. Evaluating model accuracy

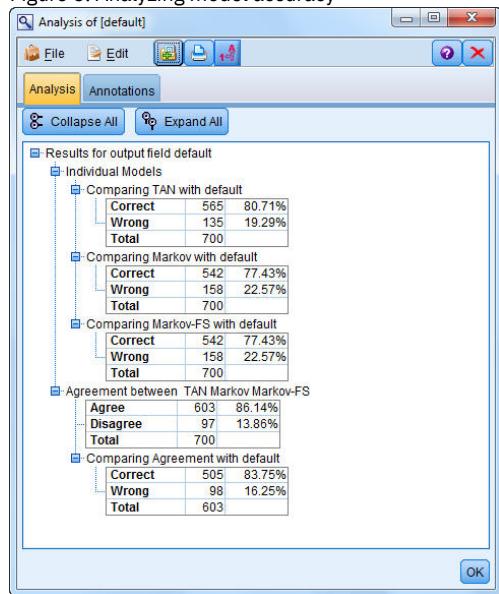

To check how well each model predicts, you could use an Analysis node instead of the Evaluation graph. This shows the accuracy in terms of percentage for both correct and incorrect predictions.

8. Attach an Analysis node to the Filter node and execute the Analysis node using its default settings.

As with the Evaluation graph, this shows that the Markov model is slightly better at predicting correctly; however, the Markov-FS model is only a few percentage points behind the Markov model. This may mean it would be better to use the Markov-FS model since it uses fewer inputs to calculate its results, thereby saving on data collection and entry time and processing time.

Figure 5. Analyzing model accuracy

Explanations of the mathematical foundations of the modeling methods used in IBM® SPSS® Modeler are listed in the *IBM SPSS Modeler Algorithms Guide*, available from the *|Documentation* directory of the installation disk.

Note also that these results are based on the training data only. To assess how well the model generalizes to other data in the real world, you would use a Partition node to hold out a subset of records for purposes of testing and validation.

Retraining a Model on a Monthly Basis (Bayesian Network)

Bayesian networks enable you to build a probability model by combining observed and recorded evidence with "common-sense" real-world knowledge to establish the likelihood of occurrences by using seemingly unlinked attributes.

This example uses the stream named *bayes_churn_retrain.str*, which references the data files named *telco_Jan.sav* and *telco_Feb.sav*. These files are available from the *Demos* directory of any IBM® SPSS® Modeler installation and can be accessed from the IBM SPSS Modeler program group on the Windows Start menu. The *bayes_churn_retrain.str* file is in the *streams* directory.

For example, suppose that a telecommunications provider is concerned about the number of customers it is losing to competitors (churn). If historic customer data can be used to predict which customers are more likely to churn in the future, these customers can be targeted with incentives or other offers to discourage them from transferring to another service provider.

This example focuses on using an existing month's churn data to predict which customers may be likely to churn in the future and then adding the following month's data to refine and retrain the model.

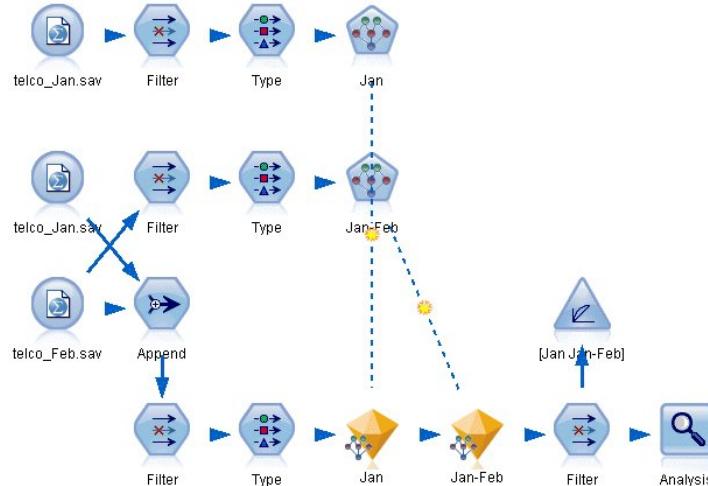

[Next](#)

- [Building the Stream](#)
- [Evaluating the model](#)

Building the Stream

1. Add a Statistics File source node pointing to *telco_Jan.sav* in the *Demos* folder.

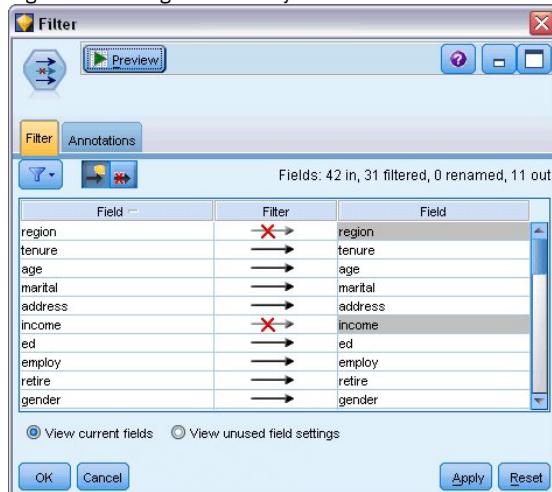

Figure 1. Bayesian Network sample stream

Previous analysis has shown you that several data fields are of little importance when predicting churn. These fields can be filtered from your data set to increase the speed of processing when you are building and scoring models.

2. Add a Filter node to the Source node.
3. Exclude all fields except *address*, *age*, *churn*, *custcat*, *ed*, *employ*, *gender*, *marital*, *reside*, *retire*, and *tenure*.
4. Click OK.

Figure 2. Filtering unnecessary fields

5. Add a Type node to the Filter node.
6. Open the Type node and click the Read Values button to populate the *Values* column.
7. In order that the Evaluation node can assess which value is true and which is false, set the measurement level for the *churn* field to Flag, and set its role to Target. Click OK.

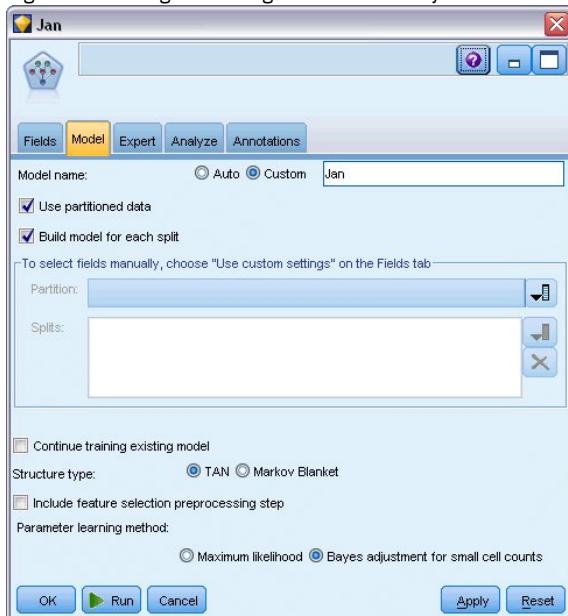

Figure 3. Selecting the target field

You can build several different types of Bayesian networks; however, for this example you are going to build a Tree Augmented Naïve Bayes (TAN) model. This creates a large network and ensures that you have included all possible links between data variables, thereby building a robust initial model.

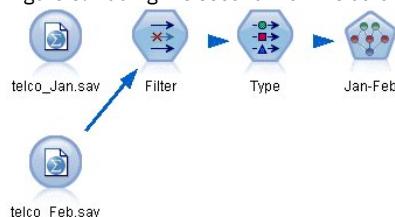

8. Attach a Bayesian Network node to the Type node.
9. On the Model tab, for Model name, select Custom and enter Jan in the text box.
10. For Parameter learning method, select Bayes adjustment for small cell counts.
11. Click Run. The model nugget is added to the stream, and also to the Models palette in the upper-right corner.

Figure 4. Creating a Tree Augmented Naïve Bayes model

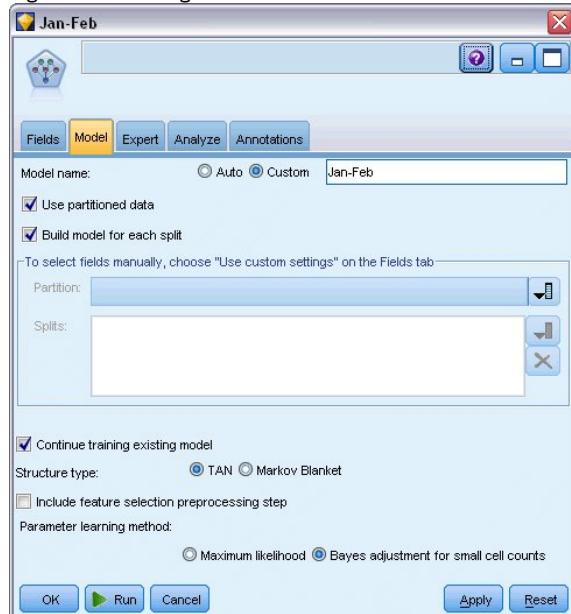

12. Add a Statistics File source node pointing to telco_Feb.sav in the Demos folder.
13. Attach this new source node to the Filter node (on the warning dialog, choose Replace to replace the connection to the previous source node).

Figure 5. Adding the second month's data

14. On the Model tab of the Bayesian Network node, for Model name, select Custom and enter Jan-Feb in the text box.
15. Select Continue training existing model.
16. Click Run. The model nugget overwrites the existing one in the stream, but is also added to the Models palette in the upper-right corner.

Figure 6. Retraining the model

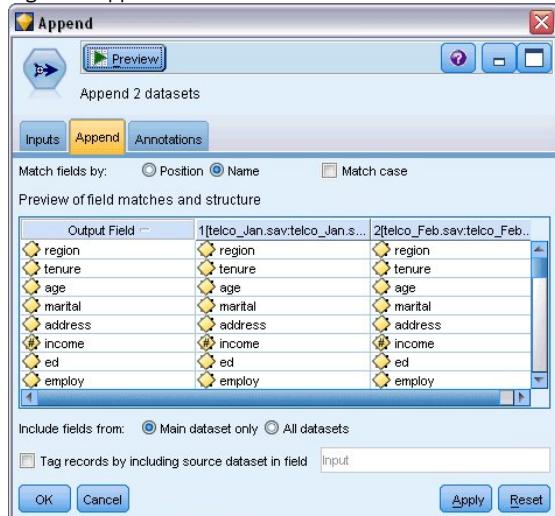

[Next](#)

Evaluating the model

To compare the models, you must combine the two datasets.

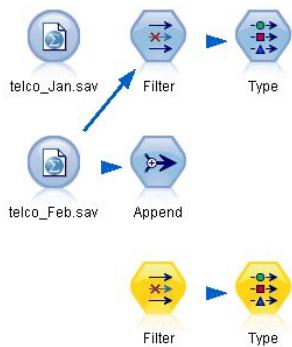

1. Add an Append node and attach both the *telco_Jan.sav* and *telco_Feb.sav* source nodes to it.

Figure 1. Append the two data sources

2. Copy the Filter and Type nodes from earlier in the stream and paste them onto the stream canvas.
3. Attach the Append node to the newly copied Filter node.

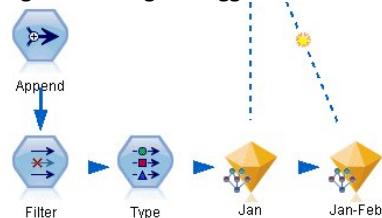

Figure 2. Pasting the copied nodes into the stream

The nuggets for the two Bayesian Network models are located in the Models palette in the upper-right corner.

4. Double-click the Jan model nugget to bring it into the stream, and attach it to the newly copied Type node.
 5. Attach the Jan-Feb model nugget already in the stream to the Jan model nugget.
 6. Open the Jan model nugget.

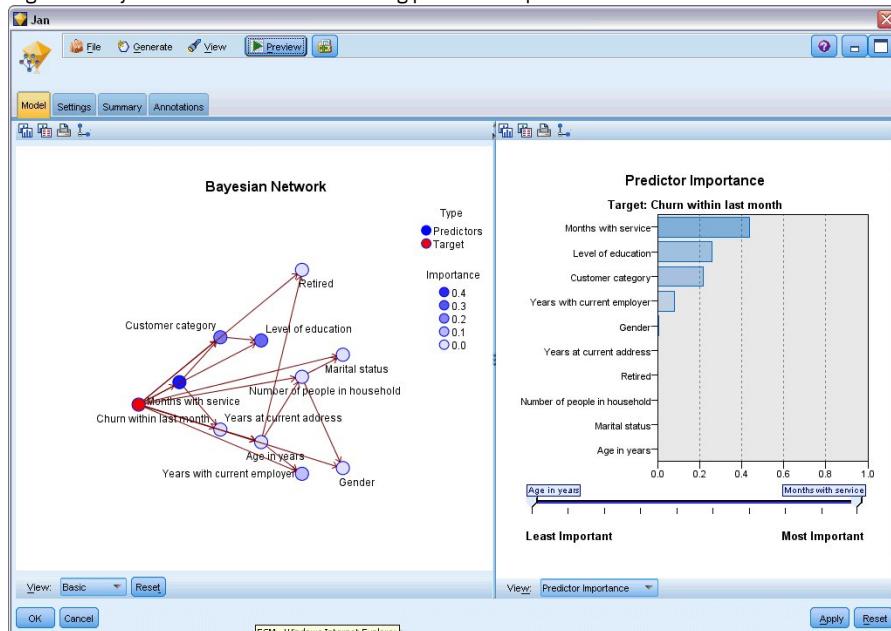

Figure 3. Adding the nuggets to the stream

The Bayesian Network model nugget Model tab is split into two columns. The left column contains a network graph of nodes that displays the relationship between the target and its most important predictors, as well as the relationship between the predictors.

The right column shows either *Predictor Importance*, which indicates the relative importance of each predictor in estimating the model, or *Conditional Probabilities*, which contains the conditional probability value for each node value and each combination of values in its parent nodes.

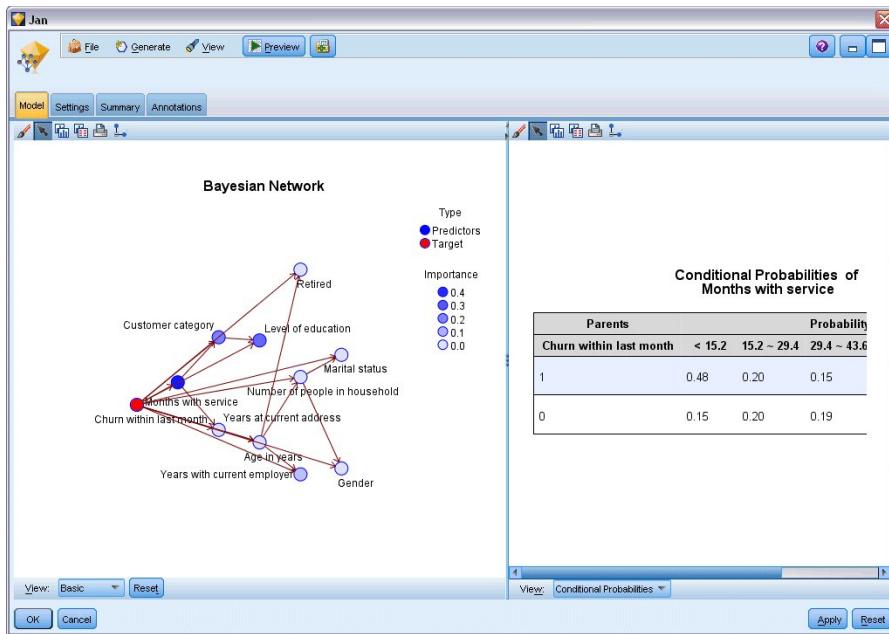

Figure 4. Bayesian Network model showing predictor importance

To display the conditional probabilities for any node, click on the node in the left column. The right column is updated to show the required details.

The conditional probabilities are shown for each bin that the data values have been divided into relative to the node's parent and sibling nodes.

Figure 5. Bayesian Network model showing conditional probabilities

7. To rename the model outputs for clarity, attach a Filter node to the Jan-Feb model nugget.
8. In the right *Field* column, rename \$B-churn as Jan and \$B1-churn as Jan-Feb.

Figure 6. Rename model field names

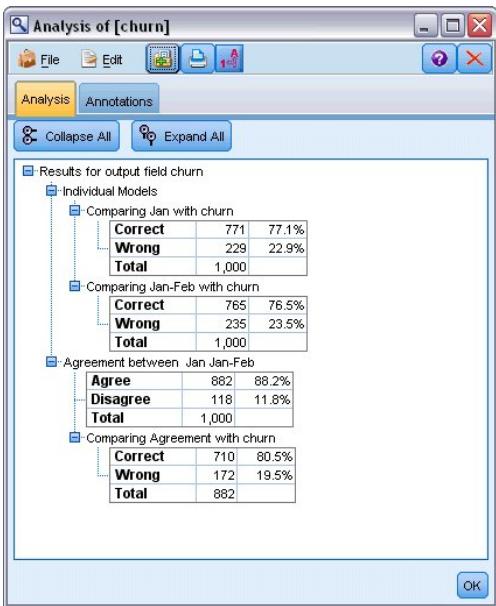

To check how well each model predicts churn, use an Analysis node; this shows the accuracy in terms of percentage for both correct and incorrect predictions.

9. Attach an Analysis node to the Filter node.
10. Open the Analysis node and click Run.

This shows that both models have a similar degree of accuracy when predicting churn.

Figure 7. Analyzing model accuracy

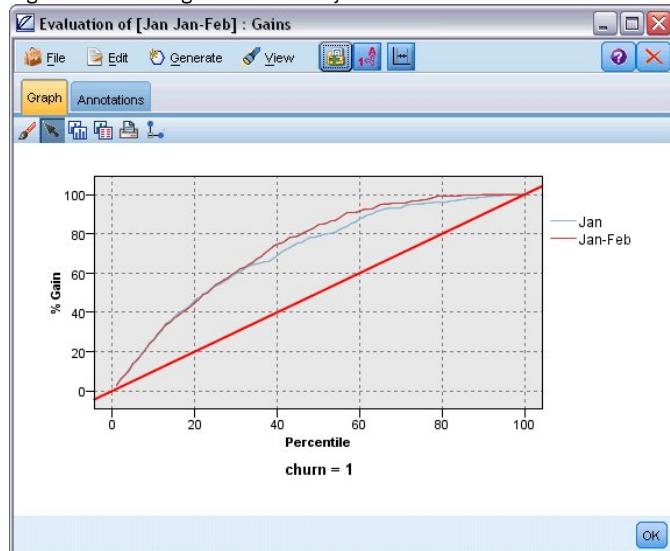

As an alternative to the Analysis node, you can use an Evaluation graph to compare the models' predicted accuracy by building a gains chart.

11. Attach an Evaluation graph node to the Filter node.

and execute the graph node using its default settings.

As with the Analysis node, the graph shows that each model type produces similar results; however, the retrained model using both months' data is slightly better because it has a higher level of confidence in its predictions.

Figure 8. Evaluating model accuracy

Explanations of the mathematical foundations of the modeling methods used in IBM® SPSS® Modeler are listed in the *IBM SPSS Modeler Algorithms Guide*, available from the *|Documentation* directory of the installation disk.

Note also that these results are based on the training data only. To assess how well the model generalizes to other data in the real world, you would use a Partition node to hold out a subset of records for purposes of testing and validation.

Retail Sales Promotion (Neural Net/C&RT)

This example deals with data that describes retail product lines and the effects of promotion on sales. (This data is fictitious.) Your goal in this example is to predict the effects of future sales promotions. Similar to the condition monitoring example, the data mining process consists of the exploration, data preparation, training, and test phases.

This example uses the streams named *goodsplot.str* and *goodslearn.str*, which reference the data files named *GOODS1n* and *GOODS2n*. These files are available from the *Demos* directory of any IBM® SPSS® Modeler installation. This can be accessed from the IBM SPSS Modeler program group on the Windows Start menu. The stream *goodsplot.str* is in the *streams* folder, while the *goodslearn.str* file is in the *streams* directory.

[Next](#)

- [Examining the Data](#)
- [Learning and Testing](#)

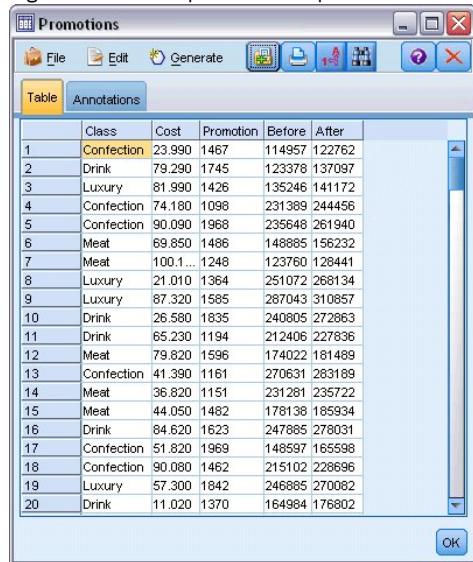

Examining the Data

Each record contains:

- *Class*. Product type.
- *Cost*. Unit price.
- *Promotion*. Index of amount spent on a particular promotion.
- *Before*. Revenue before promotion.
- *After*. Revenue after promotion.

The stream *goodsplot.str* contains a simple stream to display the data in a table. The two revenue fields (*Before* and *After*) are expressed in absolute terms; however, it seems likely that the increase in revenue after the promotion (and presumably as a result of it) would be a more useful figure.

Figure 1. Effects of promotion on product sales

The screenshot shows a software window titled "Promotions". At the top, there's a toolbar with icons for File, Edit, Generate, and others. Below the toolbar, there are two tabs: "Table" (which is selected) and "Annotations". The main area is a table with the following data:

	Class	Cost	Promotion	Before	After
1	Confection	23.990	1467	114957	122762
2	Drink	79.290	1745	123378	137097
3	Luxury	81.990	1426	135246	141172
4	Confection	74.180	1098	231389	244456
5	Confection	90.090	1968	235648	261940
6	Meat	69.850	1486	148885	156232
7	Meat	100.1...	1248	123760	128441
8	Luxury	21.010	1364	251072	268134
9	Luxury	87.320	1585	287043	310857
10	Drink	26.580	1835	240805	272863
11	Drink	65.230	1194	212406	227836
12	Meat	79.820	1596	174022	181489
13	Confection	41.390	1161	270631	283189
14	Meat	36.820	1151	231281	235722

20	Drink	11.020	1370	164984	176802

At the bottom right of the table is an "OK" button.

goodsplot.str also contains a node to derive this value, expressed as a percentage of the revenue before the promotion, in a field called *Increase* and displays a table showing this field.

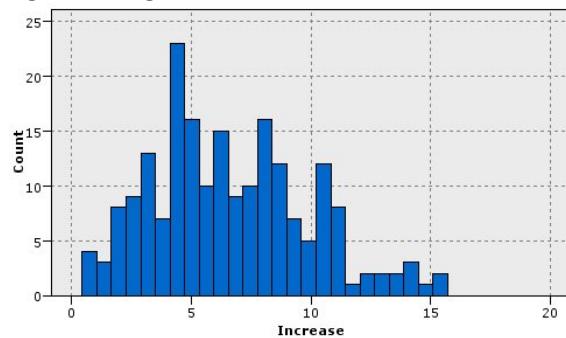

Figure 2. Increase in revenue after promotion

Promotions

	Class	Cost	Promotion	Before	After	Increase

19	Luxury	57.300	1842	246885	270082	9.396
20	Drink	11.020	1370	164984	176802	7.163

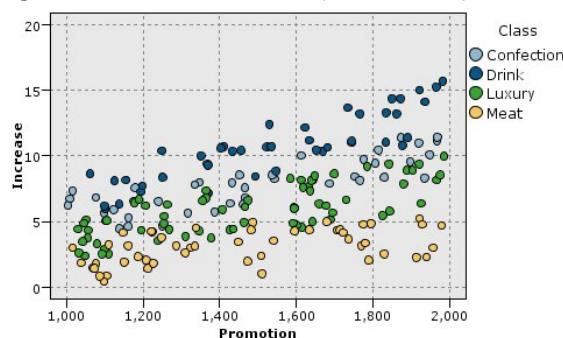

In addition, the stream displays a histogram of the increase and a scatterplot of the increase against the promotion costs expended, overlaid with the category of product involved.

Figure 3. Histogram of increase in revenue

The scatterplot shows that for each class of product, an almost linear relationship exists between the increase in revenue and the cost of promotion. Therefore, it seems likely that a decision tree or neural network could predict, with reasonable accuracy, the increase in revenue from the other available fields.

Figure 4. Revenue increase versus promotional expenditure

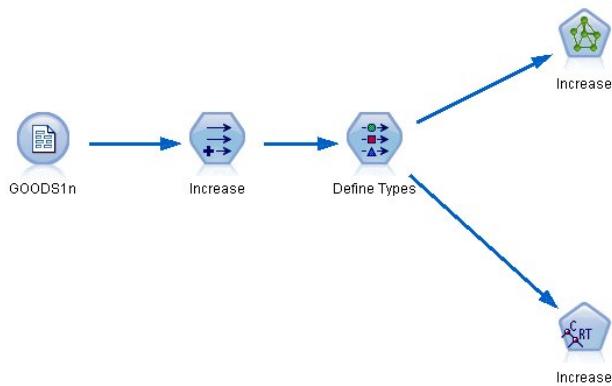

[Next](#)

Learning and Testing

The stream goodslearn.str trains a neural network and a decision tree to make this prediction of revenue increase.

Figure 1. Modeling stream goodslearn.str

Once you have executed the model nodes and generated the actual models, you can test the results of the learning process. You do this by connecting the decision tree and network in series between the Type node and a new Analysis node, changing the input (data) file to GOODS2n, and executing the Analysis node. From the output of this node, in particular from the linear correlation between the predicted increase and the correct answer, you will find that the trained systems predict the increase in revenue with a high degree of success.

Further exploration could focus on the cases where the trained systems make relatively large errors; these could be identified by plotting the predicted increase in revenue against the actual increase. Outliers on this graph could be selected using the interactive graphics within SPSS® Modeler, and from their properties, it might be possible to tune the data description or learning process to improve accuracy.

Condition Monitoring (Neural Net/C5.0)

This example concerns monitoring status information from a machine and the problem of recognizing and predicting fault states. The data is created from a fictitious simulation and consists of a number of concatenated series measured over time. Each record is a snapshot report on the machine in terms of the following:

- *Time*. An integer.
- *Power*. An integer.
- *Temperature*. An integer.
- *Pressure*. 0 if normal, 1 for a momentary pressure warning.
- *Uptime*. Time since last serviced.
- *Status*. Normally 0, changes to error code on error (101, 202, or 303).
- *Outcome*. The error code that appears in this time series, or 0 if no error occurs. (These codes are available only with the benefit of hindsight.)

This example uses the streams named *condplot.str* and *condlearn.str*, which reference the data files named *COND1n* and *COND2n*. These files are available from the *Demos* directory of any IBM® SPSS® Modeler installation. This can be accessed from the IBM SPSS Modeler program group on the Windows Start menu. The *condplot.str* and *condlearn.str* files are in the *streams* directory.

For each time series, there is a series of records from a period of normal operation followed by a period leading to the fault, as shown in the following table:

Time	Power	Temperature	Pressure	Uptime	Status	Outcome
0	1059	259	0	404	0	0
1	1059	259	0	404	0	0
		...				
51	1059	259	0	404	0	0
52	1059	259	0	404	0	0
53	1007	259	0	404	0	303
54	998	259	0	404	0	303
		...				
89	839	259	0	404	0	303
90	834	259	0	404	303	303
0	965	251	0	209	0	0
1	965	251	0	209	0	0
		...				
51	965	251	0	209	0	0
52	965	251	0	209	0	0
53	938	251	0	209	0	101
54	936	251	0	209	0	101

Time	Power	Temperature	Pressure	Uptime	Status	Outcome
			...			
208	644	251	0	209	0	101
209	640	251	0	209	101	101

The following process is common to most data mining projects:

- Examine the data to determine which attributes may be relevant to the prediction or recognition of the states of interest.
- Retain those attributes (if already present), or derive and add them to the data, if necessary.
- Use the resultant data to train rules and neural nets.
- Test the trained systems using independent test data.

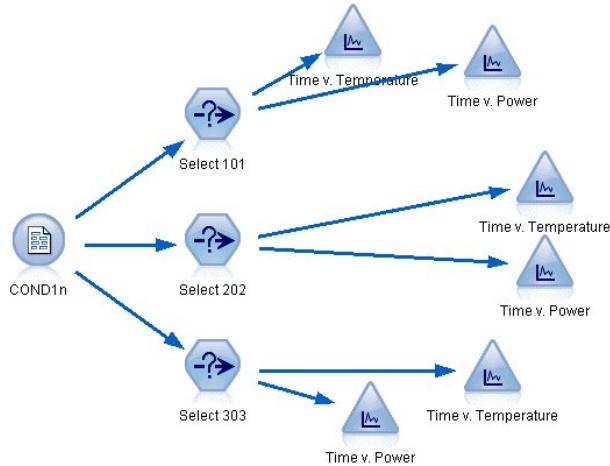

[Next](#)

- [Examining the Data](#)
- [Data Preparation](#)
- [Learning](#)
- [Testing](#)

Examining the Data

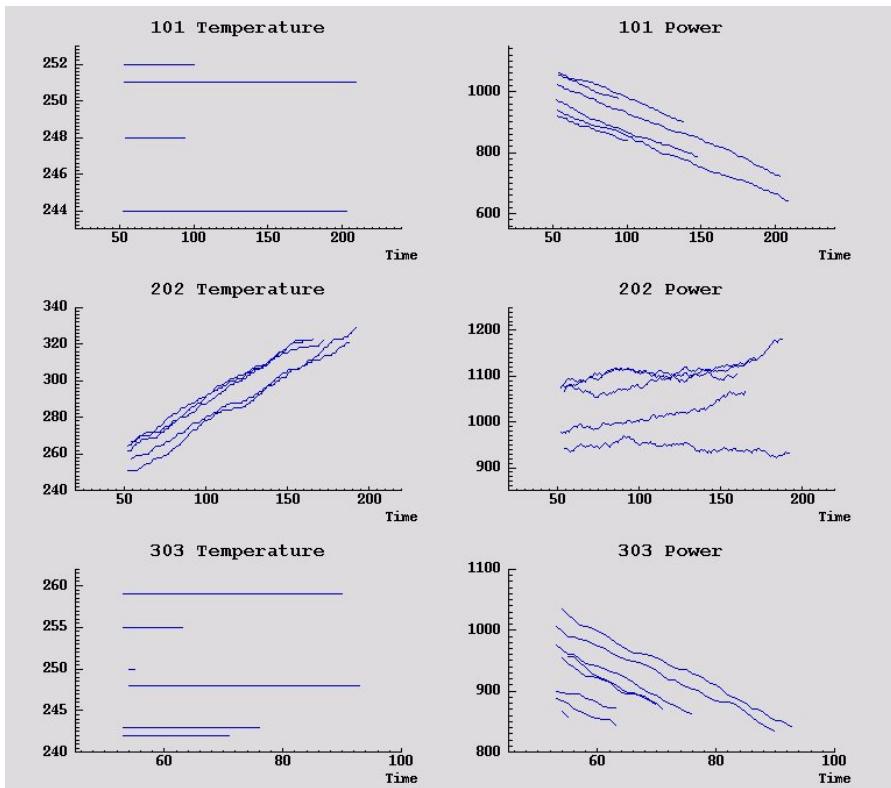

The file *condplot.str* illustrates the first part of the process. It contains a stream that plots a number of graphs. If the time series of temperature or power contains visible patterns, you could differentiate between impending error conditions or possibly predict their occurrence. For both temperature and power, the stream below plots the time series associated with the three different error codes on separate graphs, yielding six graphs. Select nodes separate the data associated with the different error codes.

Figure 1. Condplot stream

The results of this stream are shown in this figure.

Figure 2. Temperature and power over time

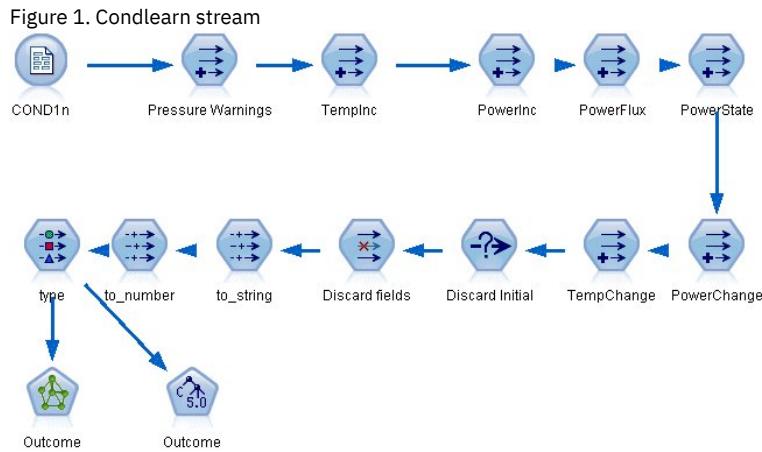

The graphs clearly display patterns distinguishing 202 errors from 101 and 303 errors. The 202 errors show rising temperature and fluctuating power over time; the other errors do not. However, patterns distinguishing 101 from 303 errors are less clear. Both errors show even temperature and a drop in power, but the drop in power seems steeper for 303 errors.

Based on these graphs, it appears that the presence and rate of change for both temperature and power, as well as the presence and degree of fluctuation, are relevant to predicting and distinguishing faults. These attributes should therefore be added to the data before applying the learning systems.

[Next](#)

Data Preparation

Based on the results of exploring the data, the stream *condlearn.str* derives the relevant data and learns to predict faults.

The stream uses a number of Derive nodes to prepare the data for modeling.

- **Variable File node.** Reads data file *COND1n*.
- **Derive Pressure Warnings.** Counts the number of momentary pressure warnings. Reset when time returns to 0.
- **Derive TempInc.** Calculates momentary rate of temperature change using `@DIFF1`.
- **Derive PowerInc.** Calculates momentary rate of power change using `@DIFF1`.

- **Derive PowerFlux**. A flag, true if power varied in opposite directions in the last record and this one; that is, for a power peak or trough.
- **Derive PowerState**. A state that starts as *Stable* and switches to *Fluctuating* when two successive power fluxes are detected. Switches back to *Stable* only when there hasn't been a power flux for five time intervals or when *Time* is reset.
- **PowerChange**. Average of *PowerInc* over the last five time intervals.
- **TempChange**. Average of *TempInc* over the last five time intervals.
- **Discard Initial (select)**. Discards the first record of each time series to avoid large (incorrect) jumps in *Power* and *Temperature* at boundaries.
- **Discard fields**. Cuts records down to *Uptime*, *Status*, *Outcome*, *Pressure Warnings*, *PowerState*, *PowerChange*, and *TempChange*.
- **Type**. Defines the role of *Outcome* as Target (the field to predict). In addition, defines the measurement level of *Outcome* as Nominal, *Pressure Warnings* as Continuous, and *PowerState* as Flag.

[Next](#)

Learning

Running the stream in *condlearn.str* trains the C5.0 rule and neural network (net). The network may take some time to train, but training can be interrupted early to save a net that produces reasonable results. Once the learning is complete, the Models tab at the upper right of the managers window flashes to alert you that two new nuggets were created: one represents the neural net and one represents the rule.

Figure 1. Models manager with model nuggets

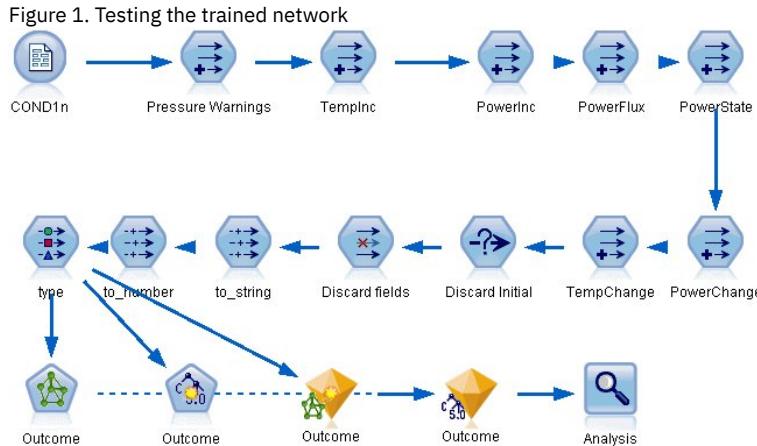

The model nuggets are also added to the existing stream, enabling us to test the system or export the results of the model. In this example, we will test the results of the model.

[Next](#)

Testing

The model nuggets are added to the stream, both of them connected to the Type node.

1. Reposition the nuggets as shown, so that the Type node connects to the neural net nugget, which connects to the C5.0 nugget.
2. Attach an Analysis node to the C5.0 nugget.
3. Edit the original source node to read the file *COND2n* (instead of *COND1n*), as *COND2n* contains unseen test data.

4. Open the Analysis node and click Run.

Doing so yields figures reflecting the accuracy of the trained network and rule.

Classifying Telecommunications Customers (Discriminant Analysis)

Discriminant analysis is a statistical technique for classifying records based on values of input fields. It is analogous to linear regression but takes a categorical target field instead of a numeric one.

For example, suppose a telecommunications provider has segmented its customer base by service usage patterns, categorizing the customers into four groups. If demographic data can be used to predict group membership, you can customize offers for individual prospective customers.

This example uses the stream named *telco_custcat_discriminant.str*, which references the data file named *telco.sav*. These files are available from the *Demos* directory of any IBM® SPSS® Modeler installation. This can be accessed from the IBM SPSS Modeler program group on the Windows Start menu. The *telco_custcat_discriminant.str* file is in the *streams* directory.

The example focuses on using demographic data to predict usage patterns. The target field *custcat* has four possible values which correspond to the four customer groups, as follows:

Value	Label
1	Basic Service
2	E-Service
3	Plus Service
4	Total Service

- [Creating the Stream](#)
- [Examining the Model](#)
- [Summary](#)

Creating the Stream

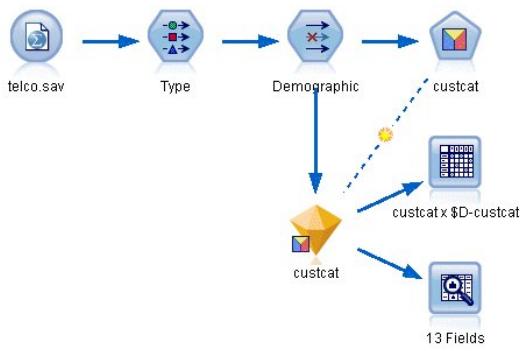

1. First, set the stream properties to show variable and value labels in the output. From the menus, choose:
File > *Stream Properties*... > *Options* > *General*
2. Make sure that *Display field and value labels in output* is selected and click *OK*.

Figure 1. Stream properties

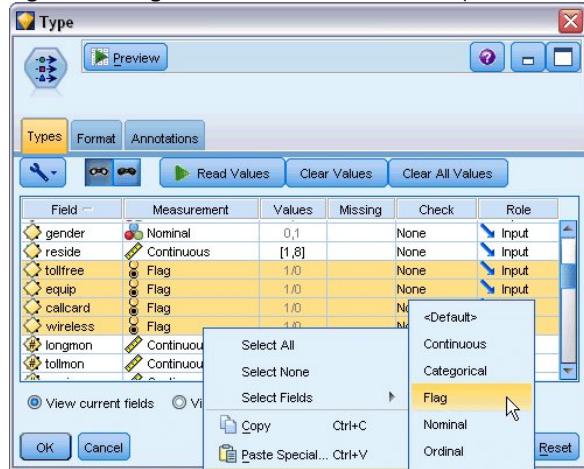

3. Add a Statistics File source node pointing to *telco.sav* in the *Demos* folder.

Figure 2. Sample stream to classify customers using discriminant analysis

- a. Add a Type node and click Read Values, making sure that all measurement levels are set correctly. For example, most fields with values 0 and 1 can be regarded as flags.

Figure 3. Setting the measurement level for multiple fields

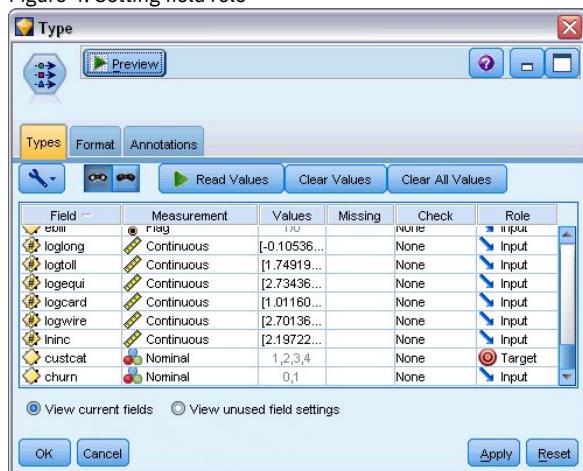

Tip: To change properties for multiple fields with similar values (such as 0/1), click the *Values* column header to sort fields by value, and then hold down the shift key while using the mouse or arrow keys to select all the fields you want to change. You can then right-click on the selection to change the measurement level or other attributes of the selected fields.

Notice that *gender* is more correctly considered as a field with a set of two values, instead of a flag, so leave its Measurement value as Nominal.

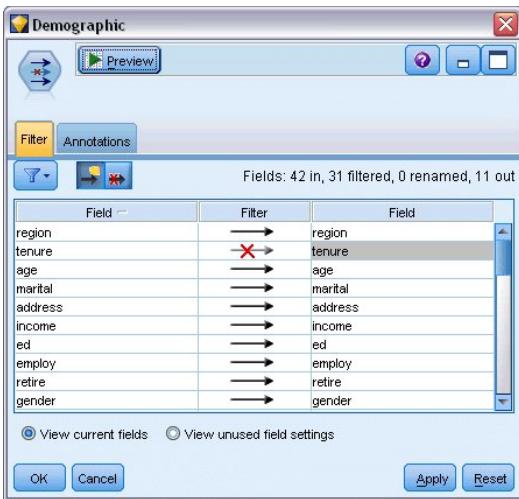

- b. Set the role for the *custcat* field to Target. All other fields should have their role set to Input.

Figure 4. Setting field role

Since this example focuses on demographics, use a Filter node to include only the relevant fields (*region, age, marital, address, income, ed, employ, retire, gender, reside, and custcat*). Other fields can be excluded for the purpose of this analysis.

Figure 5. Filtering on demographic fields

(Alternatively, you could change the role to None for these fields rather than exclude them, or select the fields you want to use in the modeling node.)

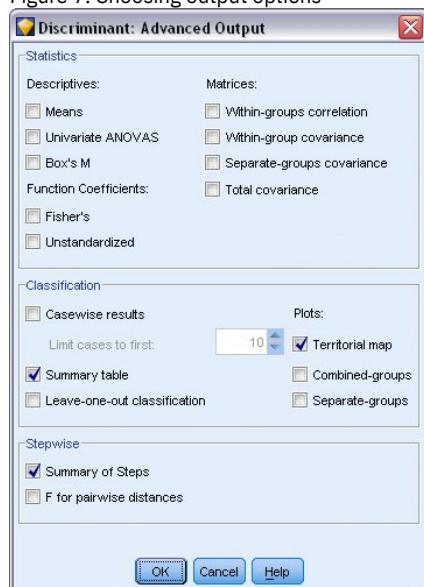

4. In the Discriminant node, click the Model tab and select the Stepwise method.

Figure 6. Choosing model options

5. On the Expert tab, set the mode to Expert and click Output.
6. Select Summary table, Territorial map, and Summary of Steps in the Advanced Output dialog box, then click OK.

Figure 7. Choosing output options

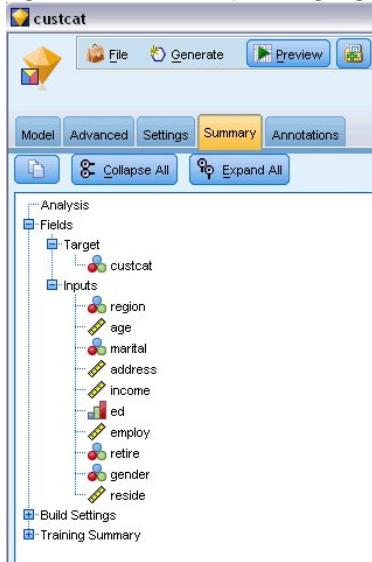

Examining the Model

1. Click Run to create the model, which is added to the stream and to the Models palette in the upper-right corner. To view its details, double-click on the model nugget in the stream.

The Summary tab shows (among other things) the target and the complete list of inputs (predictor fields) submitted for consideration.

Figure 1. Model summary showing target and input fields

For details of the discriminant analysis results:

2. Click the Advanced tab.
3. Click the "Launch in external browser" button (just below the Model tab) to view the results in your Web browser.

Stepwise Discriminant analysis

Figure 1. Variables not in the analysis

Variables Not in the Analysis

Step		Tolerance	Min. Tolerance	F to Enter	Wilks' Lambda
0	Age in years	1.000	1.000	7.521	.978
	Marital status	1.000	1.000	3.500	.990
	Years at current address	1.000	1.000	8.433	.975
	Household income in thousands	1.000	1.000	6.689	.980
	Level of education	1.000	1.000	61.454	.844
	Years with current employer	1.000	1.000	16.976	.951
	Retired	1.000	1.000	3.005	.991
	Gender	1.000	1.000	.373	.999
	Number of people in household	1.000	1.000	3.976	.988
	Age in years	.980	.980	6.125	.829
1	Marital status	.999	.999	3.803	.834
	Years at current address	.983	.983	8.487	.823
	Household income in thousands	.989	.989	6.022	.829
	Years with current employer	.953	.953	14.933	.807
	Retired	.992	.992	1.432	.840
	Gender	1.000	1.000	.358	.843
	Number of people in household	1.000	1.000	3.967	.834
	Age in years	.563	.548	.352	.807
	Marital status	.999	.952	3.903	.798

When you have a lot of predictors, the stepwise method can be useful by automatically selecting the "best" variables to use in the model. The stepwise method starts with a model that doesn't include any of the predictors. At each step, the predictor with the largest *F to Enter* value that exceeds the entry criteria (by default, 3.84) is added to the model.

The variables left out of the analysis at the last step all have *F to Enter* values smaller than 3.84, so no more are added.

Figure 2. Variables in the analysis

Variables in the Analysis

Step		Tolerance	F to Remove	Wilks' Lambda
1	Level of education	1.000	61.454	
	Level of education	.953	59.108	.951
	Years with current employer	.953	14.933	.844
	Level of education	.951	60.046	.940
	Years with current employer	.934	15.824	.834
	Number of people in household	.979	4.841	.807

This table displays statistics for the variables that are in the analysis at each step. *Tolerance* is the proportion of a variable's variance not accounted for by other independent variables in the equation. A variable with very low tolerance contributes little information to a model and can cause computational problems.

F to Remove values are useful for describing what happens if a variable is removed from the current model (given that the other variables remain). *F to Remove* for the entering variable is the same as *F to Enter* at the previous step (shown in the *Variables Not in the Analysis* table).

[Next](#)

A note of caution concerning stepwise methods

Stepwise methods are convenient, but have their limitations. Be aware that because stepwise methods select models based solely upon statistical merit, it may choose predictors that have no *practical significance*. If you have some experience with the data and have expectations about which predictors are important, you should use that knowledge and eschew stepwise methods. If, however, you have many predictors and no idea where to start, running a stepwise analysis and adjusting the selected model is better than no model at all.

[Next](#)

Checking model fit

Figure 1. Eigenvalues

Eigenvalues				
Function	Eigenvalue	% of Variance	Cumulative %	Canonical Correlation
1	.198 ^a	80.2	80.2	.407
2	.048 ^a	19.4	99.6	.214
3	.001 ^a	.4	100.0	.031

a.First 3 canonical discriminant functions were used in the analysis.

Nearly all of the variance explained by the model is due to the first two discriminant functions. Three functions are fit automatically, but due to its minuscule eigenvalue, you can fairly safely ignore the third.

Figure 2. Wilks' lambda

Wilks' Lambda				
Test of Function(s)	Wilks' Lambda	Chi-square	df	Sig.
1 through 3	.796	227.345	9	<.001
2 through 3	.953	47.486	4	<.001
3	.999	.929	1	.335

Wilks' lambda agrees that only the first two functions are useful. For each set of functions, this tests the hypothesis that the means of the functions listed are equal across groups. The test of function 3 has a significance value greater than 0.10, so this function contributes little to the model.

[Next](#)

Structure matrix

Figure 1. Structure matrix

Structure Matrix

	Function		
	1	2	3
Level of education	.966*	-.090	-.244
Years with current employer	-.182	.964*	-.193
Age in years^b	-.162	.598*	-.285
Household income in thousands^b	.109	.514*	-.190
Years at current address^b	-.151	.394*	-.214
Retired^b	-.108	.230*	-.137
Gender^b	.008	.054*	.009
Number of people in household	.232	.097	.968*
Marital status^b	.132	.134	.600*

Pooled within-groups correlations between discriminating variables and standardized canonical discriminant functions
Variables ordered by absolute size of correlation within function.

*.Largest absolute correlation between each variable and any discriminant function

b.This variable not used in the analysis.

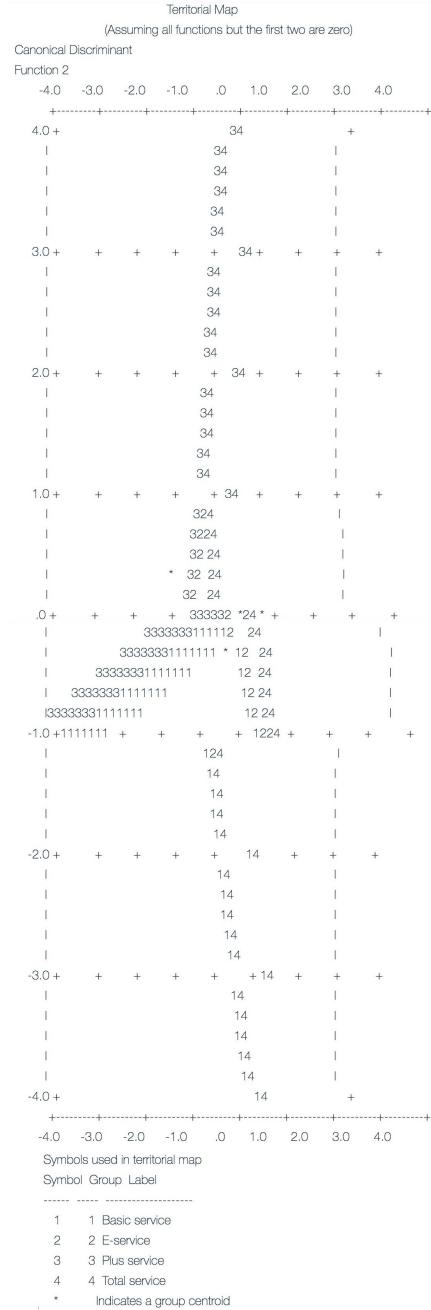

When there is more than one discriminant function, an asterisk(*) marks each variable's largest absolute correlation with one of the canonical functions. Within each function, these marked variables are then ordered by the size of the correlation.

- *Level of education* is most strongly correlated with the first function, and it is the only variable most strongly correlated with this function.
- *Years with current employer*, *Age in years*, *Household income in thousands*, *Years at current address*, *Retired*, and *Gender* are most strongly correlated with the second function, although *Gender* and *Retired* are more weakly correlated than the others. The other variables mark this function as a "stability" function.
- *Number of people in household* and *Marital status* are most strongly correlated with the third discriminant function, but this is a useless function, so these are nearly useless predictors.

[Next](#)

Territorial map

Figure 1. Territorial map

The territorial map helps you to study the relationships between the groups and the discriminant functions. Combined with the structure matrix results, it gives a graphical interpretation of the relationship between predictors and groups. The first function, shown on the horizontal axis, separates group 4 (*Total service customers*) from the others. Since *Level of education* is strongly positively correlated with the first function, this suggests that your *Total service customers* are, in general, the most highly educated. The second function separates groups 1 and 3 (*Basic service* and *Plus service customers*). *Plus service* customers tend to have been working longer and are older than *Basic service* customers. *E-service* customers are not separated well from the others, although the map suggests that they tend to be well educated with a moderate amount of work experience.

In general, the closeness of the group centroids, marked with asterisks (*), to the territorial lines suggests that the separation between all groups is not very strong.

Only the first two discriminant functions are plotted, but since the third function was found to be rather insignificant, the territorial map offers a comprehensive view of the discriminant model.

[Next](#)

Classification results

Figure 1. Classification results

		Classification Results ^a					Total	
		Customer category	Basic service	E-service	Plus service	Total service		
Original	Count	Basic service	125	11	61	69	266	
		E-service	49	15	58	95	217	
		Plus service	102	14	112	53	281	
	%	Total service	40	16	37	143	236	
		Basic service	47.0	4.1	22.9	25.9	100.0	
		E-service	22.6	6.9	26.7	43.8	100.0	
		Plus service	36.3	5.0	39.9	18.9	100.0	
		Total service	16.9	6.8	15.7	60.6	100.0	

^a39.5% of original grouped cases correctly classified.

From Wilks' lambda, you know that your model is doing better than guessing, but you need to turn to the classification results to determine how much better. Given the observed data, the "null" model (that is, one without predictors) would classify all customers into the modal group, *Plus service*. Thus, the null model would be correct 281/1000 = 28.1% of the time. Your model gets 11.4% more or 39.5% of the customers. In particular, your model excels at identifying *Total service* customers. However, it does an exceptionally poor job of classifying *E-service* customers. You may need to find another predictor in order to separate these customers.

[Next](#)

Summary

You have created a discriminant model that classifies customers into one of four predefined "service usage" groups, based on demographic information from each customer. Using the structure matrix and territorial map, you identified which variables are most useful for segmenting your customer base. Lastly, the classification results show that the model does poorly at classifying *E-service* customers. More research is required to determine another predictor variable that better classifies these customers, but depending on what you are looking to predict, the model may be perfectly adequate for your needs. For example, if you are not concerned with identifying *E-service* customers the model may be accurate enough for you. This may be the case where the *E-service* is a loss-leader which brings in little profit. If, for example, your highest return on investment comes from *Plus service* or *Total service* customers, the model may give you the information you need.

Also note that these results are based on the training data only. To assess how well the model generalizes to other data, you can use a Partition node to hold out a subset of records for purposes of testing and validation.

Explanations of the mathematical foundations of the modeling methods used in IBM® SPSS® Modeler are listed in the IBM SPSS Modeler Algorithms Guide. This is available from the |Documentation directory of the installation disk.

Analyzing interval-censored survival data (Generalized Linear Models)

When analyzing survival data with interval censoring—that is, when the exact time of the event of interest is not known but is known only to have occurred within a given interval—then applying the Cox model to the hazards of events in intervals results in a complementary log-log regression model.

Partial information from a study designed to compare the efficacy of two therapies for preventing the recurrence of ulcers is collected in *ulcer_recurrence.sav*. This dataset has been presented and analyzed elsewhere¹. Using generalized linear models, you can replicate the results for the complementary log-log regression models.

This example uses the stream named *ulcer_genlin.str*, which references the data file *ulcer_recurrence.sav*. The data file is in the *Demos* folder and the stream file is in the *streams* subfolder.

¹ Collett, D. 2003. *Modelling survival data in medical research*, 2 ed. Boca Raton: Chapman & Hall/CRC.

Creating the Stream

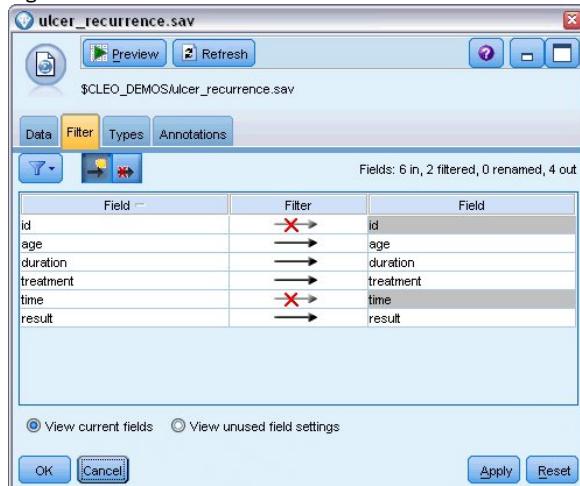

1. Add a Statistics File source node pointing to *ulcer_recurrence.sav* in the *Demos* folder.

Figure 1. Sample stream to predict ulcer recurrence

2. On the Filter tab of the source node, filter out *id* and *time*.

Figure 2. Filter unwanted fields

3. On the Types tab of the source node, set the role for the *result* field to Target and set its measurement level to Flag. A result of 1 indicates that the ulcer has recurred. All other fields should have their role set to Input.
4. Click Read Values to instantiate the data.

Figure 3. Setting field role

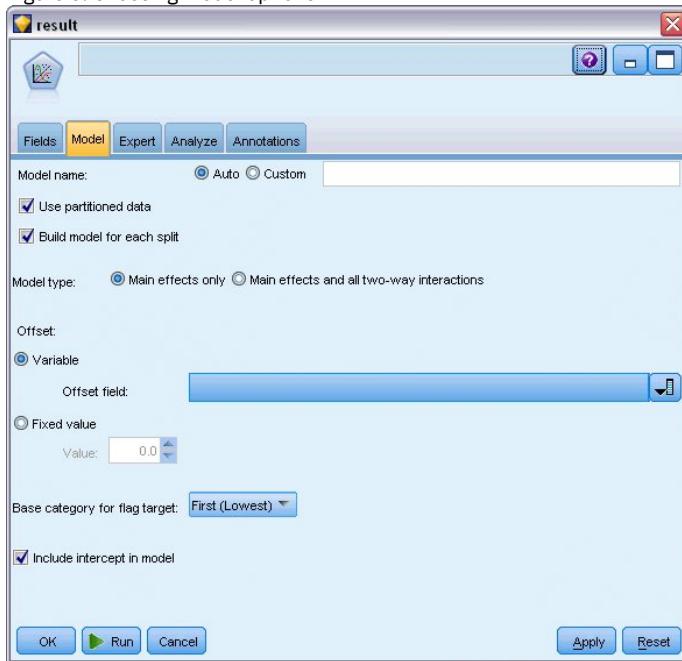

5. Add a Field Reorder node and specify *duration*, *treatment*, and *age* as the order of inputs. This determines the order in which fields are entered in the model and will help you try to replicate Collett's results.

Figure 4. Reordering fields so they are entered into the model as desired

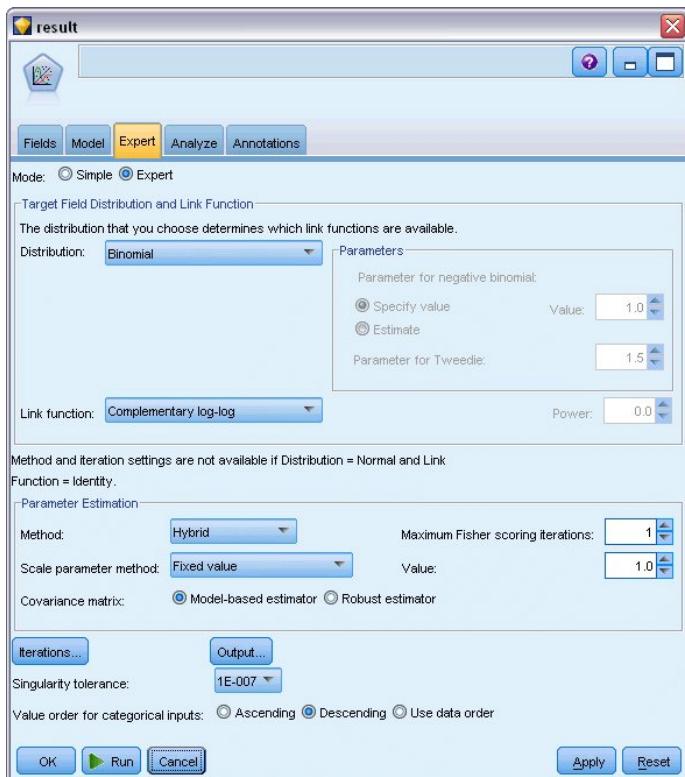

6. Attach a GenLin node to the source node; on the GenLin node, click the Model tab.
 7. Select First (Lowest) as the reference category for the target. This indicates that the second category is the event of interest, and its effect on the model is in the interpretation of parameter estimates. A continuous predictor with a positive coefficient indicates increased probability of recurrence with increasing values of the predictor; categories of a nominal predictor with larger coefficients indicate increased probability of recurrence with respect to other categories of the set.

Figure 5. Choosing model options

8. Click the Expert tab and select Expert to activate the expert modeling options.
 9. Select Binomial as the distribution and Complementary log-log as the link function.
 10. Select Fixed value as the method for estimating the scale parameter and leave the default value of 1.0.
 11. Select Descending as the category order for factors. This indicates that the first category of each factor will be its reference category; the effect of this selection on the model is in the interpretation of parameter estimates.

Figure 6. Choosing expert options

[Treatment group=1]	.378	.6288	-.855	1.610	.361	1	.548
[Treatment group=0]	0 ^a
(Scale)	1 ^b						

Dependent Variable: Result

Model: (Intercept), Treatment group

a. Set to zero because this parameter is redundant.

b. Fixed at the displayed value.

The treatment effect (the difference of the linear predictor between the two treatment levels; that is, the coefficient for *treatment=1*) is still not statistically significant, but only suggestive that treatment A [*treatment=0*] may be better than B [*treatment=1*] because the parameter estimate for treatment B is larger than that for A, and is thus associated with an increased probability of recurrence in the first 12 months. The linear predictor, (intercept + treatment effect) is an estimate of $\log(-\log(1-P(\text{recur}_{12,t})))$, where $P(\text{recur}_{12,t})$ is the probability of recurrence at 12 months for treatment t(A or B). These predicted probabilities are generated for each observation in the dataset.

6	0	2	0	49	0	0.789	0.789	0.211
7	0	1	1	71	0	0.708	0.708	0.292
8	0	1	0	41	0	0.789	0.789	0.211
9	0	1	1	23	0	0.708	0.708	0.292
10	1	1	1	37	0	0.708	0.708	0.292
11	0	1	1	38	0	0.708	0.708	0.292
12	0	2	1	76	0	0.708	0.708	0.292
13	0	2	0	38	0	0.789	0.789	0.211
14	1	1	0	27	0	0.789	0.789	0.211
15	1	1	1	47	0	0.708	0.708	0.292
16	0	1	0	54	0	0.789	0.789	0.211
17	1	1	1	38	0	0.708	0.708	0.292
18	1	2	1	27	0	0.708	0.708	0.292
19	0	2	0	58	0	0.789	0.789	0.211
20	0	1	1	75	0	0.708	0.708	0.292

There is an estimated 0.211 probability that patients assigned to treatment A will experience a recurrence in the first 12 months; 0.292 for treatment B. Note that $1 - P(\text{recur}_{12}, t)$ is the survivor probability at 12 months, which may be of more interest to survival analysts.

[Next](#)

Modeling the recurrence probability by period

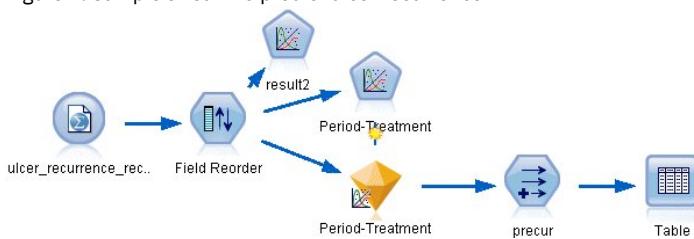

A problem with the model as it stands is that it ignores the information gathered at the first examination; that is, that many patients did not experience a recurrence in the first six months. A "better" model would model a binary response that records whether or not the event occurred during each interval. Fitting this model requires a reconstruction of the original dataset, which can be found in *ulcer_recurrence_recoded.sav*. This file contains two additional variables:

- *Period*, which records whether the case corresponds to the first examination period or the second.
- *Result by period*, which records whether there was a recurrence for the given patient during the given period.

Each original case (patient) contributes one case per interval in which it remains in the risk set. Thus, for example, patient 1 contributes two cases; one for the first examination period in which no recurrence occurred, and one for the second examination period, in which a recurrence was recorded. Patient 10, on the other hand, contributes a single case because a recurrence was recorded in the first period. Patients 16, 28, and 34 dropped out of the study after six months, and thus contribute only a single case to the new dataset.

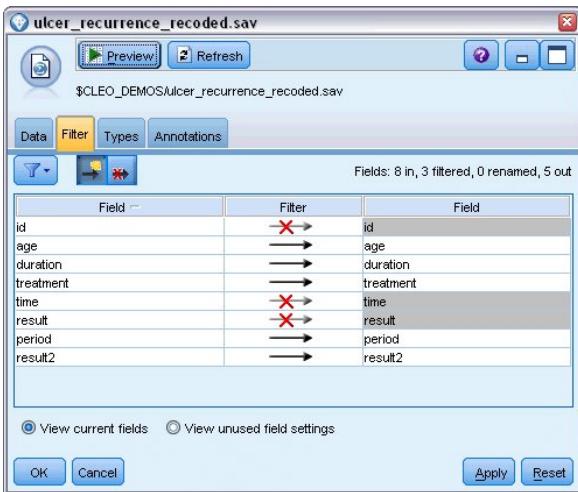

1. Add a Statistics File source node pointing to *ulcer_recurrence_recoded.sav* in the *Demos* folder.

Figure 1. Sample stream to predict ulcer recurrence

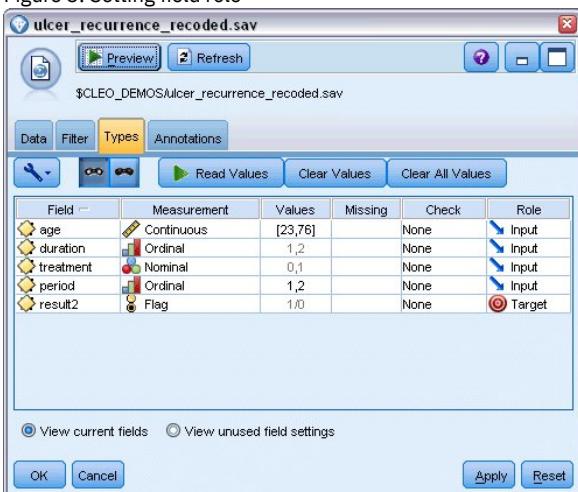

2. On the Filter tab of the source node, filter out *id*, *time*, and *result*.

Figure 2. Filter unwanted fields

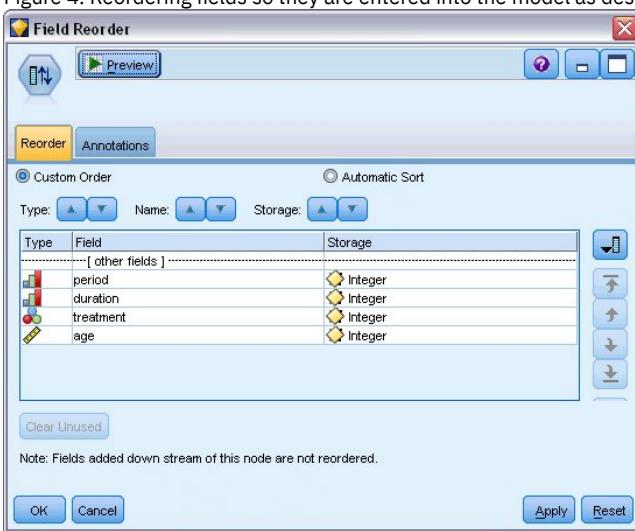

3. On the Types tab of the source node, set the role for the *result2* field to Target and set its measurement level to Flag. All other fields should have their role set to Input.

Figure 3. Setting field role

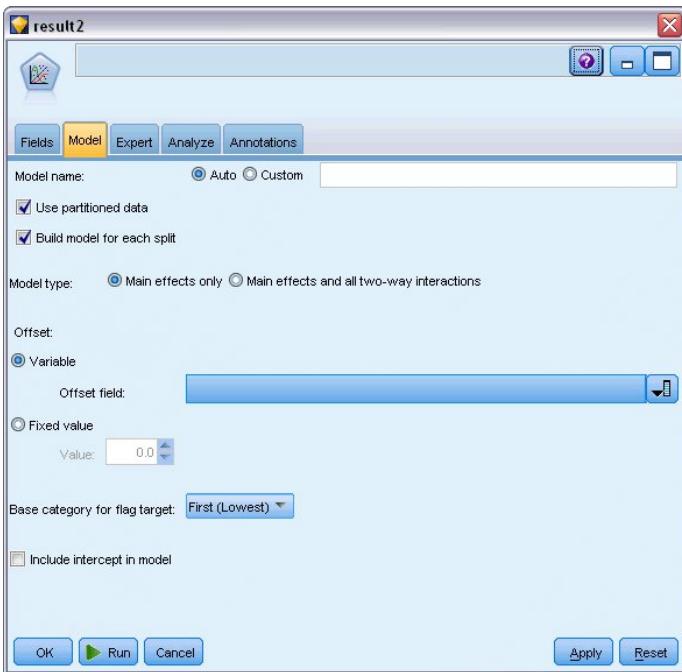

4. Add a Field Reorder node and specify *period*, *duration*, *treatment*, and *age* as the order of inputs. Making *period* the first input (and not including the intercept term in the model) will allow you to fit a full set of dummy variables to capture the period effects.

Figure 4. Reordering fields so they are entered into the model as desired

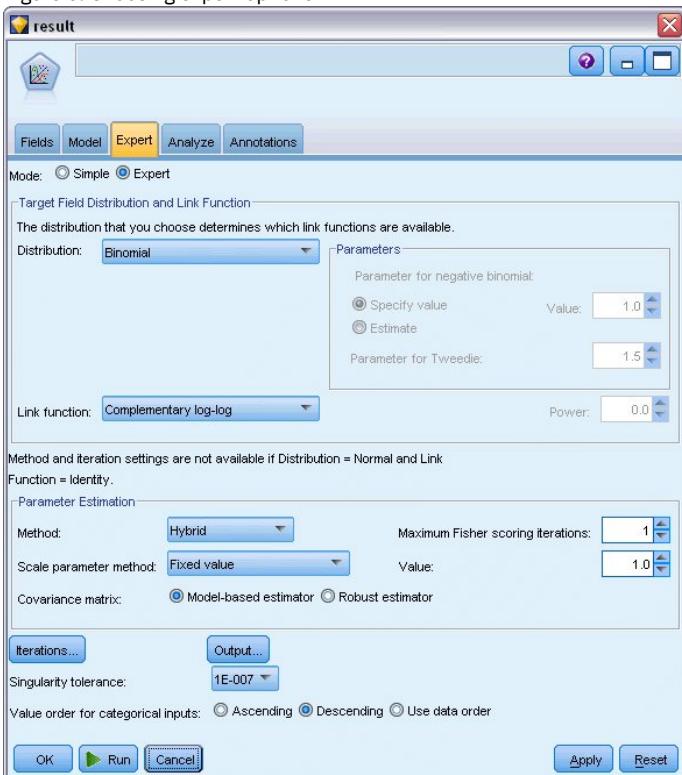

5. On the GenLin node, click the Model tab.

Figure 5. Choosing model options

6. Select First (Lowest) as the reference category for the target. This indicates that the second category is the event of interest, and its effect on the model is in the interpretation of parameter estimates.
7. Deselect Include intercept in model.
8. Click the Expert tab and select Expert to activate the expert modeling options.

Figure 6. Choosing expert options

9. Select Binomial as the distribution and Complementary log-log as the link function.
10. Select Fixed value as the method for estimating the scale parameter and leave the default value of 1.0.
11. Select Descending as the category order for factors. This indicates that the first category of each factor will be its reference category; the effect of this selection on the model is in the interpretation of parameter estimates.
12. Run the stream to create the model nugget, which is added to the stream canvas, and also to the Models palette in the upper right corner. To view the model details, right-click the nugget and choose Edit or Browse.

[Period=1]	-2.206	.5912	-3.365	-1.047	13.926	1	.000
[Treatment group=1]	.195	.6279	-1.035	1.426	.097	1	.756
[Treatment group=0]	0 ^a
(Scale)	1 ^b						

Dependent Variable: Result by period

Model: Period, Treatment group

a. Set to zero because this parameter is redundant.

b. Fixed at the displayed value.

The treatment effect is still not statistically significant but only suggestive that treatment A may be better than B because the parameter estimate for treatment B is associated with an increased probability of recurrence in the first 12 months. The period values are statistically significantly different from 0, but this is because of the fact that an intercept term is not fit. The period effect (the difference between the values of the linear predictor for [period=1] and [period=2]) is not statistically significant, as can be seen in the tests of model effects. The linear predictor (period effect + treatment effect) is an estimate of $\log(-\log(1-P(\text{recur}_p, t)))$, where $P(\text{recur}_p, t)$ is the probability of recurrence at the period p (=1 or 2, representing six months or 12 months) given treatment t (=A or B). These predicted probabilities are generated for each observation in the dataset.

14	0	2	1	1	71	0	0.817	0.817	0.183
15	0	1	1	0	41	0	0.896	0.896	0.104
16	0	2	1	0	41	0	0.847	0.847	0.153
17	0	1	1	1	23	0	0.875	0.875	0.125
18	0	2	1	1	23	0	0.817	0.817	0.183
19	1	1	1	1	37	0	0.875	0.875	0.125
20	0	1	1	1	38	0	0.875	0.875	0.125

Table 1. Estimated recurrence probabilities

Treatment	6 months	12 months
A	0.104	0.153
B	0.125	0.183

From the estimated recurrence probabilities, the survival probability through 12 months can be estimated as $1 - (P(\text{recur}_1, t) + P(\text{recur}_2, t)) \times (1 - P(\text{recur}_1, t))$; thus, for each treatment:

$$A: 1 - (0.104 + 0.153 \times 0.896) = 0.759$$

$$B: 1 - (0.125 + 0.183 \times 0.875) = 0.715$$

which again shows nonstatistically significant support for A as the better treatment.

[Next](#)

Summary

Using Generalized Linear Models, you have fit a series of complementary log-log regression models for interval-censored survival data. While there is some support for choosing treatment A, achieving a statistically significant result may require a larger study. However, there are some further avenues to explore with the existing data.

- It may be worthwhile to refit the model with interaction effects, particularly between *Period* and *Treatment group*.

Explanations of the mathematical foundations of the modeling methods used in IBM® SPSS® Modeler are listed in the *IBM SPSS Modeler Algorithms Guide*.

Related procedures

The Generalized Linear Models procedure is a powerful tool for fitting a variety of models.

- The Generalized Estimating Equations procedure extends the generalized linear model to allow repeated measurements.
- The Linear Mixed Models procedure allows you to fit models for scale dependent variables with a random component and/or repeated measurements.

Recommended readings

See the following texts for more information on generalized linear models:

Cameron, A. C., and P. K. Trivedi. 1998. *Regression Analysis of Count Data*. Cambridge: Cambridge University Press. Dobson, A. J. 2002. *An Introduction to Generalized Linear Models*, 2 ed. Boca Raton, FL: Chapman & Hall/CRC. Hardin, J. W., and J. M. Hilbe. 2003. *Generalized Linear Models and Extension*. Station, TX: Stata Press. McCullagh, P., and J. A. Nelder. 1989. *Generalized Linear Models*, 2nd ed. London: Chapman & Hall.

Using Poisson regression to analyze ship damage rates (Generalized Linear Models)

A generalized linear model can be used to fit a Poisson regression for the analysis of count data. For example, a dataset presented and analyzed elsewhere¹ concerns damage to cargo ships caused by waves. The incident counts can be modeled as occurring at a Poisson rate given the values of the predictors, and the resulting model can help you determine which ship types are most prone to damage.

This example uses the stream *ships_genlin.str*, which references the data file *ships.sav*. The data file is in the *Demos* folder and the stream file is in the *streams* subfolder.

Modeling the raw cell counts can be misleading in this situation because the *Aggregate months of service* varies by ship type. Variables like this that measure the amount of "exposure" to risk are handled within the generalized linear model as offset variables. Moreover, a Poisson regression assumes that the log of the dependent variable is linear in the predictors. Thus, to use generalized linear models to fit a Poisson regression to the accident rates, you need to use *Logarithm of aggregate months of service*.

¹ McCullagh, P., and J. A. Nelder. 1989. *Generalized Linear Models*, 2nd ed. London: Chapman & Hall.

Fitting an "overdispersed" Poisson regression

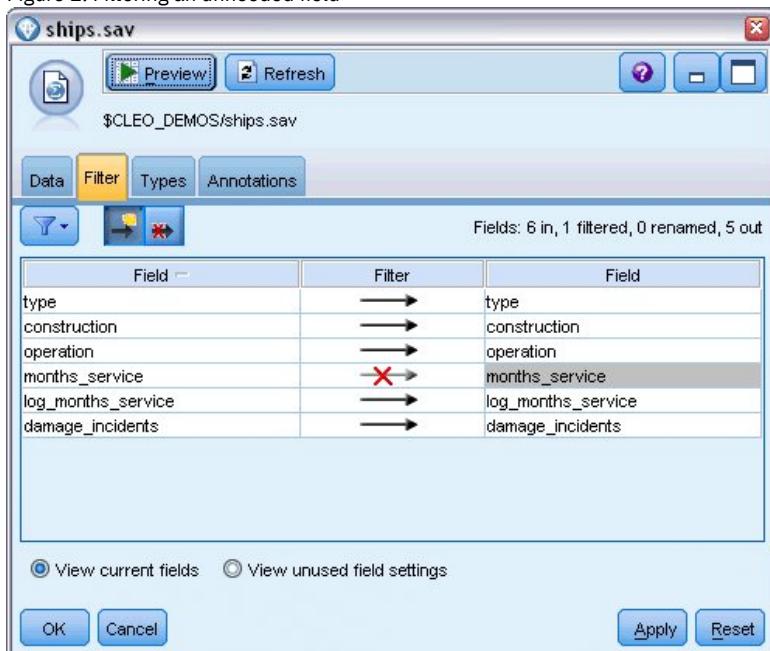

1. Add a Statistics File source node pointing to *ships.sav* in the *Demos* folder.

Figure 1. Sample stream to analyze damage rates

2. On the Filter tab of the source node, exclude the field *months_service*. The log-transformed values of this variable are contained in *log_months_service*, which will be used in the analysis.

Figure 2. Filtering an unneeded field

(Alternatively, you could change the role to None for this field on the Types tab rather than exclude it, or select the fields you want to use in the modeling node.)

3. On the Types tab of the source node, set the role for the *damage_incidents* field to Target. All other fields should have their role set to Input.
4. Click Read Values to instantiate the data.

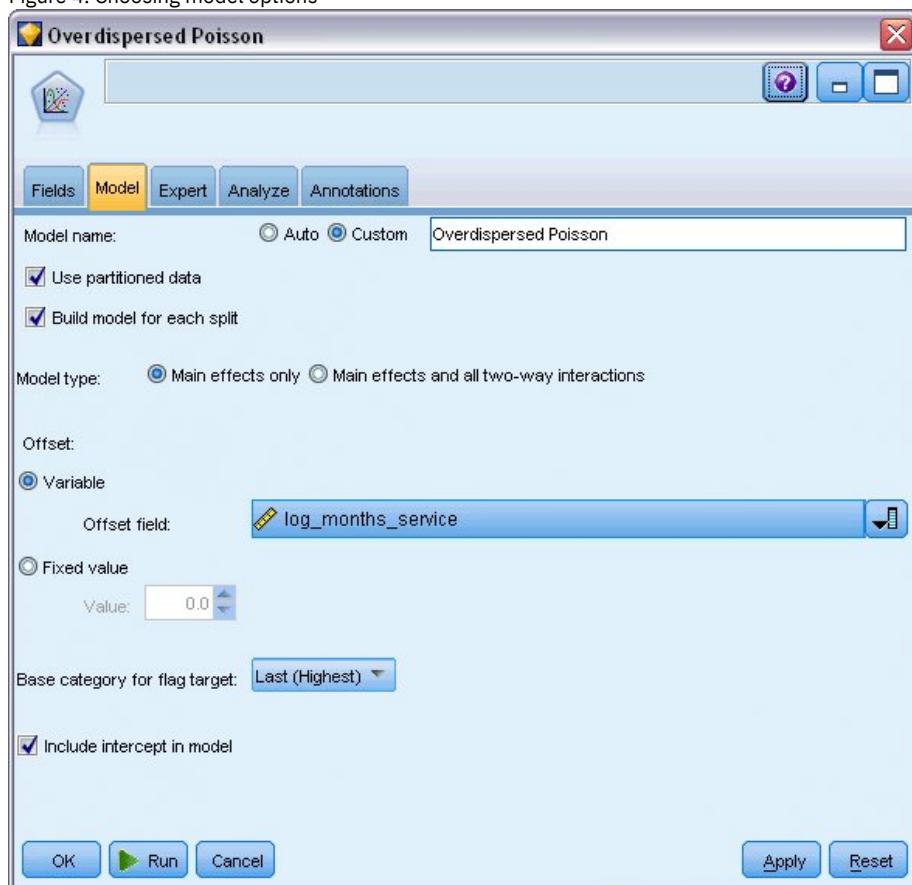

Figure 3. Setting field role

5. Attach a Genlin node to the source node; on the Genlin node, click the Model tab.

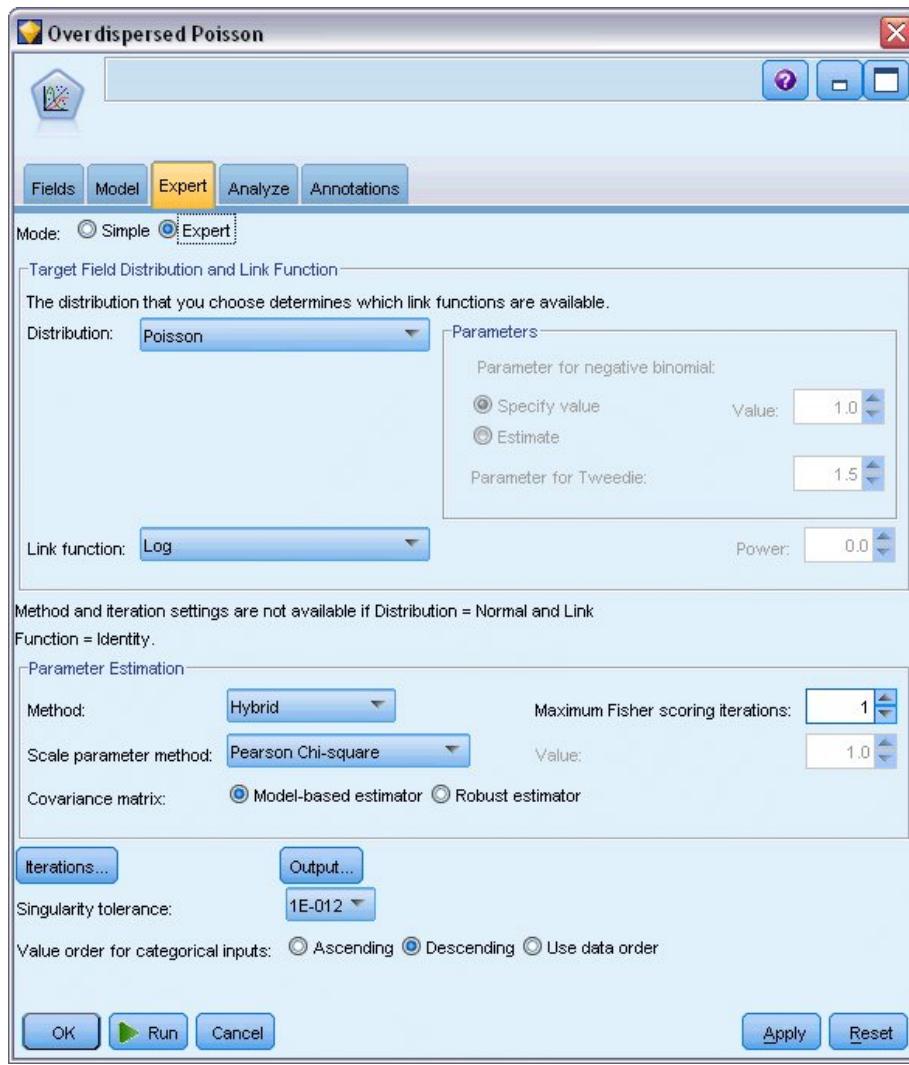

6. Select *log_months_service* as the offset variable.

Figure 4. Choosing model options

7. Click the Expert tab and select Expert to activate the expert modeling options.

Figure 5. Choosing expert options

8. Select Poisson as the distribution for the response and Log as the link function.
9. Select Pearson Chi-Square as the method for estimating the scale parameter. The scale parameter is usually assumed to be 1 in a Poisson regression, but McCullagh and Nelder use the Pearson chi-square estimate to obtain more conservative variance estimates and significance levels.
10. Select Descending as the category order for factors. This indicates that the first category of each factor will be its reference category; the effect of this selection on the model is in the interpretation of parameter estimates.
11. Click Run to create the model nugget, which is added to the stream canvas, and also to the Models palette in the upper right corner. To view the model details, right-click the nugget and choose Edit or Browse, then click the Advanced tab.

Goodness-of-fit statistics

Figure 1. Goodness-of-fit statistics

	Value	df	Value/df
Deviance	38.695	25	1.548
Scaled Deviance	22.883	25	
Pearson Chi-Square	42.275	25	1.691
Scaled Pearson Chi-Square	25.000	25	
Log Likelihood ^a	-68.281		
Akaike's Information Criterion (AIC)	154.562		
Finite Sample Corrected AIC (AICC)	162.062		
Bayesian Information Criterion (BIC)	168.299		
Consistent AIC (CAIC)	177.299		

Dependent Variable: Number of damage incidents

Model: (Intercept), type, construction, operation, offset = log_months_service

- a. The full log likelihood function is displayed and used in computing information criteria.
- b. Information criteria are in small-is-better form.

The goodness-of-fit statistics table provides measures that are useful for comparing competing models. Additionally, the *Value/df* for the Deviance and Pearson Chi-Square statistics gives corresponding estimates for the scale parameter. These values should be near 1.0 for a Poisson regression; the fact that they are greater than 1.0 indicates that fitting the overdispersed model may be reasonable.

[Ship type=1]	0 ^a
(Scale)	1.691 ^b						

Dependent Variable: Number of damage incidents

Model: (Intercept), Year of construction, Period of operation, Ship type, offset = Logarithm of aggregate months of service

a. Set to zero because this parameter is redundant.

b. Computed based on the Pearson chi-square.

The parameter estimates table summarizes the effect of each predictor. While interpretation of the coefficients in this model is difficult because of the nature of the link function, the signs of the coefficients for covariates and relative values of the coefficients for factor levels can give important insights into the effects of the predictors in the model.

- For covariates, positive (negative) coefficients indicate positive (inverse) relationships between predictors and outcome. An increasing value of a covariate with a positive coefficient corresponds to an increasing rate of damage incidents.
- For factors, a factor level with a greater coefficient indicates greater incidence of damage. The sign of a coefficient for a factor level is dependent upon that factor level's effect relative to the reference category.

You can make the following interpretations based on the parameter estimates:

- Ship type *B* [*type=2*] has a statistically significantly (*p* value of 0.019) lower damage rate (estimated coefficient of -0.543) than type *A* [*type=1*], the reference category. Type *C* [*type=3*] actually has an estimated parameter lower than *B*, but the variability in *C*'s estimate clouds the effect. See the estimated marginal means for all relations between factor levels.
- Ships constructed between 1965–69 [*construction=65*] and 1970–74 [*construction=70*] have statistically significantly (*p* values <0.001) higher damage rates (estimated coefficients of 0.697 and 0.818, respectively) than those built between 1960–64 [*construction=60*], the reference category. See the estimated marginal means for all relations between factor levels.
- Ships in operation between 1975–79 [*operation=75*] have statistically significantly (*p* value of 0.012) higher damage rates (estimated coefficient of 0.384) than those in operation between 1960–1974 [*operation=60*].

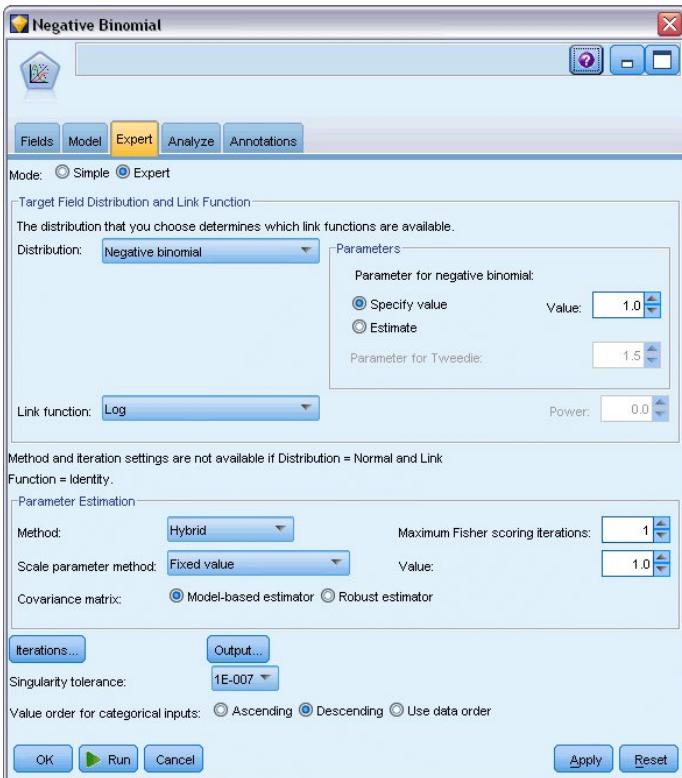

[Next](#)

Fitting alternative models

One problem with the "overdispersed" Poisson regression is that there is no formal way to test it versus the "standard" Poisson regression. However, one suggested formal test to determine whether there is overdispersion is to perform a likelihood ratio test between a "standard" Poisson regression and a negative binomial regression with all other settings equal. If there is no overdispersion in the Poisson regression, then the statistic $-2 \times (\text{log-likelihood for Poisson model} - \text{log-likelihood for negative binomial model})$ should have a mixture distribution with half its probability mass at 0 and the rest in a chi-square distribution with 1 degree of freedom.

- Select Fixed value as the method for estimating the scale parameter. By default, this value is 1.

Figure 1. Expert tab

2. To fit the negative binomial regression, copy and paste the Genlin node, attach it to the source node, open the new node and click the Expert tab.
3. Select Negative binomial as the distribution. Leave the default value of 1 for the ancillary parameter.
4. Run the stream and browse the Advanced tab on the newly-created model nuggets.

Scaled Pearson Chi-Square	42.275	25	
Log Likelihood ^a	-68.281		
Akaike's Information Criterion (AIC)	154.562		
Finite Sample Corrected AIC (AICC)	162.062		
Bayesian Information Criterion (BIC)	168.299		
Consistent AIC (CAIC)	177.299		

Dependent Variable: Number of damage incidents
Model: (Intercept), type, construction, operation, offset = log_months_service

- a. The full log likelihood function is displayed and used in computing information criteria.
- b. Information criteria are in small-is-better form.

The log-likelihood reported for the standard Poisson regression is -68.281. Compare this to the negative binomial model.

Figure 2. Goodness-of-fit statistics for negative binomial regression

	Value	df	Value/df
Deviance	11.145	25	.446
Scaled Deviance	11.145	25	
Pearson Chi-Square	8.815	25	.353
Scaled Pearson Chi-Square	8.815	25	
Log Likelihood ^a	-83.725		
Akaike's Information Criterion (AIC)	185.450		
Finite Sample Corrected AIC (AICC)	192.950		
Bayesian Information Criterion (BIC)	199.187		
Consistent AIC (CAIC)	208.187		

Dependent Variable: Number of damage incidents
Model: (Intercept), type, construction, operation, offset = log_months_service

- a. The full log likelihood function is displayed and used in computing information criteria.
- b. Information criteria are in small-is-better form.

The log-likelihood reported for the negative binomial regression is -83.725. This is actually *smaller* than the log-likelihood for the Poisson regression, which indicates (without the need for a likelihood ratio test) that this negative binomial regression does not offer an improvement over the Poisson regression.

However, the chosen value of 1 for the ancillary parameter of the negative binomial distribution may not be optimal for this dataset. Another way you could test for overdispersion is to fit a negative binomial model with ancillary parameter equal to 0 and request the Lagrange multiplier test on the Output dialog of the Expert tab. If the test is not significant, overdispersion should not be a problem for this dataset.

[Next](#)

Summary

Using Generalized Linear Models, you have fit three different models for count data. The negative binomial regression was shown not to offer any improvement over the Poisson regression. The overdispersed Poisson regression seems to offer a reasonable alternative to the standard Poisson model, but there is not a formal test for choosing between them.

Explanations of the mathematical foundations of the modeling methods used in IBM® SPSS® Modeler are listed in the *IBM SPSS Modeler Algorithms Guide*.

Related procedures

The Generalized Linear Models procedure is a powerful tool for fitting a variety of models.

- The Generalized Estimating Equations procedure extends the generalized linear model to allow repeated measurements.
- The Linear Mixed Models procedure allows you to fit models for scale dependent variables with a random component and/or repeated measurements.

Boca Raton, FL: Chapman & Hall/CRC. Hardin, J. W., and J. M. Hilbe. 2003. *Generalized Linear Models and Extension*. Station, TX: Stata Press. McCullagh, P., and J. A. Nelder. 1989. *Generalized Linear Models*, 2nd ed. London: Chapman & Hall.

Fitting a Gamma regression to car insurance claims (Generalized Linear Models)

A generalized linear model can be used to fit a Gamma regression for the analysis of positive range data. For example, a dataset presented and analyzed elsewhere [1](#) concerns damage claims for cars. The average claim amount can be modeled as having a gamma distribution, using an inverse link function to relate the mean of the dependent variable to a linear combination of the predictors. In order to account for the varying number of claims used to compute the average claim amounts, you specify *Number of claims* as the scaling weight.

This example uses the stream named *car-insurance_genlin.str*, which references the data file named *car_insurance_claims.sav*. The data file is in the *Demos* folder and the stream file is in the *streams* subfolder.

- [Recommended readings](#)

¹ McCullagh, P., and J. A. Nelder. 1989. *Generalized Linear Models*, 2nd ed. London: Chapman & Hall.

Creating the Stream

1. Add a Statistics File source node pointing to *car_insurance_claims.sav* in the *Demos* folder.

Figure 1. Sample stream to predict car insurance claims

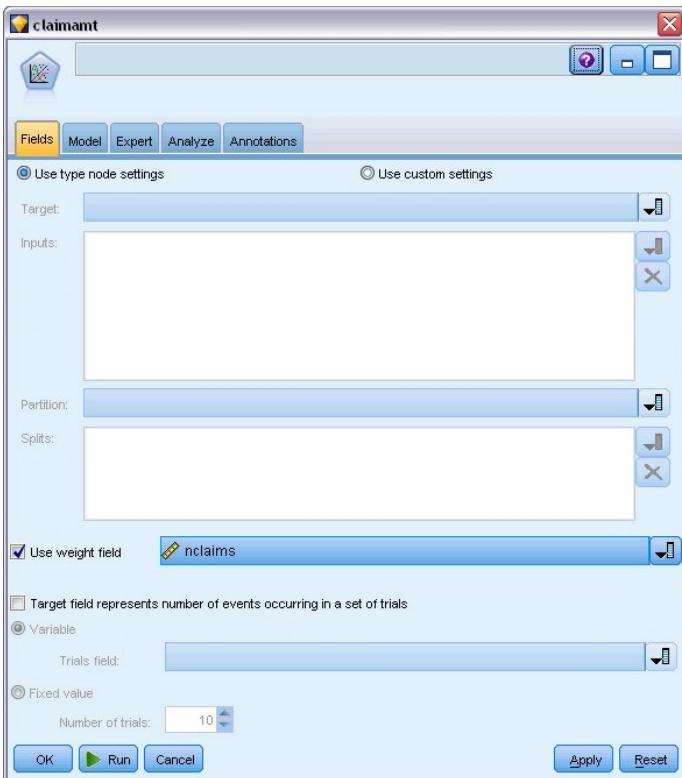

2. On the Types tab of the source node, set the role for the *claimamt* field to Target. All other fields should have their role set to Input.
3. Click Read Values to instantiate the data.

Figure 2. Setting field role

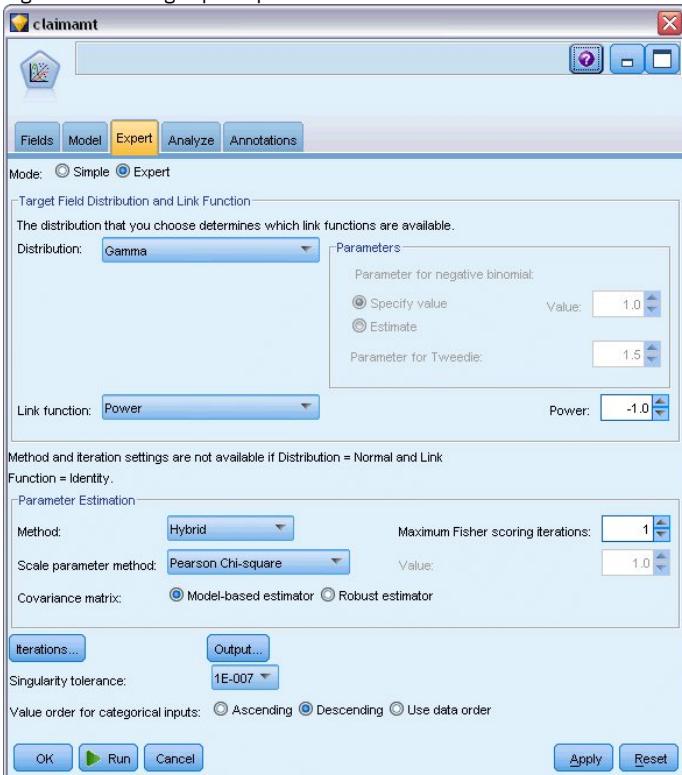

4. Attach a Genlin node to the source node; in the Genlin node, click the Fields tab.
5. Select *nclaims* as the scale weight field.

Figure 3. Choosing field options

6. Click the Expert tab and select Expert to activate the expert modeling options.

Figure 4. Choosing expert options

7. Select Gamma as the response distribution.
8. Select Power as the link function and type -1.0 as the exponent of the power function. This is an inverse link.
9. Select Pearson chi-square as the method for estimating the scale parameter. This is the method used by McCullagh and Nelder, so we follow it here in order to replicate their results.
10. Select Descending as the category order for factors. This indicates that the first category of each factor will be its reference category; the effect of this selection on the model is in the interpretation of parameter estimates.
11. Click Run to create the model nugget, which is added to the stream canvas, and also to the Models palette in the upper-right corner. To view the model details, right-click the model nugget and choose Edit or Browse, then select the Advanced tab.

Parameter estimates

Figure 1. Parameter estimates

Parameter Estimates

Parameter	B	Std. Error	95% Wald Confidence Interval		Hypothesis Test		
			Lower	Upper	Wald Chi-Square	df	Sig.

[Vehicle group=4]	-.001	.0002	-.002	-.001	61.883	1	.000
[Vehicle group=3]	-.001	.0002	-.001	.000	13.039	1	.000
[Vehicle group=2]	3.765E-5	.0002	.000	.000	.050	1	.823
[Vehicle group=1]	0 ^a
(Scale)	1.209 ^b						

Dependent Variable: Average cost of claims

Model: (Intercept), Policyholder age, Vehicle age, Vehicle group

a. Set to zero because this parameter is redundant.

b. Computed based on the Pearson chi-square.

The omnibus test and tests of model effects (not shown) indicate that the model outperforms the null model and that each of the main effects terms contribute to the model. The parameter estimates table shows the same values obtained by McCullagh and Nelder for the factor levels and the scale parameter.

Summary

Using Generalized Linear Models, you have fit a gamma regression to the claims data. Note that while the canonical link function for the gamma distribution was used in this model, a log link will also give reasonable results. In general, it is difficult to impossible to directly compare models with different link functions; however, the log link is a special case of the power link where the exponent is 0, thus you can compare the deviances of a model with a log link and a model with a power link to determine which gives the better fit (see, for example, section 11.3 of McCullagh and Nelder).

Explanations of the mathematical foundations of the modeling methods used in IBM® SPSS® Modeler are listed in the *IBM SPSS Modeler Algorithms Guide*.

Classifying Cell Samples (SVM)

Support Vector Machine (SVM) is a classification and regression technique that is particularly suitable for wide datasets. A wide dataset is one with a large number of predictors, such as might be encountered in the field of bioinformatics (the application of information technology to biochemical and biological data).

A medical researcher has obtained a dataset containing characteristics of a number of human cell samples extracted from patients who were believed to be at risk of developing cancer. Analysis of the original data showed that many of the characteristics differed significantly between benign and malignant samples. The researcher wants to develop an SVM model that can use the values of these cell characteristics in samples from other patients to give an early indication of whether their samples might be benign or malignant.

This example uses the stream named `svm_cancer.str`, available in the `Demos` folder under the `streams` subfolder. The data file is `cell_samples.data`. See the topic [Demos Folder](#) for more information.

The example is based on a dataset that is publicly available from the UCI Machine Learning Repository . The dataset consists of several hundred human cell sample records, each of which contains the values of a set of cell characteristics. The fields in each record are:

Field name	Description
<code>ID</code>	Patient identifier
<code>Clump</code>	Clump thickness
<code>UnifSize</code>	Uniformity of cell size
<code>UnifShape</code>	Uniformity of cell shape
<code>MargAdh</code>	Marginal adhesion
<code>SingEpiSize</code>	Single epithelial cell size
<code>BareNuc</code>	Bare nuclei
<code>BlandChrom</code>	Bland chromatin
<code>NormNucl</code>	Normal nucleoli
<code>Mit</code>	Mitoses
<code>Class</code>	Benign or malignant

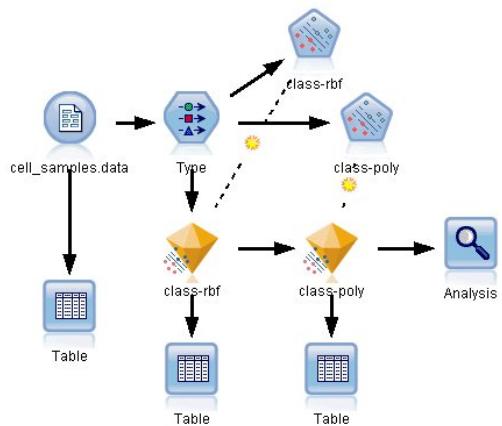

For the purposes of this example, we're using a dataset that has a relatively small number of predictors in each record.

- [Creating the Stream](#)
- [Examining the Data](#)
- [Trying a Different Function](#)
- [Comparing the Results](#)
- [Summary](#)

Creating the Stream

Figure 1. Sample stream to show SVM modeling

1. Create a new stream and add a Var File source node pointing to *cell_samples.data* in the Demos folder of your IBM® SPSS® Modeler installation.

Let's take a look at the data in the source file.

2. Add a Table node to the stream.
3. Attach the Table node to the Var File node and run the stream.

Figure 2. Source data for SVM

The screenshot shows the 'Table' dialog box with the title 'Table (11 fields, 699 records)'. The table view displays the first 20 rows of the dataset. The columns are labeled: ID, hilSize, UnifShape, MargAdh, SingEpiSize, BareNuc, BlandChrom, NormNuci, Mit, and Class. The data shows various numerical values for each patient sample, with the 'Class' column indicating the final diagnosis.

ID	hilSize	UnifShape	MargAdh	SingEpiSize	BareNuc	BlandChrom	NormNuci	Mit	Class
1	1	1	2	1	3	1	1	2	
2	4	5	7	10	3	2	1	2	
3	1	1	2	2	3	1	1	2	
4	8	1	3	4	3	7	1	2	
5	1	3	2	1	3	1	1	2	
6	10	8	7	10	9	7	1	4	
7	1	1	2	10	3	1	1	2	
8	2	1	2	1	3	1	1	2	
9	1	1	2	1	1	1	5	2	
10	1	1	2	1	2	1	1	2	
11	1	1	1	1	3	1	1	2	
12	1	1	2	1	2	1	1	2	
13	3	3	2	3	4	4	1	4	
14	1	1	2	3	3	1	1	2	
15	5	10	7	9	5	5	4	4	
16	6	4	6	1	4	3	1	4	
17	1	1	2	1	2	1	1	2	
18	1	1	2	1	3	1	1	2	
19	7	6	4	10	4	1	2	4	
20	1	1	2	1	3	1	1	2	

The *ID* field contains the patient identifiers. The characteristics of the cell samples from each patient are contained in fields *Clump* to *Mit*. The values are graded from 1 to 10, with 1 being the closest to benign.

The *Class* field contains the diagnosis, as confirmed by separate medical procedures, as to whether the samples are benign (value = 2) or malignant (value = 4).

Figure 3. Type node settings

4. Add a Type node and attach it to the Var File node.

5. Open the Type node.

We want the model to predict the value of *Class* (that is, benign (=2) or malignant (=4)). As this field can have one of only two possible values, we need to change its measurement level to reflect this.

6. In the Measurement column for the *Class* field (the last one in the list), click the value Continuous and change it to Flag.

7. Click Read Values.

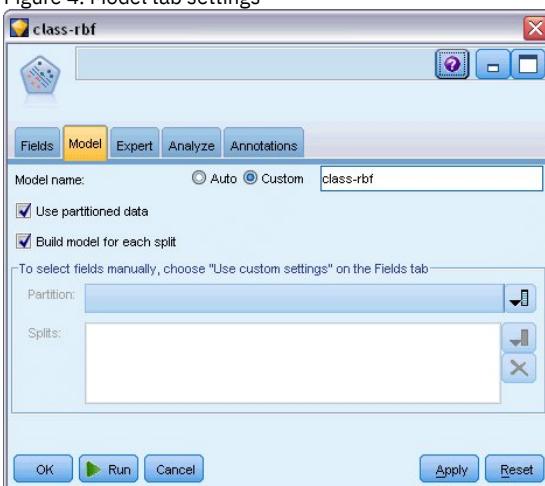

8. In the Role column, set the role for *ID* (the patient identifier) to None, as this will not be used either as a predictor or a target for the model.

9. Set the role for the target, *Class*, to Target and leave the role of all the other fields (the predictors) as Input.

10. Click OK.

The SVM node offers a choice of kernel functions for performing its processing. As there's no easy way of knowing which function performs best with any given dataset, we'll choose different functions in turn and compare the results. Let's start with the default, RBF (Radial Basis Function).

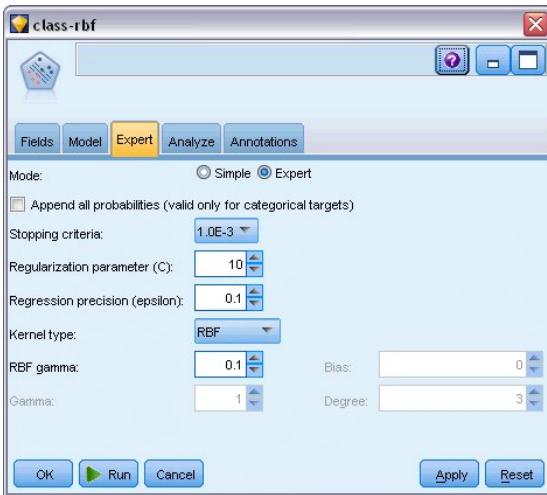

Figure 4. Model tab settings

11. From the Modeling palette, attach an SVM node to the Type node.

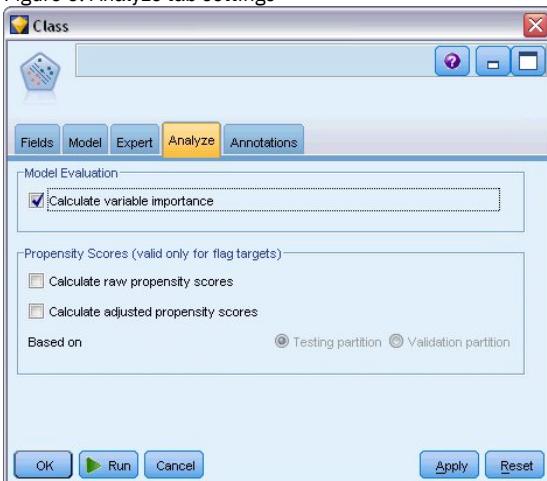

12. Open the SVM node. On the Model tab, click the Custom option for Model name and type *class-rbf* in the adjacent text field.

Figure 5. Default Expert tab settings

13. On the Expert tab, set the Mode to Expert for readability but leave all the default options as they are. Note that Kernel type is set to RBF by default. All the options are greyed out in Simple mode.

Figure 6. Analyze tab settings

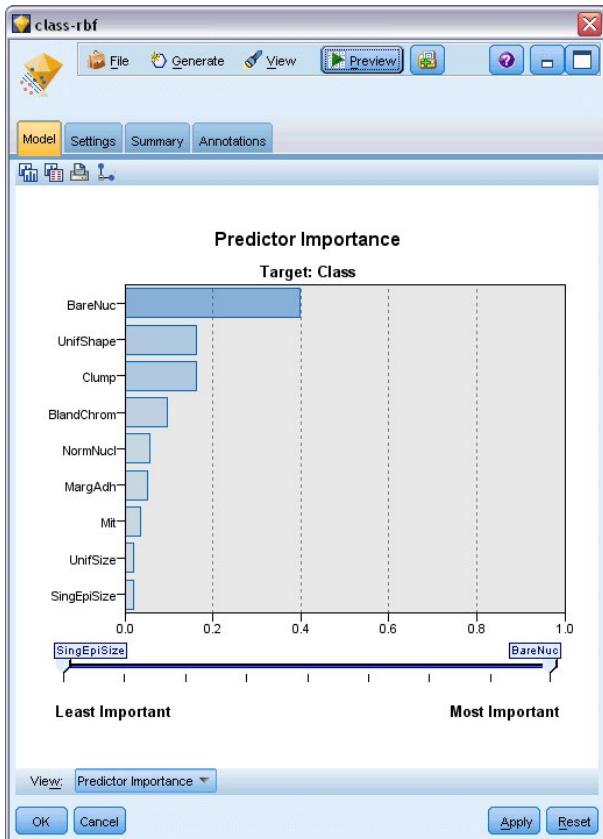

14. On the Analyze tab, select the Calculate variable importance check box.
 15. Click Run. The model nugget is placed in the stream, and in the Models palette at the top right of the screen.
 16. Double-click the model nugget in the stream.

[Next](#)

Examining the Data

Figure 1. Predictor Importance graph

On the Model tab, the Predictor Importance graph shows the relative effect of the various fields on the prediction. This shows us that *BareNuc* has easily the greatest effect, while *UnifShape* and *Clump* are also quite significant.

1. Click OK.
2. Attach a Table node to the *class-rbf* model nugget.
3. Open the Table node and click Run.

Figure 2. Fields added for prediction and confidence value

The table output shows the following data structure:

	gEpiSize	BareNuc	BlandChrom	NormNuc	Mit	Class	\$S-Class	\$SP-Class
1		1	3	1	1	2	2	0.992
2		10	3	2	1	2	4	0.899
3		2	3	1	1	2	2	0.994
4		4	3	7	1	2	4	0.915
5		1	3	1	1	2	2	0.992
6		10	9	7	1	4	4	0.999
7		10	3	1	1	2	2	0.907
8		1	3	1	1	2	2	0.997
9		1	1	1	5	2	2	0.997
10		1	2	1	1	2	2	0.996
11		1	3	1	1	2	2	0.999
12		1	2	1	1	2	2	0.999
13		3	4	4	1	4	2	0.514
14		3	3	1	1	2	2	0.989
15		9	5	5	4	4	4	0.991
16		1	4	3	1	4	4	0.691
17		1	2	1	1	2	2	0.997
18		1	3	1	1	2	2	0.995
19		10	4	1	2	4	4	0.996
20		1	3	1	1	2	2	0.986

4. The model has created two extra fields. Scroll the table output to the right to see them:

New field name	Description
\$S-Class	Value for <i>Class</i> predicted by the model.
\$SP-Class	Propensity score for this prediction (the likelihood of this prediction being true, a value from 0.0 to 1.0).

Just by looking at the table, we can see that the propensity scores (in the *\$SP-Class* column) for most of the records are reasonably high.

However, there are some significant exceptions; for example, the record for patient 1041801 at line 13, where the value of 0.514 is unacceptably low. Also, comparing *Class* with *SS-Class*, it's clear that this model has made a number of incorrect predictions, even where the propensity score was relatively high (for example, lines 2 and 4).

Let's see if we can do better by choosing a different function type.

[Next](#)

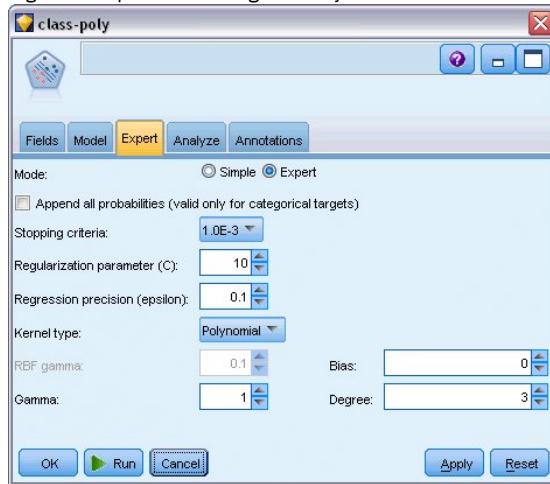

Trying a Different Function

Figure 1. Setting a new name for the model

1. Close the Table output window.
2. Attach a second SVM modeling node to the Type node.
3. Open the new SVM node.
4. On the Model tab, choose Custom and type *class-poly* as the model name.

Figure 2. Expert tab settings for Polynomial

5. On the Expert tab, set Mode to Expert.
6. Set Kernel type to Polynomial and click Run. The *class-poly* model nugget is added to the stream, and also to the Models palette at the top right of the screen.
7. Connect the *class-rbf* model nugget to the *class-poly* model nugget (choose Replace at the warning dialog).
8. Attach a Table node to the *class-poly* nugget.
9. Open the Table node and click Run.

[Next](#)

Comparing the Results

Figure 1. Fields added for Polynomial function

The screenshot shows a 'Table' node window with 15 fields and 699 records. The columns include 'ormNucl', 'Mit', 'Class', '\$S-Class', '\$SP-Class', '\$S1-Class', and '\$SP1-Class'. The '\$S1-Class' and '\$SP1-Class' columns contain values ranging from 0.992 to 1.000.

	ormNucl	Mit	Class	\$S-Class	\$SP-Class	\$S1-Class	\$SP1-Class
78		1	2	2	0.992	2	0.998
79		1	2	2	0.968	2	0.967
80		1	2	2	0.998	2	0.994
81		1	2	2	0.986	2	0.991
82		1	2	2	0.996	2	0.997
83		1	2	2	0.991	2	0.998
84		1	2	2	0.970	2	0.998
85	0	7	4	4	0.992	4	1.000
86	0	10	4	4	0.974	4	1.000
87		1	4	4	0.786	4	0.958
88		3	4	4	0.988	4	0.935
89		1	2	2	0.995	2	0.997
90		1	2	2	0.998	2	0.991
91		1	2	2	0.999	2	0.993
92		1	2	2	0.998	2	0.996
93		1	2	2	0.995	2	0.997
94		1	2	2	0.999	2	0.994
95		1	2	2	0.998	2	0.995
96		1	2	2	0.999	2	0.993
97		1	2	2	0.999	2	0.995

1. Scroll the table output to the right to see the newly added fields.

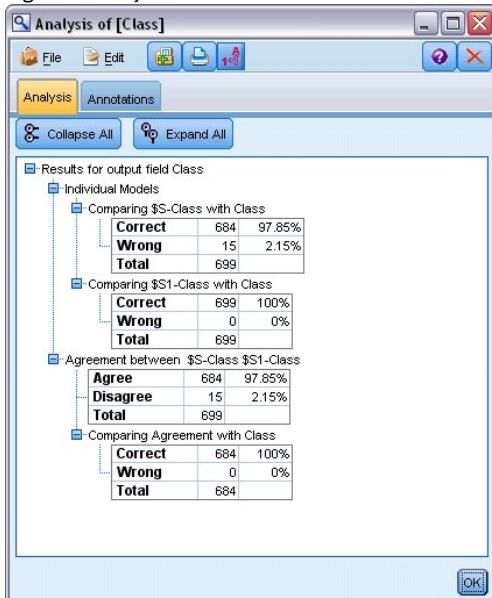

The generated fields for the Polynomial function type are named **\$S1-Class** and **\$SP1-Class**.

The results for Polynomial look much better. Many of the propensity scores are 0.995 or better, which is very encouraging.

2. To confirm the improvement in the model, attach an Analysis node to the *class-poly* model nugget.

Open the Analysis node and click Run.

Figure 2. Analysis node

This technique with the Analysis node enables you to compare two or more model nuggets of the same type. The output from the Analysis node shows that the RBF function correctly predicts 97.85% of the cases, which is still quite good. However, the output shows that the Polynomial function has correctly predicted the diagnosis in every single case. In practice you are unlikely to see 100% accuracy, but you can use the Analysis node to help determine whether the model is acceptably accurate for your particular application.

In fact, neither of the other function types (Sigmoid and Linear) performs as well as Polynomial on this particular dataset. However, with a different dataset, the results could easily be different, so it's always worth trying the full range of options.

[Next](#)

Summary

You have used different types of SVM kernel functions to predict a classification from a number of attributes. You have seen how different kernels give different results for the same dataset and how you can measure the improvement of one model over another.

Using Cox Regression to Model Customer Time to Churn

As part of its efforts to reduce customer churn, a telecommunications company is interested in modeling the "time to churn" in order to determine the factors that are associated with customers who are quick to switch to another service. To this end, a random sample of customers is selected and their time spent as customers, whether they are still active customers, and various other fields are pulled from the database.

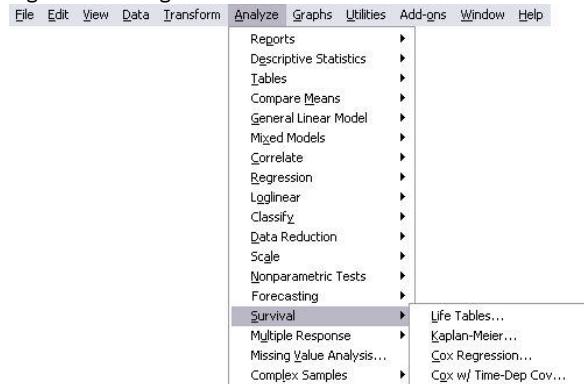

This example uses the stream *telco_coxreg.str*, which references the data file *telco.sav*. The data file is in the *Demos* folder and the stream file is in the *streams* subfolder. See the topic [Demos Folder](#) for more information.

Censored Cases

Figure 1. Case processing summary

		N	Percent
Cases available in analysis	Event ^a	274	27.4%
	Censored	726	72.6%
	Total	1000	100.0%
Cases dropped	Cases with missing values	0	0.0%
	Cases with negative time	0	0.0%
	Censored cases before the earliest event in a stratum	0	0.0%
	Total	0	0.0%
Total		1000	100.0%

a. Dependent Variable: Months with service

The status variable identifies whether the event has occurred for a given case. If the event has not occurred, the case is said to be censored. Censored cases are not used in the computation of the regression coefficients but are used to compute the baseline hazard. The case processing summary shows that 726 cases are censored. These are customers who have not churned.

Figure 2. Categorical Covariate dialog box

The categorical variable codings are a useful reference for interpreting the regression coefficients for categorical covariates, particularly dichotomous variables. By default, the reference category is the "last" category. Thus, for example, even though *Married* customers have variable values of 1 in the data file, they are coded as 0 for the purposes of the regression.

 - h. Variable(s) Entered at Step Number 8: equipmon
 - i. Variable(s) Entered at Step Number 9: ebill
 - j. Variable(s) Entered at Step Number 10: callid
 - k. Variable(s) Entered at Step Number 11: internet
 - l. Variable(s) Entered at Step Number 12: reside
- m. Beginning Block Number 0, Initial Log Likelihood function: -2 Log likelihood: 3526.364
n. Beginning Block Number 1, Method = Forward Stepwise (Likelihood Ratio)

The model-building process employs a forward stepwise algorithm. The omnibus tests are measures of how well the model performs. The chi-square change from previous step is the difference between the -2 log-likelihood of the model at the previous step and the current step. If the step was to add a variable, the inclusion makes sense if the significance of the change is less than 0.05. If the step was to remove a variable, the exclusion makes sense if the significance of the change is greater than 0.10. In twelve steps, twelve variables are added to the model.

Figure 2. Variables in the equation (step 12 only)

Step 12		B	SE	Wald	df	Sig.	Exp(B)
		address	-.035	.009	14.543	1	.000
	employ	-.051	.010	25.767	1	.000	.950
	reside	-.103	.046	5.037	1	.025	.902
	equip	-1.948	.381	26.180	1	.000	.143
	callcard	.777	.151	26.451	1	.000	2.175
	longmon	-.233	.022	115.619	1	.000	.792
	equipmon	-.042	.011	15.377	1	.000	.859
	multiline	.612	.145	17.854	1	.000	1.844
	voice	.501	.157	10.197	1	.001	.606
	internet	-.362	.160	5.114	1	.024	.697
	callid	-.464	.148	9.790	1	.002	.629
	ebill	-.399	.156	6.557	1	.010	.671

The final model includes *address*, *employ*, *reside*, *equip*, *callcard*, *longmon*, *equipmon*, *multiline*, *voice*, *internet*, *callid*, and *ebill*. To understand the effects of individual predictors, look at *Exp(B)*, which can be interpreted as the predicted change in the hazard for a unit increase in the predictor.

- The value of *Exp(B)* for *address* means that the churn hazard is reduced by $100\% - (100\% \times 0.966) = 3.4\%$ for each year a customer has lived at the same address. The churn hazard for a customer who has lived at the same address for five years is reduced by $100\% - (100\% \times 0.966^5) = 15.88\%$.
- The value of *Exp(B)* for *callcard* means that the churn hazard for a customer who does not subscribe to the calling card service is 2.175 times that of a customer with the service. Recall from the categorical variable codings that *No* = 1 for the regression.
- The value of *Exp(B)* for *internet* means that the churn hazard for a customer who does not subscribe to the internet service is 0.697 times that of a customer with the service. This is somewhat worrisome because it suggests that customers with the service are leaving the company faster than customers without the service.

Figure 3. Variables not in the model (step 12 only)

		Score	df	Sig.
Step 12	age	.122	1	.726
	marital	.648	1	.421
	income	1.476	1	.224
	ed	6.328	4	.176
	ed(1)	.007	1	.934
	ed(2)	.203	1	.652
	ed(3)	.835	1	.361
	ed(4)	5.773	1	.016
	retire	.013	1	.908
	gender	.214	1	.644
	tollfree	3.243	1	.072
	wireless	.668	1	.414
	tollmon	.000	1	.987
	cardmon	3.163	1	.075
	wiremon	1.084	1	.298
	pager	1.808	1	.179
	callwait	.266	1	.606
	forward	2.201	1	.138
	confer	2.568	1	.109
	custcat	.864	3	.834
	custcat(1)	.466	1	.495
	custcat(2)	.450	1	.502
	custcat(3)	.019	1	.889

Variables left out of the model all have score statistics with significance values greater than 0.05. However, the significance values for *tollfree* and *cardmon*, while not less than 0.05, are fairly close. They may be interesting to pursue in further studies.

Figure 2. Choosing advanced output options

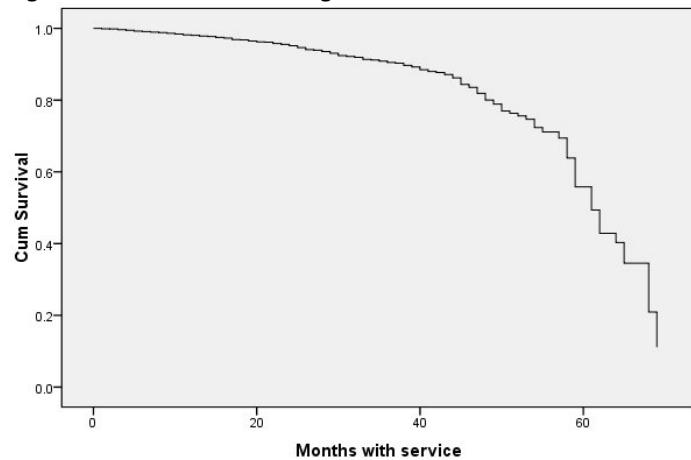

This table displays the average value of each predictor variable. This table is a useful reference when looking at the survival plots, which are constructed for the mean values. Note, however, that the "average" customer doesn't actually exist when you look at the means of indicator variables for categorical predictors. Even with all scale predictors, you are unlikely to find a customer whose covariate values are all close to the mean. If you want to see the survival curve for a particular case, you can change the covariate values at which the survival curve is plotted in the Plots dialog box. If you want to see the survival curve for a particular case, you can change the covariate values at which the survival curve is plotted in the Plots group of the Advanced Output dialog.

[Next](#)

Survival Curve

Figure 1. Survival curve for "average" customer

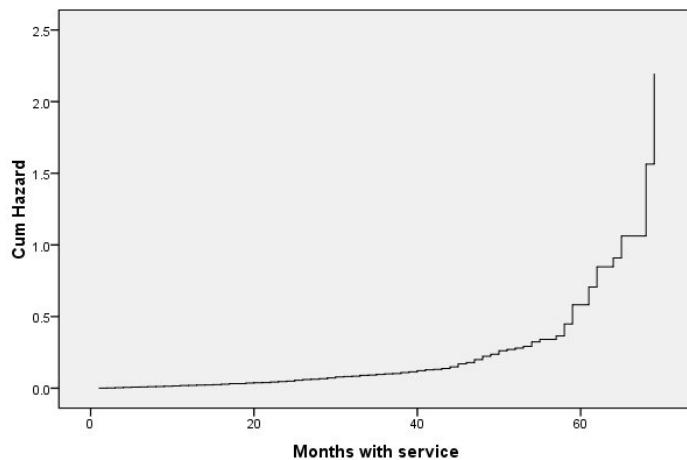

The basic survival curve is a visual display of the model-predicted time to churn for the "average" customer. The horizontal axis shows the time to event. The vertical axis shows the probability of survival. Thus, any point on the survival curve shows the probability that the "average" customer will remain a customer past that time. Past 55 months, the survival curve becomes less smooth. There are fewer customers who have been with the company for that long, so there is less information available, and thus the curve is blocky.

[Next](#)

Hazard Curve

Figure 1. Hazard curve for "average" customer

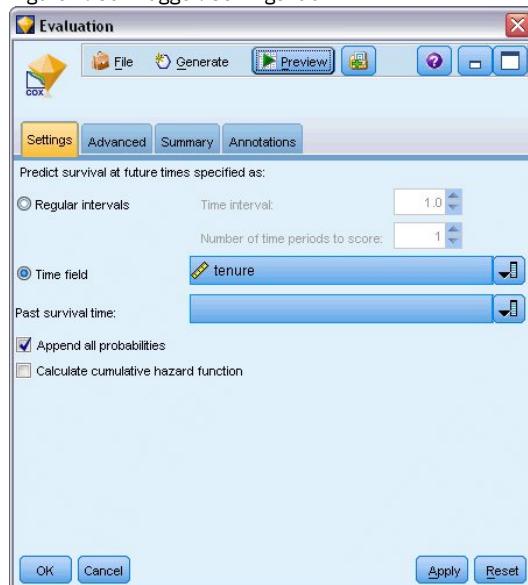

The basic hazard curve is a visual display of the cumulative model-predicted potential to churn for the "average" customer. The horizontal axis shows the time to event. The vertical axis shows the cumulative hazard, equal to the negative log of the survival probability. Past 55 months, the hazard curve, like the survival curve, becomes less smooth, for the same reason.

[Next](#)

Evaluation

The stepwise selection methods guarantee that your model will have only "statistically significant" predictors, but it does not guarantee that the model is actually good at predicting the target. To do this, you need to analyze scored records.

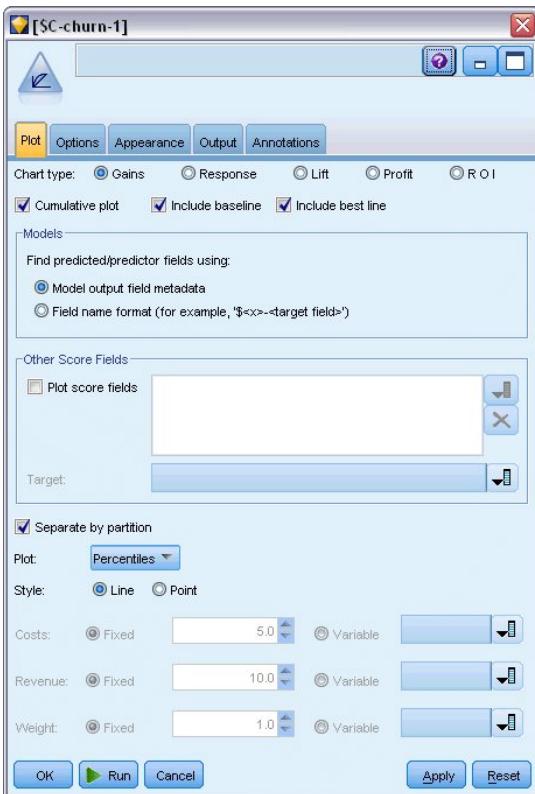

Figure 1. Cox nugget: Settings tab

1. Place the model nugget on the canvas and attach it to the source node, open the nugget and click the Settings tab.
2. Select Time field and specify *tenure*. Each record will be scored at its length of tenure.
3. Select Append all probabilities.

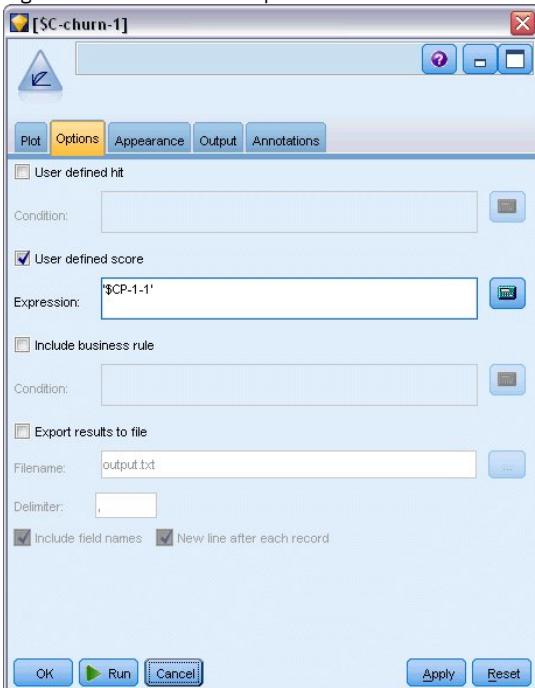

This creates scores using 0.5 as the cutoff for whether a customer churns; if their propensity to churn is greater than 0.5, they are scored as a churner. There is nothing magical about this number, and a different cutoff may yield more desirable results. For one way to think about choosing a cutoff, use an Evaluation node.

Figure 2. Evaluation node: Plot tab

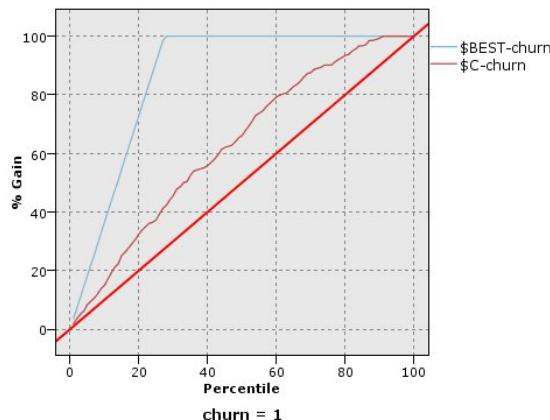

4. Attach an Evaluation node to the model nugget; on the Plot tab, select Include best line.
5. Click the Options tab.

Figure 3. Evaluation node: Options tab

6. Select User defined score and type '\$CP-1-1' as the expression. This is a model-generated field that corresponds to the propensity to churn.
7. Click Run.

Figure 4. Gains chart

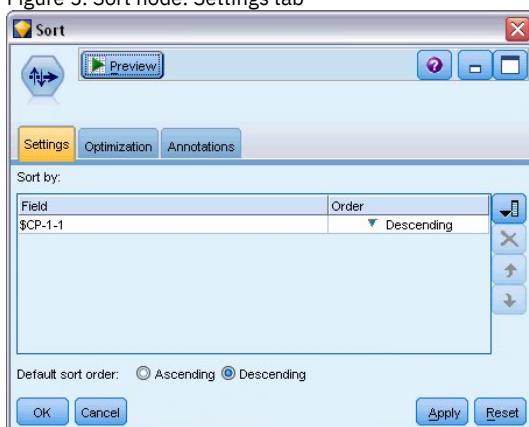

The cumulative gains chart shows the percentage of the overall number of cases in a given category "gained" by targeting a percentage of the total number of cases. For example, one point on the curve is at (10%, 15%), meaning that if you score a dataset with the model and sort all of the cases by predicted propensity to churn, you would expect the top 10% to contain approximately 15% of all of the cases that actually take the category 1 (churners). Likewise, the top 60% contains approximately 79.2% of the churners. If you select 100% of the scored dataset, you obtain all of the churners in the dataset.

The diagonal line is the "baseline" curve; if you select 20% of the records from the scored dataset at random, you would expect to "gain" approximately 20% of all of the records that actually take the category 1. The farther above the baseline a curve lies, the greater the gain. The "best" line shows the curve for a "perfect" model that assigns a higher churn propensity score to every chunner than every non-chunner. You can use the cumulative gains chart to help choose a classification cutoff by choosing a percentage that corresponds to a desirable gain, and then mapping that percentage to the appropriate cutoff value.

What constitutes a "desirable" gain depends on the cost of Type I and Type II errors. That is, what is the cost of classifying a chunner as a non-chunner (Type I)? What is the cost of classifying a non-chunner as a chunner (Type II)? If customer retention is the primary concern, then you want to lower your Type I error; on the cumulative gains chart, this might correspond to increased customer care for customers in the top 60% of predicted propensity of 1, which captures 79.2% of the possible churners but costs time and resources that could be spent acquiring new customers. If lowering the cost of maintaining your current customer base is the priority, then you want to lower your Type II error. On the chart, this might correspond to increased customer care for the top 20%, which captures 32.5% of the churners. Usually, both are important concerns, so you have to choose a decision rule for classifying customers that gives the best mix of sensitivity and specificity.

Figure 5. Sort node: Settings tab

8. Say that you have decided that 45.6% is a desirable gain, which corresponds to taking the top 30% of records. To find an appropriate classification cutoff, attach a Sort node to the model nugget.
9. On the Settings tab, choose to sort by **\$CP-1-1** in descending order and click OK.

Figure 6. Table

Table (34 fields, 1,000 records)

Irn	\$C-churn-1	\$CP-churn-1	\$CP-0-1	\$CP-1-1
292	0	0.744	0.744	0.256
293	0	0.745	0.745	0.255
294	0	0.745	0.745	0.255
295	0	0.746	0.746	0.254
296	0	0.748	0.748	0.252
297	0	0.749	0.749	0.251
298	0	0.749	0.749	0.251
299	0	0.750	0.750	0.250
300	0	0.752	0.752	0.248
301	0	0.752	0.752	0.248
302	0	0.754	0.754	0.246
303	0	0.754	0.754	0.246
304	0	0.755	0.755	0.245
305	0	0.756	0.756	0.244
306	0	0.757	0.757	0.243
307	0	0.757	0.757	0.243
308	0	0.758	0.758	0.242
309	0	0.759	0.759	0.241
310	0	0.761	0.761	0.239
311	0	0.762	0.762	0.238

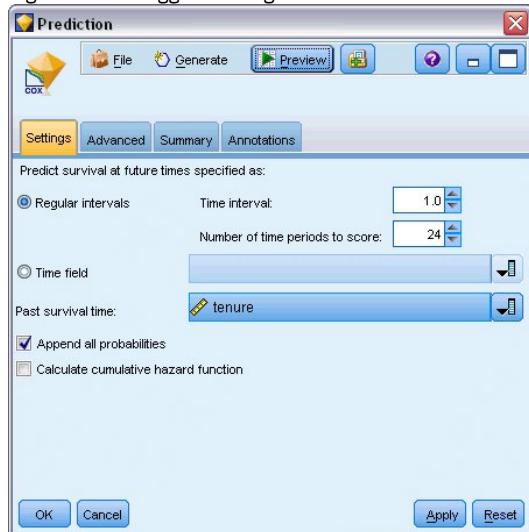

10. Attach a Table node to the Sort node.
11. Open the Table node and click Run.

Scrolling down the output, you see that the value of \$CP-1-1 is 0.248 for the 300th record. Using 0.248 as a classification cutoff should result in approximately 30% of the customers scored as churners, capturing approximately 45% of the actual total churners.

Tracking the Expected Number of Customers Retained

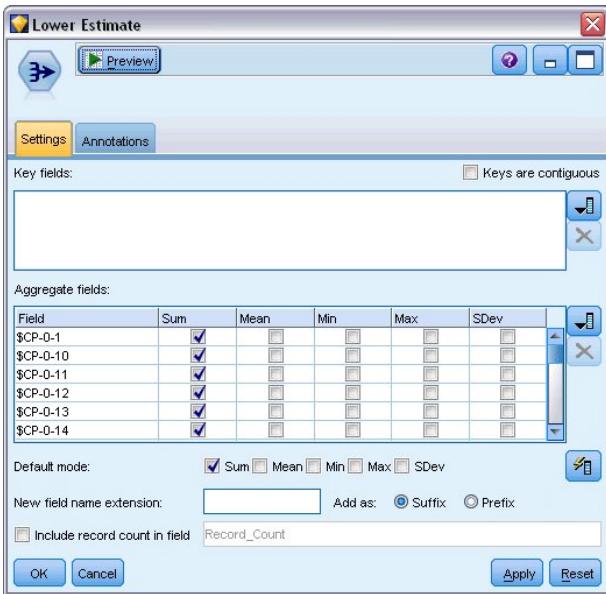

Once satisfied with a model, you want to track the expected number of customers in the dataset that are retained over the next two years. The null values, which are customers whose total tenure (future time + tenure) falls beyond the range of survival times in the data used to train the model, present an interesting challenge. One way to deal with them is to create two sets of predictions, one in which null values are assumed to have churned, and another in which they are assumed to have been retained. In this way you can establish upper and lower bounds on the expected number of customers retained.

Figure 1. Cox nugget: Settings tab

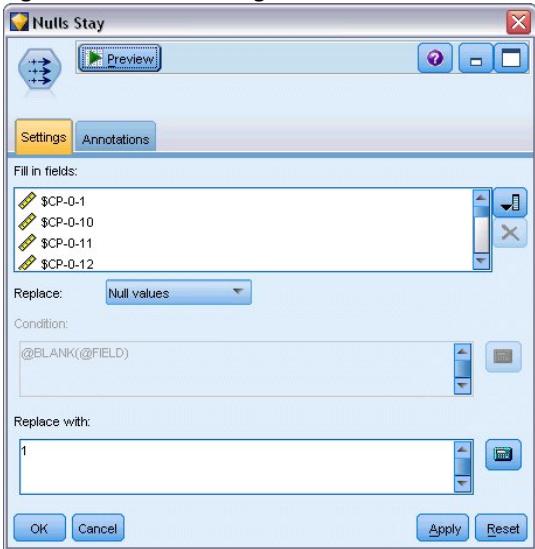

1. Double-click the model nugget in the Models palette (or copy and paste the nugget on the stream canvas) and attach the new nugget to the Source node.
2. Open the nugget to the Settings tab.
3. Make sure Regular Intervals is selected, and specify 1.0 as the time interval and 24 as the number of periods to score. This specifies that each record will be scored for each of the following 24 months.
4. Select *tenure* as the field to specify the past survival time. The scoring algorithm will take into account the length of each customer's time as a customer of the company.
5. Select Append all probabilities.

Figure 2. Aggregate node: Settings tab

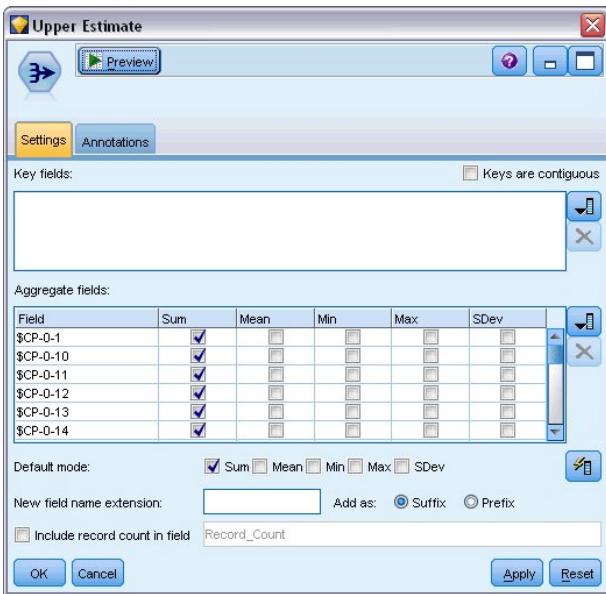

6. Attach an Aggregate node to the model nugget; on the Settings tab, deselect Mean as a default mode.
7. Select \$CP-0-1 through \$CP-0-24, the fields of form \$CP-0-n, as the fields to aggregate. This is easiest if, on the Select Fields dialog, you sort the fields by Name (that is, alphabetical order).
8. Deselect Include record count in field.
9. Click OK. This node creates the "lower bound" predictions.

Figure 3. Filler node: Settings tab

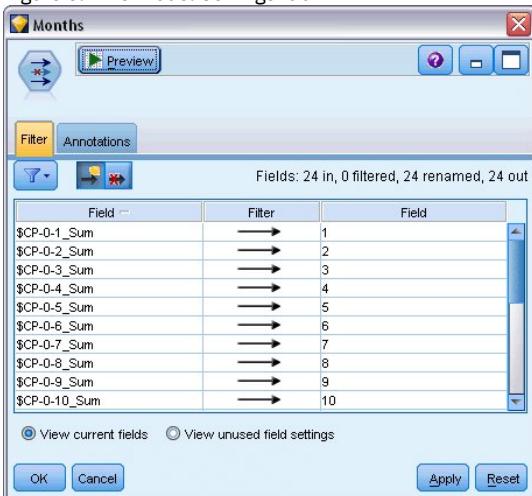

10. Attach a Filler node to the Coxreg nugget to which we just attached the Aggregate node; on the Settings tab, select \$CP-0-1 through \$CP-0-24, the fields of form \$CP-0-n, as the fields to fill in. This is easiest if, on the Select Fields dialog, you sort the fields by Name (that is, alphabetical order).
11. Choose to replace Null values with the value 1.
12. Click OK.

Figure 4. Aggregate node: Settings tab

13. Attach an Aggregate node to the Filler node; on the Settings tab, deselect Mean as a default mode.
14. Select \$CP-0-1 through \$CP-0-24, the fields of form \$CP-0-n, as the fields to aggregate. This is easiest if, on the Select Fields dialog, you sort the fields by Name (that is, alphabetical order).
15. Deselect Include record count in field.
16. Click OK. This node creates the "upper bound" predictions.

Figure 5. Filter node: Settings tab

17. Attach an Append node to the two Aggregate nodes, then attach a Filter node to the Append node.
18. On the Settings tab of the Filter node, rename the fields to 1 through 24. Through the use of a Transpose node, these field names will become values for the x-axis in charts downstream.

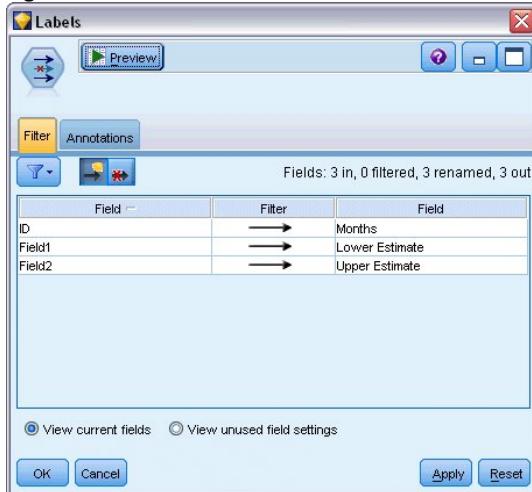

Figure 6. Transpose node: Settings tab

19. Attach a Transpose node to the Filter node.

20. Type 2 as the number of new fields.

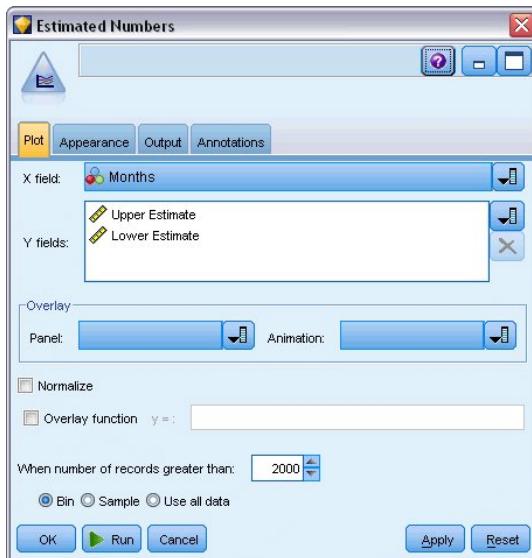

Figure 7. Filter node: Filter tab

21. Attach a Filter node to the Transpose node.

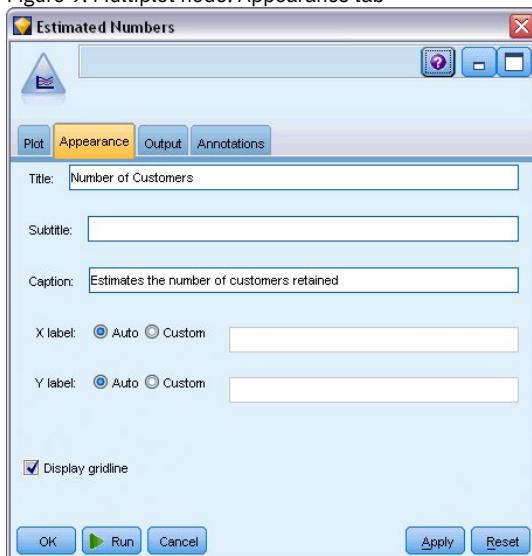

22. On the Settings tab of the Filter node, rename *ID* to *Months*, *Field1* to *Lower Estimate*, and *Field2* to *Upper Estimate*.

Figure 8. Multiplot node: Plot tab

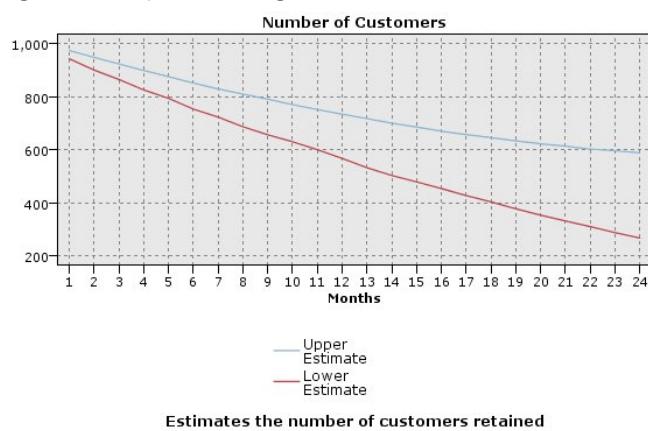

23. Attach a Multiplot node to the Filter node.
 24. On the Plot tab, *Months* as the X field, *Lower Estimate* and *Upper Estimate* as the Y fields.

Figure 9. Multiplot node: Appearance tab

25. Click the Appearance tab.
 26. Type *Number of Customers* as the title.
 27. Type *Estimates the number of customers retained* as the caption.
 28. Click Run.

Figure 10. Multiplot estimating the number of customers retained

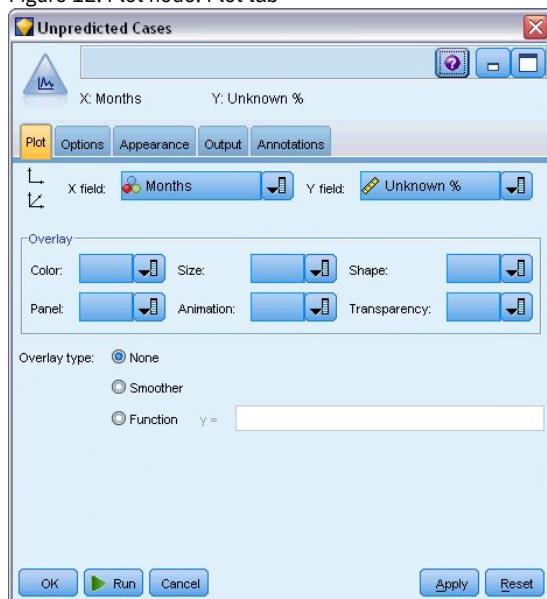

The upper and lower bounds on the estimated number of customers retained are plotted. The difference between the two lines is the number of customers scored as null, and therefore whose status is highly uncertain. Over time, the number of these customers increases. After 12 months, you can expect to retain between 601 and 735 of the original customers in the dataset; after 24 months, between 288 and 597.

Figure 11. Derive node: Settings tab

29. To get another look at how uncertain the estimates of the number of customers retained are, attach a Derive node to the Filter node.
30. On the Settings tab of the Derive node, type *Unknown %* as the derive field.
31. Select Continuous as the field type.
32. Type $(100 * ('Upper Estimate' - 'Lower Estimate')) / 'Lower Estimate'$ as the formula. *Unknown %* is the number of customers "in doubt" as a percentage of the lower estimate.
33. Click OK.

Figure 12. Plot node: Plot tab

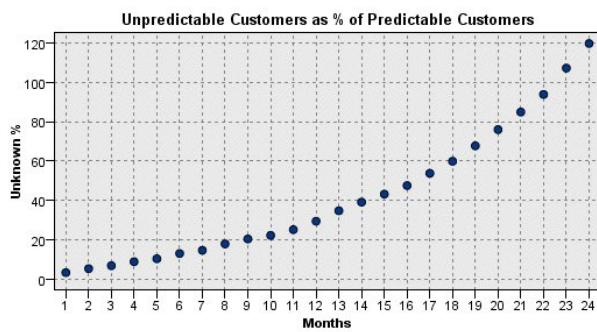

34. Attach a Plot node to the Derive node.
35. On the Plot tab of the Plot node, select *Months* as the X field and *Unknown %* as the Y field.
36. Click the Appearance tab.

Figure 13. Plot node: Appearance tab

37. Type Unpredictable Customers as % of Predictable Customers as the title.
 38. Execute the node.

Figure 14. Plot of unpredictable customers

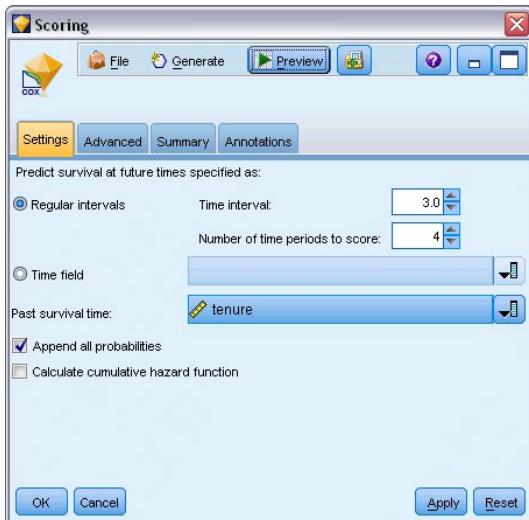

Through the first year, the percentage of unpredictable customers increases at a fairly linear rate, but the rate of increase explodes during the second year until, by month 23, the number of customers with null values outnumber the expected number of customers retained.

[Next](#)

Scoring

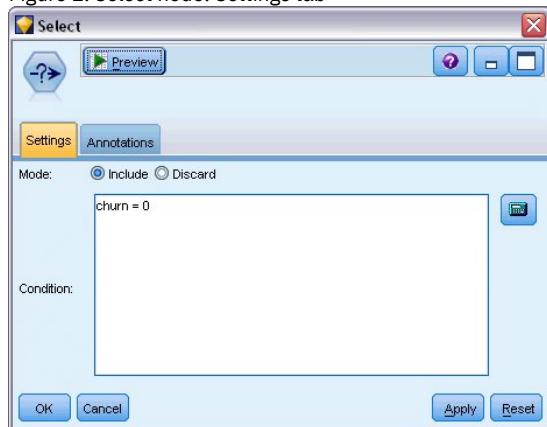

Once satisfied with a model, you want to score customers to identify the individuals most likely to churn within the next year, by quarter.

Figure 1. Coxreg nugget: Settings tab

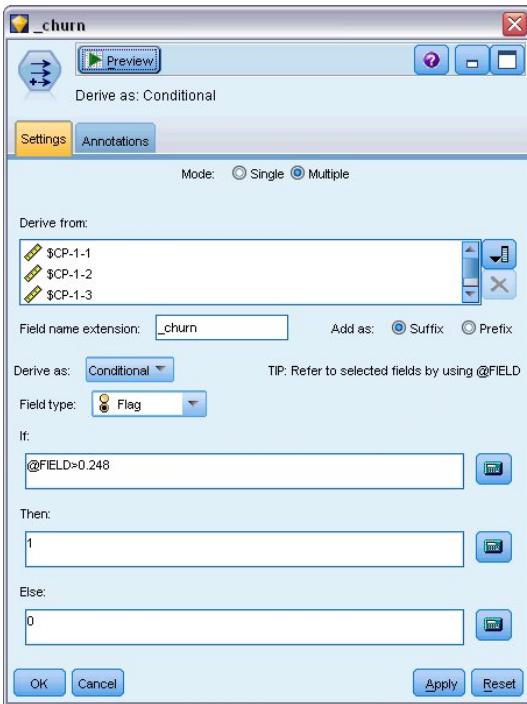

1. Attach a third model nugget to the Source node and open the model nugget.
2. Make sure Regular Intervals is selected, and specify 3.0 as the time interval and 4 as the number of periods to score. This specifies that each record will be scored for the following four quarters.
3. Select *tenure* as the field to specify the past survival time. The scoring algorithm will take into account the length of each customer's time as a customer of the company.
4. Select Append all probabilities. These extra fields will make it easier to sort the records for viewing in a table.

Figure 2. Select node: Settings tab

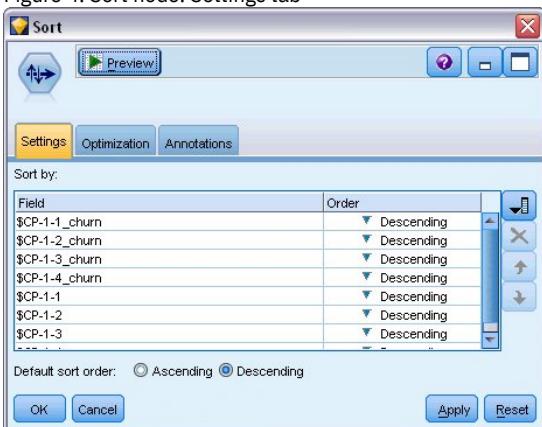

5. Attach a Select node to the model nugget; on the Settings tab, type `churn=0` as the condition. This removes customers who have already churned from the results table.

Figure 3. Derive node: Settings tab

6. Attach a Derive node to the Select node; on the Settings tab, select Multiple as the mode.
7. Choose to derive from \$CP-1-1 through \$CP-1-4, the fields of form \$CP-1-n, and type _churn as the suffix to add. This is easiest if, on the Select Fields dialog, you sort the fields by Name (that is, alphabetical order).
8. Choose to derive the field as a Conditional.
9. Select Flag as the measurement level.
10. Type @FIELD>0.248 as the If condition. Recall that this was the classification cutoff identified during Evaluation.
11. Type 1 as the Then expression.
12. Type 0 as the Else expression.
13. Click OK.

Figure 4. Sort node: Settings tab

14. Attach a Sort node to the Derive node; on the Settings tab, choose to sort by \$CP-1-1_churn through \$CP-1-4-churn and then \$CP-1-1 through \$CP-1-4, all in descending order. Customers who are predicted to churn will appear at the top.

Figure 5. Field Reorder node: Reorder tab

15. Attach a Field Reorder node to the Sort node; on the Reorder tab, choose to place `$CP-1-1_churn` through `$CP-1-4` in front of the other fields. This simply makes the results table easier to read, and so is optional. You will need to use the buttons to move the fields into the position shown in the figure.

Figure 6. Table showing customer scores

	\$CP-1-1_churn	\$CP-1-1	\$CP-1-2_churn	\$CP-1-2	\$CP-1-3_churn	\$CP-1-3	\$CP-1-4_churn	\$CP-1-4	tenur
255	0	0.032	0	0.075	0	0.147	1	0.298	49
256	0	0.027	0	0.064	0	0.127	1	0.260	49

272	0	0.062	0	0.105	0	0.151	0	0.191	23
273	0	0.062	0	0.130	0	0.163	0	0.212	44
274	0	0.061	0	0.123	0	0.182	0	0.241	4

16. Attach a Table node to the Field Reorder node and execute it.

264 customers are expected to churn by the end of the year, 184 by the end of the third quarter, 103 by the second, and 31 in the first. Note that given two customers, the one with a higher propensity to churn in the first quarter does not necessarily have a higher propensity to churn in later quarters; for example, see records 256 and 260. This is likely due to the shape of the hazard function for the months following the customer's current tenure; for example, customers who joined because of a promotion might be more likely to switch early on than customers who joined because of a personal recommendation, but if they do not then they may actually be more loyal for their remaining tenure. You may want to re-sort the customers to obtain different views of the customers most likely to churn.

Figure 7. Table showing customers with null values

Table (50 fields, 726 records)

At the bottom of the table are customers with predicted null values. These are customers whose total tenure (future time + *tenure*) falls beyond the range of survival times in the data used to train the model.

[Next](#)

Summary

Using Cox regression, you have found an acceptable model for the time to churn, plotted the expected number of customers retained over the next two years, and identified the individual customers most likely to churn in the next year. Note that while this is an acceptable model, it may not be the best model. Ideally you should at least compare this model, obtained using the Forward stepwise method, with one created using the Backward stepwise method.

Explanations of the mathematical foundations of the modeling methods used in IBM® SPSS® Modeler are listed in the *IBM SPSS Modeler Algorithms Guide*.

Market Basket Analysis (Rule Induction/C5.0)

This example deals with fictitious data describing the contents of supermarket baskets (that is, collections of items bought together) plus the associated personal data of the purchaser, which might be acquired through a loyalty card scheme. The goal is to discover groups of customers who buy similar products and can be characterized demographically, such as by age, income, and so on.

This example illustrates two phases of data mining:

- Association rule modeling and a web display revealing links between items purchased
- C5.0 rule induction profiling the purchasers of identified product groups

Note: This application does not make direct use of predictive modeling, so there is no accuracy measurement for the resulting models and no associated training/test distinction in the data mining process.

This example uses the stream named *baskrule*, which references the data file named *BASKETS1n*. These files are available from the *Demos* directory of any IBM® SPSS® Modeler installation. This can be accessed from the IBM SPSS Modeler program group on the Windows Start menu. The *baskrule* file is in the *streams* directory.

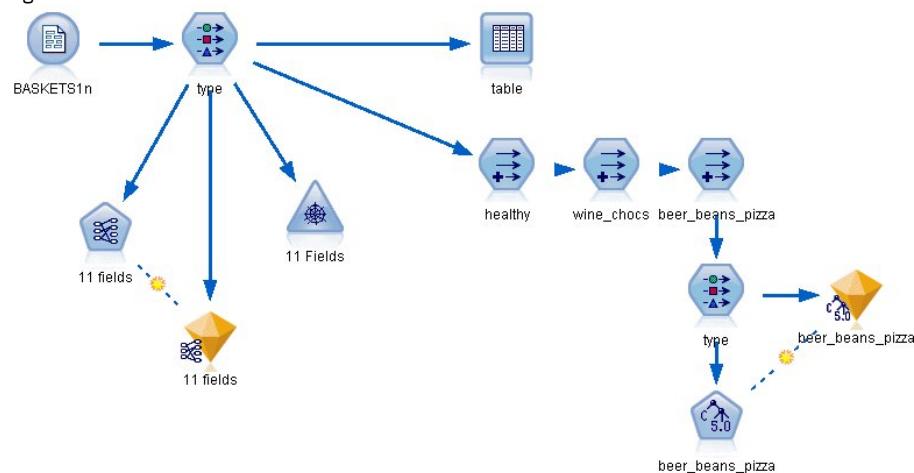

[Next](#)

- [Accessing the Data](#)
- [Discovering affinities in basket contents](#)
- [Profiling the Customer Groups](#)
- [Summary](#)

Accessing the Data

Using a Variable File node, connect to the dataset *BASKETS1n*, selecting to read field names from the file. Connect a Type node to the data source, and then connect the node to a Table node. Set the measurement level of the field *cardid* to *Typeless* (because each loyalty card ID occurs only once in the dataset and can therefore be of no use in modeling). Select *Nominal* as the measurement level for the field *sex* (this is to ensure that the Apriori modeling algorithm will not treat *sex* as a flag).

Figure 1. baskrule stream

Now run the stream to instantiate the Type node and display the table. The dataset contains 18 fields, with each record representing a basket.

The 18 fields are presented in the following headings.

Basket summary:

- *cardid*. Loyalty card identifier for customer purchasing this basket.
- *value*. Total purchase price of basket.
- *pmethod*. Method of payment for basket.

Personal details of cardholder:

- *sex*
- *homeown*. Whether or not cardholder is a homeowner.
- *income*
- *age*

Basket contents—flags for presence of product categories:

- *fruitveg*
- *freshmeat*
- *dairy*
- *cannedveg*
- *cannedmeat*
- *frozenmeal*
- *beer*
- *wine*
- *softdrink*
- *fish*
- *confectionery*

[Next](#)

Discovering affinities in basket contents

First, you need to acquire an overall picture of affinities (associations) in the basket contents using Apriori to produce association rules. Select the fields to be used in this modeling process by editing the Type node and setting the role of all of the product categories to *Both* and all other roles to *None*. (*Both* means that the field can be either an input or an output of the resultant model.)

Note: You can set options for multiple fields using Shift-click to select the fields before specifying an option from the columns.

Figure 1. Selecting fields for modeling

Once you have specified fields for modeling, attach an Apriori node to the Type node, edit it, select the option Only true values for flags, and click run on the Apriori node. The result, a model on the Models tab at the upper right of the managers window, contains association rules that you can view by using the context menu and selecting Browse.

Figure 2. Association rules

11 fields			
Model Settings Summary Annotations			
Consequent	Antecedent	Support %	Confidence %
frozenmeal	beer cannedveg	16.7	87.425
cannedveg	beer frozenmeal	17.0	85.882
beer	frozenmeal cannedveg	17.3	84.393

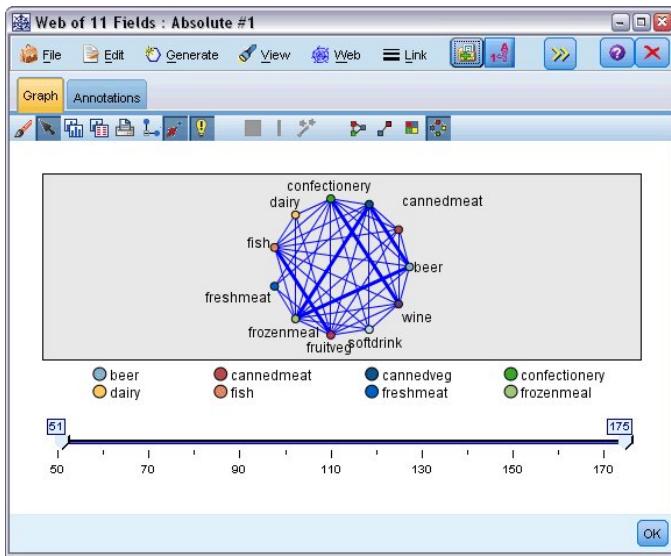

These rules show a variety of associations between frozen meals, canned vegetables, and beer. The presence of two-way association rules, such as:

```
frozenmeal -> beer
beer -> frozenmeal
```

suggests that a web display (which shows only two-way associations) might highlight some of the patterns in this data.

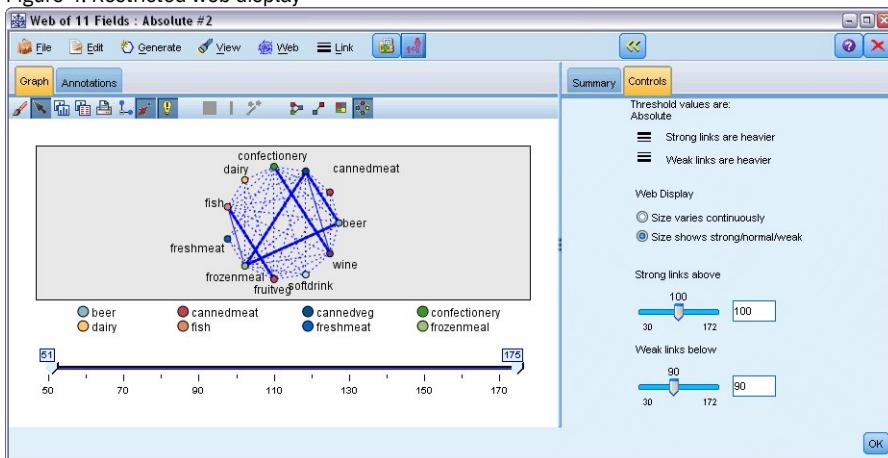

Attach a Web node to the Type node, edit the Web node, select all of the basket contents fields, select Show true flags only, and click run on the Web node.

Figure 3. Web display of product associations

Because most combinations of product categories occur in several baskets, the strong links on this web are too numerous to show the groups of customers suggested by the model.

Figure 4. Restricted web display

1. To specify weak and strong connections, click the yellow double arrow button on the toolbar. This expands the dialog box showing the web output summary and controls.
2. Select Size shows strong/normal/weak.
3. Set weak links below 90.
4. Set strong links above 100.

In the resulting display, three groups of customers stand out:

- Those who buy fish and fruits and vegetables, who might be called "healthy eaters"
- Those who buy wine and confectionery
- Those who buy beer, frozen meals, and canned vegetables ("beer, beans, and pizza")

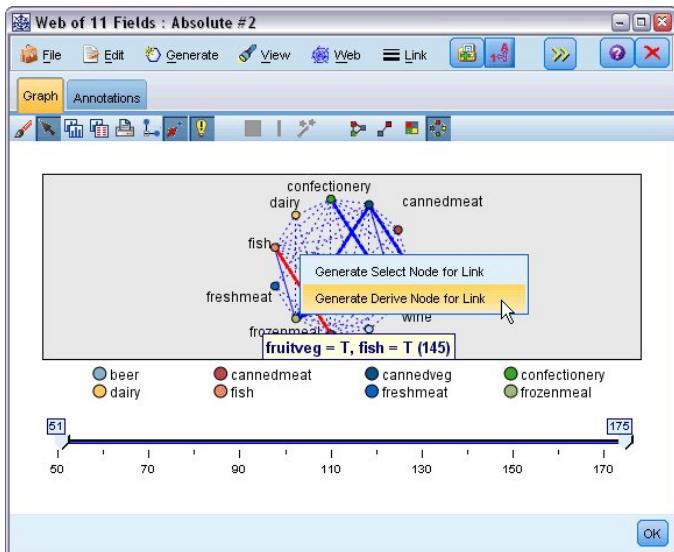

[Next](#)

Profiling the Customer Groups

You have now identified three groups of customers based on the types of products they buy, but you would also like to know who these customers are--that is, their demographic profile. This can be achieved by tagging each customer with a flag for each of these groups and using rule induction (C5.0) to build rule-based profiles of these flags.

First, you must derive a flag for each group. This can be automatically generated using the web display that you just created. Using the right mouse button, click the link between *fruitveg* and *fish* to highlight it, then right-click and select Generate Derive Node For Link.

Figure 1. Deriving a flag for each customer group

Edit the resulting Derive node to change the Derive field name to *healthy*. Repeat the exercise with the link from *wine* to *confectionery*, naming the resultant Derive field *wine_chocs*.

For the third group (involving three links), first make sure that no links are selected. Then select all three links in the *cannedveg*, *beer*, and *frozenmeal* triangle by holding down the shift key while you click the left mouse button. (Be sure you are in Interactive mode rather than Edit mode.) Then from the web display menus choose:

Generate...Derive Node ("And")

Change the name of the resultant Derive field to *beer_beans_pizza*.

To profile these customer groups, connect the existing Type node to these three Derive nodes in series, and then attach another Type node. In the new Type node, set the role of all fields to *None*, except for *value*, *pmethod*, *sex*, *hometown*, *income*, and *age*, which should be set to *Input*, and the relevant customer group (for example, *beer_beans_pizza*), which should be set to *Target*. Attach a C5.0 node, set the Output type to Rule set, and click run on the node. The resultant model (for *beer_beans_pizza*) contains a clear demographic profile for this customer group:

```
Rule 1 for T:
if sex = M
and income <= 16,900
then T
```

The same method can be applied to the other customer group flags by selecting them as the output in the second Type node. A wider range of alternative profiles can be generated by using Apriori instead of C5.0 in this context; Apriori can also be used to profile all of the customer group flags simultaneously because it is not restricted to a single output field.

[Next](#)

Summary

This example reveals how IBM® SPSS® Modeler can be used to discover affinities, or links, in a database, both by modeling (using Apriori) and by visualization (using a web display). These links correspond to groupings of cases in the data, and these groups can be investigated in detail and profiled by modeling (using C5.0 rule sets).

In the retail domain, such customer groupings might, for example, be used to target special offers to improve the response rates to direct mailings or to customize the range of products stocked by a branch to match the demands of its demographic base.

Assessing New Vehicle Offerings (KNN)

Nearest Neighbor Analysis is a method for classifying cases based on their similarity to other cases. In machine learning, it was developed as a way to recognize patterns of data without requiring an exact match to any stored patterns, or cases. Similar cases are near each other and dissimilar cases are distant from each other. Thus, the distance between two cases is a measure of their dissimilarity.

Cases that are near each other are said to be “neighbors.” When a new case (holdout) is presented, its distance from each of the cases in the model is computed. The classifications of the most similar cases – the nearest neighbors – are tallied and the new case is placed into the category that contains the greatest number of nearest neighbors.

You can specify the number of nearest neighbors to examine; this value is called k . The pictures show how a new case would be classified using two different values of k . When $k = 5$, the new case is placed in category 1 because a majority of the nearest neighbors belong to category 1. However, when $k = 9$, the new case is placed in category 0 because a majority of the nearest neighbors belong to category 0.

Nearest neighbor analysis can also be used to compute values for a continuous target. In this situation, the average or median target value of the nearest neighbors is used to obtain the predicted value for the new case.

An automobile manufacturer has developed prototypes for two new vehicles, a car and a truck. Before introducing the new models into its range, the manufacturer wants to determine which existing vehicles on the market are most like the prototypes--that is, which vehicles are their "nearest neighbors", and therefore which models they will be competing against.

The manufacturer has collected data about the existing models under a number of categories, and has added the details of its prototypes. The categories under which the models are to be compared include price in thousands (*price*), engine size (*engine_s*), horsepower (*horsepow*), wheelbase (*wheelbas*), width (*width*), length (*length*), curb weight (*curb_wgt*), fuel capacity (*fuel_cap*) and fuel efficiency (*mpg*).

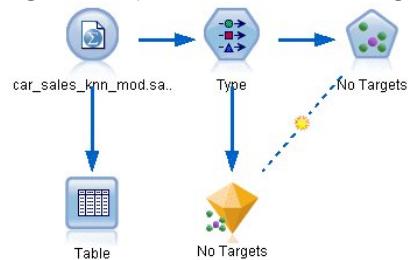

This example uses the stream named *car_sales_knn.str*, available in the *Demos* folder under the *streams* subfolder. The data file is *car_sales_knn_mod.sav*. See the topic [Demos Folder](#) for more information.

[Next](#)

- [Creating the Stream](#)
- [Examining the output](#)
- [Summary](#)

Creating the Stream

Figure 1. Sample stream for KNN modeling

Create a new stream and add a Statistics File source node pointing to *car_sales_knn_mod.sav* in the *Demos* folder of your IBM® SPSS® Modeler installation.

First, let's see what data the manufacturer has collected.

1. Attach a Table node to the Statistics File source node.
2. Open the Table node and click Run.

Figure 2. Source data for cars and trucks

	manufact	model	sales	resale	type	price	engine_s	horsepow	wheelbas	width

157	Volvo	S80	18.969	\$null\$	0.0...	36...	2.900	201.000	109.900	72.1...
158	newC...	\$null\$	\$null\$	\$n...	21...	1.500	76.000	106.300	67.9...	
159	newT...	\$null\$	\$null\$	\$n...	34...	3.500	167.000	109.800	75.2...	

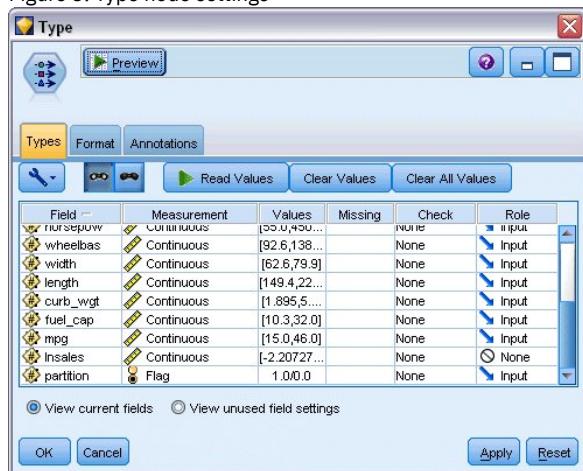

The details for the two prototypes, named *newCar* and *newTruck*, have been added at the end of the file.

We can see from the source data that the manufacturer is using the classification of "truck" (value of 1 in the *type* column) rather loosely to mean any non-automobile type of vehicle.

The last column, *partition*, is necessary in order that the two prototypes can be designated as holdouts when we come to identify their nearest neighbors. In this way, their data will not influence the calculations, as it is the rest of the market that we want to consider. Setting the *partition* value of the two holdout records to 1, while all the other records have a 0 in this field, enables us to use this field later when we come to set the focal records--the records for which we want to calculate the nearest neighbors.

Leave the table output window open for now, as we'll be referring to it later.

Figure 3. Type node settings

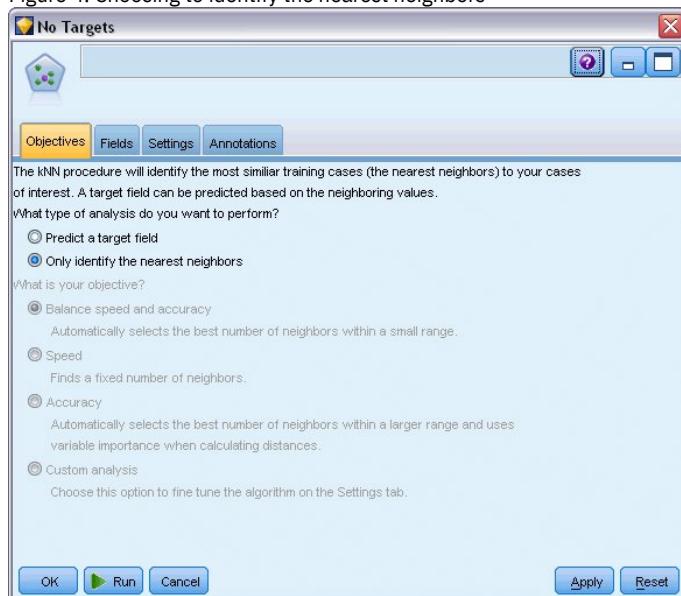

3. Add a Type node to the stream.
4. Attach the Type node to the Statistics File source node.
5. Open the Type node.

We want to make the comparison only on the fields *price* through *mpg*, so we'll leave the role for all these fields set to Input.

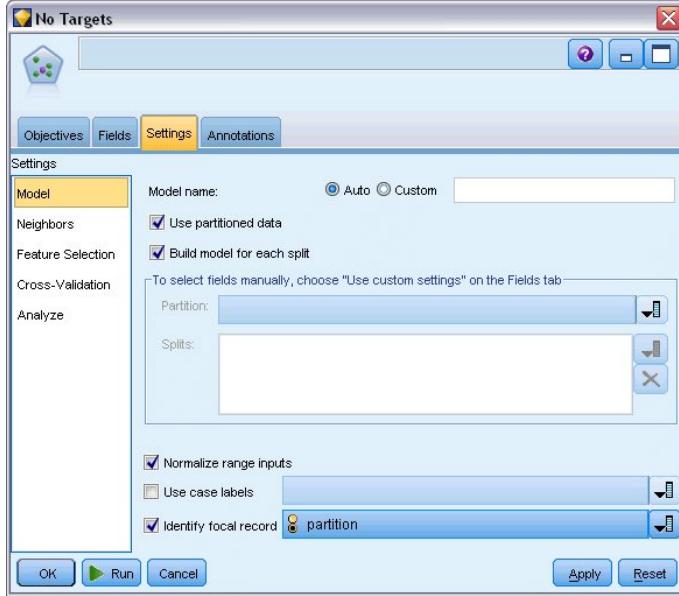

6. Set the role for all the other fields (*manufact* through *type*, plus *Insales*) to None.
7. Set the measurement level for the last field, *partition*, to Flag. Make sure that its role is set to Input.
8. Click Read Values to read the data values into the stream.
9. Click OK.

Figure 4. Choosing to identify the nearest neighbors

10. Attach a KNN node to the Type node.
 11. Open the KNN node.
- We're not going to be predicting a target field this time, because we just want to find the nearest neighbors for our two prototypes.
12. On the Objectives tab, choose Only identify the nearest neighbors.
 13. Click the Settings tab.

Figure 5. Using the partition field to identify the focal records

Now we can use the *partition* field to identify the focal records--the records for which we want to identify the nearest neighbors. By using a flag field, we ensure that records where the value of this field is set to 1 become our focal records.

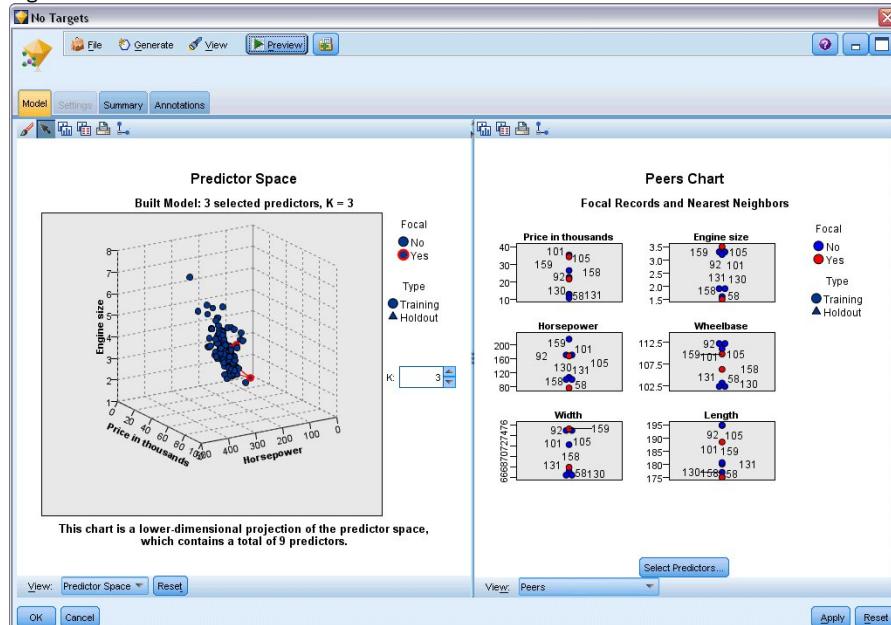

As we've seen, the only records that have a value of 1 in this field are *newCar* and *newTruck*, so these will be our focal records.

14. On the Model panel of the Settings tab, select the Identify focal record check box.
15. From the drop-down list for this field, choose partition.
16. Click the Run button.

[Next](#)

Examining the output

Figure 1. The Model Viewer window

A model nugget has been created on the stream canvas and in the Models palette. Open either of the nuggets to see the Model Viewer display, which has a two-panel window:

- The first panel displays an overview of the model called the main view. The main view for the Nearest Neighbor model is known as the **predictor space**.
- The second panel displays one of two types of views:

An auxiliary model view shows more information about the model, but is not focused on the model itself.

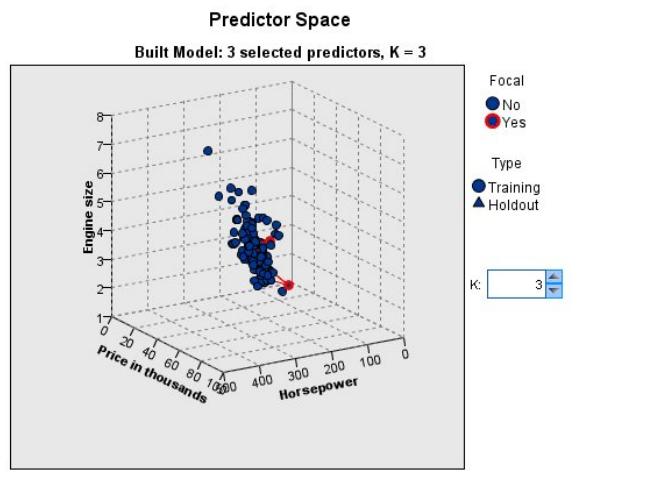

A linked view is a view that shows details about one feature of the model when you drill down on part of the main view.

[Next](#)

- [Predictor Space](#)
- [Peers Chart](#)
- [Neighbor and Distance Table](#)

Predictor Space

Figure 1. Predictor space chart

The predictor space chart is an interactive 3-D graph that plots data points for three features (actually the first three input fields of the source data), representing price, engine size and horsepower.

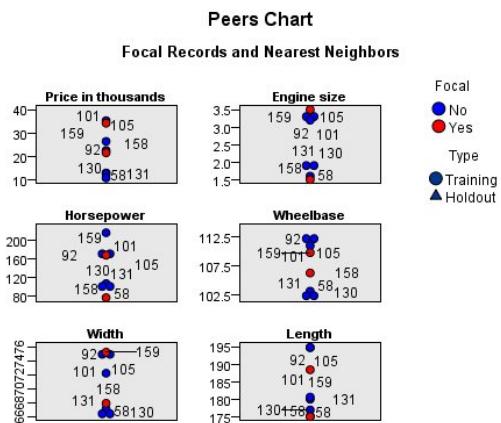

Our two focal records are highlighted in red, with lines connecting them to their k nearest neighbors.

By clicking and dragging the chart, you can rotate it to get a better view of the distribution of points in the predictor space. Click the Reset button to return it to the default view.

[Next](#)

Peers Chart

Figure 1. Peers chart

The default auxiliary view is the peers chart, which highlights the two focal records selected in the predictor space and their k nearest neighbors on each of six features--the first six input fields of the source data.

The vehicles are represented by their record numbers in the source data. This is where we need the output from the Table node to help identify them.

If the Table node output is still available:

1. Click the Outputs tab of the manager pane at the top right of the main IBM® SPSS® Modeler window.
 2. Double-click the entry Table (16 fields, 159 records).

If the table output is no longer available:

3. On the main IBM SPSS Modeler window, open the Table node.
4. Click Run.

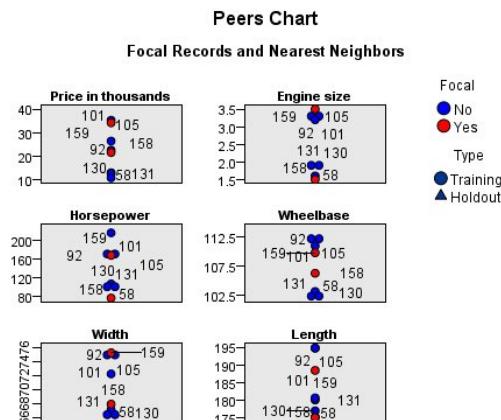

Figure 2. Identifying records by record number

Table (16 fields, 159 records)

	manufact	model	sales	resale	type	price	engine_s	horsepow	wheelbas	width
140	Toyota	Celica	33.269	15.445	0...0...	16.0...	1.800	140.000	102.400	68.3...
141	Toyota	Tacoma	84.087	9.575	1...0...	11.0...	2.400	142.000	103.300	66.5...

150	Volksw...	GTI	5.596	13.760	0...0...	17.0...	2.000	115.000	98.900	68.3...
151	Volksw...	Beetle	49.463	\$null\$	0...0...	15.0...	2.000	115.000	98.900	67.9...
152	Volvo	S40	16.957	\$null\$	0...0...	23.0...	1.900	160.000	100.500	67.6...
153	Volvo	V40	3.545	\$null\$	0...0...	24.0...	1.900	160.000	100.500	67.6...
154	Volvo	S70	15.245	\$null\$	0...0...	27.0...	2.400	168.000	104.900	69.3...
155	Volvo	V70	17.531	\$null\$	0...0...	28.0...	2.400	168.000	104.900	69.3...
156	Volvo	C70	3.493	\$null\$	0...0...	45.0...	2.300	236.000	104.900	71.5...
157	Volvo	S80	18.969	\$null\$	0...0...	36.0...	2.900	201.000	109.900	72.1...
158		newC...	\$null\$	\$null\$	\$n...\$	21.0...	1.500	76.000	106.300	67.9...
159		newT...	\$null\$	\$null\$	\$n...\$	34.0...	3.500	167.000	109.800	75.2...

Scrolling down to the bottom of the table, we can see that *newCar* and *newTruck* are the last two records in the data, numbers 158 and 159 respectively.

Figure 3. Comparing features on the peers chart

From this we can see on the peers chart, for example, that *newTruck* (159) has a bigger engine size than any of its nearest neighbors, while *newCar* (158) has a smaller engine than any of *its* nearest neighbors.

For each of the six features, you can move the mouse over the individual dots to see the actual value of each feature for that particular case.

But which vehicles are the nearest neighbors for *newCar* and *newTruck*?

The peers chart is a little bit crowded, so let's change to a simpler view.

5. Click the View drop-down list at the bottom of the peers chart (the entry that currently says Peers).
 6. Select Neighbor and Distance Table.

[Next](#)

Neighbor and Distance Table

Figure 1. Neighbor and distance table

K Nearest Neighbors and Distances					
Focal Record	Displayed for Initial Focal Records				
	Nearest Neighbors			Nearest Distances	
	1	2	3	1	2
158	131	130	58	0.979	0.990
159	105	92	101	0.580	0.634

That's better. Now we can see the three models to which each of our two prototypes are closest in the market.

For *newCar* (focal record 158) they are the Saturn SC (131), the Saturn SL (130), and the Honda Civic (58).

No great surprises there--all three are medium-size saloon cars, so *newCar* should fit in well, particularly with its excellent fuel efficiency.

For *newTruck* (focal record 159), the nearest neighbors are the Nissan Quest (105), the Mercury Villager (92), and the Mercedes M-Class (101).

As we saw earlier, these are not necessarily trucks in the traditional sense, but simply vehicles that are classed as not being automobiles. Looking at the Table node output for its nearest neighbors, we can see that *newTruck* is relatively expensive, as well as being one of the heaviest of its type. However, fuel efficiency is again better than its closest rivals, so this should count in its favor.

[Next](#)

Summary

We've seen how you can use nearest-neighbor analysis to compare a wide-ranging set of features in cases from a particular data set. We've also calculated, for two very different holdout records, the cases that most closely resemble those holdouts.

Uncovering causal relationships in business metrics (TCM)

A business tracks various key performance indicators that describe the financial state of the business over time, and they also track a number of metrics that they can control. They are interested in using temporal causal modeling to uncover causal relationships between the controllable metrics and the key performance indicators. They would also like to know about any causal relationships among the key performance indicators.

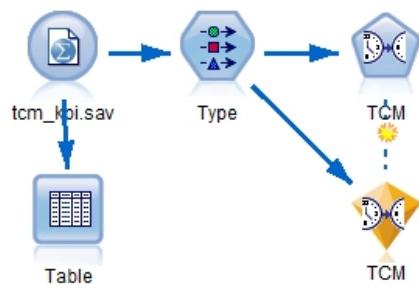

The data file tcm_kpi.sav contains weekly data on the key performance indicators and the controllable metrics. Data for the key performance indicators is stored in fields with the prefix *KPI*. Data for the controllable metrics is stored in fields with the prefix *Lever*.

Creating the stream

Figure 1. Sample stream for TCM modeling

1. Create a new stream and add a Statistics File source node pointing to *tcm_kpi.sav* in the *Demos* folder of your IBM® SPSS® Modeler installation.
2. Attach a Table node to the Statistics File source node.
3. Open the Table node and click Run to take a look at the data. It contains weekly data on the key performance indicators and the controllable metrics. Data for the key performance indicators is stored in fields with the prefix *KPI*, and data for the controllable metrics is stored in fields with the prefix *Lever*.

Figure 2. Source data for key performance indicators and controllable metrics

The screenshot shows a table with 31 fields and 112 records. The columns are labeled: date, Lever1, Lever2, Lever3, Lever4, Lever5, KPI_1, and KPI_2. The data is as follows:

	date	Lever1	Lever2	Lever3	Lever4	Lever5	KPI_1	KPI_2
1	2008-09-07	6.816	1.176	101.839	88.258	2027.711	1.829	1891.833
2	2008-09-14	6.091	1.172	120.610	103.803	2343.404	2.162	2125.261
3	2008-09-21	8.108	1.093	70.512	81.053	1813.224	1.809	1848.765

4. Add a Type node to the stream.
5. Attach the Type node to the Statistics File source node.

[Next](#)

Running the analysis

1. Attach a TCM node to the Type node, then open the TCM node and go to the Observations section of the Fields tab.

Figure 1. Temporal Causal Modeling, observations

2. Select *date* from the Date/time field and select *Weeks* from the Time interval field.

3. Click Time Series and select Use predefined roles.

In the sample data set *tcm_kpi.sav*, the fields *Lever1* through *Lever5* have the role of Input and *KPI_1* through *KPI_25* have the role of Both. When Use predefined roles is selected, fields with a role of Input are treated as candidate inputs and fields with a role of Both are treated as both candidate inputs and targets for temporal causal modeling.

The temporal causal modeling procedure determines the best inputs for each target from the set of candidate inputs. In this example, the candidate inputs are the fields *Lever1* through *Lever5* and the fields *KPI_1* through *KPI_25*.

4. Click Run.

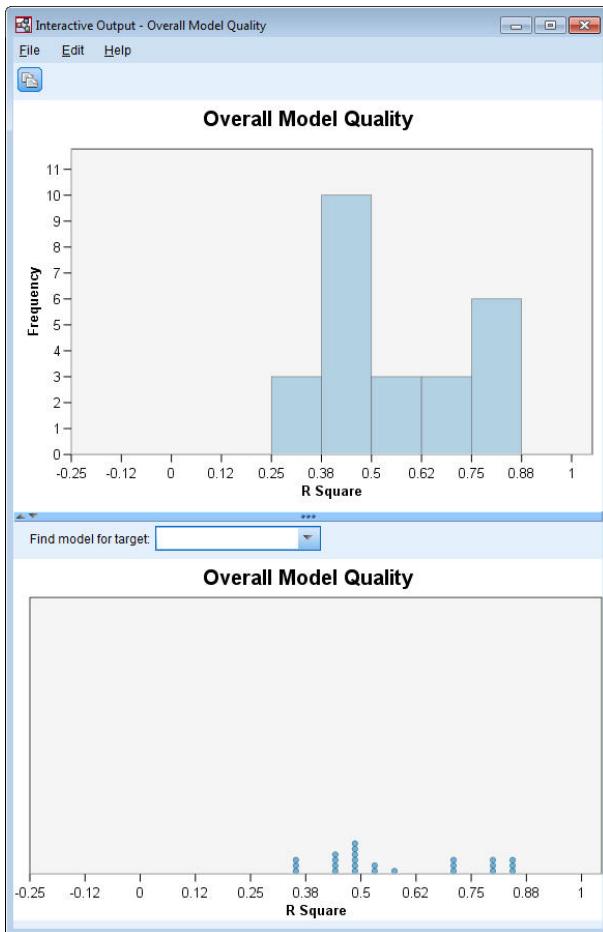

[Next](#)

Overall Model Quality Chart

The Overall Model Quality output item, which is generated by default, displays a bar chart and an associated dot plot of the model fit for all models. There is a separate model for each target series. The model fit is measured by the chosen fit statistic. This example uses the default fit statistic, which is R Square.

The Overall Model Quality item contains interactive features. To enable the features, activate the item by double-clicking the Overall Model Quality chart in the Viewer.

Figure 1. Overall Model Quality

Clicking a bar in the bar chart filters the dot plot so that it displays only the models that are associated with the selected bar. Hovering over a dot in the dot plot displays a tooltip that contains the name of the associated series and the value of the fit statistic. You can find the model for a particular target series in the dot plot by specifying the series name in the Find model for target box.

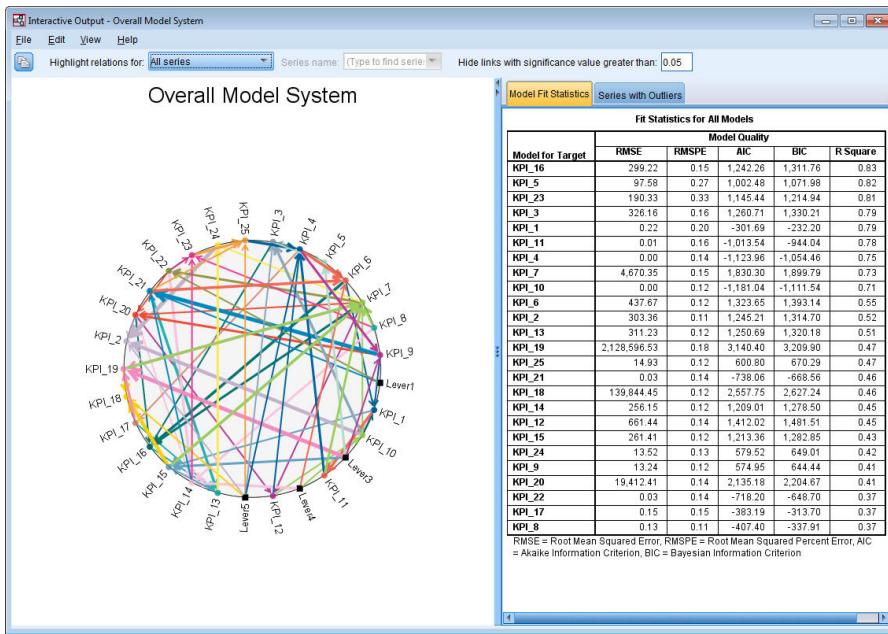

[Next](#)

Overall Model System

The Overall Model System output item, which is generated by default, displays a graphical representation of the causal relations between series in the model system. By default, relations for the top 10 models are shown, as determined by the value of the R Square fit statistic. The number of top models (also referred to as best-fitting models) and the fit statistic are specified on the Series to Display settings (on the Build Options tab) of the Temporal Causal Modeling dialog.

The Overall Model System item contains interactive features. To enable the features, activate the item by double-clicking the Overall Model System chart in the Viewer. In this example, it is most important to see the relations between all series in the system. In the interactive output, select All series from the Highlight relations for drop-down list.

Figure 1. Overall Model System, view for all series

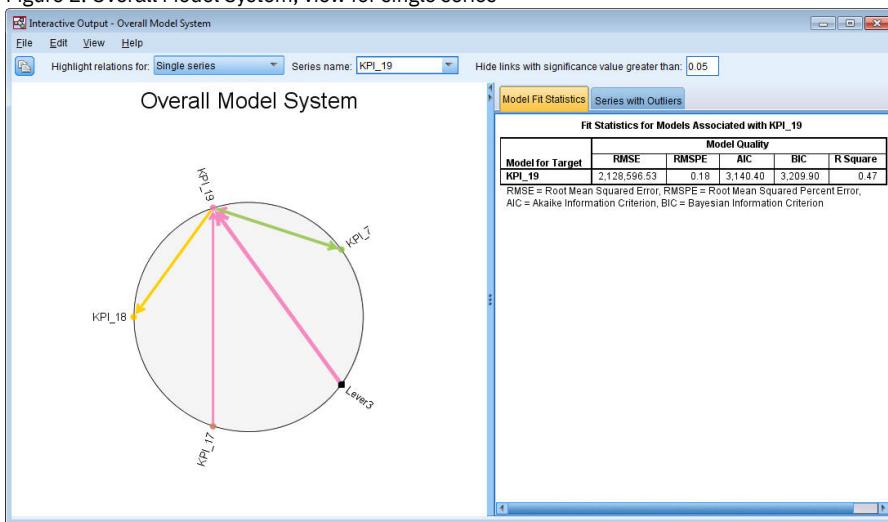

All lines that connect a particular target to its inputs have the same color, and the arrow on each line points from an input to the target of that input. For example, *Lever3* is an input to *KPI_19*.

The thickness of each line indicates the significance of the causal relation, where thicker lines represent a more significant relation. By default, causal relations with a significance value greater than 0.05 are hidden. At the 0.05 level, only *Lever1*, *Lever3*, *Lever4*, and *Lever5* have significant causal relations with the key performance indicator fields. You can change the threshold significance level by entering a value in the field that is labeled Hide links with significance value greater than.

In addition to uncovering causal relations between *Lever* fields and key performance indicator fields, the analysis also uncovered relations among the key performance indicator fields. For example, *KPI_10* was selected as an input to the model for *KPI_2*.

You can filter the view to show only the relations for a single series. For example, to view only the relations for *KPI_19*, click the label for *KPI_19*, right-click, and select Highlight relations for series.

Figure 2. Overall Model System, view for single series

This view shows the inputs to *KPI_19* that have a significance value less than or equal to 0.05. It also shows that, at the 0.05 significance level, *KPI_19* was selected as an input to both *KPI_18* and *KPI_7*.

In addition to displaying the relations for the selected series, the output item also contains information about any outliers that were detected for the series. Click the Series with Outliers tab.

Figure 3. Outliers for KPI_19
Series with Outliers for KPI_19

Series	Time	Observed Value
KPI_19	2008-10-12	7,358,201.68
	2009-04-05	2.10E+007
	2010-09-19	6,492,157.97

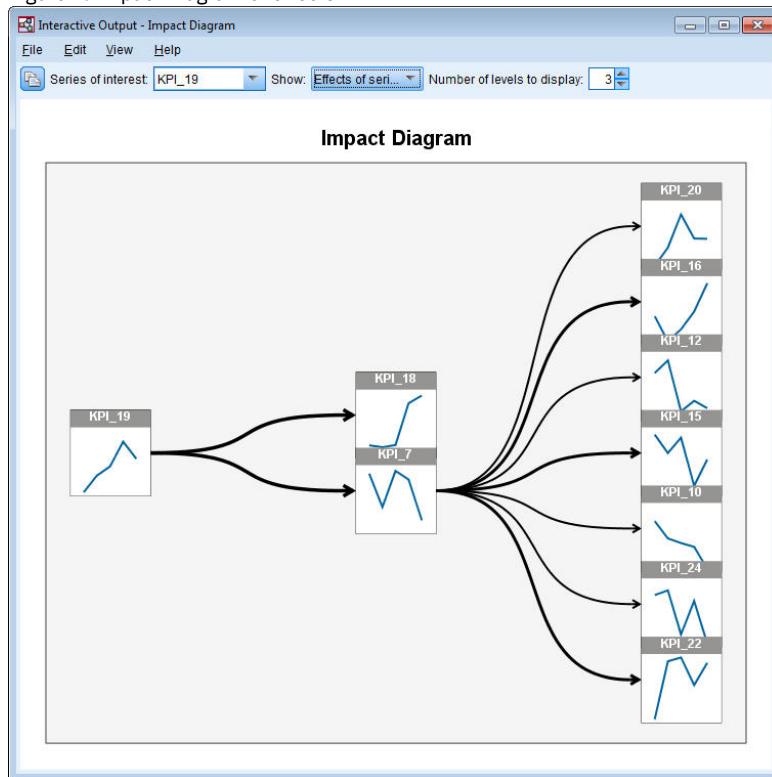

Three outliers were detected for *KPI_19*. Given the model system, which contains all of the discovered connections, it is possible to go beyond outlier detection and determine the series that most likely causes a particular outlier. This type of analysis is referred to as outlier root cause analysis and is covered in a later topic in this case study.

[Next](#)

Impact Diagrams

You can obtain a complete view of all relations that are associated with a particular series by generating an impact diagram. Click the label for *KPI_19* in the Overall Model System chart, right-click, and select Create Impact Diagram.

Figure 1. Impact Diagram of effects

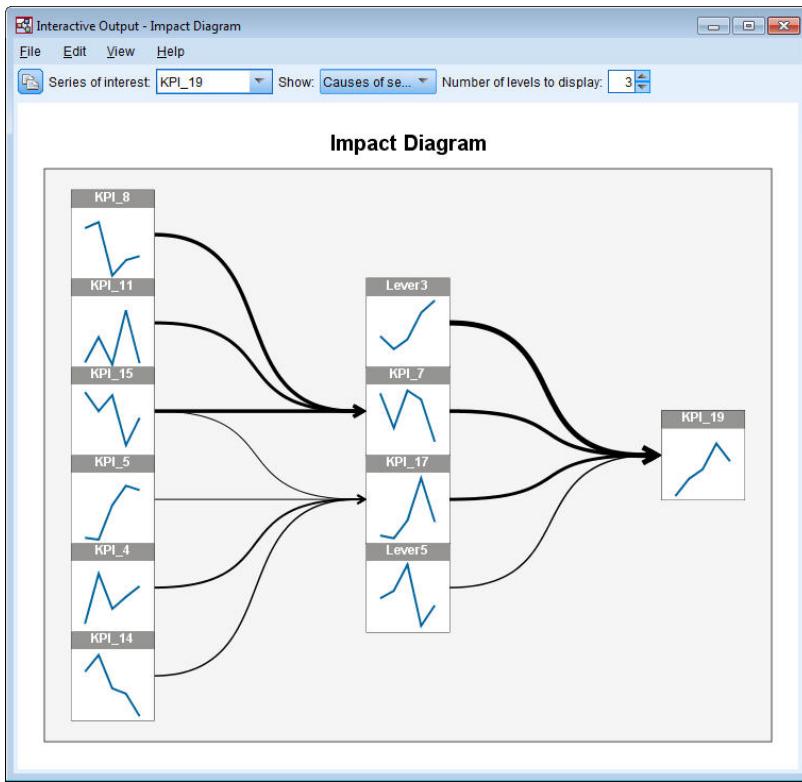

When an impact diagram is created from the Overall Model System, as in this example, it initially shows the series that are affected by the selected series. By default, impact diagrams show three levels of effects, where the first level is just the series of interest. Each additional level shows more indirect effects of the series of interest. You can change the value of the Number of levels to display to show more or fewer levels of effects. The impact diagram for this example shows that *KPI_19* is a direct input to both *KPI_18* and *KPI_7*, but it indirectly affects a number of series through its effect on series *KPI_7*. As in the overall model system, the thickness of the lines indicates the significance of the causal relations.

The chart that is displayed in each node of the impact diagram shows the last $L+1$ values of the associated series at the end of the estimation period and any forecast values, where L is the number of lag terms that are included in each model. You can obtain a detailed sequence chart of these values by single-clicking the associated node.

Double-clicking a node sets the associated series as the series of interest, and regenerates the impact diagram based on that series. You can also specify a series name in the Series of interest box to select a different series of interest.

Impact diagrams can also show the series that affect the series of interest. These series are referred to as *causes*. To see the series that affect *KPI_19*, select Causes of series from the Show drop-down.

Figure 2. Impact Diagram of causes

This view shows that the model for *KPI_19* has four inputs and that *Lever3* has the most significant causal connection with *KPI_19*. It also shows series that indirectly affect *KPI_19* through their effects on *KPI_7* and *KPI_17*. The same concept of levels that was discussed for effects also applies to causes. Likewise, you can change the value of the Number of levels to display to show more or fewer levels of causes.

[Next](#)

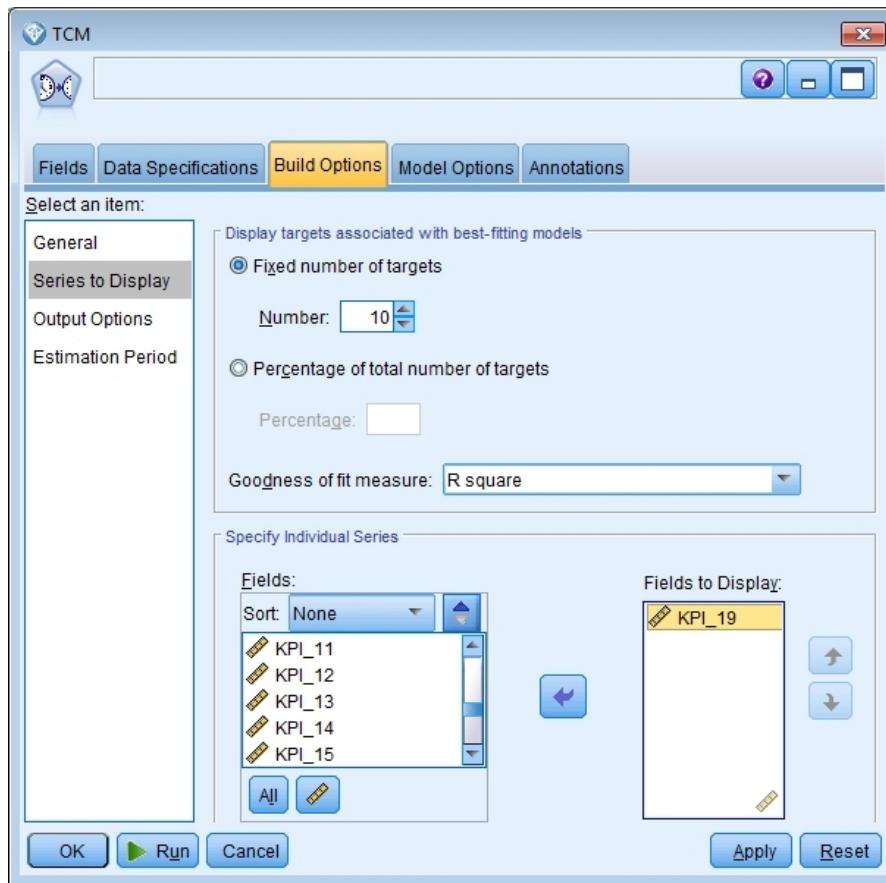

Determining root causes of outliers

Given a temporal causal model system, it is possible to go beyond outlier detection and determine the series that most likely causes a particular outlier. This process is referred to as outlier root cause analysis and must be requested on a series by series basis. The analysis requires a temporal causal model system and the data that was used to build the system. In this example, the active dataset is the data that was used to build the model system.

To run outlier root cause analysis:

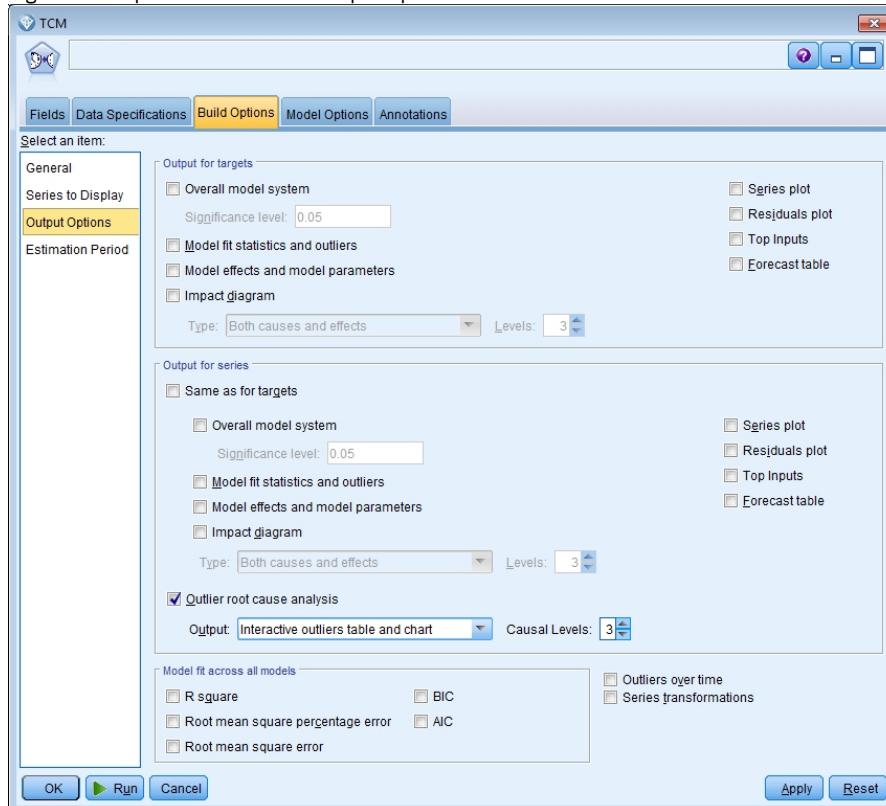

1. In the TCM dialog, go to the Build Options tab and then click Series to Display in the Select an item list.

Figure 1. Temporal Causal Model Series to Display

2. Move *KPI_19* to the Fields to display list.
3. Click Output options in the Select an item list on the Options tab.

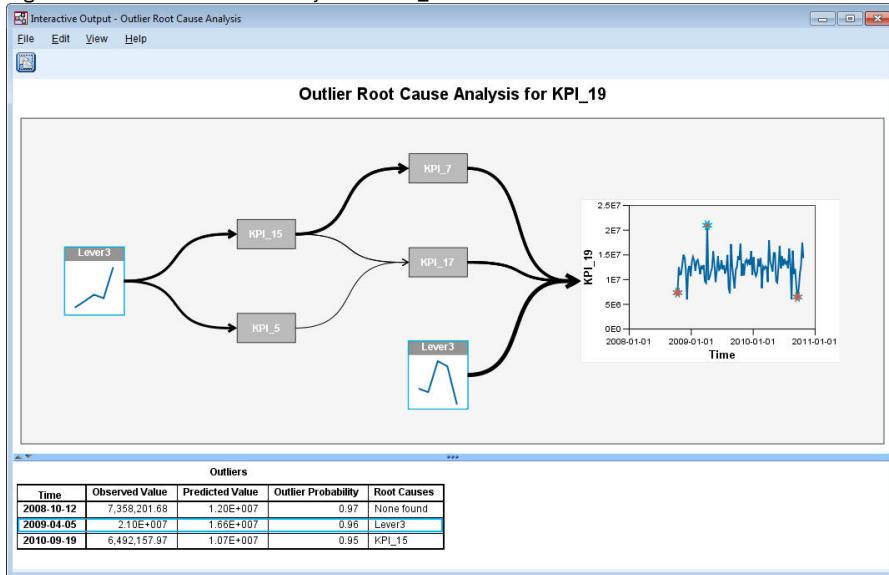

Figure 2. Temporal Causal Model Output Options

4. Deselect Overall model system, Same as for targets, R square, and Series transformations.
5. Select Outlier root cause analysis and keep the existing settings for Output and Causal levels.
6. Click Run.

7. Double-click the Outlier Root Cause Analysis chart for *KPI_19* in the Viewer to activate it.

Figure 3. Outlier Root Cause Analysis for *KPI_19*

The results of the analysis are summarized in the Outliers table. The table shows that root causes were found for the outliers at 2009-04-05 and 2010-09-19, but no root cause was found for the outlier at 2008-10-12. Clicking a row in the Outliers table highlights the path to the root cause series, as shown here for the outlier at 2009-04-05. This action also highlights the selected outlier in the sequence chart. You can also click the icon for an outlier directly in the sequence chart to highlight the path to the root cause series for that outlier.

For the outlier at 2009-04-05, the root cause is *Lever3*. The diagram shows that *Lever3* is a direct input to *KPI_19*, but that it also indirectly influences *KPI_19* through its effect on other series that affect *KPI_19*. One of the configurable parameters for outlier root cause analysis is the number of causal levels to search for root causes. By default, three levels are searched. Occurrences of the root cause series are displayed up to the specified number of causal levels. In this example, *Lever3* occurs at both the first causal level and the third causal level.

Each node in the highlighted path for an outlier contains a chart whose time range depends on the level at which the node occurs. For nodes in the first causal level, the range is T-1 to T-L where T is the time at which the outlier occurs and L is the number of lag terms that are included in each model. For nodes in the second causal level, the range is T-2 to T-L-1; and for the third level the range is T-3 to T-L-2. You can obtain a detailed sequence chart of these values by single-clicking the associated node.

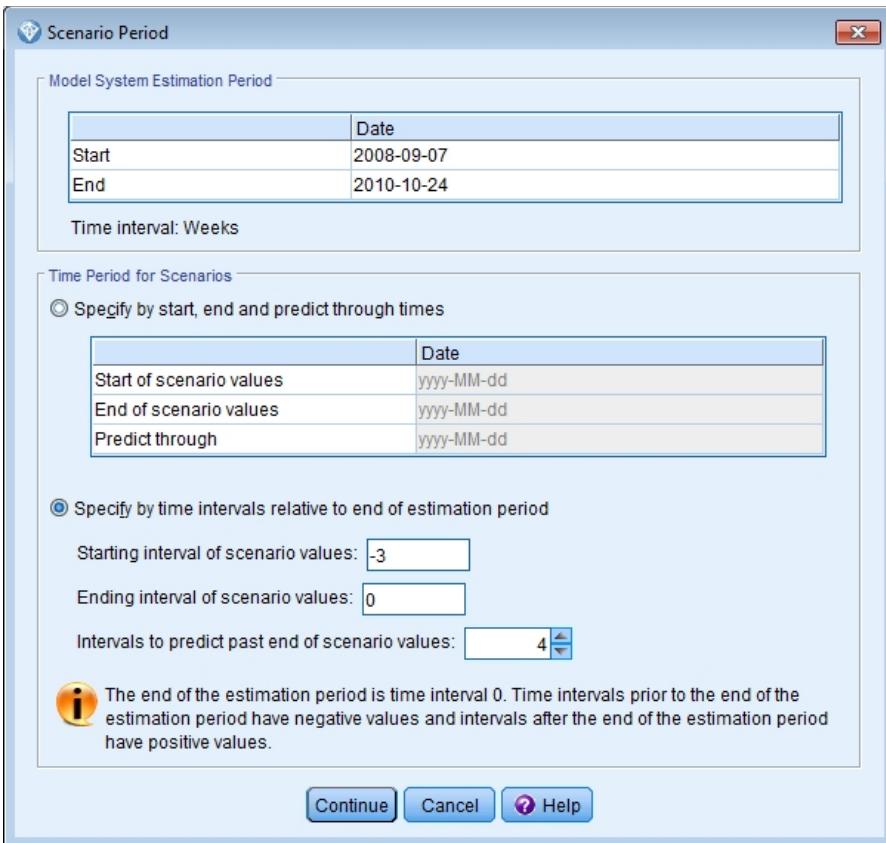

Running scenarios

Given a temporal causal model system, you can run user-defined scenarios. A *scenario* is defined by a time series, that is referred to as the *root series*, and a set of user-defined values for that series over a specified time range. The specified values are then used to generate predictions for the time series that are affected by the root series. The analysis requires a temporal causal model system and the data that was used to build the system. In this example, the active dataset is the data that was used to build the model system.

To run scenarios:

1. In the TCM output dialog, click the Scenario Analysis button.
2. In the Temporal Causal Model Scenarios dialog, click Define Scenario Period.

Figure 1. Scenario Period

3. Select Specify by time intervals relative to end of estimation period.
4. Enter **-3** for the starting interval and enter **0** for the ending interval.

These settings specify that each scenario is based on values that are specified for the last four time intervals in the estimation period. For this example, the last four time intervals means the last four weeks. The time range over which the scenario values are specified is referred to as the *scenario period*.

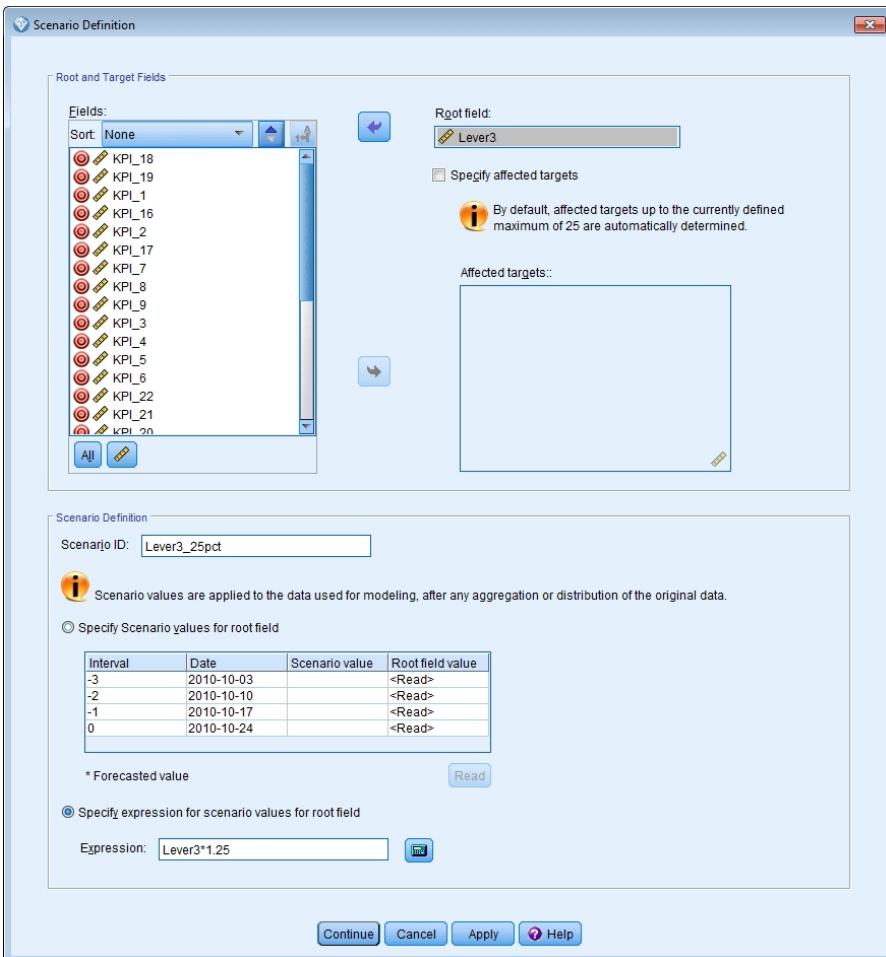

5. Enter **4** for the intervals to predict past the end of the scenarios values.

This setting specifies that predictions are generated for four time intervals beyond the end of the scenario period.

6. Click Continue.

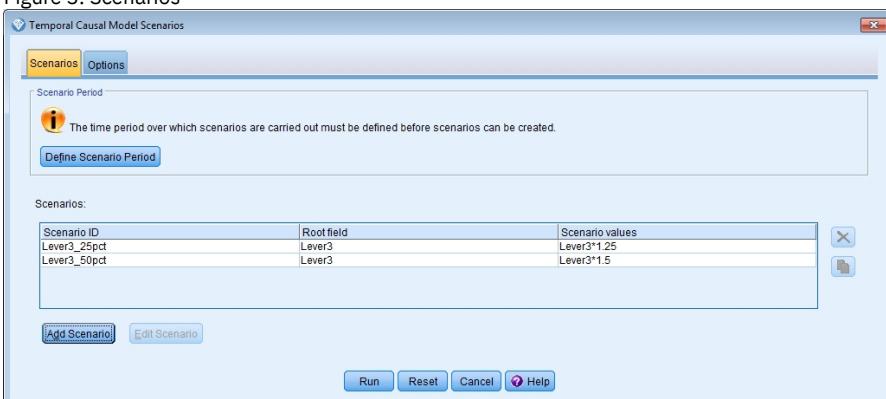

7. Click Add Scenario on the Scenarios tab.

Figure 2. Scenario Definition

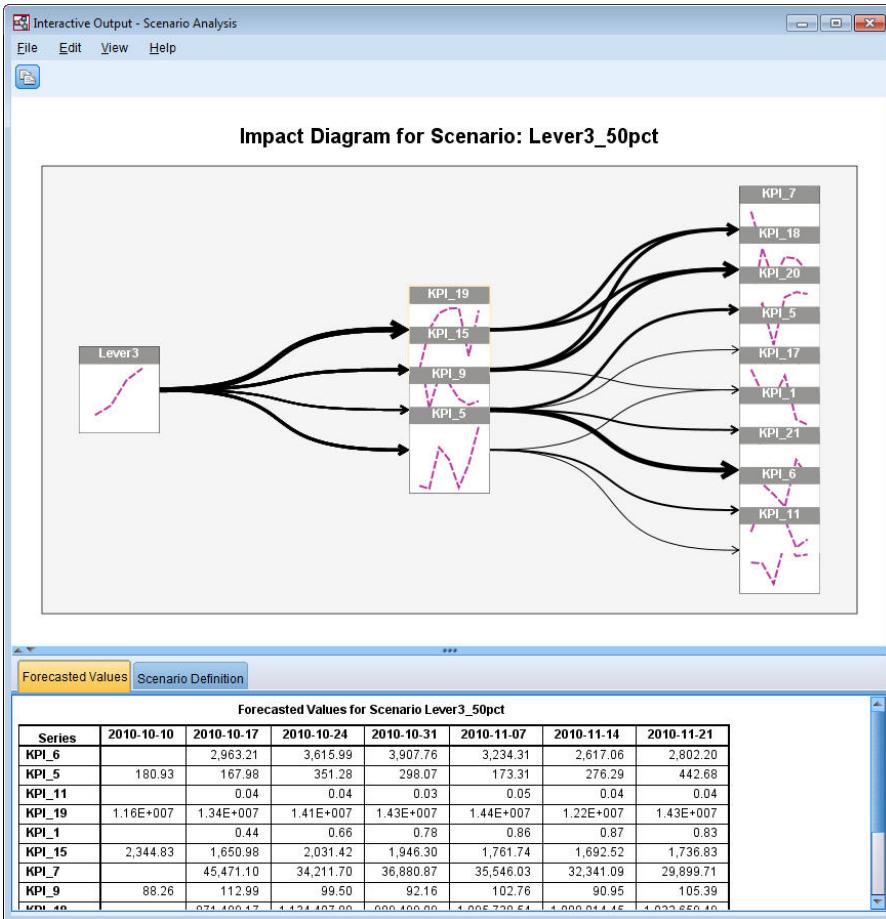

8. Move *Lever3* to the Root Field box to examine how specified values of *Lever3* in the scenario period affect predictions of the other series that are causally affected by *Lever3*.
9. Enter *Lever3_25pct* for the scenario ID.
10. Select Specify expression for scenario values for root field and enter *Lever3*1.25* for the expression.
This setting specifies that the values for *Lever3* in the scenario period are 25% larger than the observed values. For more complex expressions, you can use the Expression Builder by clicking the calculator icon.
11. Click Continue.
12. Repeat steps 10 - 14 to define a scenario that has *Lever3* for the root field, *Lever3_50pct* for the scenario ID, and *Lever3*1.5* for the expression.

Figure 3. Scenarios

13. Click the Options tab and enter 2 for the maximum level for affected targets.
14. Click Run.
15. Double-click the Impact Diagram chart for *Lever3_50pct* in the Viewer to activate it.

Figure 4. Impact Diagram for Scenario: *Lever3_50pct*

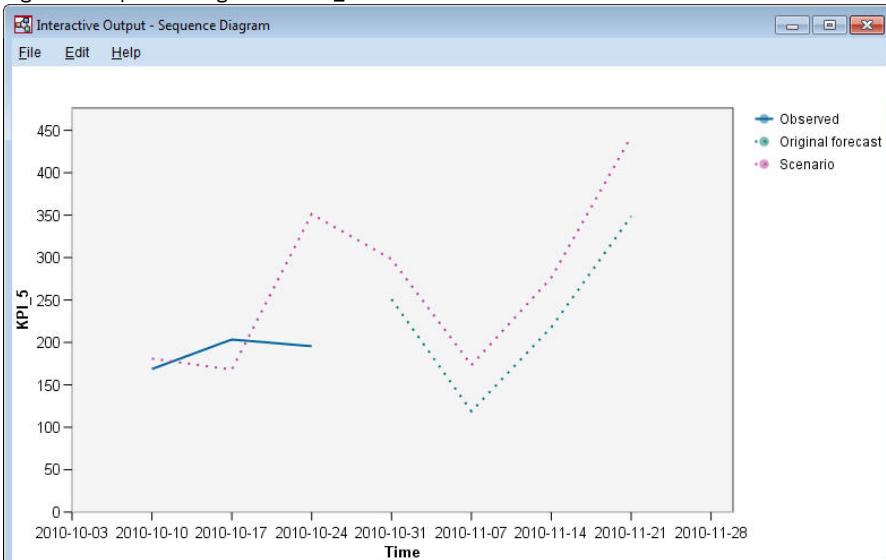

The Impact Diagram shows the series that are affected by the root series *Lever3*. Two levels of effects are shown because you specified 2 for the maximum level for affected targets.

The Forecasted Values table includes the predictions for all of the series that are affected by *Lever3*, up to the second level of effects. Predictions for target series in the first level of effects start at the first time period after the beginning of the scenario period. In this example, predictions for target series in the first level start at 2010-10-10. Predictions for target series in the second level of effects start at the second time period after the beginning of the scenario period. In this example, predictions for target series in the second level start at 2010-10-17. The staggered nature of the predictions reflects the fact that the time series models are based on lagged values of the inputs.

- Click the node for *KPI_5* to generate a detailed sequence diagram.

Figure 5. Sequence Diagram for KPI_5

The sequence chart shows the predicted values from the scenario, and it also shows the values of the series in the absence of the scenario. When the scenario period contains times within the estimation period, the observed values of the series are shown. For times beyond the end of the estimation period, the original forecasts are shown.

Glossary

P

practical significance

A statistical test will answer the question, "Is there a difference between two groups?" but not the follow-up "Is that difference large enough for me to care?" It is up to you to determine whether test results are useful to your situation.

IBM SPSS Modeler Gold

- [Overview](#)
 - [Prerequisites](#)
 - [Installing IBM SPSS Modeler Gold](#)
 - [Post-installation steps](#)
 - [Passport Advantage part numbers](#)
-

Overview

This guide includes information about installing and configuring the SPSS product components for IBM® SPSS® Modeler Gold version 18.4.

SPSS Modeler Gold is a suite of the following SPSS products:

- IBM SPSS Collaboration and Deployment Services version 8.4
- IBM SPSS Modeler version 18.4

This guide contains general steps for installing and configuring these products and their various adapters and components, with links to existing installation instructions.

Documentation for all IBM SPSS products is available on the [IBM Documentation](#) site. Search for SPSS. Documentation is also available in PDF format at the following locations:

- [IBM SPSS Collaboration and Deployment Services 8.4 PDF documentation](#)
- [IBM SPSS Modeler 18.4 PDF documentation](#)

SPSS Modeler Gold topology

The following boxes represent the machines that make up a recommended SPSS Modeler Gold deployment, and list all the possible components that can be installed. Depending on your environment and your needs, note that your specific deployment may be organized differently, and may not include every possible software component. This is one example, and these machines will be referred to as *Server 1*, *Server 2*, and *Clients* throughout this document.

Figure 1. SPSS Modeler Gold Topology

Server 1 (IBM SPSS Collaboration and Deployment Services machine)

- IBM Installation Manager
- A supported web application server (WebSphere, for example)
- A supported database (IBM DB2, for example)
- IBM SPSS Collaboration and Deployment Services Repository Server
- IBM SPSS Collaboration and Deployment Services Scoring Adapter for PMML
- IBM SPSS Modeler Adapter for IBM SPSS Collaboration and Deployment Services

Server 2 (IBM SPSS Modeler Server machine)

- IBM SPSS Modeler Server
- IBM SPSS Modeler Essentials for R
- IBM SPSS Modeler Text Analytics Server
- IBM SPSS Data Access Pack

Clients

- IBM SPSS Deployment Manager client (includes the Administration Consoles)
- IBM SPSS Modeler client
- IBM SPSS Modeler Essentials for R
- IBM SPSS Modeler Scoring Adapter
- IBM SPSS Modeler Text Analytics Client
- IBM SPSS Collaboration and Deployment Services – Essentials for Python

Prerequisites

Before installing and configuring the IBM® SPSS® Modeler Gold products, it is assumed the environment meets all prerequisite system requirements such as a supported application server and database. Review the system requirements for each IBM SPSS product you plan to install before proceeding (for example, to ensure your application server and database are supported by all IBM SPSS components to be installed).

The following prerequisites are required:

IBM Installation Manager

IBM Installation Manager version 1.9.1 is required on *Server 1* for installing many of the products in the suite. For more information, see the [Installation Manager documentation](#).

Web Application Server

You must install and configure a supported application server. For example, if using WebSphere, configure the following items:

- Create a WebSphere profile (called *AppSrv1*, for example)
- Keep the default security active
- Create a WebSphere admin user (called *wsadmin*, for example)

Database

You must install and configure your database to be used as a data source, to host the IBM SPSS Collaboration and Deployment Services Repository. A repository database must be running and accessible before you install and configure the IBM SPSS Collaboration and Deployment Services Repository server.

For example, if using IBM Db2, configure the following items:

- Create a Db2 admin user (called *db2admin*, for example)
- Create database users if they'll be required later
- Create an IBM SPSS Collaboration and Deployment Services Repository database instance by running the example Db2 script included with IBM SPSS Collaboration and Deployment Services. See [this documentation](#) for details.

Note: For complete instructions and details about database requirements, see the [the IBM SPSS Collaboration and Deployment Services documentation](#).

Installation files

Installation files for all SPSS Modeler Gold products to be installed must be downloaded from Passport Advantage and copied to the appropriate machine. Or you can point to the Passport Advantage site during installation for some components. For a list of the required Passport Advantage part numbers, and which machine to place each downloaded file on, see [Passport Advantage part numbers](#).

Microsoft Silverlight

If you use Microsoft Internet Explorer to view visualizations, you must have Microsoft Silverlight 5 or later installed on your computer. Firefox or iPad users do not need Silverlight.

Installing IBM® SPSS® Modeler Gold

The installation instructions here are organized by the machines the products will be installed on. See the [Overview](#) for a recommendation of which components to install on which machine. We recommend following the installation order outlined in this section.

- [IBM SPSS Collaboration and Deployment Services Server components \(Server 1\)](#)
 - [IBM SPSS Modeler Server components \(Server 2\)](#)
 - [Client components](#)
 - [Optional components](#)
-

IBM SPSS Collaboration and Deployment Services Server components (Server 1)

Complete the following steps to install components on *Server 1*.

Before you can install, IBM Installation Manager must have access to the repository that contains the IBM SPSS product packages. You must also shut down your application server.

If you are installing from a repository that is not on the Passport Advantage® site, you must specify the repository in the preferences before you install. For more information, see [Repository preferences](#).

1. Start Installation Manager in wizard mode by running the `IBMMIM` application file. For more information, see [Start Installation Manager](#).
2. In Installation Manager, click Install. Installation Manager searches the defined repositories for available packages. If no available packages are found, verify that you specified repository preferences correctly.
3. The Install page of Installation Manager lists all the packages that were found in the repository that Installation Manager searched. Installation Manager will check Fix Central on the Web for the latest fix pack versions of the packages. Be sure you install the latest fix packs for all SPSS components installed.
4. Select the following packages and then click Next.
 - IBM SPSS Collaboration and Deployment Services - Repository Server (base offering)
 - IBM SPSS Collaboration and Deployment Services Scoring Adapter for PMML
 - IBM® SPSS® Modeler Adapter for IBM SPSS Collaboration and Deployment Services

Note: IBM SPSS Collaboration and Deployment Services - Repository Server is the base offering. The other packages are extensions and will be installed on top of (into the directory of) the base Repository Server offering.

5. On the Licenses page, accept the license agreement and click Next to continue.
 6. On the Location page, enter the path for the shared resources directory in the Shared Resources Directory field. The shared resources directory contains resources that can be shared by multiple package groups. Click Next.
 7. Click Next to continue the installation.
 8. On the next Location page, select the translations to install for packages in the package group. The corresponding language translations for the graphical user interface and documentation are installed. Choices apply to all packages that are installed in this package group. This option may not apply to all product installations. Click Next to continue.
 9. The Features page shows the package features that will be installed. Accept all defaults. You can click a feature to view its brief description under Details.
 10. On the Summary page, review your choices before you install the packages.
- On Windows, Installation Manager checks for running processes. If processes are blocking the installation, a list of these processes is shown in the Blocking Processes section. You must stop these processes before you continue the installation. Click Stop All Blocking Processes. If there are no processes that must be stopped, you do not see this list. The running processes lock files that must be accessed or modified by Installation Manager.

11. Click Install. When the installation process completes, you receive a confirmation message.
 12. Run the Repository configuration utility. See the instructions online [here](#).
 13. Start the WebSphere application server and then use the Windows Control Panel to start the IBM SPSS Collaboration and Deployment Services Server. Go to Control Panel, then Administrative Tools, then Services.
 14. Wait a few minutes and then verify the Repository server status by launching browser-based IBM SPSS Collaboration and Deployment Services Deployment Manager. See the instructions [here](#).
-

IBM SPSS Modeler Server components (Server 2)

Complete the following steps to install components on *Server 2*.

Important: Install the latest Fix Packs for all components.

1. Install SPSS® Modeler Server. See the installation instructions available online [here](#) for Windows or [here](#) for UNIX.
 2. Edit the SPSS Modeler Server options.cfg file, if necessary (for example, to update the server port number). See the documentation available online [here](#).
 3. Install IBM® SPSS Modeler Text Analytics Server into SPSS Modeler Server. See the SPSS Modeler Premium installation instructions available online [here](#).
 4. Install SPSS Modeler Essentials for R. See the installation instructions available online [here](#). Note in the instructions that you must first download and install R from [here](#).
 5. Install the IBM SPSS Data Access Pack. See the installation instructions available online [here](#) for Windows or [here](#) for UNIX.
 6. Use the Windows Control Panel to start the SPSS Modeler Server and the Text Analytics Server. Go to Control Panel, then Administrative Tools, then Services.
-

Client components

Complete the following steps to install client software.

Important: Install the latest Fix Packs for all components.

1. Install IBM® SPSS® Deployment Manager Client. See the installation instructions available online [here](#).
Note: Deployment Manager includes the administration consoles.
 2. Install IBM SPSS Modeler Client. See the installation instructions available online [here](#).
 3. Install SPSS Modeler Essentials for R. See the installation instructions available online [here](#). Note in the instructions that you must first install an R environment from [here](#).
 4. Install IBM SPSS Modeler Text Analytics. See the SPSS Modeler Premium Client installation instructions available online [here](#).
 5. If you want to use ODBC from the client without connecting to SPSS Modeler Server, then install the IBM SPSS Data Access Pack. See the installation instructions available online [here](#) for Windows or [here](#) for UNIX.
-

Optional components

Additional IBM® SPSS® Collaboration and Deployment Services components are available for installation. To install any of the following, click the links to see the installation instructions.

- [IBM SPSS Collaboration and Deployment Services - Essentials for Python](#)
- [IBM SPSS Collaboration and Deployment Services Remote Scoring Server](#)
- [IBM SPSS Collaboration and Deployment Services Remote Process Server](#)

Note: The Remote Scoring Server and the Remote Process Server are usually installed on different machines, and they are typically not installed on the same machine as the IBM SPSS Collaboration and Deployment Services Repository (the repository already contains the functionality). For more information about these components, see the IBM SPSS Collaboration and Deployment Services documentation.

Post-installation steps

After installation, perform the following required configuration steps. Depending on your environment, additional configuration may be required.

- [IBM SPSS Collaboration and Deployment Services Server components \(Server 1\)](#)
- [IBM SPSS Modeler Server components \(Server 2\)](#)
- [Client components](#)

- [Other](#)
-

IBM SPSS Collaboration and Deployment Services Server components (Server 1)

1. Start the repository server. For instructions, see [here](#).
 2. Verify the repository is running by accessing browser-based IBM® SPSS® Deployment Manager. Navigate to the login page at <http://<repository host>/<port number>/security/login> and specify the admin login credentials that were specified during repository configuration.
 3. For additional information about post-installation steps for IBM SPSS Collaboration and Deployment Services, see the documentation [here](#).
-

IBM® SPSS Modeler Server components (Server 2)

1. To configure the SPSS® Modeler Server, see [this documentation](#) (for Windows) or [this documentation](#) (for UNIX) and follow the instructions in these sections:
 - *Checking the Server Status*
 - *Connecting End Users*
 - *IBM SPSS Data Access Pack Technology*
 2. Use the IBM SPSS Data Access Pack to configure an ODBC driver that points to your database. See [this PDF](#) (for Windows) or [this PDF](#) (for UNIX).
-

Client components

Perform the following configuration on the client machine(s). The first 4 steps use the IBM® SPSS® Deployment Manager client software.

1. Open Deployment Manager client, go to the Content Explorer tab, and create a new content server connection if you have not done so already. See the instructions [here](#). After creating the connection, double-click it and log on (you can use the *admin* account password that was specified during Repository installation).
 2. Create a new IBM SPSS Modeler Server definition and associated credentials definition.
For additional instructions about creating server definitions and credentials, see the online documentation [here](#).
 3. Go to the Server Administration tab and create an administered server connection if you have not done so already. Then create users and groups as required for your deployment and assign them roles. For instructions on creating groups and assigning roles, see the documentation [here](#).
 4. For each SPSS Modeler Client, create a connection to the IBM SPSS Modeler Server hosted on *Server 2*, using [these](#) instructions.
 5. Open SPSS Modeler Client and create a connection to the IBM SPSS Collaboration and Deployment Services Repository hosted on *Server 1*. See the instructions available [here](#).
 6. If you installed IBM SPSS Collaboration and Deployment Services - Essentials for Python, see the instructions [here](#) to verify the installation.
-

Other

Administration consoles

- To facilitate easier server administration and configuration, IBM® SPSS® Deployment Manager client includes the IBM SPSS Modeler Administration Console. This provides for a single place to administer all SPSS Modeler servers.
The console can be used to perform tasks such as starting and stopping servers and changing configuration settings.
-

Passport Advantage part numbers

The following table lists the [Passport Advantage](#) part number for each eAssembly that makes up the IBM® SPSS® Modeler Gold offering. For a complete list of all eImages included in each of the eAssemblies listed below, see the SPSS Modeler Gold sections of the table at the end of the IBM SPSS Modeler 18.4 [download document](#).

Table 1. Passport Advantage parts

SPSS component	Part number
IBM SPSS Modeler Gold 18.4 Multiplatform Multilingual eAssembly ¹	G06C3ML ¹
IBM SPSS Modeler Gold Keyless 18.4 Multiplatform eAssembly ²	G06C4ML ²
IBM SPSS Modeler Server Gold 18.4 Microsoft Windows Multilingual eAssembly	G06C8ML

¹ This eAssembly will be used if you intend to install *concurrent* user clients (and, therefore, need to supply license keys). If you only have entitlements to concurrent users, you will not see the *IBM SPSS Modeler Gold Keyless 18.4 Multiplatform eAssembly* download.

² This eAssembly will be used if you intend to install *authorized* user clients (which do not need to be licensed via keys). You will only see this download option if you have authorized users (or both authorized users and concurrent users).

IBM SPSS Modeler considerations for GDPR readiness

Information about features of IBM® SPSS® Modeler that you can configure, and aspects of the product's use, that you should consider to help your organization with GDPR readiness.

For PID(s): 5725-A64, 5725-A65

Notice:

This document is intended to help you in your preparations for GDPR readiness. It provides information about features of SPSS Modeler that you can configure, and aspects of the product's use, that you should consider to help your organization with GDPR readiness. This information is not an exhaustive list, due to the many ways that clients can choose and configure features, and the large variety of ways that the product can be used in itself and with third-party applications and systems.

Clients are responsible for ensuring their own compliance with various laws and regulations, including the European Union General Data Protection Regulation. Clients are solely responsible for obtaining advice of competent legal counsel as to the identification and interpretation of any relevant laws and regulations that may affect the clients' business and any actions the clients may need to take to comply with such laws and regulations.

The products, services, and other capabilities described herein are not suitable for all client situations and may have restricted availability. IBM does not provide legal, accounting, or auditing advice or represent or warrant that its services or products will ensure that clients are in compliance with any law or regulation.

GDPR

General Data Protection Regulation (GDPR) has been adopted by the European Union and will apply from May 25, 2018.

Why is GDPR important?

GDPR establishes a stronger data protection regulatory framework for processing of personal data of individuals. GDPR brings:

- New and enhanced rights for individuals
- Widened definition of personal data
- New obligations for processors
- Potential for significant financial penalties for non-compliance
- Compulsory data breach notification

Product configuration - considerations for GDPR readiness

Offering Configuration

The following sections provide considerations for configuring SPSS Modeler to help your organization with GDPR readiness.

To configure SPSS Modeler such that it supports GDPR readiness, IBM recommends that you:

- Activate the encryption of data in motion (data that is transferred over a data network between SPSS Modeler client applications and SPSS Modeler Server; data between SPSS Modeler Server and external execution servers such as IBM SPSS Collaboration and Deployment Services Server or IBM SPSS Analytic Server).
- Do not share passwords for the operation of SPSS Modeler between multiple persons.
- Apply a firewall in front of the offering to avoid security vulnerabilities.

Data Life Cycle

GDPR requires that personal data is:

- Processed lawfully, fairly and in a transparent manner in relation to individuals.
- Collected for specified, explicit and legitimate purposes.
- Adequate, relevant and limited to what is necessary.
- Accurate and, where necessary, kept up to date. Every reasonable step must be taken to ensure that inaccurate personal data are erased or rectified without delay.
- Kept in a form which permits identification of the data subject for no longer than necessary.

What is the end-to-end process through which personal data go through when using SPSS Modeler?

What types of data flow through SPSS Modeler?

SPSS Modeler is a powerful predictive analytics platform that is designed to bring predictive intelligence to decisions made by individuals, groups, systems, and your enterprise. SPSS Modeler scales from desktop deployments to integration with operational systems to provide you with a range of advanced algorithms and techniques. The scalable client-server architecture enables users to access everything from flat files to big data environments. SPSS Modeler provides powerful data mining abilities and enables users to visualize each step of the data mining process.

SPSS Modeler doesn't decide what data is sensitive and what is not sensitive. The data asset to be stored by SPSS Modeler can include personal data or not, which is fully dependent on your purpose. Also, you have total control of how your data is handled, used, and stored by SPSS Modeler. Only for debugging and auditing purposes, the personal information that Modeler collects includes the user ID used to log in to SPSS Modeler, the IP address for the connection, and the database connection information.

Where in the process?

- Authentication: All operations to SPSS Modeler must be authenticated. When users connect to SPSS Modeler Server via SPSS Modeler client, users must log on to the server with an authenticated user ID on the operating system where the server is running. SPSS Modeler will prompt users to input the password once the connection is closed (for example, when SPSS Modeler client is restarted). SPSS Modeler doesn't store passwords.
- Logging: The files `server_logging.log`, `server_sessions.log`, and `server_tracing_<sequence>.log` on the server application side are used to collect usage data as logs for diagnostic purposes. SPSS Modeler administrators can enable/disable the logs or change the log level based on his/her needs. This is fully controlled by the authorized administrator. The file `client_logging.log` on the client application side is used to collect usage data as logs for diagnostic purposes. SPSS Modeler client application users can enable/disable the logs or change the log level based on his/her needs. This is fully controlled by the authorized user.
- Configuration: SPSS Modeler configuration is stored in a configuration file that is restricted by file-level authentication and encryption.

For what purpose?

SPSS Modeler software doesn't store business data by itself. SPSS Modeler can import data from a data source or export data to a data destination. The data source and data destination might be: file, database, IBM SPSS Collaboration and Deployment Services, or IBM SPSS Analytic Server.

The business data are mainly used by SPSS Modeler for data mining purposes. The operational data that is captured in the logs and files will be used mainly for SPSS Modeler troubleshooting purposes.

Personal data used for online contact with IBM

SPSS clients can submit online comments/feedback/requests to contact IBM about SPSS subjects in a variety of ways, primarily:

- Public comments area on pages in the SPSS community on IBM developerWorks®
- Public comments area on pages of SPSS product documentation in IBM Documentation
- Public comments in the SPSS space of dWAnswers
- Feedback forms in the SPSS community

Typically, only the client name and e-mail address are used, to enable personal replies for the subject of the contact, and the use of personal data conforms to the [IBM Online Privacy Statement](#).

Data Collection

When assessing your use of SPSS Modeler and the requirements of GDPR, you should consider the types of personal data which in your circumstances are passing through SPSS Modeler.

Account data encompasses several scenarios. The user name is collected in the log files server_sessions.log and server_logging.log on the remote SPSS Modeler Server. IBM SPSS Analytic Server logon information is collected in the file client_logging.log if you connect to IBM SPSS Analytic Server directly from SPSS Modeler client. The database and other systems' logon information will only be collected in the files server_logging.log or server_tracing_**.log. Client data isn't collected in the logs.

Data Storage

The following Data Storage mechanisms are used by SPSS Modeler, which users may wish to consider when assessing their GDPR readiness.

- Storage of account data: Account data can be securely stored in a SPSS Modeler working file (.str) which is restricted by file authentication and encryption, or repository authentication and encryption (IBM SPSS Collaboration and Deployment Services). SPSS Modeler doesn't store user passwords in any way.
- Storage of client data: For client data that's stored in database, it requires database level authentication and encryption. For client data stored on the file system, it requires file system access control. For client data stored in other collaboration systems (for example, IBM SPSS Collaboration and Deployment Services or IBM SPSS Analytic Server), it requires access control of the corresponding system.

Data Access

- In SPSS Modeler, access control to personal data can be achieved by operating system permissions to files generated by SPSS Modeler (for example, stream files, log files, and preferences files).
- Roles and access rights: SPSS Modeler doesn't manage any roles or access rights by itself. Access control can be achieved by the operating system or other collaboration systems (database, IBM SPSS Collaboration and Deployment Services, or IBM SPSS Analytic Server).
- Separation of duties: SPSS Modeler does not manage any duties separation by itself. Access control can be achieved by the operating system or other collaboration systems (database, IBM SPSS Collaboration and Deployment Services, or IBM SPSS Analytic Server).
- Administrators: SPSS Modeler doesn't have any administrators, and access control can be achieved by the operating system or other collaboration systems (database, IBM SPSS Collaboration and Deployment Services, or IBM SPSS Analytic Server).
- Activity logs: The logs include info about who connects to the SPSS Modeler Server, when to start the process, and when to close the session. This information is stored in SPSS Modeler log files, whose access is restricted by file level authentication and encryption.

Data Processing

- Encryption in motion: SSL or TLS is supported by SPSS Modeler when SPSS Modeler is connecting to other systems (database, IBM SPSS Collaboration and Deployment Services, or IBM SPSS Analytic Server).
- Encryption at rest: When a SPSS Modeler stream (.str) is saved, you can select an option to encrypt the file.

Data Deletion

Right to Erasure

Article 17 of the GDPR states that data subjects have the right to have their personal data removed from the systems of controllers and processors - without undue delay - under a set of circumstances.

Data Deletion Characteristics

- Client data deletion: Client data can be deleted via features in the SPSS Modeler user interface.
- Account data deletion: Account data can be deleted via features in the SPSS Modeler user interface.

Data Monitoring

You should regularly test, assess, and evaluate the effectiveness of your technical and organizational measures to comply with GDPR. These measures should include ongoing privacy assessments, threat modeling, centralized security logging, and monitoring, among others.

The SPSS Modeler logs allow clients to track who connects to the SPSS Modeler Server, when, start of session, start of process, and close of session.

Responding to Data Subject Rights

- Right to Access: SPSS Modeler doesn't manage any roles or access rights by itself. This is performed via the operating system or other collaboration systems (database, IBM SPSS Collaboration and Deployment Services, or IBM SPSS Analytic Server).
- Right to Modify: SPSS Modeler has the capability to work with client data. Only the authorized user can modify or correct the data through SPSS Modeler client.
- Right to Restrict Processing: SPSS Modeler client can stop a running stream at any time to force the server to stop processing the client data.
- Right to Object: When objects (all kinds of outputs and models) are generated during the running of SPSS Modeler streams, the client user can delete these objects directly. When objects (such as database, file system, and others) are exported from SPSS Modeler, only the authorized user can access and delete them.
- Right to Be Forgotten: Same as Right to Object above.
- Right to Data Portability: SPSS Modeler supports data portability to a great extent. You can export models to PMML and used them outside of SPSS Modeler. SPSS Modeler streams can be saved and deployed to other systems. Model output can be exported to several file types such as flat file, IBM SPSS Statistics format file, SAS format file, database tables etc.
