IBM SPSS Modeler V18.4.0 documentation

Welcome to the IBM® SPSS® Modeler documentation, where you can find information about how to install and use SPSS Modeler.

While IBM values the use of inclusive language, terms that are outside of IBM's direct influence are sometimes required for the sake of maintaining user understanding. As other industry leaders join IBM in embracing the use of inclusive language, IBM will continue to update the documentation to reflect those changes.

Installation instructions

The following instructions are for installing IBM® SPSS® Modeler version 18.4.0 using the license type concurrent license. This document is for users who are installing on their desktop computers.

- [System requirements](#)
- [Installing](#)
- [Licensing your product](#)
- [Configuring IBM SPSS Modeler to work with IBM SPSS Statistics](#)
- [Database Access](#)
- [Checking out/in a commuter license](#)
- [Applying fix packs](#)
- [Uninstalling](#)

System requirements

To view system requirements, go to <https://www.ibm.com/software/reports/compatibility/clarity/softwareReqsForProduct.html>.

Installing

Important: To install, you must be logged on to your computer with administrator privileges.

- [Installing from a downloaded file](#)
- [Silent installation](#)
- [Notes for installation](#)

Installing from a downloaded file

You must run the installer as administrator:

1. Double-click the file that you downloaded and extract all the files to some location on your computer.
2. Using Windows Explorer, browse to the location where you extracted the files.
3. Right-click *setup.exe* and choose Run as Administrator.
4. Follow the instructions that appear on the screen. See [Notes for installation](#) for any special instructions.

Silent installation

Silent mode enables an installation to run on its own without any interaction; installing silently can free system administrators from the task of monitoring each installation and providing input to prompts and dialog boxes. This method is especially useful when you are installing SPSS® Modeler on a number of different computers that have identical hardware.

Note: You must have administrator privileges to be able to run silent installations.

Windows - silent installation

You can complete a silent installation on Windows systems by using Microsoft Installer (MSI). Use *msiexec.exe* to install the MSI package.

The following options can be used:

Table 1. Silent installation options

Option	Description
/i	Specifies that the program is to install the product.
/i*v	Specifies verbose logging. For example, this form of log can be useful if you need to troubleshoot an installation.
/qn	Runs the installation without running the external user interface sequence.
/s	Specifies silent mode.
/v	Specifies that the Setup Program passes the parameter string to the call it makes to the MSI executable file (<i>msiexec.exe</i>). The following syntax requirements apply if you use this option: <ul style="list-style-type: none">• You must place a backslash (\) in front of any quotation marks (" ") that are within existing quotation marks.• Do not include a space between the /v option and its arguments.• Multiple parameters that are entered with the /v option must be separated with a space.• To create a log file, specify the directory and file name at the end of the command. The directory must exist before you start the silent installation.
/x	Specifies that the program is to uninstall the product.

An example of the MSI command is shown below.

Important: This command restarts the machine automatically. Ensure you save and close any open applications before running the command.

```
C:>msiexec.exe /i ModelerClient64.msi /qn /l*v  
c:\temp\Modeler_Silent_Install.log  
INSTALLDIR="C:\Program Files\IBM\SPSS\Modeler\19"  
LICENSETYPE="Network"  
LHOST="netlicense.mylocation.mycompany.com"
```

Note: Depending on your system, you might need to change the .msi file in the preceding example. The .msi versions for SPSS Modeler Client are shown in the following list.

- ModelerClient32.msi - 32-bit
- ModelerClient64.msi - 64-bit

If you are using a single license for your SPSS Modeler Client installation, remove the LICENSETYPE parameter and modify LHOST to = "no-net", as shown in the example below.

```
C:>msiexec.exe /i ModelerClient64.msi /qn /l*v  
c:\temp\Modeler_Silent_Install.log  
INSTALLDIR="C:\Program Files\IBM\SPSS\Modeler\19"  
LHOST="no-net"
```

When the installation is complete, ensure you run the License Authorization Wizard application to license SPSS Modeler Client.

Windows - silent uninstalling

The following text shows an example of the MSI command to silently uninstall the software:

```
C:>msiexec.exe /x ModelerClient64.msi /qn /norestart
```

Notes for installation

This section contains special instructions for this installation.

Older versions of IBM® SPSS® Modeler. On Windows, the installation will automatically find and upgrade 18.1 or later installations of IBM SPSS Modeler, so there's no need to uninstall the older version. If you have a pre-18.1 version installed, you'll need to uninstall it. On Linux and Mac, the installation does not automatically find 18.1 or later installations. But if you choose a directory that has an 18.1 or later installation present, the 18.1.1 or later installation will automatically upgrade it.

Licensing your product

You must run the License Authorization Wizard to license your product.

- [Using the license authorization wizard](#)
-

Using the license authorization wizard

Note: You might be prompted for administrator credentials. Without the correct credentials, you will not be able to run the License Authorization Wizard.

1. To launch the License Authorization Wizard, click License Product on the Welcome dialog or choose License Authorization Wizard in the Windows Start menu program group for IBM® SPSS® Modeler. You must run as administrator. Right-click the License Authorization Wizard shortcut and choose Run As Administrator.
2. Select Concurrent user license. When prompted, enter the license manager server name or IP address. This is the IP address or the name of the server on which the network license manager is running. If you have multiple addresses or names, separate them with a tilde (for example, server1~server2~server3). Contact your administrator if you do not have this information.
Note: Depending on your environment, you may need verify that TCP port 7 is open. The License Authorization Wizard needs to contact the license manager server one time on port 7 to verify it exists.

Invalid digital signature on installation

IBM® SPSS® Modeler products use IBM-issued certification for digital signing. In certain circumstances you may see the following error on trying to install SPSS Modeler products:

```
Error 1330. A file that is required cannot be installed because the cabinet file filename has an invalid digital signature...
```

All Windows users

You see this message if you try to install SPSS Modeler products on a machine that has no Internet connection and does not have the correct certificate installed. Use the following procedure to correct this problem.

1. Click OK to acknowledge the message.
2. Click Cancel to exit from the installer.
3. If the machine on which you want to install has no Internet connection, perform the next step on an Internet-connected machine and copy the .cer file to the machine where you want to install.

4. Go to <https://support.symantec.com>, search for VeriSign Class 3 Primary Certification Authority - G5 root certificate, and download it. Save it as a .cer file.
5. Double-click the .cer file.
6. On the General tab, click Install Certificate.
7. Follow the instructions in the Certificate Import Wizard, using the default options and clicking Finish at the end.
8. Retry the installation.

Configuring IBM SPSS Modeler to work with IBM SPSS Statistics

To enable IBM® SPSS® Modeler to use the Statistics Transform, Statistics Model, and Statistics Output nodes, you must have a copy of IBM SPSS Statistics installed and licensed on the computer where the stream is run.

If running IBM SPSS Modeler in local (standalone) mode, the licensed copy of IBM SPSS Statistics must be on the local computer.

When you have finished installing this copy of SPSS Modeler Client, you will also need to configure it to work with IBM SPSS Statistics. From the main client menu, choose:

Tools > Options > Helper Applications

and on the IBM SPSS Statistics tab, specify the location of the local IBM SPSS Statistics installation you want to use. For more information, see the *Source, Process and Output Nodes* guide or the online help for Helper Applications.

In addition, if running in distributed mode against a remote IBM SPSS Modeler Server, you also need to run a utility at the IBM SPSS Modeler Server host to create the **statistics.ini** file, which indicates to IBM SPSS Modeler Server the installation path for IBM SPSS Statistics Server. To do this, from the command prompt, change to the IBM SPSS Modeler Server bin directory and, for Windows, run:

```
statisticsutility -location=<statistics_installation_path>/bin
```

Alternatively, for UNIX, run:

```
./statisticsutility -location=<statistics_installation_path>/bin
```

Following is an example of what is placed in the **statistics.ini** file located in the IBM SPSS Modeler Server /bin directory after running the utility in IBM SPSS Modeler Server:

```
[LOCATION]
STATISTICS_PATH=C:\Program Files\IBM\SPSS\StatisticsServer\<version>
```

If you do not have a licensed copy of IBM SPSS Statistics on your local machine, you can still run the Statistics File node against a IBM SPSS Statistics server, but attempts to run other IBM SPSS Statistics nodes will display an error message.

Database Access

To read or write to a database, you must have an ODBC data source installed and configured for the relevant database, with read or write permissions as needed. The IBM SPSS Data Access Pack includes a set of ODBC drivers that can be used for this purpose, and these drivers are available from the download site. If you have questions about creating or setting permissions for ODBC data sources, contact your database administrator.

Supported ODBC drivers

For the latest information on which databases and ODBC drivers are supported and tested for use with IBM® SPSS® Modeler, see the product compatibility matrices on the corporate Support site (<http://www.ibm.com/support>).

Where to install drivers

Note: ODBC drivers must be installed and configured on each computer where processing may occur.

- If you are running IBM SPSS Modeler in local (standalone) mode, the drivers must be installed on the local computer.
- If you are running IBM SPSS Modeler in distributed mode against a remote IBM SPSS Modeler Server, the ODBC drivers need to be installed on the computer where IBM SPSS Modeler Server is installed.
- If you need to access the same data sources from both IBM SPSS Modeler and IBM SPSS Modeler Server, the ODBC drivers must be installed on both computers.
- If you are running IBM SPSS Modeler over Terminal Services, the ODBC drivers need to be installed on the Terminal Services server on which you have IBM SPSS Modeler installed.

Checking out/in a commuter license

Network licenses normally require that you are connected to the network to run IBM® SPSS® Modeler. If your administrator enabled commuter licenses, you can check out a commuter license to use the network license when you are not connected to the network. For example, you may want to run IBM SPSS Modeler on the train when you don't have a network connection. Before disconnecting from your network and catching the train, you could check out a commuter license for a limited amount of time. You will need to reconnect to the network and check the license back in before the time expires. Otherwise, IBM SPSS Modeler will stop working.

Network licenses are enabled and configured by your administrator. If you would like to use this feature and can't, check with your administrator.

Important: Even if you are able to run IBM SPSS Modeler because you are reconnected to the network, be sure to check the license back in. Doing so will allow other users to take advantage of the commuter license.

Check out a license

1. Choose Commuter License in the Windows Start menu program group for IBM SPSS Modeler.
2. Select the license that you want to check out.
3. In the Duration box, enter the number of days for which you want to check out the license. There is a limit that your administrator configures.
4. Click Check Out.

The commuter license will expire after the number of days specified by Duration. You can also manually check the license back in at any time.

You may receive a message in the following format:

Error while checkout with error code: <code>

Common codes are as follows.

Code	Meaning
77	All available licenses have been checked out.
1402	Attempt to check out license that has been reserved for another user.

Check in a license

1. Choose Commuter License in the Windows Start menu program group for IBM SPSS Modeler.
2. Select the license that you want to check in. License(s) that you checked out are indicated by a check mark.
3. Click Check In.

Applying fix packs

To ensure problem-free operation, keep your product at the latest fix pack level. Complete all of the necessary pre-installation and post-installation tasks as described in the fix pack instructions.

Uninstalling

To completely uninstall IBM® SPSS® Modeler:

1. Use the Windows Control Panel to remove IBM SPSS Modeler.

Installation instructions

The following instructions are for installing IBM® SPSS® Modeler version 18.4.0 using the license type authorized user license. This document is for users who are installing on their desktop computers.

- [System requirements](#)
- [Installing](#)
- [Licensing your product](#)
- [Configuring IBM SPSS Modeler to work with IBM SPSS Statistics](#)

- [Database Access](#)
 - [Applying fix packs](#)
 - [Uninstalling](#)
 - [Updating, modifying, and renewing IBM SPSS Modeler](#)
-

System requirements

To view system requirements, go to <https://www.ibm.com/software/reports/compatibility/clarity/softwareReqsForProduct.html>.

- [Authorization code](#)

You will also need your authorization code(s). In some cases, you might have multiple codes. You will need all of them.

Authorization code

You will also need your authorization code(s). In some cases, you might have multiple codes. You will need all of them.

You should have received separate instructions for obtaining your authorization code. If you cannot find your authorization code, contact Customer Service by visiting <https://www.ibm.com/products/spss-modeler/support>.

Installing

Important: To install, you must be logged on to your computer with administrator privileges.

- [Installing from a downloaded file](#)
 - [Silent installation](#)
 - [Notes for installation](#)
-

Installing from a downloaded file

You must run the installer as administrator:

1. Double-click the file that you downloaded and extract all the files to some location on your computer.
 2. Using Windows Explorer, browse to the location where you extracted the files.
 3. Right-click `setup.exe` and choose Run as Administrator.
 4. Follow the instructions that appear on the screen. See [Notes for installation](#) for any special instructions.
-

Silent installation

Silent mode enables an installation to run on its own without any interaction; installing silently can free system administrators from the task of monitoring each installation and providing input to prompts and dialog boxes. This method is especially useful when you are installing SPSS® Modeler on a number of different computers that have identical hardware.

Note: You must have administrator privileges to be able to run silent installations.

Windows - silent installation

You can complete a silent installation on Windows systems by using Microsoft Installer (MSI). Use `msiexec.exe` to install the MSI package.

The following options can be used:

Table 1. Silent installation options

Option	Description
<code>/i</code>	Specifies that the program is to install the product.
<code>/i*v</code>	Specifies verbose logging. For example, this form of log can be useful if you need to troubleshoot an installation.
<code>/qn</code>	Runs the installation without running the external user interface sequence.

Option	Description
/s	Specifies silent mode.
/v	Specifies that the Setup Program passes the parameter string to the call it makes to the MSI executable file (msiexec.exe). The following syntax requirements apply if you use this option: <ul style="list-style-type: none"> You must place a backslash (\) in front of any quotation marks (" ") that are within existing quotation marks. Do not include a space between the /v option and its arguments. Multiple parameters that are entered with the /v option must be separated with a space. To create a log file, specify the directory and file name at the end of the command. The directory must exist before you start the silent installation.
/x	Specifies that the program is to uninstall the product.

An example of the MSI command is shown below.

Important: This command restarts the machine automatically. Ensure you save and close any open applications before running the command.

```
C:>msiexec.exe /i ModelerClient64.msi /qn /l*v
c:\temp\Modeler_Silent_Install.log
INSTALLDIR="C:\Program Files\IBM\SPSS\Modeler\19"
LICENSETYPE="Network"
LSHOST="netlicense.mylocation.mycompany.com"
```

Note: Depending on your system, you might need to change the .msi file in the preceding example. The .msi versions for SPSS Modeler Client are shown in the following list.

- ModelerClient32.msi - 32-bit
- ModelerClient64.msi - 64-bit

If you are using a single license for your SPSS Modeler Client installation, remove the LICENSETYPE parameter and modify LSHOST to ="no-net", as shown in the example below.

```
C:>msiexec.exe /i ModelerClient64.msi /qn /l*v
c:\temp\Modeler_Silent_Install.log
INSTALLDIR="C:\Program Files\IBM\SPSS\Modeler\19"
LSHOST="no-net"
```

When the installation is complete, ensure you run the License Authorization Wizard application to license SPSS Modeler Client.

Windows - silent uninstalling

The following text shows an example of the MSI command to silently uninstall the software:

```
C:>msiexec.exe /x ModelerClient64.msi /qn /norestart
```

Notes for installation

This section contains special instructions for this installation.

Older versions of IBM® SPSS® Modeler. On Windows, the installation will automatically find and upgrade 18.1 or later installations of IBM SPSS Modeler, so there's no need to uninstall the older version. If you have a pre-18.1 version installed, you'll need to uninstall it. On Linux and Mac, the installation does not automatically find 18.1 or later installations. But if you choose a directory that has an 18.1 or later installation present, the 18.1.1 or later installation will automatically upgrade it.

Licensing your product

You must run the License Authorization Wizard to license your product.

Note: Licenses are tied to your computer's hardware with a **lock code**. If you replace your computer or its hardware, you will have a new lock code and will need to repeat the authorization process. This is also true if you re-image your computer. If you find out that you exceeded the allowable number of authorizations specified in the license agreement, go to <https://www.ibm.com/products/spss-modeler/support> to contact the Client Care team for assistance.

Important: The license is sensitive to time changes. If you must change the system time and then cannot run the product, contact the Client Care team for assistance by visiting <https://www.ibm.com/products/spss-modeler/support>.

- [Using the license authorization wizard](#)
- [Viewing your license](#)

Using the license authorization wizard

Note: You might be prompted for administrator credentials. Without the correct credentials, you will not be able to run the License Authorization Wizard.

1. To launch the License Authorization Wizard, click License Product on the Welcome dialog or choose License Authorization Wizard in the Windows Start menu program group for IBM® SPSS® Modeler. You must run as administrator. Right-click the License Authorization Wizard shortcut and choose Run As Administrator.
2. Select Authorized user license. When prompted, enter one or more authorization codes.
You should have received separate instructions for obtaining your authorization code. If you cannot find your authorization code, contact Customer Service by visiting <https://www.ibm.com/products/spss-modeler/support>.

The License Authorization Wizard sends your authorization code over the Internet to IBM Corp. and automatically retrieves your license. If your computer is behind a proxy, click Connect to the internet through a proxy server and enter the appropriate settings.

If the authorization process fails, you will be prompted to send an e-mail message. Choose whether you want to send the e-mail message through your desktop e-mail program or through a Web-based e-mail application.

- If you choose the desktop option, a new message with the appropriate information will be created automatically.
- If you choose the Web-based option, you must first create a new message in your Web-based e-mail program. Then copy the message text from the License Authorization Wizard and paste it into your e-mail application.

Send the e-mail message and respond to the prompt in the License Authorization Wizard. The e-mail message will be processed almost instantaneously. You can click Enter License Code(s) to enter any license code(s) that you receive. If you already closed the License Authorization Wizard, restart it and select Authorized user license. On the Enter Codes panel, add the license code that you received and click Next to complete the process.

Viewing your license

You can view the license by relaunching the License Authorization Wizard. The first panel displays the licensing information. Click Cancel when done, and click Yes when prompted about canceling.

Invalid digital signature on installation

IBM® SPSS® Modeler products use IBM-issued certification for digital signing. In certain circumstances you may see the following error on trying to install SPSS Modeler products:

Error 1330. A file that is required cannot be installed because the cabinet file filename has an invalid digital signature...

All Windows users

You see this message if you try to install SPSS Modeler products on a machine that has no Internet connection and does not have the correct certificate installed. Use the following procedure to correct this problem.

1. Click OK to acknowledge the message.
2. Click Cancel to exit from the installer.
3. If the machine on which you want to install has no Internet connection, perform the next step on an Internet-connected machine and copy the .cer file to the machine where you want to install.
4. Go to <https://support.symantec.com>, search for VeriSign Class 3 Primary Certification Authority - G5 root certificate, and download it. Save it as a .cer file.
5. Double-click the .cer file.
6. On the General tab, click Install Certificate.
7. Follow the instructions in the Certificate Import Wizard, using the default options and clicking Finish at the end.
8. Retry the installation.

Configuring IBM SPSS Modeler to work with IBM SPSS Statistics

To enable IBM® SPSS® Modeler to use the Statistics Transform, Statistics Model, and Statistics Output nodes, you must have a copy of IBM SPSS Statistics installed and licensed on the computer where the stream is run.

If running IBM SPSS Modeler in local (standalone) mode, the licensed copy of IBM SPSS Statistics must be on the local computer.

When you have finished installing this copy of SPSS Modeler Client, you will also need to configure it to work with IBM SPSS Statistics. From the main client menu, choose:

Tools > Options > Helper Applications

and on the IBM SPSS Statistics tab, specify the location of the local IBM SPSS Statistics installation you want to use. For more information, see the *Source, Process and Output Nodes* guide or the online help for Helper Applications.

In addition, if running in distributed mode against a remote IBM SPSS Modeler Server, you also need to run a utility at the IBM SPSS Modeler Server host to create the **statistics.ini** file, which indicates to IBM SPSS Modeler Server the installation path for IBM SPSS Statistics Server. To do this, from the command prompt, change to the IBM SPSS Modeler Server bin directory and, for Windows, run:

```
statisticsutility -location=<statistics_installation_path>/bin
```

Alternatively, for UNIX, run:

```
./statisticsutility -location=<statistics_installation_path>/bin
```

Following is an example of what is placed in the **statistics.ini** file located in the IBM SPSS Modeler Server /bin directory after running the utility in IBM SPSS Modeler Server:

```
[LOCATION]
STATISTICS_PATH=C:\Program Files\IBM\SPSS\StatisticsServer\<version>
```

If you do not have a licensed copy of IBM SPSS Statistics on your local machine, you can still run the Statistics File node against a IBM SPSS Statistics server, but attempts to run other IBM SPSS Statistics nodes will display an error message.

Database Access

To read or write to a database, you must have an ODBC data source installed and configured for the relevant database, with read or write permissions as needed. The IBM SPSS Data Access Pack includes a set of ODBC drivers that can be used for this purpose, and these drivers are available from the download site. If you have questions about creating or setting permissions for ODBC data sources, contact your database administrator.

Supported ODBC drivers

For the latest information on which databases and ODBC drivers are supported and tested for use with IBM® SPSS® Modeler, see the product compatibility matrices on the corporate Support site (<http://www.ibm.com/support>).

Where to install drivers

Note: ODBC drivers must be installed and configured on each computer where processing may occur.

- If you are running IBM SPSS Modeler in local (standalone) mode, the drivers must be installed on the local computer.
- If you are running IBM SPSS Modeler in distributed mode against a remote IBM SPSS Modeler Server, the ODBC drivers need to be installed on the computer where IBM SPSS Modeler Server is installed.
- If you need to access the same data sources from both IBM SPSS Modeler and IBM SPSS Modeler Server, the ODBC drivers must be installed on both computers.
- If you are running IBM SPSS Modeler over Terminal Services, the ODBC drivers need to be installed on the Terminal Services server on which you have IBM SPSS Modeler installed.

Applying fix packs

To ensure problem-free operation, keep your product at the latest fix pack level. Complete all of the necessary pre-installation and post-installation tasks as described in the fix pack instructions.

Uninstalling

To completely uninstall IBM® SPSS® Modeler:

1. Use the Windows Control Panel to remove IBM SPSS Modeler.

Updating, modifying, and renewing IBM® SPSS® Modeler

If you purchase additional options or renew your license, you will receive a new authorization code (or codes). .

Installation overview

The following instructions are for installing IBM® SPSS® Modeler version 18.4.0 on a Mac OS.

- [System requirements](#)
- [Installing](#)

System requirements

To view system requirements, go to <https://www.ibm.com/software/reports/compatibility/clarity/softwareReqsForProduct.html>.

- [License types](#)

License types

There are two types of licenses:

Authorized user license

If you are an individual who purchased IBM® SPSS® Modeler for yourself, you have an authorized user license. An authorized user license has an associated code that authorizes individual installations of the product.

If you are part of an organization, you might have an authorized user license for a specified number of users. The same authorization code is valid until the number of authorizations exceeds the specified number.

Concurrent user license

A concurrent user license is a "floating" license that can be used simultaneously (concurrently) by a specified number of users. Each installation of the product is not authorized. Instead, the product is authorized on a server machine through an application called the *license manager*. When the product starts up, it communicates with the server machine and checks if a license is currently available.

Installing

- [Installing from a downloaded file](#)
- [Notes for installation](#)

Installing from a downloaded file

1. Mount the installer disk image by double-clicking the file that you downloaded.
2. In the mounted disk image, double-click the installer file, and then follow the instructions that appear on the screen. See [Notes for installation](#) for any special instructions.

Notes for installation

This section contains special instructions for this installation.

Installer language. The first panel of the installer prompts for an installer language. By default, the language that matches your locale is selected. If you would like to display the installer in another language, select the language. Click OK when you are ready to proceed.

Older versions of SPSS® Modeler. The installation does not automatically overwrite earlier installations of SPSS Modeler. You have to uninstall older versions manually.

Authorized user license installation

- [Authorization code](#)
 - [Licensing your product](#)
 - [Using the license authorization wizard](#)
 - [Viewing your license](#)
 - [Updating, modifying, and renewing SPSS® Modeler](#)
-

Authorization code

You will need your authorization code(s). In some cases, you might have multiple codes. You will need all of them.

You should have received separate instructions for obtaining your authorization code. If you cannot find your authorization code, contact Customer Service by visiting <https://www.ibm.com/products/spss-modeler/support>.

Licensing your product

You must run the License Authorization Wizard to license your product.

Note: Licenses are tied to your computer's hardware with a lock code. If you replace your computer or its hardware, you will have a new lock code and will need to repeat the authorization process. This is also true if you re-image your computer. If you find out that you exceeded the allowable number of authorizations specified in the license agreement, go to <https://www.ibm.com/products/spss-modeler/support> to contact the Client Care team for assistance.

Important: The license is sensitive to time changes. If you must change the system time and then cannot run the product, contact the Client Care team for assistance by visiting <https://www.ibm.com/products/spss-modeler/support>.

Using the license authorization wizard

1. To launch the License Authorization Wizard, click License Product on the Welcome dialog or click the License Authorization Wizard icon in the SPSS® Modeler application folder.

2. Select Authorized user license. When prompted, enter one or more authorization codes.

You should have received separate instructions for obtaining your authorization code. If you cannot find your authorization code, contact Customer Service by visiting <https://www.ibm.com/products/spss-modeler/support>.

The License Authorization Wizard sends your authorization code over the Internet to IBM® Corp. and automatically retrieves your license. If your computer is behind a proxy, click Connect to the internet through a proxy server and enter the appropriate settings.

If the authorization process fails, you are prompted to send an e-mail message. Choose whether you want to send the e-mail message through your desktop e-mail program or through a Web-based e-mail application.

- If you choose the desktop option, a new message with the appropriate information is created automatically.
- If you choose the Web-based option, you must create a new message in your Web-based e-mail program. Then copy the message text from the License Authorization Wizard and paste it into your e-mail application.

Send the e-mail message and respond to the prompt in the License Authorization Wizard. The e-mail message is processed almost instantaneously. You can click Enter License Code(s) to enter any license code(s) that you receive. If you already closed the License Authorization Wizard, restart it and select Authorized user license. On the Enter Codes panel, add the license code that you received and click Next to complete the process.

Viewing your license

You can view the license by relaunching the License Authorization Wizard. The first panel displays the licensing information. Click Cancel when done, and, when prompted about canceling, click Yes.

Updating, modifying, and renewing SPSS® Modeler

If you purchase additional options or renew your license, you will receive a new authorization code (or codes). For instructions on using the authorization code(s), see [Licensing your product](#).

Concurrent user license installation

- [Using the license authorization wizard](#)
- [Checking out/in a commuter license](#)

Using the license authorization wizard

1. To launch the License Authorization Wizard, click License Product on the Welcome dialog or click the License Authorization Wizard icon in the SPSS® Modeler application folder.
2. To launch the License Authorization Wizard, run *law.exe*, which can be found in the license manager installation directory.
3. Select Concurrent user license. When prompted, enter the license manager server name or IP address. This is the IP address or the name of the server on which the network license manager is running. If you have multiple addresses or names, separate them with a tilde (for example, *server1~server2~server3*). Contact your administrator if you do not have this information.

Checking out/in a commuter license

Network licenses normally require that you are connected to the network to run SPSS® Modeler. If your administrator enabled commuter licenses, you can check out a commuter license to use the network license when you are not connected to the network. For example, you may want to run SPSS Modeler on the train when you don't have a network connection. Before disconnecting from your network and catching the train, you could check out a commuter license for a limited amount of time. You will need to reconnect to the network and check the license back in before the time expires. Otherwise, SPSS Modeler will stop working.

Network licenses are enabled and configured by your administrator. If you would like to use this feature and can't, check with your administrator.

Important: Even if you are able to run SPSS Modeler because you are reconnected to the network, be sure to check the license back in. Doing so will allow other users to take advantage of the commuter license.

Check out a license

1. Double-click *Commuter Utility* in the installation directory.
2. Select the license that you want to check out.
3. In the Duration box, enter the number of days for which you want to check out the license. There is a limit that your administrator configures.
4. Click Check Out.

The commuter license will expire after the number of days specified by Duration. You can also manually check the license back in at any time.

You may receive a message in the following format:

Error while checkout with error code: <code>

Common codes are as follows.

Code	Meaning
77	All available licenses have been checked out.
1402	Attempt to check out license that has been reserved for another user.

Check in a license

1. Double-click *Commuter Utility* in the installation directory.
2. Select the license that you want to check in. License(s) that you checked out are indicated by a check mark.
3. Click Check In.

After installation

Depending on the components you have for SPSS® Modeler, you may have to carry out further configuration after installing the main software. For example, this might be to connect to a database, or to use data that is compatible with IBM® SPSS Statistics.

- [Configuring IBM SPSS Modeler to work with IBM SPSS Statistics](#)
 - [Database Access](#)
 - [Applying fix packs](#)
 - [Uninstalling](#)
-

Configuring IBM SPSS Modeler to work with IBM SPSS Statistics

To enable IBM® SPSS® Modeler to use the Statistics Transform, Statistics Model, and Statistics Output nodes, you must have a copy of IBM SPSS Statistics installed and licensed on the computer where the stream is run.

If running IBM SPSS Modeler in local (standalone) mode, the licensed copy of IBM SPSS Statistics must be on the local computer.

When you have finished installing this copy of SPSS Modeler Client, you will also need to configure it to work with IBM SPSS Statistics. From the main client menu, choose:

Tools > Options > Helper Applications

and on the IBM SPSS Statistics tab, specify the location of the local IBM SPSS Statistics installation you want to use. For more information, see the *Source, Process and Output Nodes* guide or the online help for Helper Applications.

In addition, if running in distributed mode against a remote IBM SPSS Modeler Server, you also need to run a utility at the IBM SPSS Modeler Server host to create the **statistics.ini** file, which indicates to IBM SPSS Modeler Server the installation path for IBM SPSS Statistics Server. To do this, from the command prompt, change to the IBM SPSS Modeler Server bin directory and, for Windows, run:

```
statisticsutility -location=<statistics_installation_path>/bin
```

Alternatively, for UNIX, run:

```
./statisticsutility -location=<statistics_installation_path>/bin
```

Following is an example of what is placed in the **statistics.ini** file located in the IBM SPSS Modeler Server /bin directory after running the utility in IBM SPSS Modeler Server:

```
[LOCATION]
STATISTICS_PATH=C:\Program Files\IBM\SPSS\StatisticsServer\<version>
```

If you do not have a licensed copy of IBM SPSS Statistics on your local machine, you can still run the Statistics File node against a IBM SPSS Statistics server, but attempts to run other IBM SPSS Statistics nodes will display an error message.

Database Access

To read or write to a database, you must have an ODBC data source installed and configured for the relevant database, with read or write permissions as needed. If you have questions about creating or setting permissions for ODBC data sources, contact your database administrator.

Supported ODBC drivers

For the latest information on which databases and ODBC drivers are supported and tested for use with IBM® SPSS® Modeler, see the product compatibility matrices on the corporate Support site (<http://www.ibm.com/support>).

Where to install drivers

Note: ODBC drivers must be installed and configured on each computer where processing may occur.

- If you are running IBM SPSS Modeler in local (standalone) mode, the drivers must be installed on the local computer.
- If you are running IBM SPSS Modeler in distributed mode against a remote IBM SPSS Modeler Server, the ODBC drivers need to be installed on the computer where IBM SPSS Modeler Server is installed. For IBM SPSS Modeler Server on UNIX systems, see also "Configuring ODBC drivers on UNIX systems" later in this section.
- If you need to access the same data sources from both IBM SPSS Modeler and IBM SPSS Modeler Server, the ODBC drivers must be installed on both computers.
- If you are running IBM SPSS Modeler over Terminal Services, the ODBC drivers need to be installed on the Terminal Services server on which you have IBM SPSS Modeler installed.

Applying fix packs

To ensure problem-free operation, keep your product at the latest fix pack level. Complete all of the necessary pre-installation and post-installation tasks as described in the fix pack instructions.

Uninstalling

The IBM SPSS modeler installation files are hidden under the Home folder. Before you uninstall IBM SPSS modeler, enable the view of hidden folders in your Home folder.

Complete the following steps to uninstall IBM SPSS Modeler on Mac OS.

1. Move the installation folder to Bin.
The default installation folder is /Applications/IBM/SPSS/Modeler/18.4.0.
2. Move the file Library/Preferences/com.ibm.spss.plist from the Home folder to Bin.
3. Move the folder ./IBM/SPSS/Modeler/18.4.0 (located in Home folder) to Bin.
4. Remove any extension commands that you installed.
The extension commands are in the ext folder. Move the folder ./IBM/SPSS/Modeler/18.4.0/ext to Bin
5. Empty Bin.

Administrator's guide

The following instructions are for administrators at sites with the license type concurrent license for IBM® SPSS® Modeler 18.4.0. This license allows you to install IBM SPSS Modeler on any number of computers. However, only the number of users for which you purchased the license can run the application concurrently.

- [Before you start](#)
- [Installing the concurrent license manager](#)
- [Licensing your product](#)
- [Testing the license manager](#)
- [Installing the product on the local desktop computers](#)
- [Administering the concurrent license](#)

Before you start

You will need your authorization code. The authorization code enables you to get a license for the concurrent license manager. The **concurrent license manager** controls your concurrent license and allows end users to run IBM® SPSS® Modeler.

You should have received separate instructions for obtaining your authorization code. If you cannot find your authorization code, contact Customer Service by visiting <https://www.ibm.com/products/spss-modeler/support>.

To ensure that you set up the concurrent license correctly, follow these steps:

1. **Install the concurrent license manager.** The concurrent license manager is the utility that will serve up the concurrent licenses to end users. You can install the license manager on any computer on your network. This is typically a server to which desktop computers can connect. See the topic [Installing the concurrent license manager](#) for more information.
2. **Lic平 your product.** This action will give the license manager the required information for serving up the licenses. See the topic [Licensing your product](#) for more information.
3. **Test the concurrent license manager.** You should test license manager to make sure it is serving up licenses. See the topic [Testing the license manager](#) for more information.
4. **Install IBM SPSS Modeler on the local desktop computers.** You or your end users will complete the full installation on the desktop computers. During an installation, an end user can specify the computer on which the license manager is running. When an end user tries to launch IBM SPSS Modeler, the product communicates with this license manager to get a license. If a license is available, IBM SPSS Modeler launches. See the topic [Installing the product on the local desktop computers](#) for more information.

No administration steps are required for the installation, but if any problems arise, see [Administering the concurrent license](#).

- [Citrix and Terminal Services](#)
- [Mixed licensing](#)

Citrix and Terminal Services

You can install and publish the IBM® SPSS® Modeler application on your Citrix or Terminal Services Server the same way that you install and publish other Windows applications.

Mixed licensing

IBM® SPSS® Modeler has limited support for a mixed licensing environment (a combination of local authorized user licenses and concurrent licenses). In a typical environment, all licenses are handled locally or through the concurrent license manager. For example, if the main product is licensed through the concurrent license manager, options are also licensed through the concurrent license manager.

The only option for mixed licensing is to license the main product through the concurrent license manager and to license the options on the end user's computer with *licenseactivator*. To set up this type of mixed licensing, install IBM SPSS Modeler with a concurrent license. Then use *licenseactivator* on the end user's computer to license the options. For more information about *licenseactivator*, see [Using licenseactivator to install a license automatically](#).

IBM SPSS Modeler does not support the opposite scenario to license the main product locally and to license the options through the concurrent license manager.

Installing the concurrent license manager

Before end users install IBM® SPSS® Modeler on their desktop computers, you must install the concurrent license manager. This utility is a continuously executing service or daemon that you will typically install on one computer on your network. (You also have the option of installing on multiple computers, in which case you would set up redundant license managers. For more information, see the topic [Setting up redundant license servers](#).) You do not install the concurrent license manager on the end users' desktop computers.

Whenever an end user starts a concurrent-licensed IBM SPSS application, the application will request a license from the license manager. This utility will deliver licenses up to a fixed number of simultaneous end users, determined by the license that you have purchased. After this number has been met, any further requests for licenses will be refused. If you find that end users are often being refused licenses, you can contact your sales representative to purchase a license that will allow more simultaneous users.

Note: The license manager will record the number of active end-user sessions and information about each session in a log file, which you can use to troubleshoot connection problems. See the topic [Obtaining log information](#) for more information.

Multiple operating systems

The platform on which the concurrent license manager is running does not have to match the platform on which the client is running. For example, a Linux license manager can serve up licenses for Windows clients.

Administering the license manager

You administer the license manager using the license manager administrator, which is available only for Windows. Therefore, you need at least one Windows machine on which to install the license manager administrator.

System requirements

The computer on which you install the concurrent license manager must meet the minimum operating system requirements. The license manager does not require a server class machine.

Important: If a firewall is running on the computer on which the license manager is installed, you must open port 5093 for UDP. Otherwise, client computers will not be able to retrieve a license from the license manager. Furthermore, if you are using redundant license manager machines, you must open port 5099 for UDP to enable the license manager machines to communicate with each other.

- [Upgrading the license manager](#)
- [Installing the license manager on Windows](#)
- [Installing the license manager on Mac OS](#)
- [Installing the license manager on non-Windows systems](#)
- [Installing the license manager administrator](#)

Upgrading the license manager

If you have a previous version of the license manager installed, you must perform the following steps:

1. Go to the directory in which you installed the old license manager.
2. Copy the *lservrc* file. On Windows, look in the *winnt* subdirectory.
3. Save the *lservrc* file to a safe location.
4. If any users have checked out computer licenses, make sure those users check the licenses back in. See the topic [Configuring computer licenses](#) for information about obtaining a list of checked out licenses.
5. Shutdown the license manager. See the topic [Starting and stopping the license manager](#) for more information.
6. Uninstall the old license manager. See the topic [Uninstalling the license manager](#) for more information.
7. Install the new license manager. For information about installing on Windows, see the topic [Installing the license manager on Windows](#). For information about installing on UNIX/Linux, see the topic [Installing the license manager on non-Windows systems](#).
8. Copy the saved *lservrc* file to the directory in which you installed the new license manager or the *winnt* subdirectory of the installation directory on Windows. If you accepted the default location on Windows, check the C:\Program Files (x86)\Common Files\SafeNet Sentinel\Sentinel RMS License Manager\WinNT folder.

Installing the license manager on Windows

Note: You must launch the installer as administrator. When instructed to launch an installer file, right-click the file and choose Run As Administrator.

Note: Ensure that the machine on which you are installing has Java installed.

1. For your downloaded eImage file, use an archive utility such as WinZip to extract all the files in the appropriate eImage.
2. Extract the contents of the archive that contains the license manager and tools.
3. Run setup.exe from the extracted manager directory and follow the instructions that appear on the screen.
4. To install the license manager administrator on the same machine as the license manager, run setup.exe from the extracted tools directory and follow the instructions that appear on the screen. You also have the option of installing the license manager administrator on another Windows machine if you want to administer the license manager remotely.

Installing the license manager on Mac OS

1. Insert the concurrent licensing tools DVD into the DVD drive of the network computer on which you want to run the license manager. Look for the archive that contains the license manager and tools for your operating system.

-or-

If you downloaded an eImage file, go to the location where you downloaded the file.

2. Extract the contents of the archive that contains the license manager and tools to the location where you want to install the license manager.
3. Install the license manager administrator on a Windows machine. See the topic [Installing the license manager administrator](#) for more information.
4. Refer to [Starting and stopping the license manager](#) for information about starting the license manager.

Installing the license manager on non-Windows systems

1. Go to the location where you downloaded your eImage file.
2. Extract the contents of the archive that contains the license manager and tools to the location where you want to install the license manager.
3. Install the license manager administrator on a Windows machine. See the topic [Installing the license manager administrator](#) for more information.
4. Refer to [Starting and stopping the license manager](#) for information about starting the license manager.

Installing the license manager administrator

The Windows-only license manager administrator is used to administer the license manager. If you installed the license manager on a non-Windows machine, you must install the license manager administrator on a Windows machine.

1. For your downloaded eImage file, use an archive utility such as WinZip to extract all the files in the appropriate eImage.
2. Extract the contents of the archive that contains the license manager and tools.
3. Run setup.exe from the extracted tools directory and follow the instructions that appear on the screen.

Licensing your product

On non-Windows operating systems, you must install the license from the command prompt after installing the license manager.

Note: Licenses are tied to the network computer's physical or virtual hardware with a **lock code**. If you replace the network computer or its hardware, you will have a new lock code and will need to contact your sales representative to obtain a new authorization code. If you are installing on a virtual machine, you need to ensure that you select a lock code that does not change on restart. For more information, see [Installing a license in a virtual environment](#).

Important: The license is sensitive to time changes. If you must change the system time and then cannot run the product, contact the Client Care team for assistance by visiting <https://www.ibm.com/products/spss-modeler/support>.

- [Installing a license in a virtual environment](#)
- [Installing a license from the command prompt](#)
- [Adding a license](#)
- [Viewing your license](#)

Installing a license in a virtual environment

If you installed the concurrent license manager in a virtual environment, there are special instructions for licensing. On a virtual machine the hardware is virtual, and the locking code that ties the license manager to the license might change when the virtual machine is restarted. To ensure the license manager works correctly, you need to find a locking code that does not change when the virtual machine is restarted. When you find a stable locking code, you will use it to license the license manager.

Important:

If you choose a locking code that does change on reboot, the license manager will stop working. The IBM® SPSS® application will not be able to retrieve a license and will fail to start.

Checking the locking code

1. Open a command prompt.
2. Change to the following directory.
 - Windows. The license manager administrator installation directory. If you accepted the default location during installation, the license manager administrator installation directory is C:\Program Files (x86)\Common Files\SafeNet Sentinel\SafeNet License Manager\WinNT.
 - Other platforms. The license manager installation directory.
3. At the command prompt, type `echo!d` (Windows) or `./echo!d` (other platforms).

You will see something like the following in the output:

Locking Code 1 : 4-12A1B

The number that appears immediately before the hyphen (-) is the locking code criteria. The locking code criteria is a number that represents the virtual hardware that is used for the locking code (in this example, it is 4, which represents the OS volume serial ID). The number after the hyphen is the locking code itself (in this example, it is 12A1B).

Following are the possible locking code criteria.

Locking code criteria	Virtual hardware
2	IP address
4	OS volume serial ID
8	Hostname
10	Ethernet card

Confirming that the locking code is stable

1. After checking the locking code, restart the virtual machine.

2. Check the locking code again (see [Checking the locking code](#)).
 - If the locking code **doesn't change**, reboot and check a few more times. If the locking code is stable, you are ready to license (see [Licensing the license manager with the new locking code](#)).
 - If the locking code **does change**, you need to update the locking code (see [Updating the locking code](#)).

Updating the locking code

1. In a text editor, open echoid.dat, which you can find in the following directory.
 - Windows. The license manager administrator installation directory. If you accepted the default location during installation, the license manager administrator installation directory is C:\Program Files (x86)\Common Files\SafeNet Sentinel\Sentinel RMS License Manager\WinNT.
 - Other platforms. The license manager installation directory.
2. You will see a single hexadecimal number that represents the current locking code criteria. Change this number to one of the acceptable locking code criteria in hexadecimal format.

Locking code criteria in hexadecimal format	Virtual hardware
0x002	IP address
0x004	OS volume serial ID
0x008	Hostname
0x010	Ethernet card

Licensing the license manager with the new locking code

After you find and update to a stable locking code, there are no further licensing steps that are particular to virtual environments. Use the command prompt to complete installation of the license.

Installing a license from the command prompt

You have two options for installing from the command prompt. You can use *licenseactivator* to get a license from the Internet automatically, or you can use *echoid* to get a license manually.

Note: When using silent installation for redundant license servers you must restart the machine when the installation is finished.

- [Using licenseactivator to install a license automatically](#)
- [Installing a license manually](#)

Using licenseactivator to install a license automatically

The computer on which you are installing the license must be connected to the Internet. If it isn't, install the license manually. See the topic [Installing a license manually](#) for more information.

1. Log in as the user who installed the license manager.
2. Open a command prompt and change directories to the license manager administrator installation directory. This is the directory in which you installed the *license manager administrator*, not the directory in which you installed IBM® SPSS® Modeler. If you accepted the default location on Windows, check the C:\Program Files (x86)\Common Files\SafeNet Sentinel\Sentinel RMS License Manager\WinNT folder.
3. You typically have an authorization code. In the simplest case, you enter the following at the command prompt/terminal window. See below for more details about the command prompt usage.

Windows: licenseactivator <auth-code>

UNIX/Linux/MacOS: ./licenseactivator <auth-code>

where <auth-code> is your authorization code.

You should see a message that the license was added successfully. If it wasn't, note the error code and try installing the license manually. See the topic [Installing a license manually](#) for more information.

When you use *licenseactivator*, it licenses the product and writes a log file to its directory. The name of the log file is *licenseactivator_<month>_<day>_<year>.log*. If any errors occur, you can check the log file for more information. This information is also useful if you contact IBM Corp. for support.

Using licenseactivator with Authorization Codes

licenseactivator is typically used with one or more authorization codes that you received when you purchased the product. Enter all of the text on one line.

Windows:

```
licenseactivator authcode1[:authcode2:...:authcodeN] [PROXYHOST=proxy-hostname] [PROXYPORt=proxy-port-number]
[PROXYUSER=proxy-userid] [PROXPASS=proxy-password]
```

UNIX/Linux/MacOS:

```
./licenseactivator authcode1[:authcode2:...:authcodeN] [PROXYHOST=proxy-hostname] [PROXYPORt=proxy-port-number]
[PROXYUSER=proxy-userid] [PROXPASS=proxy-password]
```

- Multiple authorization codes are separated by colons (:).
- The proxy settings are optional, but you may need them if your computer is behind a proxy. Which proxy settings are needed depend on your specific proxy configuration. You might need all of them.

PROXYHOST

The server name or IP address of the proxy host

PROXYPORt

The port number for connecting to the Internet through the proxy

PROXYUSER

If required, the user ID for the proxy

PROXPASS

If required, the password associated with the user ID

Using licenseactivator with License Codes

In less common scenarios, IBM Corp. may have sent you a *license*.

Windows:

```
licenseactivator licensocode[:licensocode2:...:licensocodeN]
```

UNIX/Linux/MacOS:

```
./licenseactivator licensocode[:licensocode2:...:licensocodeN]
```

- Multiple license codes are separated by colons (:).
- When using license codes, *licenseactivator* does not connect to the Internet, so you do not need to specify proxy information.

Installing a license manually

1. Log in as the user who installed the license manager.
2. Open a command prompt and change directories to the license manager administrator installation directory. Note that this is the directory in which you installed the *license manager administrator*, not the directory in which you installed IBM® SPSS® Modeler. If you accepted the default location on Windows, check the C:\Program Files (x86)\Common Files\SafeNet Sentinel\Sentinel RMS License Manager\WinNT folder.
3. Get the lock code for the server machine. At the command prompt, type `echoid` (Windows) or `./echoid` (other platforms).
4. Send the lock code and your authorization code to IBM Corp. by calling your local office or sending an e-mail message to `spsscs@us.ibm.com`. IBM Corp. will then provide a license code or a file containing a license code.
5. Use *licenseactivator* to enter the license code or codes.

Adding a license

You may want to add a license at a later time. The process for adding a license is the same as installing the original license.

Viewing your license

You can view your concurrent license (including the number of users) in the WlmAdmin application. For information about the WlmAdmin application and specifics about viewing the license, see [Administering the concurrent license](#).

Testing the license manager

To make sure the license manager is serving up licenses correctly, you should test it.

1. If you haven't installed the license manager administrator on another machine, install it on a Windows machine that is *not* running the license manager you want to test. See the topic [Installing the license manager administrator](#) for more information.
2. Install another license manager on a Windows machine that is *not* running the license manager you want to test. See the topic [Installing the license manager on Windows](#) for more information.
3. Start the WlmAdmin application. See the topic [Starting the WlmAdmin Application](#) for more information.
4. Add the remote license manager server that you want to test. See the topic [Adding a server](#) for more information.
5. View the licenses on the remote server. See the topic [Viewing details about a license](#) for more information.

If you are able to view the license, the license manager is ready for local desktop computers to connect to it. You can proceed with installing the product on local desktop computers. If you are not able to view the license, review the previous steps to ensure the license manager was installed correctly.

Installing the product on the local desktop computers

You have two options for installing the full product locally on an end user's computer. You can manually install on each computer, or you can use an application like Systems Management Server (SMS) to push the installation to the computers running Windows.

To manually install on a local desktop

1. **Make the installation media available.** Download the eImage for the product and extract the files to a shared network drive.
2. **Copy the installation instructions and prepare licensing information.** Make as many copies of the product installation instructions as you need. The installation instructions are available from the download site. Look for the instructions that correspond to your license type. After installation, the end user must enter the IP address or the name of the network computer on which the concurrent license manager is running. Fill out this information in the space provided at the beginning of the instructions before copying them.
3. **Distribute the installation materials to end users.** Distribute the downloaded file (or network location), the installation instructions, and the licensing information to end users who can manually install on each computer as needed.

To push to the local desktops running Windows

Because IBM® SPSS® Modeler installations are compatible with Microsoft Windows Installer (MSI), you can push an installation to the end-user desktop computers.

- [Pushing an installation to Windows computers](#)

Pushing an installation to Windows computers

Pushing an installation is a method for remotely distributing software to any number of end users without any user intervention. You can push the full installation of IBM® SPSS® Modeler to the end-user desktop computers running Windows. The technology that you are using for pushing the installation must support the MSI 3.0 engine or higher.

- [Uninstalling a Previous Version](#)
- [Properties for push installations](#)
- [MSI files](#)
- [Command line example](#)
- [Using SMS to push the installation](#)
- [Using Group Policy or related technology to push the installation](#)
- [Pushing an uninstallation](#)

Uninstalling a Previous Version

If you are going to push to the same directory in which a previous version of IBM® SPSS® Modeler was installed, you need to uninstall the old version. You must manually uninstall any IBM SPSS Modeler versions prior to 11.0 since push installations were not available for those versions. You can push the uninstallation as you push an installation. See the topic [Pushing an uninstallation](#) for more information.

Properties for push installations

Following are the properties that you can use for push installations. All properties are case sensitive. Values must be quoted if they contain spaces.

Table 1. Properties for push installations

Property	Description	Valid values	Default (If Applicable)
INSTALLDIR	The directory where IBM® SPSS® Modeler should be installed on the end user's desktop computer. This property is optional. If it is excluded, the default is C:\Program Files\IBM\SPSS\Modeler\18.4.0.	A valid path such as C:\Program Files\IBM\SPSS\Modeler\18.4.0.	C:\Program Files\IBM\SPSS\Modeler\18.4.0
LICENSETYPE	The license type. The value is case sensitive.	Network	
LSHOST	The IP addresses or the names of the network computer or computers on which the concurrent license manager is running.	One or more valid IP addresses or network computer names. Multiple addresses or names are separated by tildes (for example, server1~server2~server3).	

MSI files

Extract the contents of your downloaded eImage to access the MSI file. The file is located under the *modeler|<architecture>* directory, where <architecture> is 32bit or 64bit.

Command line example

Following is a command line that you could use to push a product installation. Enter all of the text on one line.

```
MsiExec.exe /i "modelerclient.msi" /qn /L*v logfile.txt  
INSTALLDIR="C:\Program Files\IBM\SPSS\Modeler\18.4.0" LICENSETYPE="Network" LSHOST="mylicserver"
```

Using SMS to push the installation

The basic steps for using Systems Management Servers (SMS) to push IBM® SPSS® Modeler are:

1. Extract the contents of your downloaded eImage and copy the appropriate subdirectory under the *modeler|<architecture>* directory to a directory on a network computer.
2. Edit the .pdf file located in the copied directory. Using a text editor, modify the value of CommandLine by adding the appropriate properties. For a list of the available properties, refer to [Properties for push installations](#). Make sure to specify the correct MSI file in the command line.
3. Create a package from the .pdf file and distribute the package to the end-user desktop machines.

Using Group Policy or related technology to push the installation

1. Extract the contents of your downloaded eImage and copy the appropriate subdirectory under the *modeler|<architecture>* directory to a directory on a network computer.
2. Using an application like ORCA, edit the Properties table in the appropriate file under the copied folder. ORCA is part of the Windows 2003 Server SDK, which you can find at <http://www.microsoft.com/downloads> by searching for the SDK. For a list of the properties that you can add to the Properties table, refer to [Properties for push installations](#). Make sure to use the correct MSI file.
3. Create a package using the edited file and distribute the package to the end-user desktop computers.

Pushing an uninstallation

Note: When you push the uninstall command, the end user loses customizations. If specific users require customizations, you can exclude those users from the distribution and ask them to install the product manually.

If you push an installation of a later version of IBM® SPSS® Modeler, you may want to uninstall first. You can do this silently by pushing the following command. Enter all of the text on one line.

```
MsiExec.exe /X{} /qn /L*v logfile.txt  
ALLUSERS=1 REMOVE="ALL"
```

The product code for a specific version is in the *setup.ini* file within each version's installed folders.

Administering the concurrent license

The license manager maintains your concurrent license. To administer the license manager itself and to view information about the concurrent licenses that it is maintaining, you can use the WlmAdmin application, which is the main user interface for the license manager administrator. If you are administering a license manager on a non-Windows machine or a remote Windows machine, install the license manager administrator on a separate Windows machine. See the topic [Installing the license manager administrator](#) for more information.

Note: If you need additional administration information, refer to the SafeNet documentation, which is installed with the license manager administrator. This documentation is in the *help\Content* directory in the license manager administration installation directory (for example, C:\Program Files (x86)\Common Files\SafeNet Sentinel\Sentinel RMS License Manager\help\Content).

- [Starting the WlmAdmin Application](#)
- [Adding a server](#)
- [Obtaining log information](#)
- [Viewing details about a license](#)
- [Setting up redundant license servers](#)
- [Configuring computer licenses](#)
- [Configuring license reservations](#)
- [Starting and stopping the license manager](#)
- [Uninstalling the license manager](#)
- [Uninstalling the license manager administrator](#)
- [Troubleshooting Desktop Computers](#)

Starting the WlmAdmin Application

From the Windows Start menu, choose:

[All] Programs>IBM>SPSS License Tools><version>>Sentinel RMS Server Administration

Adding a server

Before you can administer a license manager, you need to add its server to the WlmAdmin application. You have two options for adding the server.

To manually add a server

1. From the WlmAdmin application menus, choose:
Edit>Defined Server List
2. In the Defined Server List dialog, enter the name or IP address of the server on which the license manager is running.
3. Click Add.
4. Click OK.

The server now appears in the Defined Servers lists in the left pane of the WlmAdmin application.

To view a list of servers on the subnet

1. In the left pane of the WlmAdmin application, click the + sign next to Subnet Servers.

A list of license manager servers on your subnet appears. If you can't find a specific server with this method, manually add it as described above.

Obtaining log information

If end users have difficulty checking out licenses, the log files may contain useful information. You can use the `LSERVOPTS` environment variable and the `-f <trace-log-file>` and `-l <usage-log-file>` options to specify that log files should be created. For more information about this environment variable and its options, refer to the SafeNet documentation in the `Content` directory in the license manager administrator installation directory.

Viewing details about a license

You can view details about licenses that you added either manually or through the License Authorization Wizard.

1. In the left pane of the WlmAdmin application, click the + sign next to the license manager server to see the license(s).
2. Click the name of the license. The right pane displays details about the license. Codes are used to identify the licenses. The first part of the code indicates the feature. The second part indicates the version.

To see the names associated with the feature codes

1. Using a command prompt, change to the directory in which the license manager administrator is installed.
2. Type `lmshowlic <server>` (Windows) or `./lmshowlic <server>` (other operating systems), where `<server>` is the name or IP address of the server on which the license manager is running.

The output lists all the features available on the server, grouped by product and version.

Setting up redundant license servers

You can set up multiple, redundant license servers that support the same users. Redundant servers can help prevent any interruption that may occur when a server crashes. Another redundant server can take over the management of the license when the first server crashes.

You will need a special license code to enable the redundancy feature, as described in the following steps. For assistance with creating a redundant license key or any other licensing issue, contact IBM Support by phone or e-mail. You can find contact information at <http://www.ibm.com/planetwide>.

There must be an odd number of servers (at least three of them), and a majority must be running at the same time. For example, if there are three redundant license servers, two of them must be running.

To prepare each redundant license server

1. Install the license manager. See the topic [Installing the concurrent license manager](#) for more information.
2. Using a command prompt, change to the directory in which you installed the license manager.
3. Get the lock code for each server machine. At the command prompt, type `echoid` (Windows) or `./echoid` (other operating systems).
4. Write down the lock code. You will need the lock code for the next steps.
5. Repeat these steps for each redundant license server.

To activate the redundant licenses

1. Go to the IBM SPSS License Key Center (<https://spss.subscribenet.com/control/ibmp/login>).
2. Create a concurrent authorization code.
3. After the concurrent authorization code is created, click the code and then scroll down until you see the fields for Lock Code. You will now have the ability to add multiple lock codes to the license key.
4. Using the lock codes from the previous steps, enter the lock codes into the appropriate fields.
5. Click Submit.

To set up the redundant license server pool

1. If a license manager is running on any of the redundant license servers, stop the license manager on each computer.
2. From the WlmAdmin application menus, choose:
`Edit > Redundant License File`

This action opens the `WrlfTool` application.

3. From the WrlfTool application menus, choose:
File > New
4. For each redundant license server, click Add to specify the hostname and IP address of each server.
5. Change the order of the servers to indicate the order in which the redundant license servers are used. The first one in the list is the primary server.
6. Click Add License to add the license(s) that you received from Customer Service or your local office. If you received multiple licenses, be sure to add every one.
7. Click OK.
8. Click Done when you are finished.

To save the redundant license file

1. From the WrlfTool application menus, choose:
File > Save As
2. Save the redundant license file (*lsvrflf*) to an easily accessible location. You will need to copy the file in the next steps.

To configure the redundant license servers

1. Copy the redundant license file (*lsvrflf*) to the *winnt* subfolder of the license manager installation directory on Windows. If you accepted the default location, check the C:\Program Files (x86)\Common Files\SafeNet Sentinel\Sentinel RMS License Manager folder. On other operating systems, copy the file directly to the license manager installation directory. There must be at least three redundant license servers.
2. Start the license manager on each redundant license server.

To configure end-user computers

When the end user installs the product, the user specifies all redundant servers, with the server names or IP addresses separated by a tilde (for example, *server1~server2~server3*). The setup program then adds the necessary configuration information to the end user's computer. If the product is already installed on the desktop computers, you can perform the following manual steps to add the configuration information. You can also push an uninstall followed by a new install that defines all the servers. Refer to [Pushing an installation to Windows computers](#) for information about pushing installations.

1. Using a text editor, open *spssprod.inf*. On Windows, this file is located in the product installation directory on the desktop computer.
2. Change the value of **DAEMONHOST** to the server names or IP addresses separated by a tilde (~). For example:

```
DAEMONHOST=server1~server2~server3
```

3. Save *spssprod.inf*.

Configuring commuter licenses

Commuter licenses allow your end users to check out licenses from the license manager, so that they can use the license when not connected to the network. Commuter licenses are enabled by default. Instructions for actually checking out the commuter license appear in the end user installation instructions.

You can restrict the percentage of licenses that are enabled for commuting on the license manager server. It's a good idea to restrict commuter licenses to prevent all the licenses (tokens) from being used up by commuters. After the specified percentage of licenses have been used by commuters, no more will be available until the commuter licenses expire or are checked back in. You can also configure the maximum duration for which an end user can check out a license. The default maximum duration is 3 days.

Important: If you are using redundant license servers with commuter licenses, only the primary license server allows users to check out and check in commuter licenses. If the primary license server is down, end users will not be able to check out and check in licenses.

To set the percentage of available commuter licenses

1. Create an **LSERVOPTS** environment variable on the license manager server. This variable is created during the license manager installation on Windows, so you need to complete this step only for the other operating systems.
2. Edit the value of the **LSERVOPTS** environment variable to include **-com <percentage>**, where **<percentage>** is a numeric value between 0 and 100 indicating the percentage of licenses that are available for commuting. Specifying 0 disables commuter licenses. This switch is included by default on Windows and is set to 0.
3. Restart the computer on which the license manager is running.

To set the maximum duration for commuter licenses

The maximum length of time a user can check out a commuter license is specified by the **CommuterMaxLife** setting in the spssprod.inf file (on Windows) or the commutelicense.ini file (on Mac OS) on the *desktop* computer. On **Windows**, this file is located in the product installation directory on the desktop computer. On **Mac OS**, this file is located in the product installation directory on the desktop computer under Resources/Activation. Open the file and look for **CommuterMaxLife**. Set the value of this option to the maximum number of days for which an end user can check out a commuter license. This should be a number between 1 and 30. You can also set this value when you push the installation. See the topic [Pushing an installation to Windows computers](#) for more information.

Note: This functionality works off the date, not the time. For example, if you set the **CommuterMaxLife** option to one day, then check a license out at 9 a.m., this license does not get checked back in until midnight on the following day. So although **CommuterMaxLife** is set to one day, the license is actually held for 39 hours.

To obtain a list of checked out licenses from the command line

You can find out which users have checked out licenses.

1. Using a command prompt, change to the directory in which the license manager administrator is installed.
2. Type `lsmon <server>` (Windows) or `./lsmon <server>` (other operating systems), where `<server>` is the name or IP address of the server on which the license manager is running. You can omit the license server name if you want to view checked out licenses for only the localhost server.

To obtain a list of checked out licenses from the WlmAdmin application

You can also view checked out licenses in the WlmAdmin application:

1. In the left pane of the WlmAdmin application, click the + sign next to the license manager server.
2. Click the + sign next to Clients. Clients using the concurrent license are listed. If no clients are listed, no users are using the concurrent license.
3. Select a particular Client to view whether the client has a checked out license. Review the Detailed Information area in the right pane after selection.

Configuring license reservations

You can create a reservation file, which specifies how many licenses are reserved for specific users or groups of users. Users are identified by network IDs or computer names (*not* IP addresses). For example, you can set up a reservation file that reserves the license for a group of power users. Licenses will always be available for these users. You can also use the reservations to prevent certain users from accessing the license.

To create a new reservation file

1. From the WlmAdmin application menus, choose:
`Edit > Reservation File`
This action opens the Wlsgrmgr application.
2. From the Wlsgrmgr application menus, choose `File > New`.

To add licenses and users to the reservation file

1. From the Wlsgrmgr application menus, choose:
`Feature > Add`
2. Click Next on the first screen of the wizard.
3. Specify the feature code associated with the license that you want to reserve. Refer to [Viewing details about a license](#) for information about getting the feature codes associated with licenses. Also define a specific version, which is entered as it appears in the WlmAdmin application (for example, 160). The version is not optional. Ignore the Capacity controls, because capacity licenses are not supported.
4. Click Next.
5. Specify a name for a group of users. The name is arbitrary, but you should make it descriptive (for example, Sales).
6. Specify the number of licenses that are reserved for the group. Group members can still access all licenses, but the number of licenses you specify will no longer be available for users who are not included in the group. That is, if you have 10 licenses and you reserve five, members of the group have 10 licenses available to them, while other users have only five.
7. On the Members window, click Add to specify a user or computer name associated with the group (do not use IP addresses). If the user or machine is included in the group, that user or machine can use the reserved license. If the user or machine is excluded from the group,

that user or machine cannot access the license at all. Specify as many users or machines as needed. Note that groups must be mutually exclusive. Therefore, different groups for the same license cannot contain common users or computers.

8. Click Finish when all users have been added to the group.
9. Add other groups or licenses as needed. You can also modify or delete licenses and groups by right-clicking one and choosing Properties.

To save the reservation file

1. When finished defining the reservation file, from the menus choose:
File > Save As
2. Save the file to an easily accessible location. You will need to copy the file in the next step.
3. To enable the license server to automatically find the *lserv* file at start up, copy the file to the *winnt* subfolder of the license manager installation directory on Windows. If you accepted the default location, check the C:\Program Files (x86)\Common Files\SafeNet\Sentinel\Sentinel RMS License Manager folder. On other operating systems, copy the file directly to the license manager installation directory.
4. If you want the same reservations to apply for all redundant servers, copy the reservation file (*lserv*) to each server.
5. Restart each license manager when finished.

Starting and stopping the license manager

The method for starting the license manager depends on your operating system.

Windows

On Windows machines, the license manager is a System Service. The service is automatically started by default. However, if you need to start it manually:

1. In the Windows Control Panel, double-click Administrative Tools.
2. Double-click Services.
3. Locate Sentinel RMS License Manager in the Services list.
4. Right-click the service and choose Start or Stop.

Other operating systems

On other operating systems, the license manager is a daemon service. Complete the following steps to start it manually. You can also configure the license manager to start automatically (instructions follow).

1. Using the command prompt, browse to the directory in which you installed the license manager.
 2. **Starting.** As root, type `./lserv &` at the command prompt and press Enter.
 3. **Stopping.** As root, type `./lsrvdown <hostname>` at the command prompt, where `<hostname>` is the network name of the computer on which the license manager is running. Then press Enter.
- [Configuring the license manager to start automatically](#)

Configuring the license manager to start automatically

Windows

1. In the Windows Control Panel, double-click Administrative Tools.
2. Double-click Services.
3. Locate Sentinel RMS License Manager in the Services list.
4. Right-click the service and choose Properties.
5. Set the Startup type to Automatic.
6. Click OK.

Other operating systems

1. Add `./lserv &` to one of the operating system startup files.

Uninstalling the license manager

Windows

1. From the Windows Start menu, choose:
[Settings > Control Panel](#)
2. Double-click Add/Remove Programs.
3. Select Sentinel RMS License Manager and then click Remove.
4. Click Yes when prompted to remove the license manager.

Other operating systems

1. Using the command prompt, browse to the directory to which you installed the license manager.
2. As root, stop the license manager by typing `./lsrvdown <hostname>` at the command prompt, where `<hostname>` is the network name of the computer on which the license manager is running. Then press Enter.
3. Remove the directory where the license manager is installed.

Uninstalling the license manager administrator

1. From the Windows Start menu, choose:
[Settings > Control Panel](#)
2. Double-click Add/Remove Programs.
3. Select License Tools and then click Remove.
4. Click Yes when prompted to remove the concurrent licensing tools.

Troubleshooting Desktop Computers

If the end users' desktop computers are having trouble finding the license manager:

1. Run `lswhere` to verify that the desktop computer can find the network computer on which the license manager is running. See the topic [Running lswhere](#) for more information.
 2. Make sure the license manager service is running on the network computer.
 3. Check the appropriate `spssprod.inf` file. On Windows, this file is located in the product installation directory on the desktop computer. Open `spssprod.inf` and make sure `DAEMONHOST` is set to the correct name or IP address of the computer on which the license manager is running. If you are using redundant servers, this should define all of them. Each name is separated by a tilde (~) character. For example, if the license manager computers are `SERVER1`, `SERVER2`, and `SERVER3`, `DAEMONHOST` is set to `SERVER1~SERVER2~SERVER3`.
- [Running lswhere](#)

Running lswhere

You can run `lswhere` from an end user's desktop computer to check which computer is running the concurrent license manager.

1. Using a command prompt, change the current directory to the IBM® SPSS® Modeler installation directory.
2. Type `lswhere`.

Administrator's guide

The following instructions are for administrators at sites with the license type authorized user license for IBM® SPSS® Modeler 18.4.0. This license allows you to install IBM SPSS Modeler on multiple computers, limited to the number for which you purchased the license.

- [Before you start](#)
- [Installing the product on the local desktop computers](#)

Before you start

You will need your authorization code. The authorization code enables you and your end users to get a license for IBM® SPSS® Modeler.

You should have received separate instructions for obtaining your authorization code. If you cannot find your authorization code, contact Customer Service by visiting <https://www.ibm.com/products/spss-modeler/support>.

- [Citrix and Terminal Services](#)

Citrix and Terminal Services

You need a concurrent license to use IBM® SPSS® Modeler on Terminal Services. Contact IBM Corp. for information about transferring your license.

Installing the product on the local desktop computers

You have two options for installing the full product locally on an end user's computer. You can manually install on each computer, or you can use an application like Systems Management Server (SMS) to push the installation to the computers running Windows.

To manually install on a local desktop

1. **Make the installation media available.** Download the eImage for the product and extract the files to a shared network drive.
2. **Copy the installation instructions and prepare licensing information.** Make as many copies of the product installation instructions as you need. The installation instructions are available from the download site. Look for the instructions that correspond to your license type. After installation, the end user must enter the authorization code for your site. Fill out this information in the space provided at the beginning of the instructions before copying them.
Note: If a proxy server is preventing authorization, consider using *licenseactivator*. This allows you to enter the proxy ID and password. See the topic [Using licenseactivator](#) for more information.
3. **Distribute the installation materials to end users.** Distribute the downloaded file (or network location), the installation instructions, and the licensing information to end users who can manually install on each computer as needed.

To push to the local desktops running Windows

Because IBM® SPSS® Modeler installations are compatible with Microsoft Windows Installer (MSI), you can push an installation to the end-user desktop computers.

- [Pushing an installation to Windows computers](#)
- [Using licenseactivator](#)
- [License File](#)

Pushing an installation to Windows computers

Pushing an installation is a method for remotely distributing software to any number of end users without any user intervention. You can push the full installation of IBM® SPSS® Modeler to the end-user desktop computers running Windows. The technology that you are using for pushing the installation must support the MSI 3.0 engine or higher.

- [Uninstalling a Previous Version](#)
- [Properties for push installations](#)
- [MSI files](#)
- [Command line example](#)
- [Using SMS to push the installation](#)
- [Using Group Policy or related technology to push the installation](#)
- [Pushing an uninstallation](#)

Uninstalling a Previous Version

If you are going to push to the same directory in which a previous version of IBM® SPSS® Modeler was installed, you need to uninstall the old version. You must manually uninstall any IBM SPSS Modeler versions prior to 11.0 since push installations were not available for those versions. You can push the uninstallation as you push an installation. See the topic [Pushing an uninstallation](#) for more information.

Properties for push installations

Following are the properties that you can use for push installations. All properties are case sensitive. Values must be quoted if they contain spaces.

Table 1. Properties for push installations

Property	Description	Valid values	Default (If Applicable)
INSTALLDIR	The directory where IBM® SPSS® Modeler should be installed on the end user's desktop computer. This property is optional. If it is excluded, the default is C:\Program Files\IBM\SPSS\Modeler\18.4.0 .	A valid path such as C:\Program Files\IBM\SPSS\Modeler\18.4.0.	C:\Program Files\IBM\SPSS\Modeler\18.4.0
AUTHCODE	The authorization code. If this property is specified, the product is authorized automatically using the authorization code. If this property is <i>not</i> specified, each end user must run the License Authorization Wizard to authorize manually.	One or more valid authorization codes. Multiple authorization codes are separated by colons (for example, authcode1:authcode2).	
PROXY_USERID	The user ID for the proxy. This parameter is necessary when you specify the AUTHCODE parameter and your site is using a proxy that requires a user ID and password to connect to the Internet. This parameter works only if the Local Area Network (LAN) settings in the Internet Settings control panel reference a specific proxy server address and port.	A valid proxy user ID.	
PROXY_PASSWORD	The password for the proxy user. Refer to the discussion of PROXY_USERID for more information.	A password associated with the proxy user ID.	

MSI files

Extract the contents of your downloaded eImage to access the MSI file. The file is located under the *modeler|<architecture>* directory, where <architecture> is 32bit or 64bit.

Command line example

Following is a command line that you could use to push a product installation. Enter all of the text on one line.

```
MsiExec.exe /i "modelerclient.msi" /qn /L*v logfile.txt  
INSTALLDIR="C:\Program Files\IBM\SPSS\Modeler\18.4.0" AUTHCODE="3241a2314b23c4d5f6ea"
```

Using SMS to push the installation

The basic steps for using Systems Management Servers (SMS) to push IBM® SPSS® Modeler are:

1. Extract the contents of your downloaded eImage and copy the appropriate subdirectory under the *modeler|<architecture>* directory to a directory on a network computer.
2. Edit the *.pdf* file located in the copied directory. Using a text editor, modify the value of CommandLine by adding the appropriate properties. For a list of the available properties, refer to [Properties for push installations](#) . Make sure to specify the correct MSI file in the command line.
3. Create a package from the *.pdf* file and distribute the package to the end-user desktop machines.

Using Group Policy or related technology to push the installation

1. Extract the contents of your downloaded eImage and copy the appropriate subdirectory under the *modeler|<architecture>* directory to a directory on a network computer.
 2. Using an application like ORCA, edit the Properties table in the appropriate file under the copied folder. ORCA is part of the Windows 2003 Server SDK, which you can find at <http://www.microsoft.com/downloads> by searching for the SDK. For a list of the properties that you can add to the Properties table, refer to [Properties for push installations](#). Make sure to use the correct MSI file.
 3. Create a package using the edited file and distribute the package to the end-user desktop computers.
-

Pushing an uninstallation

Note: When you push the uninstall command, the end user loses customizations. If specific users require customizations, you can exclude those users from the distribution and ask them to install the product manually.

If you push an installation of a later version of IBM® SPSS® Modeler, you may want to uninstall first. You can do this silently by pushing the following command. Enter all of the text on one line.

```
MsiExec.exe /X{} /qn /L*v logfile.txt  
ALLUSERS=1 REMOVE="ALL"
```

The product code for a specific version is in the *setup.ini* file within each version's installed folders.

Using licenseactivator

licenseactivator allows you to authorize end-user computers without using the License Authorization Wizard. This command-line tool is located in the directory in which you installed IBM® SPSS® Modeler.

When you use *licenseactivator*, it licenses the product and writes a log file to its directory. The name of the log file is *licenseactivator_<month>_<day>_<year>.log*. If any errors occur, you can check the log file for more information. This information is also useful if you contact IBM Corp. for support.

Using licenseactivator with Authorization Codes

licenseactivator is typically used with one or more authorization codes that you received when you purchased the product. Enter all of the text on one line.

Windows:

```
licenseactivator authcode1[:authcode2:...:authcodeN] [PROXYHOST=proxy-hostname] [PROXYPORT=proxy-port-number]  
[PROXYUSER=proxy-userid] [PROXPASS=proxy-password]
```

UNIX/Linux/MacOS:

```
./licenseactivator authcode1[:authcode2:...:authcodeN] [PROXYHOST=proxy-hostname] [PROXYPORT=proxy-port-number]  
[PROXYUSER=proxy-userid] [PROXPASS=proxy-password]
```

- Multiple authorization codes are separated by colons (:).
- The proxy settings are optional, but you may need them if your computer is behind a proxy. Which proxy settings are needed depend on your specific proxy configuration. You might need all of them.

PROXYHOST

The server name or IP address of the proxy host

PROXYPORT

The port number for connecting to the Internet through the proxy

PROXYUSER

If required, the user ID for the proxy

PROXPASS

If required, the password associated with the user ID

Using licenseactivator with License Codes

In less common scenarios, IBM Corp. may have sent you a *license*.

Windows:

```
licenseactivator licensocode[:licensocode2:...:licensocodeN]
```

UNIX/Linux/MacOS:

```
./licenseactivator licensecode[:licensecode2:...:licensecodeN]
```

- Multiple license codes are separated by colons (:).
 - When using license codes, *licenseactivator* does not connect to the Internet, so you do not need to specify proxy information.
-

License File

Licensing the product creates a file called *lservrc* in the product installation directory. You can maintain a copy of this file for each end-user computer. Although the license file will work only on the computer for which it was created, the copy can be useful when there is a need to uninstall and reinstall the product. After reinstalling, you can copy the *lservrc* file back into the product installation directory. This step allows you to avoid relicensing the product.

IBM® SPSS® Modeler Scoring Adapter Installation

- [IBM SPSS Modeler scoring adapter installation](#)
-

IBM® SPSS Modeler scoring adapter installation

For some databases it is possible to enable SQL pushback of the majority of the SPSS® Modeler model nuggets. In this way, model scoring can be performed within the database, avoiding the need to extract the data before scoring. This pushback can either use the native SQL within SPSS Modeler or, where available, use additional SQL scoring adapters that are tailored for different databases.

The scoring adapters support scoring of most model nuggets in a stream, with the following exceptions:

- Association Rules (with list data), TimeSeries, Sequence, PCA, STP, and TCM are not supported.
- Association models do not support transactional format.
- Text Analytics (TA) - Field mode is supported in Db2 LUW but not the other databases. When using the TA scoring adapter in field mode, the returned row length may contain many scoring output columns, which can result in some database limits being exceeded. For example, you might see the error message TOO MANY ITEMS RETURNED IN SELECT OR INSERT LIST. Sometimes these limits can be changed in the database but, if that is not possible, the recommended approach is to use record mode to score the model.

The use of scoring adapters that enable data to be scored by the generated models within the database to avoid data transfer. SPSS Modeler enables integration with IBM and non-IBM databases, and enable models to be deployed faster and with greater efficiency.

Where scoring adapters are installed into the relevant databases the SQL generation option generates scoring adapter SQL by default, unless you specifically choose to override this. The databases for which scoring adapters are available are:

- Netezza
 - Teradata
 - Db2 LUW
 - [About scoring](#)
 - [Migrating to a new version](#)
 - [Installing IBM SPSS Modeler Server Scoring Adapter for Netezza](#)
 - [Installing IBM SPSS Modeler Server Scoring Adapter for Teradata](#)
 - [Installing IBM SPSS Modeler Server scoring adapter for Db2 LUW](#)
-

About scoring

In IBM® SPSS® Modeler, scoring data is defined as deploying a predictive model on new data with an unknown outcome. This predictive model processes incoming data and gives a predictive score about the likelihood or probability of an event. For example, when an online payment transaction takes place, a predictive model processes the input data and provides a predictive score which gives the probability of a transaction being either genuine or a fraud.

The normal process within SPSS Modeler is that when a predictive model receives incoming data it evaluates the input using historical data from a database and creates an output of a predicted score. This score gives a probability about an event for which a predictive analysis model is built.

The predictive model process using a scoring adapter differs from this in that the scoring adapter enables the evaluation of each record and for producing a score, or prediction, in the database without the need to export the data from database, run it through the model, and import it back again thereby making the whole process quicker.

Migrating to a new version

If you're upgrading to a new version of the IBM® SPSS® Modeler Server Scoring Adapter, take note of the following information.

- Adapter migration is supported from the previous version only. Migration from older versions is not supported. For example, for IBM SPSS Collaboration and Deployment Services 8.1.1 with Modeler Adapter 18.1.1, migration from IBM SPSS Collaboration and Deployment Services 7 with Modeler Adapter 17.1 is supported.
- Modeler Adapter can be installed at the same time as IBM SPSS Collaboration and Deployment Services or after IBM SPSS Collaboration and Deployment Services installation.

For complete details and instructions regarding migration, see the *Migration* section of the IBM SPSS Collaboration and Deployment Services Repository Server installation and configuration guide. The migration process for Modeler Adapter is the same as the process described in the guide. The guide is available in the IBM SPSS Collaboration and Deployment Services IBM Documentation at <https://www.ibm.com/docs/SS69YH>.

Installing IBM® SPSS® Modeler Server Scoring Adapter for Netezza

If you have a previous version of the scoring adapter for Netezza installed, first you must uninstall it as follows:

1. Locate the executable file named Uninstall IBM SPSS Modeler Server Scoring Adapter for Netezza in the Netezza scoring adapter's installation directory. It's in a folder named Uninstall IBM SPSS Modeler Server Scoring Adapter for Netezza.
2. Run the executable file either from the console or by using the graphical user interface (GUI). Follow the instructions in the uninstaller to uninstall the scoring adapter.
3. If you receive a message that some items could not be removed, go to the root directory where the adapter had been (the cfscoring directory, for example) and run the command `rm -rf` on the listed directories that were not removed. This will remove them.
4. Proceed with the following steps to install the new version of the scoring adapter.

Depending on the configuration of your database you can install either from the console or by using a graphical user interface (GUI); however, the first step is the same for both methods:

- Run the *install.bin* install script. Ensure that *install.bin* can be executed by *nz* user and run it as that user.

Console Installation

1. Introduction details are displayed. Press Enter to continue.
2. Licensing information is displayed. Read the license, type *Y* to accept it, and press Enter to continue.
3. You are prompted to type the installation location. The default installation location is shown; however, if your installation is different, type the revised location and press Enter.
Note: The installation must be under the /nz/export/ path.
4. You are prompted to enter the database name, database user name, and database password.
Note: The database user must have database access permissions to initialize the database and register the udf modules.
5. A pre-installation summary is displayed to confirm your entries so far. Press Enter to continue.
6. A message is displayed to say the installation routine is ready to run. Press Enter to continue.
7. A progress bar is displayed whilst the installation routine runs. When the installation is complete, press Enter to exit from the installer.

GUI Installation

1. Introduction details are displayed. Click Next to continue.
2. Licensing information is displayed. Read the license, select the option to accept it, and click Next to continue.
3. You are prompted to select the installation location. The default installation location is shown; however, if your installation is different, click Choose to browse for the revised location. When the correct location is shown, click Next.
4. You are prompted to enter the database name, database user name, and database password.
Note: The database user must have database access permissions to initialize the database and register the UDF modules.
5. A pre-installation summary is displayed to confirm your entries so far. Click Install to continue.
6. A progress bar is displayed whilst the installation routine runs. When the installation is complete, click Done to exit from the installer.

When you have completed these steps the scoring adapter is ready to receive work.

Note: The Netezza UDF has a 64 field limit that can be processed by the scoring adapter. If that field limit is exceeded, the validation error message: SQL Validation Error: HY000[46] ERROR: Cannot pass more than 64 arguments to a function is displayed and model scoring continues without using the scoring adapter.

Installing IBM SPSS Modeler Server Scoring Adapter for Teradata

If you have a previous version of the scoring adapter for Teradata installed, first you must uninstall it as follows:

1. Locate the executable file named Uninstall IBM SPSS Modeler Server Scoring Adapter for Teradata in the Teradata scoring adapter's installation directory. It's in a folder named Uninstall IBM SPSS Modeler Server Scoring Adapter for Teradata.
2. Run the executable file either from the console or by using the graphical user interface (GUI). Follow the instructions in the uninstaller to uninstall the scoring adapter.
3. If you receive a message that some items could not be removed, go to the root directory where the adapter had been (the cfscoring directory, for example) and run the command `rm -rf` on the listed directories that were not removed. This will remove them.
4. Proceed with the following steps to install the new version of the scoring adapter.

Depending on the configuration of your database you can install either from the console or by using a graphical user interface (GUI); however, the first step is the same for both methods:

- Log in as either *root* or *DBA user* and run the *install.bin* install script. You must have access permissions for the installation folder to do this. The installing user must also have **CREATE FUNCTION** permissions.

Console Installation

1. Introduction details are displayed. Press Enter to continue.
2. Licensing information is displayed. Read the license, type **Y** to accept it, and press Enter to continue.
3. You are prompted to type the installation location. The default installation location is shown; however, if your installation is different, type the revised location and press Enter.
4. Enter the database TDPID. Press Enter to continue.
5. Enter the user name. Press Enter to continue.
6. Enter the password. Press Enter to continue.
7. A pre-installation summary is displayed to confirm your entries so far. Press Enter to continue.
8. A message is displayed to say the installation routine is ready to run. Press Enter to continue.
9. A progress bar is displayed whilst the installation routine runs. When the installation is complete, press Enter to exit from the installer.
10. If the *Components* table exists in your database a confirmation message is displayed. Either enter **Y** to continue creating tables and functions in your database, or enter **N** to skip this step. *Note:* If you skip this step you must manually create tables and functions later using initdb.sh, which is stored in the <installation path>\setup folder.

GUI Installation

1. Introduction details are displayed. Click Next to continue.
2. Licensing information is displayed. Read the license, select the option to accept it, and click Next to continue.
3. You are prompted to select the installation location. The default installation location is shown; however, if your installation is different, click Choose to browse for the revised location. When the correct location is shown, click Next.
4. Enter the database TDPID, name, and password and click Next to continue.
5. A pre-installation summary is displayed to confirm your entries so far. Click Install to continue.
6. A progress bar is displayed whilst the installation routine runs. When the installation is complete, click Done to exit from the installer.
7. If the *Components* table exists in your database a confirmation message is displayed. Either click Yes to continue creating tables and functions in your database, or click No to skip this step. *Note:* If you skip this step you must manually create tables and functions later using initdb.sh, which is stored in the <installation path>\setup folder.

When you have completed these steps the scoring adapter is ready to receive work.

Note: The UDFs and COMPONENTS table are installed into the default database of the user who installs the scoring adapter.

Sharing the scoring adapter

To share the scoring adapter for use by other Teradata users:

1. Grant the following privileges to the user:
 - SELECT and EXECUTE FUNCTION on the database where the scoring adapter is installed.
 - INSERT on the COMPONENTS table on the database where the scoring adapter is installed.
2. When a database connection is made to Teradata with the scoring adapter installed, open the Database Preset dialog box, enable Use Server Scoring Adapter Schema and select the schema from the Server Scoring Adapter Schema drop down list.

Note: The Database Preset dialog box varies for different databases and is not supported by scripting; therefore, this step can only be done in SPSS® Modeler Client.

Preventing SQL errors for date or time entries

If the ODBC driver for the Date or Time format is set to Integer, and your input table contains fields that are coded as Date, Time, or Timestamp; Teradata displays a SQL error message and is unable to process those fields.

To prevent this error from happening follow these steps:

1. Open the ODBC Data Source Administrator.
2. Open the DSN that uses the Teradata driver.
3. Click on Options >> to open the Teradata ODBC Driver Options dialog box.
4. On the top right side of the dialog box, set the Date Time Format to AAA.
5. Save your changes.
6. In IBM® SPSS Modeler Server, remove the connection and then reconnect to the DSN that uses the Teradata driver.

Note: On Unix/Linux, the option is called: DateTimeFormat.

Teradata drivers and null datetime_now values

When using the DataDirect Teradata driver, the `SQL_COLUMN_TYPE` may return a null value. The alternative is to use the native Teradata driver.

Installing IBM SPSS Modeler Server scoring adapter for Db2 LUW

Note: The Db2 LUW scoring adapter is only available on Db2 running on LINUX or AIX.

Note: The IBM® SPSS® Modeler Server Scoring Adapter may conflict with the Db2 LUW ANALYZE_TABLE embedded process for SAS because they share the same Db2 built in support.

If you have a previous version of the scoring adapter for Db2 LUW installed, first you must uninstall it as follows:

1. Locate the executable file named Uninstall IBM SPSS Modeler Server Scoring Adapter for DB2 in the Db2 scoring adapter's installation directory. It's in a folder named Uninstall IBM SPSS Modeler Server Scoring Adapter for DB2.
2. Run the executable file either from the console or by using the graphical user interface (GUI). Follow the instructions in the uninstaller to uninstall the scoring adapter.
3. If you receive a message that some items could not be removed, go to the root directory where the adapter had been (the cfscoring directory, for example) and run the command `rm -rf` on the listed directories that were not removed. This will remove them.
4. Proceed with the following steps to install the new version of the scoring adapter.

Before installation, you need to shut down the Db2 LUW ANALYZE_TABLE embedded process using the `db2ida_epspss.sh` script provided in the IBM SPSS Modeler Server scoring adapter installation folder. To do this, use the Db2 command: `db2ida_epspss.sh stop`.

After installation, the Db2 LUW ANALYZE_TABLE embedded process should start automatically using `db2start`. However, if you install the adapter while a Db2 instance is active, you can start the Db2 LUW ANALYZE_TABLE embedded process manually by using the command: `db2ida_epspss.sh start`.

Note: The Db2 LUW ANALYZE_TABLE doesn't support the WITH table-expression clause if it contains UNION ALL. This may cause an error if you attempt to use this expression in a IBM SPSS Modeler node which generates UNION or UNION ALL SQL, such as the Append node.

Depending on the configuration of your database you can install either from the console or by using a graphical user interface (GUI); however, the first step is the same for both methods:

- Run the `install.bin` install script. Ensure that `install.bin` can be executed by db2 user and run it as that user.

Console Installation

1. Introduction details are displayed. Press Enter to continue.
2. Licensing information is displayed. Read the license, type 1 to accept it and press Enter.
3. You are prompted to type the installation location. The default installation location is shown; however, if your installation is different, type the revised location and press Enter.
4. You are prompted to enter the database name, database user name, and database password.
5. A pre-installation summary is displayed to confirm your entries so far. Press Enter to continue.
6. A message is displayed to say the installation routine is ready to run. Press Enter to continue.
7. A progress bar is displayed whilst the installation routine runs. When the installation is complete, press Enter to exit from the installer.

GUI Installation

1. Introduction details are displayed. Click Next to continue.
2. Licensing information is displayed. Read the license, select the option to accept it, and click Next to continue.
3. You are prompted to select the installation location. The default installation location is shown; however, if your installation of is different, click Choose to browse for the revised location. When the correct location is shown, click Next.
4. You are prompted to enter the database name, database user name, and database password.
5. A pre-installation summary is displayed to confirm your entries so far. Click Install to continue.
6. A progress bar is displayed whilst the installation routine runs. When the installation is complete, click Done to exit from the installer.

When you have completed these steps the scoring adapter is ready to receive work.

Note: If you have problems scoring large Text Mining models via the Database Scoring Adapters for Db2 LUW, you may need to modify the database table column size parameter. If you encounter errors related to failing to insert the model into the components table, use a Db2 command such as the following to increase the column size parameter as appropriate:

```
ALTER TABLE COMPONENTS ALTER COLUMN MODELDS2 SET DATA TYPE BLOB (48M) ;
```

Installation instructions

The following instructions are for installing IBM® SPSS® Modeler Server version 18.4.0.

IBM SPSS Modeler Server can be installed and configured to run in distributed analysis mode together with one or more client installations. This provides superior performance on large datasets, since memory-intensive operations can be run on the server without downloading data to the client computer. At least one IBM SPSS Modeler Client installation must be present to run an analysis.

Whenever you install a new version, be sure to distribute IBM SPSS Modeler Server product's host name and port number to the end users.

- [System requirements](#)
- [Installing](#)
- [After You Install IBM SPSS Modeler Server](#)
- [Uninstalling](#)

System requirements

To view system requirements, go to <https://www.ibm.com/software/reports/compatibility/clarity/softwareReqsForProduct.html>.

- [Additional requirements](#)

Additional requirements

Client software

The client software must be at the same release level as the IBM® SPSS® Modeler Server software.

You must ensure that kernel limits on the system are sufficient for the operation of IBM SPSS Modeler Server. The data, memory, file, and processes ulimits are particularly important and should be set to unlimited within the IBM SPSS Modeler Server environment. To do this:

1. Add the following commands to modelersrv.sh:

```
ulimit -d unlimited  
ulimit -m unlimited  
ulimit -f unlimited  
ulimit -u unlimited
```

In addition, set the stack limit to the maximum allowed by your system (`ulimit -s XXXX`), for example:

```
ulimit -s 64000
```

2. Restart IBM SPSS Modeler Server.

You also need the `gzip` file compression utility and `GNU cpio` installed and on the PATH in order for the installer to be able to decompress the installation files. In addition, on the machine running SPSS Modeler Server, you should set the locale to EN_US.UTF-8.

XL C++ runtime and XL FORTRAN runtime

If installing on PowerLinux, for SPSS Modeler Server to start correctly on P8LE servers (Ubuntu and RedHat), you must install the XL C++ runtime and the XL FORTRAN runtime (version 16.1.1 or later). If these libraries aren't installed, SPSS Modeler Server won't start.

To install the **XL C/C++ runtime** as root, issue the following commands:

```
1. wget
   http://public.dhe.ibm.com/software/server/POWER/Linux/rte/xlcpp/le/rhel7/repo/repodata/repomd.xml.key
2. rpm --import repomd.xml.key
3. wget
   http://public.dhe.ibm.com/software/server/POWER/Linux/rte/xlcpp/le/rhel7/ibm-xlc-compiler-runtime.repo
4. cp ibm-xlc-compiler-runtime.repo /etc/yum.repos.d/
5. yum install libxlc libxlsmp
```

To install the **XL FORTRAN runtime** as root, issue the following commands:

```
1. wget
   http://public.dhe.ibm.com/software/server/POWER/Linux/rte/xlf/le/rhel7/repo/repodata/repomd.xml.key
2. rpm --import repomd.xml.key
3. wget
   http://public.dhe.ibm.com/software/server/POWER/Linux/rte/xlf/le/rhel7/ibm-xlf-compiler-runtime.repo
4. cp ibm-xlf-compiler-runtime.repo /etc/yum.repos.d/
5. yum install libxlf
```

Installing

You can install IBM® SPSS® Modeler Server as *root* or as a non-root user. If your site restricts the use of the *root* password, use an authentication method that supports running as non-root (see the IBM SPSS Modeler Server and Performance Guide). Then install the product as the user who will run the daemon. You should perform all actions as non-root, or perform all actions as root. Note that you need the root password to start and stop the server.

Note: The installation will fail if you attempt to install SPSS Modeler Server on Linux as a user who doesn't have execute permissions for files in /tmp. To avoid this, you must either have execute permissions to files within /tmp for the InstallAnywhere SPSS Modeler installs to succeed or, if this is not present on your environment, you can set and export *IATEMPDIR* to a location where you do have permissions in order to run the install.

Important: The file system on which you install IBM SPSS Modeler Server must be mounted with the **suid** option. The product will not work correctly if the file system is mounted with the **nosuid** option.

1. **From your downloaded installation media, extract the installation files.** The downloaded media file is a compressed archive. Extract the files in the archive.
2. **From your downloaded installation media, run the installation file.** The downloaded media contains a *.bin* file; run this file.
3. **Check hard drive space.** In addition to the permanent hard drive space specified in <http://www.ibm.com/software/analytics/spss/products/modeler/requirements.html>, you need temporary disk space for the installer files. The installer files are extracted to your system's temporary folder. If there is not enough space in the temporary folder, the installer files are extracted to your home folder. If neither location has enough space, the installer cannot continue. In this case, you can temporarily set the *IATEMPDIR* environment variable to a location with adequate space. This location should have at least 2.5 gigabyte (GB) of free space.
4. **Check the destination directory.** By default, IBM SPSS Modeler Server is installed to */usr/IBM/SPSS/ModelerServer/<version>* . If desired, you can change this path in the graphical installation wizard or the command line installation. If you are going to run the silent installer, you can set the value for *USER_INSTALL_DIR* in *installer.properties*. Regardless, you need read and write permissions to the installation directory, so log on with an account that has sufficient permissions. *Note:* If you are upgrading by adding a new version of the product, install the new version in a separate directory.
5. **Change execute permissions of installer.** Be sure that the installer is executable by the user who will run the installer.
6. **Run the installer.** You can run the installer in a graphical user interface, from the command line, or silently. Instructions for each method appear below.
 - [Graphical installation wizard](#)
 - [Command line installation](#)
 - [Silent installation](#)

Graphical installation wizard

The graphical installation wizard displays a graphical interface that will ask you about installation parameters. You will need an X Window System.

1. At the UNIX prompt, change to the directory where the installer file was copied or extracted:
2. Run the installer by executing the following command:
 `./<installer_name>`
3. After the installation wizard is launched, follow the instructions that appear on the screen.

Command line installation

The command line installation uses command prompts to specify installation parameters.

1. At the UNIX prompt, change to the directory where the installer file was copied or extracted:
2. Run the installer by executing the following command:
 `./<installer_name> -i console`

Where `<installer_name>` is the installer .bin file.

3. Follow the instructions that appear on the screen.

Silent installation

Silent mode enables the installation without any user interaction. Installation parameters are specified as a properties file.

To complete a silent installation on Linux or UNIX systems:

1. In the same location where you copied the installer files, create an `installer.properties` file.
2. In a text editor, set the `installer.properties` values. The following text shows an example of an `installer.properties` file:

```
=====
# Thu Jan 29 11:35:37 GMT 2015
# Replay feature output
#
# -----
# This file was built by the Replay feature of InstallAnywhere.
# It contains variables that were set by Panels, Consoles or Custom Code.

#Indicate whether the license agreement been accepted
#-----
LICENSE_ACCEPTED=TRUE

#Server Mode
#-----
SERVEMODE_SELECT_OPTION=\"1\"

#Choose Install Folder
#-----
USER_INSTALL_DIR=/usr/IBM/SPSS/ModelerServer/17.0

#Install
=====
```

3. The value for `SERVEMODE_SELECT_OPTION` depends on the type of installation you have. You can choose from the following values:
 - 0 - Non-Production Mode. If you purchased a separate non-production installation, enter this option. This installation cannot be employed for production use.
 - 1 - Production Mode. A production installation is a standard installation of SPSS® Modeler Server. It is appropriate for production use.
4. Ensure that the value for `USER_INSTALL_DIR` matches your installation directory location. The directory path cannot contain spaces.
5. Save the file.
6. Run the installer by using the following command:

```
./<installer_name> -i silent -f installer.properties
```

Where `<installer_name>` is the installer .bin file.

After You Install IBM SPSS Modeler Server

This section describes some required and optional steps that you can perform after installation. It does not describe all possible configuration options. You can find information about all the configuration options in the *IBM® SPSS® Modeler Server and Performance Guide*.

Note: Installation logs are placed into the uninstall folder by default. For example:

<Installation_folder_path>/Uninstall_IBM_SPSS_MODELER_SERVER/Logs.

- [Installing IBM SPSS Modeler Batch](#)
 - [Configuring IBM SPSS Modeler to Work with IBM SPSS Statistics](#)
 - [Enabling IBM SPSS Statistics Programmability](#)
 - [Starting the Process](#)
 - [Checking the Server Status](#)
 - [Connecting End Users](#)
 - [IBM SPSS Data Access Pack Technology](#)
-

Installing IBM SPSS Modeler Batch

IBM® SPSS® Modeler Batch provides the complete analytical capabilities of the standard IBM SPSS Modeler Client but without access to the regular user interface. Batch mode allows you to perform long-running or repetitive tasks without your intervention and without the presence of the user interface on the screen. It must be run in distributed mode along with IBM SPSS Modeler Server (local mode is not supported).

For more information, see the *IBM SPSS Modeler Batch User's Guide*.

Installing IBM SPSS Modeler Batch on Linux

1. Change directories to the modelbat directory.
2. Change to the relevant platform directory.
3. Run the .bin install script. Make sure the .bin can be executed by **root**. For example:

```
./modelerserverlinux64.bin -i console
```

or:

```
./modelerbatchlinux.bin -i console
```

4. Introduction details are displayed. Press Enter to continue.
5. Licensing information is displayed. Read the license, type 1 to accept it, and press Enter to continue.
6. You are prompted to type the installation location. To use the default directory (for example: /usr/IBM/SPSS/ModelerServer/<nn> or: /usr/IBM/SPSS/ModelerBatch/<nn>, where <nn> is the version number), press Enter. If you specify a directory other than the default, make sure that the path name does not contain extended ASCII characters, the space character, or the ampersand (&) character.
7. You are prompted to confirm the installation location. When it is correct, type y and press Enter.
8. A pre-installation summary is displayed to confirm your entries so far. Press Enter to continue.
9. A message is displayed to say the installation routine is ready to run. Press Enter to continue.
10. A progress bar is displayed whilst the installation routine runs. When the installation is complete, press Enter to exit from the installer.

Configuring IBM SPSS Modeler to Work with IBM SPSS Statistics

To enable IBM® SPSS® Modeler to use the Statistics Transform, Statistics Model, and Statistics Output nodes, you must have a copy of IBM SPSS Statistics installed and licensed on the computer where the stream is run.

If running IBM SPSS Modeler in local (standalone) mode, the licensed copy of IBM SPSS Statistics must be on the local computer.

When you have finished installing this copy of SPSS Modeler Client, you will also need to configure it to work with IBM SPSS Statistics. From the main client menu, choose:

Tools > Options > Helper Applications

and on the IBM SPSS Statistics tab, specify the location of the local IBM SPSS Statistics installation you want to use. For more information, see the *Source, Process and Output Nodes* guide or the online help for Helper Applications.

In addition, if running in distributed mode against a remote IBM SPSS Modeler Server, you also need to run a utility at the IBM SPSS Modeler Server host to create the **statistics.ini** file, which indicates to IBM SPSS Statistics the installation path for IBM SPSS Modeler Server. To do this, from the command prompt, change to the IBM SPSS Modeler Server **bin** directory and, for Windows, run:

```
statisticsutility -location=<IBM SPSS Statistics_installation_path>/bin
```

Alternatively, for UNIX, run:

```
./statisticsutility -location=<IBM SPSS Statistics_installation_path>/bin
```

If you do not have a licensed copy of IBM SPSS Statistics on your local machine, you can still run the Statistics File node against a IBM SPSS Statistics server, but attempts to run other IBM SPSS Statistics nodes will display an error message.

Enabling IBM SPSS Statistics Programmability

If you have IBM® SPSS® Statistics installed and you want to be able to call its Python or R plugins through the IBM SPSS Statistics nodes in IBM SPSS Modeler Server, you must take the following steps on the UNIX server to enable the plugins.

1. Log in as the superuser.
2. Export environment variables as follows:
 - Linux. `export LD_LIBRARY_PATH=[plugin_install_directory]/lib:$LD_LIBRARY_PATH`

Starting the Process

IBM® SPSS® Modeler Server runs as a daemon process and has root privileges by default. IBM SPSS Modeler Server can be configured to run without root privileges. Refer to the *IBM SPSS Modeler Server and Performance Guide* for more information. You need to choose an authentication method that does not require that the daemon runs as root.

Start the application by running a startup script, `modelersrv.sh`, which is included in the installation directory. The startup script configures the environment for and executes the software.

1. Log in as `root`. Alternatively, you can log in as `non-root` if the non-root user is also the user who installed IBM SPSS Modeler Server.
2. Change to the IBM SPSS Modeler Server installation directory. The startup script must be run from this location.
3. Run the startup script. For example, at the UNIX prompt type:

```
./modelersrv.sh start
```

Checking the Server Status

1. At the UNIX prompt, type:
`/modelersrv.sh list`
2. Look at the output, which is similar to what the UNIX `ps` command produces. If the server is running, you will see it as the first process in the list.

IBM® SPSS® Modeler Server is now ready to accept connections from end users when they have been authorized. See the topic [Connecting End Users](#) for more information.

Connecting End Users

End users connect to IBM® SPSS® Modeler Server by logging in from the client software. See the *IBM SPSS Modeler Server and Performance Guide* for a description of how the software works and what you need to do to administer it. You must give end users the information that they need to connect, including the IP address or host name of the server machine.

IBM SPSS Data Access Pack Technology

To read or write to a database, you must have an ODBC data source installed and configured for the relevant database, with read or write permissions as needed. The IBM SPSS Data Access Pack includes a set of ODBC drivers that can be used for this purpose, and these drivers are available from the download site. If you have questions about creating or setting permissions for ODBC data sources, contact your database administrator.

Supported ODBC drivers

For the latest information on which databases and ODBC drivers are supported and tested for use with IBM® SPSS® Modeler, see the product compatibility matrices on the corporate Support site (<http://www.ibm.com/support>).

Where to install drivers

Note: ODBC drivers must be installed and configured on each computer where processing may occur.

- If you are running IBM SPSS Modeler in local (standalone) mode, the drivers must be installed on the local computer.
- If you are running IBM SPSS Modeler in distributed mode against a remote IBM SPSS Modeler Server, the ODBC drivers need to be installed on the computer where IBM SPSS Modeler Server is installed. For IBM SPSS Modeler Server on UNIX systems, see also "Configuring ODBC drivers on UNIX systems" later in this section.
- If you need to access the same data sources from both IBM SPSS Modeler and IBM SPSS Modeler Server, the ODBC drivers must be installed on both computers.
- If you are running IBM SPSS Modeler over Terminal Services, the ODBC drivers need to be installed on the Terminal Services server on which you have IBM SPSS Modeler installed.

Configuring ODBC drivers on UNIX systems

By default, the DataDirect Driver Manager is not configured for IBM SPSS Modeler Server on UNIX systems. To configure UNIX to load the DataDirect Driver Manager, enter the following commands:

```
cd <modeler_server_install_directory>/bin  
rm -f libspssodbc.so
```

Then run this command if you want to use the UTF8 driver wrapper:

```
ln -s libspssodbc_datadirect.so libspssodbc.so
```

Or run this command instead if you want to use the UTF16 driver wrapper:

```
ln -s libspssodbc_datadirect_utf16.so libspssodbc.so
```

Doing so removes the default link and creates a link to the DataDirect Driver Manager.

Note: The UTF16 driver wrapper is required to use SAP HANA or IBM Db2 CLI drivers for some databases. DashDB requires the IBM Db2 CLI driver.

To configure SPSS Modeler Server:

1. Configure the SPSS Modeler Server start up script modelersrv.sh to source the IBM SPSS Data Access Pack odbc.sh environment file by adding the following line to modelersrv.sh:

```
. /<pathtoSDAPinstall>/odbc.sh
```

Where <pathtoSDAPinstall> is the full path to your IBM SPSS Data Access Pack installation.

2. Restart SPSS Modeler Server.

In addition, for SAP HANA and IBM Db2 only, add the following parameter definition to the DSN in your odbc.ini file to avoid buffer overflows during connection:

```
DriverUnicodeType=1
```

Note: The libspssodbc_datadirect_utf16.so wrapper is also compatible with the other SPSS Modeler Server supported ODBC drivers.

- [Configuring IBM SPSS Modeler Server for Data Access](#)

Configuring IBM SPSS Modeler Server for Data Access

If you want to use the IBM® SPSS® Data Access Pack with IBM SPSS Modeler Server, you will need to configure the startup scripts. This is a critical step because data access will not work otherwise. For instructions, refer to the *IBM SPSS Modeler Server and Performance Guide*.

Uninstalling

Uninstall IBM® SPSS® Modeler Server by removing the program files and, if you have configured the system for automatic startup, disabling automatic startup.

To Remove the Program Files

1. Stop the server process. Instructions for stopping the server process are in the *IBM SPSS Modeler Server and Performance Guide*.

2. Remove the installation directory.

Silent removal of an installation

Silent mode enables software to be uninstalled without any user interaction. To silently remove an installation in IBM SPSS Modeler Server:

1. Run the uninstaller by executing the following command:

```
./<installer_path>/Uninstall_IBM_SPSS_MODELER_SERVER/Uninstall_IBM_SPSS_MODELER_SERVER -i silent
```

Where <installer_path> is the path name to the IBM SPSS Modeler Server installation directory.

To Disable Automatic Startup

The IBM SPSS Modeler Server includes a script that you can use to configure your system to start the server daemon automatically when the computer is rebooted (the instructions appear in the *IBM SPSS Modeler Server and Performance Guide*).

Installation instructions

The following instructions are for installing IBM® SPSS® Modeler Server version 18.4.0.

IBM SPSS Modeler Server can be installed and configured to run in distributed analysis mode together with one or more client installations. This provides superior performance on large datasets, since memory-intensive operations can be run on the server without downloading data to the client computer. At least one IBM SPSS Modeler Client installation must be present to run an analysis.

Whenever you install a new version, be sure to distribute IBM SPSS Modeler Server product's host name and port number to the end users.

- [System requirements](#)
 - [Installing](#)
 - [After You Install IBM SPSS Modeler Server](#)
 - [Uninstalling](#)
-

System requirements

To view system requirements, go to <https://www.ibm.com/software/reports/compatibility/clarity/softwareReqsForProduct.html>.

Installing

The Setup program installs the following components:

- A Windows service that manages end-user requests.
- Software that handles the data mining process .

Note: IBM® SPSS® Modeler Server must be installed on a hard drive on the computer on which the Setup program is running.

Windows Server

1. Double-click the downloaded file and extract the installation files.
2. Using Windows Explorer, browse to the location where the installation files were extracted.
3. Click on setup.exe.
Note: You must run setup.exe as administrator:

4. On the AutoPlay menu, choose Install IBM SPSS Modeler Server and then follow the instructions that appear on the screen.

- [Destination](#)
 - [Silent installation](#)
 - [IP Address and Port Number](#)
-

Destination

You can install in a different destination folder, but you must install on the computer from which the setup is being run (you cannot install to a network location).

If you are installing on the same computer with other Server products, install in a *separate* directory. Do not install multiple Server products in the same directory.

Silent installation

Silent mode enables an installation to run on its own without any interaction; installing silently can free system administrators from the task of monitoring each installation and providing input to prompts and dialog boxes. This method is especially useful when you are installing SPSS® Modeler Server on a number of different computers that have identical hardware.

Note: You must have administrator privileges to be able to run silent installations.

Windows - silent installation

You can complete a silent installation on Windows systems by using Microsoft Installer (MSI). Use msieexec.exe to install the MSI package.

The following options can be used:

Table 1. Silent installation options

Option	Description
/i	Specifies that the program is to install the product.
/l*v	Specifies verbose logging. For example, this form of log can be useful if you need to troubleshoot an installation.
/qn	Runs the installation without running the external user interface sequence.
/s	Specifies silent mode.
/v	Specifies that the Setup Program passes the parameter string to the call it makes to the MSI executable file (msieexec.exe). The following syntax requirements apply if you use this option: <ul style="list-style-type: none">• You must place a backslash (\) in front of any quotation marks (" ") that are within existing quotation marks.• Do not include a space between the /v option and its arguments.• Multiple parameters that are entered with the /v option must be separated with a space.• To create a log file, specify the directory and file name at the end of the command. The directory must exist before you start the silent installation.
/x	Specifies that the program is to uninstall the product.

The following text shows an example of the MSI command:

```
c:\>msieexec.exe /i ModelerServer64.msi /qn /l*v  
c:\temp\Modeler_Silent_Install.log  
INSTALLDIR="C:\Program Files\IBM\SPSS\ModelerServer\19"  
SERVERMOD=1
```

Where the value for SERVERMOD depends on the type of installation you have. You can choose from the following values:

- 0 - Non-Production Mode. If you purchased a separate non-production installation, enter this option. This installation cannot be employed for production use.
- 1 - Production Mode. A production installation is a standard installation of SPSS Modeler Server. It is appropriate for production use.

Windows - silent uninstalling

The following text shows an example of the MSI command to silently uninstall the software:

```
c:\>msieexec.exe /x ModelerServer64.msi /qn /norestart
```

IP Address and Port Number

The Setup program will supply a default IP address and port number for the server computer to use. If necessary, the port number can be updated in the configuration file (*options.cfg*) or with the Administration Console included in IBM® SPSS® Deployment Manager.

Invalid digital signature on installation

IBM® SPSS® Modeler products use IBM-issued certification for digital signing. In certain circumstances you may see the following error on trying to install SPSS Modeler products:

```
Error 1330. A file that is required cannot be installed because the cabinet file filename has an invalid digital signature...
```

All Windows users

You see this message if you try to install SPSS Modeler products on a machine that has no Internet connection and does not have the correct certificate installed. Use the following procedure to correct this problem.

1. Click OK to acknowledge the message.
 2. Click Cancel to exit from the installer.
 3. If the machine on which you want to install has no Internet connection, perform the next step on an Internet-connected machine and copy the .cer file to the machine where you want to install.
 4. Go to <https://support.symantec.com>, search for VeriSign Class 3 Primary Certification Authority - G5 root certificate, and download it. Save it as a .cer file.
 5. Double-click the .cer file.
 6. On the General tab, click Install Certificate.
 7. Follow the instructions in the Certificate Import Wizard, using the default options and clicking Finish at the end.
 8. Retry the installation.
-

After You Install IBM SPSS Modeler Server

This section describes some required and optional steps that you can perform after installation. It does not describe all possible configuration options. You can find information about all the configuration options in the *IBM® SPSS® Modeler Server and Performance Guide*.

Note: Installation logs are placed into the uninstall folder by default. For example:

`<Installation_folder_path>/Uninstall_IBM_SPSS_MODELER_SERVER/Logs`.

- [Installing IBM SPSS Modeler Batch](#)
 - [Configuring IBM SPSS Modeler to Work with IBM SPSS Statistics](#)
 - [Checking the Server Status](#)
 - [Connecting End Users](#)
 - [IBM SPSS Data Access Pack Technology](#)
-

Installing IBM SPSS Modeler Batch

IBM® SPSS® Modeler Batch provides the complete analytical capabilities of the standard IBM SPSS Modeler Client but without access to the regular user interface. Batch mode allows you to perform long-running or repetitive tasks without your intervention and without the presence of the user interface on the screen. It must be run in distributed mode along with IBM SPSS Modeler Server (local mode is not supported).

Follow the steps for Windows Server in [Installing](#), except, on the AutoPlay menu, choose Install IBM SPSS Modeler Batch and then follow the instructions that appear on the screen.

For more information, see the *IBM SPSS Modeler Batch User's Guide*.

Configuring IBM SPSS Modeler to Work with IBM SPSS Statistics

To enable IBM® SPSS® Modeler to use the Statistics Transform, Statistics Model, and Statistics Output nodes, you must have a copy of IBM SPSS Statistics installed and licensed on the computer where the stream is run.

If running IBM SPSS Modeler in local (standalone) mode, the licensed copy of IBM SPSS Statistics must be on the local computer.

When you have finished installing this copy of SPSS Modeler Client, you will also need to configure it to work with IBM SPSS Statistics. From the main client menu, choose:

Tools > Options > Helper Applications

and on the IBM SPSS Statistics tab, specify the location of the local IBM SPSS Statistics installation you want to use. For more information, see the *Source, Process and Output Nodes* guide or the online help for Helper Applications.

In addition, if running in distributed mode against a remote IBM SPSS Modeler Server, you also need to run a utility at the IBM SPSS Modeler Server host to create the **statistics.ini** file, which indicates to IBM SPSS Statistics the installation path for IBM SPSS Modeler Server. To do this, from the command prompt, change to the IBM SPSS Modeler Server *bin* directory and, for Windows, run:

```
statisticsutility -location=<IBM SPSS Statistics installation path>/bin
```

Alternatively, for UNIX, run:

```
./statisticsutility -location=<IBM SPSS Statistics installation path>/bin
```

If you do not have a licensed copy of IBM SPSS Statistics on your local machine, you can still run the Statistics File node against a IBM SPSS Statistics server, but attempts to run other IBM SPSS Statistics nodes will display an error message.

Checking the Server Status

1. On the computer where you installed IBM® SPSS® Modeler Server, select Services from Administrative Tools on the Control Panel.
2. Locate IBM SPSS Modeler Server in the list. If the service is not started, double-click its name and start it on the dialog box that appears. Note that if the service startup is configured to be Automatic, the service will start automatically whenever the computer is restarted.
3. Click OK to close the dialog box.

IBM SPSS Modeler Server is now ready to accept connections from end users when they have been authorized. See the topic [Connecting End Users](#) for more information.

Connecting End Users

End users connect to IBM® SPSS® Modeler Server by logging in from the client software. See the *IBM SPSS Modeler Server and Performance Guide* for a description of how the software works and what you need to do to administer it. You must give end users the information that they need to connect, including the IP address or host name of the server machine. You also need to enable local logon for end users by adding them to the local logon policy. From the Windows Control Panel, choose Administrative Tools, then Local Security Policy, then Local Policies, then User Rights Assignment, then double-click Log On Locally and add users or groups.

IBM SPSS Data Access Pack Technology

To read or write to a database, you must have an ODBC data source installed and configured for the relevant database, with read or write permissions as needed. The IBM SPSS Data Access Pack includes a set of ODBC drivers that can be used for this purpose, and these drivers are available from the download site. If you have questions about creating or setting permissions for ODBC data sources, contact your database administrator.

Supported ODBC drivers

For the latest information on which databases and ODBC drivers are supported and tested for use with IBM® SPSS® Modeler, see the product compatibility matrices on the corporate Support site (<http://www.ibm.com/support>).

Where to install drivers

Note: ODBC drivers must be installed and configured on each computer where processing may occur.

- If you are running IBM SPSS Modeler in local (standalone) mode, the drivers must be installed on the local computer.
- If you are running IBM SPSS Modeler in distributed mode against a remote IBM SPSS Modeler Server, the ODBC drivers need to be installed on the computer where IBM SPSS Modeler Server is installed.
- If you need to access the same data sources from both IBM SPSS Modeler and IBM SPSS Modeler Server, the ODBC drivers must be installed on both computers.
- If you are running IBM SPSS Modeler over Terminal Services, the ODBC drivers need to be installed on the Terminal Services server on which you have IBM SPSS Modeler installed.

Uninstalling

1. From the Windows Start menu choose:

Settings > Control Panel

2. From the Control Panel, choose Add/Remove Programs.
3. Click the Change or Remove Programs button on the left, choose IBM® SPSS® Modeler Server from the list, and click Change/Remove.

Note: If you have more than one version of IBM SPSS Modeler Server installed on the computer, be sure to choose the version that you want to remove.

A message will be displayed when uninstallation is complete. This may take several minutes.

IBM SPSS Modeler Premium component overview

IBM® SPSS® Modeler Premium includes IBM SPSS Modeler Text Analytics.

IBM SPSS Modeler Text Analytics

SPSS Modeler Text Analytics offers powerful text analytic capabilities, which use advanced linguistic technologies and Natural Language Processing (NLP) to rapidly process a large variety of unstructured text data and, from this text, extract and organize the key concepts. Furthermore, SPSS Modeler Text Analytics can group these concepts into categories.

Around 80% of data held within an organization is in the form of text documents—for example, reports, Web pages, e-mails, and call center notes. Text is a key factor in enabling an organization to gain a better understanding of their customers' behavior. A system that incorporates NLP can intelligently extract concepts, including compound phrases. Moreover, knowledge of the underlying language allows classification of terms into related groups, such as products, organizations, or people, using meaning and context. As a result, you can quickly determine the relevance of the information to your needs. These extracted concepts and categories can be combined with existing structured data, such as demographics, and applied to modeling by using SPSS Modeler and its full suite of data mining tools to yield better and more-focused decisions.

Linguistic systems are knowledge sensitive—the more information contained in their dictionaries, the higher the quality of the results. SPSS Modeler Text Analytics is delivered with a set of linguistic resources, such as dictionaries for terms and synonyms, libraries, and templates. This product further allows you to develop and refine these linguistic resources to your context. Fine-tuning of the linguistic resources is often an iterative process and is necessary for accurate concept retrieval and categorization. Custom templates, libraries, and dictionaries for specific domains, such as CRM and genomics, are also included.

Installing IBM® SPSS® Modeler Premium Client

- [System requirements](#)
 - [Installing](#)
 - [After you install SPSS Modeler Premium](#)
 - [Removing IBM SPSS Modeler Premium](#)
-

System requirements

General requirements

IBM® SPSS® Modeler Premium must be installed on a system where SPSS Modeler Client is already installed.

To view the system requirements, go to <https://www.ibm.com/software/reports/compatibility/clarity/softwareReqsForProduct.html>.

SPSS Modeler Text Analytics requirements

Upgrading from earlier versions. Before installing SPSS Modeler Text Analytics version 18.4.0 you should save and export any TAPs, templates, and libraries from your current version that you want to use in the new version. We recommend that you save these files to a directory that will not get deleted or overwritten when you install the latest version.

After you install the latest version of SPSS Modeler Text Analytics you can load the saved TAP file, add any saved libraries, or import and load any saved templates to use them in the latest version.

Installing

Important: To install, you must be logged on to your computer with administrator privileges.

- [Installing from a downloaded file](#)
 - [Installing from a network location](#)
 - [Silent installation](#)
 - [Installing on Windows systems](#)
 - [Installing on UNIX systems](#)
 - [Silent installation](#)
-

Installing from a downloaded file

Windows XP

1. Double-click the file that you downloaded and extract all the files to some location on your computer.
2. Using Windows Explorer, browse to the location where you extracted the files and double-click *setup.exe*.
3. Follow the instructions that appear on the screen.

Windows Vista and later

Note: You must run the installer as administrator:

1. Double-click the file that you downloaded and extract all the files to some location on your computer.
 2. Using Windows Explorer, browse to the location where you extracted the files.
 3. Right-click *setup.exe* and choose Run as Administrator.
 4. Follow the instructions that appear on the screen.
-

Installing from a network location

1. Using Windows Explorer, browse to the location that your administrator provided for the *setup.exe* file.
 2. Right-click *setup.exe* and choose Run as Administrator.
 3. On the autoplay menu, click Install IBM® SPSS® Modeler Premium.
 4. Follow the instructions that appear on the screen.
-

Silent installation

Silent mode enables an installation to run on its own without any interaction; installing silently can free system administrators from the task of monitoring each installation and providing input to prompts and dialog boxes. This method is especially useful when you are installing SPSS® Modeler Premium on a number of different computers that have identical hardware.

Note: You must have administrator privileges to be able to run silent installations.

Windows - silent installation

You can complete a silent installation on Windows systems by using Microsoft Installer (MSI). Use *msiexec.exe* to install the MSI package.

The following options can be used:

Table 1. Silent installation options

Option	Description
<i>/i</i>	Specifies that the program is to install the product.
<i>/1*v</i>	Specifies verbose logging. For example, this form of log can be useful if you need to troubleshoot an installation.
<i>/qn</i>	Runs the installation without running the external user interface sequence.
<i>/s</i>	Specifies silent mode.

Option	Description
/v	Specifies that the Setup Program passes the parameter string to the call it makes to the MSI executable file (msiexec.exe). The following syntax requirements apply if you use this option: <ul style="list-style-type: none"> • You must place a backslash (\) in front of any quotation marks (" ") that are within existing quotation marks. • Do not include a space between the /v option and its arguments. • Multiple parameters that are entered with the /v option must be separated with a space. • To create a log file, specify the directory and file name at the end of the command. The directory must exist before you start the silent installation.
/x	Specifies that the program is to uninstall the product.

The following text shows an example of the MSI command:

```
c:>msiexec.exe /i ModelerPremium64.msi /qn /l*v
c:\temp\Modeler_Silent_Install.log
AgreeToLicense=true
```

Note: Depending on your system, you might need to change the ModelerPremium64.msi file in the preceding example.

Windows - silent uninstalling

The following text shows an example of the MSI command to silently uninstall the software:

```
C:>msiexec.exe /x ModelerPremium64.msi /qn /norestart
```

After you install SPSS Modeler Premium

SPSS Modeler Text Analytics data directory location

SPSS® Modeler Text Analytics will use the default installation locations to update and write files as necessary in the normal operation of SPSS Modeler Text Analytics .

On the SPSS Modeler Text Analytics client, data is written to a database that is installed to C:\ProgramData\IBM\SPSS\TextAnalytics\<version>\tmwb_<version>.db.

SPSS Modeler Text Analytics on Windows Vista

If you are installing SPSS Modeler Text Analytics on Windows Vista you must complete an additional step after you complete the installation.

Add modify permissions to the file: C:\ProgramData\IBM\SPSS\TextAnalytics\<version>\tmwb_<version>.db. This prevents various errors being created when trying to load templates or execute a text mining model builder.

Removing IBM SPSS Modeler Premium

To uninstall IBM® SPSS® Modeler Premium, perform the following steps:

1. From the Windows Start menu choose:
Settings > Control Panel
2. From the Control Panel, choose Add or Remove Programs.
3. Click Change or Remove Programs.
4. Select IBM SPSS Modeler Premium from the list of currently installed programs, and click Change/Remove. If you have more than one version installed on the computer, be sure to select the version that you want to remove.

A message will be displayed when the uninstallation process completes.

Installing IBM® SPSS® Modeler Premium Server

- [System requirements](#)
- [Installing](#)
- [Removing IBM SPSS Modeler Premium Server](#)

System requirements

IBM® SPSS® Modeler Premium Server must be installed on a system where SPSS Modeler Server is already installed. The requirements for IBM SPSS Modeler Premium Server are identical to those for SPSS Modeler Server.

Installing

Important: To install, you must be logged on to your computer with administrator privileges.

- [Installing from a downloaded file](#)
- [Installing from a network location](#)
- [Silent installation](#)
- [Installing on Windows systems](#)
- [Installing on UNIX systems](#)
- [Silent installation](#)

Installing on Windows systems

IBM® SPSS® Modeler Premium Server must be installed to the SPSS Modeler Server installation location. If SPSS Modeler Server is not installed, the IBM SPSS Modeler Premium Server installation will fail.

To install IBM SPSS Modeler Premium Server, perform the following steps.

1. Log on to the server computer with administrator privileges.
2. For your downloaded eAssembly:
 - Double-click the file and extract the installation files.
 - Go to the location where the installation files were extracted and double-click *Server64.exe*.
3. Follow the instructions that appear on the screen.
4. Restart the SPSS Modeler Server host when installation has completed.

Installing on UNIX systems

IBM® SPSS® Modeler Premium Server must be installed to the SPSS Modeler Server installation location. If SPSS Modeler Server is not installed, the IBM SPSS Modeler Premium Server installation will fail.

You must ensure that kernel limits on the system are sufficient for the operation of IBM SPSS Modeler Premium Server. We recommend that at least 4GB is available. Use the command **ulimit -a** to establish the existing size and increase it if required.

To install SPSS Modeler Premium Server, perform the following steps:

1. Ensure that SPSS Modeler is not running on the target machine.
2. Log in as the user that installed SPSS Modeler ServerProfessional, and ensure this user can execute the installer.
3. For your downloaded eAssembly:
 - Double-click the file and extract the installation files to a convenient location.
 - Change directories to the location where the installation files were extracted.

Note: If you are in a shell, instead of a user interface, extract the files by using the command `unzip <image name>.zip`.
4. Run the .bin file (for example; premium_server_aix64.bin or premium_server_zlinux64.bin).
5. Follow the displayed instructions. When prompted for an installation directory, use the SPSS Modeler Server installation directory. If you specify a different directory, an error message is displayed.
6. When installation has completed, restart the SPSS Modeler Server host.

Silent installation

Silent mode enables an installation to run on its own without any interaction; installing silently can free system administrators from the task of monitoring each installation and providing input to prompts and dialog boxes. This method is especially useful when you are installing SPSS® Modeler Premium on a number of different computers that have identical hardware.

Note: You must have administrator privileges to be able to run silent installations.

Windows - silent installation

You can complete a silent installation on Windows systems by using Microsoft Installer (MSI). Use msieexec.exe to install the MSI package.

The following options can be used:

Table 1. Silent installation options

Option	Description
/i	Specifies that the program is to install the product.
/l*v	Specifies verbose logging. For example, this form of log can be useful if you need to troubleshoot an installation.
/qn	Runs the installation without running the external user interface sequence.
/s	Specifies silent mode.
/v	Specifies that the Setup Program passes the parameter string to the call it makes to the MSI executable file (msiexec.exe). The following syntax requirements apply if you use this option: <ul style="list-style-type: none">• You must place a backslash (\) in front of any quotation marks (" ") that are within existing quotation marks.• Do not include a space between the /v option and its arguments.• Multiple parameters that are entered with the /v option must be separated with a space.• To create a log file, specify the directory and file name at the end of the command. The directory must exist before you start the silent installation.
/x	Specifies that the program is to uninstall the product.

The following text shows an example of the MSI command:

```
c:\>msiexec.exe /i ModelerPremiumServer64.msi /qn /L*v  
c:\temp\Modeler_Silent_Install.log  
AgreeToLicense=true
```

Note: Depending on your system, you might need to change the ModelerPremiumServer64.msi file in the preceding example.

Windows - silent uninstalling

The following text shows an example of the MSI command to silently uninstall the software:

```
c:\>msiexec.exe /x ModelerPremium64.msi /qn /norestart
```

Linux / UNIX - silent installation

To complete a silent installation on Linux or UNIX systems:

1. In the same location where you copied the installer files, create an installer.properties file.
2. In a text editor, set the installer.properties values. The following text shows an example of an installer.properties file:

```
=====  
# Thu Jan 29 11:35:37 GMT 2015  
# Replay feature output  
# -----  
# This file was built by the Replay feature of InstallAnywhere.  
# It contains variables that were set by Panels, Consoles or Custom Code.  
  
#Indicate whether the license agreement been accepted  
#-----  
LICENSE_ACCEPTED=TRUE  
  
#Choose Install Folder  
#-----  
USER_INSTALL_DIR=/usr/IBM/SPSS/ModelerServer/17.0  
  
#Install  
=====
```

3. Ensure that the value for **USER_INSTALL_DIR** matches your installation directory location. The directory path cannot contain spaces.
4. Save the file.
5. Run the installer by using the following command:

```
./<installer_name> -i silent -f installer.properties
```

Where <installer_name> is the installer .bin file.

Linux / UNIX - silent uninstalling

To silently uninstall the software, you can run the uninstaller in one of two ways:

- Execute the following command:

```
./<installer_path>/Uninstall_IBM_SPSS_MODELER_PREMIUM_SERVER/Uninstall_IBM_SPSS_MODELER_PREMIUM_SERVER  
-i silent
```

Where <installer_path> is the path name to the IBM® SPSS Modeler Server installation directory.

- Alternatively, if you have an installer.properties file, the following text shows an example of the command to silently uninstall the software:

```
./premium_server_linux64.bin -i silent -f ./installer.properties
```

Removing IBM® SPSS® Modeler Premium Server

- [Removing from Windows systems](#)
- [Removing from UNIX systems](#)

Removing from Windows systems

To uninstall IBM® SPSS® Modeler Premium Server, perform the following steps:

1. From the Windows Start menu choose:
Settings > Control Panel
2. From the Control Panel, choose Add or Remove Programs.
3. Click Change or Remove Programs.
4. Select IBM SPSS Modeler Premium Server from the list of currently installed programs, and click Change/Remove. If you have more than one version installed on the computer, be sure to select the version that you want to remove.

A message will be displayed when the uninstallation process completes.

Removing from UNIX systems

To uninstall IBM® SPSS® Modeler Premium Server, remove the program files and, if you have configured the system for automatic start up, disable automatic start up.

IBM® SPSS® Modeler - Essentials for R: Installation Instructions

- [Overview](#)
- [Install the IBM SPSS Modeler application](#)
- [Download and install R](#)
- [Download and install IBM SPSS Modeler - Essentials for R](#)
- [Repairing an installation](#)
- [Uninstalling IBM SPSS Modeler - Essentials for R components](#)

Overview

This document contains the instructions for installing IBM® SPSS® Modeler - Essentials for R.

IBM SPSS Modeler - Essentials for R provides you with tools you need to start using custom R scripts for model building and scoring within the Extension nodes in IBM SPSS Modeler. It includes the IBM SPSS Modeler - Integration Plug-in for R for IBM SPSS Modeler 18.4.0.

To use the R nodes in IBM SPSS Modeler Client, you must have the following components installed on the local machine:

- IBM SPSS Modeler 18.4.0. See the topic [Install the IBM SPSS Modeler application](#) for more information.

- R environment. See the topic [Download and install R](#) for more information.
- IBM SPSS Modeler - Essentials for R. See the topic [Download and install IBM SPSS Modeler - Essentials for R](#).

To use the R nodes with IBM SPSS Modeler Server, you must have the following components installed on the server machine:

- IBM SPSS Modeler Server 18.4.0. See the topic [Install the IBM SPSS Modeler application](#) for more information.
- R environment. See the topic [Download and install R](#) for more information.
- IBM SPSS Modeler - Essentials for R. See the topic [Download and install IBM SPSS Modeler - Essentials for R](#) for more information. The bit rate of IBM SPSS Modeler - Essentials for R that is installed must be the same as the installed version of IBM SPSS Modeler Server.

Notes:

- The Windows installer for IBM SPSS Modeler - Essentials for R is the same for both IBM SPSS Modeler and IBM SPSS Modeler Server. For example, the 64-bit installer for IBM SPSS Modeler - Essentials for R applies to both the 64-bit version of IBM SPSS Modeler and the 64-bit version of IBM SPSS Modeler Server.
- Starting with version 18.2.2, there's no longer a separate IBM SPSS Modeler - Essentials for R installer for Mac. It's part of the default SPSS Modeler installation, and the default R_HOME: path is /Library/Frameworks/R.framework/Resources. If you use a different path, you must edit the file config.ini located under /Applications/IBM/SPSS/Modeler/<version>/SPSSModeler.app/Contents/ext/bin/pasw.rstats and change config.ini to switch to your \${R_HOME} path on Mac.

Install the IBM SPSS Modeler application

There are no additional operating system and hardware requirements. The components that are installed with IBM® SPSS® Modeler - Essentials for R work with any valid IBM SPSS Modeler license.

If you have not already done so, follow the instructions that are provided with the software to install one of the IBM SPSS Modeler applications on the computer where you will install IBM SPSS Modeler - Essentials for R.

Note: If you are using Windows, and are installing IBM SPSS Modeler - Essentials for R on a desktop machine, you must also install IBM SPSS Modeler 18.4.0 on the desktop machine. If you are installing IBM SPSS Modeler - Essentials for R on a server machine, you must also install IBM SPSS Modeler Server 18.4.0 on the server machine.

Download and install R

Version 18.4.0 of IBM® SPSS® Modeler - Essentials for R requires an installation of R. Version 4.0.4 is recommended. Install R on the computer where you will install IBM SPSS Modeler - Essentials for R.

Prerequisites

The target computer where you will install Essentials for R must have X11. If the target computer has a physical display, then it most likely has X11. The steps that follow describe the process for installing X11, if necessary.

1. Install the X11 client and server

- For Linux distributions that use `yum`, install the X11 client and server software with:

```
yum groupinstall "X Window System" "Desktop" "Fonts" "General Purpose Desktop"
yum update xorg-x11-server-Xorg
yum install xorg-x11-server-Xvfb.x86_64
```

- For Linux distributions that use `apt-get`, install the X11 client and server software with:

```
apt-get install xorg xterm
apt-get install xserver-xorg xserver-xorg-core xserver-xorg-dev
apt-get install xvfb
```

2. Install openGL

- For Linux distributions that use `yum`, install openGL with:

```
yum install mesa-libGL-devel mesa-libGLU-devel libpng-devel
```

- For Linux distributions that use `apt-get`, install openGL with:

```
apt-get install libgl1-mesa-glx libgl1-mesa-dev libglu1-mesa libglu1-mesa-dev
```

3. Start Xvfb. For more information, see <http://www.x.org/archive/X11R7.6/doc/man/man1/Xvfb.1.xhtml>.

4. Set the `DISPLAY` environment variable. The general form for the `DISPLAY` variable is:

```
export DISPLAY=<Hostname>:<D>.<S>
```

In the preceding statement,

<Hostname> is the name of the computer that hosts the X display server. To specify localhost, omit the value of <Hostname>. <D> is the display number of the Xvfb instance. <s> is the screen number, which is typically 0.

Note: The DISPLAY environment variable must be set before you start the IBM SPSS Modeler server.

5. 4.0.4 is the recommended R version. Note that the versions of zlib, bzip2, xz, and pcre that were included with old versions of R have been removed. So if you choose to install R from source, you must install the dependent packages zlib, bzip2, xz, pcre, and curl. You must also set the shared library path by adding the following line to the .bash_profile for the user who runs R or /usr/local/lib/etc/ld.so.conf.

```
export LD_LIBRARY_PATH=/usr/local/lib:$LD_LIBRARY_PATH
```

For more information, see the *R Installation and Administration* manual at <https://www.r-project.org/>.

- For Linux distributions that use yum, install packages with:
 - yum install zlib zlib-devel
 - yum install bzip2 bzip2-devel
 - yum install xz xz-devel
 - yum install pcre pcre-devel
 - yum install libcurl libcurl-devel
- For Linux distributions that use apt-get, install packages with:
 - apt-get install zlib1g zlib1g-dev
 - apt-get install bzip2 bzip2-dev libbz2-dev
 - apt-get install liblzma-dev
 - apt-get install libpcre3 libpcre3-dev

Note that for libcurl, you can install one of them:

- apt-get install libcurl4-openssl-dev
- apt-get install libcurl4-gnutls-dev
- apt-get install libcurl4-nss-dev

In addition to installing X11, we also recommend installing tcl/tk before installing R.

Installing R from a package manager

Your distribution's repository may include R. If so, you can install R using your distribution's standard package manager (such as the RPM Package Manager or the Synaptic Package Manager).

- For Linux distributions that use yum, you can install R with `yum install R`.
- For Linux distributions that use apt-get, you can install R from the command:

```
apt-get install r-base=<Version> r-base-core=<Version> r-base-dev=<Version>
```

where <Version> is the name of the version. Note that you might need to update the file /etc/apt/source.list to add new sources.

Building and installing R from source

The source for R is available from <ftp://ftp.stat.math.ethz.ch/Software/CRAN/src/base/R-3/>.

1. Create a temporary directory where you will uncompress and unpack the R source. For example, at a command prompt type:
`mkdir ~/Rsource`

2. Download the source code for building R, for example *R-4.0.4.tar.gz*, and save it to the temporary directory.

3. Change to the temporary directory. For example, at a command prompt type:

```
cd  
~/Rsource
```

4. Uncompress and unpack the R source to the temporary directory. For example, at a command prompt type:
`tar xzf R-4.0.4.tar.gz`

5. Change to the source directory. For example, at a command prompt type:

```
cd  
R-4.0.4
```

Note: To install R to the default directory, you must run the following step as root, either by logging in as root or using the `sudo` command. It is recommended that you read the information in *doc/html/R-admin.html* (located under the directory where you unpacked the R source) before proceeding with configuring, building and installing R.

6. Run the following commands to specify necessary compiler settings (see the special settings for PowerLinux):

```
export CC="gcc -m64"  
export CXXFLAGS="-m64 -O2 -g"  
export FFLAGS="-m64 -O2 -g"  
export FCFLAGS="-m64 -O2 -g"  
export LDFLAGS="-L/usr/local/lib64"  
export LIBnn=lib
```

PowerLinux settings:

```
export CC=<XLC_PATH>/bin/xlc_r -q64"
export CFLAGS="-g -O2 -qstrict -qfloat=nomaf:fenv"
export F77=<XLF_PATH>/xlf_r -q64"
export FFLAGS="-g -O3 -qstrict -qfloat=nomaf:fenv -qextname"
export CXX=<XLC_PATH>/bin/xlc_r -q64"
export CPICFLAGS=-qpic
export CXXPICFLAGS=-qpic
export FPICFLAGS=-qpic
export SHLIB_LDFLAGS=-qmksrhobj
export SHLIB_CXXLDFLAGS=-G
export FC=<XLF_PATH>/xlf_r -q64"
export FCFLAGS="-g -O3 -qstrict -qfloat=nomaf:fenv -qextname"
export FCPICFLAGS=-qpic
export CXX1XSTD=-qlanglvl=extended0x
```

Where <XLC_PATH> and <XLF_PATH> are the locations of IBM XL C/C++ for Linux and IBM XL Fortran for Linux respectively.

If installing R on PowerLinux P8LE servers (Ubuntu or RedHat), you must install the XL C/C++ Compiler and the XL Fortran Compiler (16.1.1.12 or later).

Also for PowerLinux, run these commands:

```
xlf -qpreprocess -qnoobject -d src/modules/lapack/dlapack.f
mv -f Fdlapack.f src/modules/lapack/dlapack.f
xlf -qpreprocess -qnoobject -d src/extrablas/blas.f
mv -f Fblas.f src/extrablas/blas.f
```

7. Configure, build, and install R. Be sure to configure R with the `--enable-R-shlib` and `--with-x` arguments. For example, at a command prompt type (see the special settings for PowerLinux):

```
./configure --enable-R-shlib --with-x && make && make install
```

PowerLinux settings:

```
./configure --enable-R-shlib --with-x --with-readline=no --disable-openmp&& gmake
&& gmake install
```

For details about building R on IBM z Systems, see <https://github.com/linux-on-ibm-z/docs/wiki/Building-R>.

Note: The readline entry is optional, depending on how your system is configured.

Download and install IBM SPSS Modeler - Essentials for R

Be sure to use a version of IBM® SPSS® Modeler - Essentials for R that is compatible with the version of IBM SPSS Modeler on your machine. Within a major version of IBM SPSS Modeler, such as 18.0, you must use a version of IBM SPSS Modeler - Essentials for R that has the same major version.

For users who are working in distributed mode (with IBM SPSS Modeler Server) please install IBM SPSS Modeler - Essentials for R on the server machine.

Log on to Passport Advantage and download version 18.4.0 of IBM SPSS Modeler - Essentials for R. Be sure to download the version of IBM SPSS Modeler - Essentials for R for the operating system of your IBM SPSS Modeler application.

Tip: After installing IBM SPSS Modeler - Essentials for R, if you ever need to know what version is installed, you can run the following command in the R console.

```
packageVersion("ibmspsscf92")
```

- [Install IBM SPSS Modeler - Essentials for R for Windows](#)
- [Install IBM SPSS Modeler - Essentials for R for UNIX](#)
- [IBM SPSS Modeler - Essentials for R for Mac](#)
- [Silent installation](#)
- [Running Extension nodes in IBM SPSS Modeler Solution Publisher and IBM SPSS Collaboration and Deployment Services](#)

Install IBM SPSS Modeler - Essentials for R for Windows

Windows Vista, Windows 7, or Windows Server 2008

You must run the installer as administrator:

1. Using Windows Explorer, browse to the folder where you downloaded the file.
2. Right-click the downloaded file and choose Run as Administrator.
3. Follow the instructions that are displayed on the screen.

Pushing an installation

As an alternative to the manual installation described above, you can push the installation to Windows computers. This is most useful for network administrators who need to install to multiple end users. Following is the form of the command line for pushing an installation:

```
<installer_name> -i silent
```

Here, `<installer_name>` is the name of the installer file for IBM® SPSS® Modeler - Essentials for R, for example:
`SPSS_Modeler_ESSENTIALS_<version>_win64.exe`.

Increasing the memory limit

Under Windows, R imposes a limit on the total memory allocation that is available to an R executable session. This limit restricts the embedded R process `r_start.exe`.

If required, you can modify the numeric value to increase the memory limit; to do this, add an option in the end of the `C:\Program Files\IBM\SPSS\Modeler\<version>\ext\bin\pasw.rstats\config.ini` file. For example, to raise the limit to 4096Mb:

```
Max_Mem_Size=4096
```

Install IBM SPSS Modeler - Essentials for R for UNIX

1. Start a terminal application.
2. Change to the directory where you downloaded IBM® SPSS® Modeler - Essentials for R. At the command prompt, type:
`./<<filename>>`

where `<<filename>>` is the name of the file you downloaded. You must ensure that this file has execute permission before you attempt to run the command.

Note: You must run the previous command as root, either by logging in as root or (if installing as non-root) by using the `sudo` command and having write permission to `<SPSS Modeler installation directory>/ext/bin` and `<USER_R_HOME>`. In addition, you need to install the `gcc` and `gfortran` compilers before you install IBM SPSS Modeler - Essentials for R.

3. Follow the instructions that are displayed on the screen. When prompted for the location of R, you can obtain the R home directory by running `R.home()` from the R prompt.

Note: To ensure that SPSS Modeler can launch R successfully, export the library search paths that are required by `libR.so` to the `DLLIBPATH` variable in the `modelersrv.sh` file in the SPSS Modeler Server installation directory. To find all the `libR.so` libraries that are referenced, use the command `ldd <R_HOME>/lib/libR.so`.

IBM SPSS Modeler - Essentials for R for Mac

Starting with version 18.2.2, there's no longer a separate IBM® SPSS® Modeler - Essentials for R installer for Mac. It's part of the default SPSS Modeler installation, and the default `R_HOME`: path is `/Library/Frameworks/R.framework/Resources`. If you use a different path, you must edit the file `config.ini` located under `/Applications/IBM/SPSS/Modeler/<version>/SPSSModeler.app/Contents/ext/bin/pasw.rstats` and change `config.ini` to switch to your `${R_HOME}` path on Mac.

Silent installation

As an alternative to the manual installations described previously, you can also run a silent installation. This is most useful for network administrators who need to install to multiple end users. To run a silent installation, do the following:

1. Start a terminal application.
2. Change to the directory where you downloaded IBM® SPSS® Modeler - Essentials for R.
3. Using a text editor, create a response file named `install.properties`.
4. Add the following properties and associated values to the response file:

```
USER_INSTALL_DIR=<R 4.0.4 home directory>
FRONTEND_INSTALL_DIR=<IBM SPSS Modeler location>/ext/bin
```

where <R 4.0.4 home directory> is the installation location of R 4.0.4 and <IBM SPSS Modeler location> is the installation location of IBM SPSS Modeler. For example, on UNIX:

```
USER_INSTALL_DIR=/usr/local/lib/R  
FRONTEND_INSTALL_DIR=/usr/IBM/SPSS/ModelerServer/19/ext/bin
```

For example, on Windows:

```
USER_INSTALL_DIR=C:\\Program Files\\R\\R-4.0.4  
FRONTEND_INSTALL_DIR=C:\\Program Files\\IBM\\SPSS\\Modeler\\18.4.0\\ext\\bin
```

5. Save install.properties to the directory that contains the .bin file for IBM SPSS Modeler - Essentials for R and change to that directory.
6. On UNIX, run the installer with the following command:

```
./<installer_name> -i silent
```

where <installer_name> is the name of the .bin file for IBM SPSS Modeler - Essentials for R. Note that you must run the previous command as root, either by logging in as root or using the **sudo** command.

On Windows, run the installer with the following command:

```
<installer_name> -i silent
```

where <installer_name> is the name of the installer file for IBM SPSS Modeler - Essentials for R, for example **SPSS_Modeler_REssentials_<version>_win32.exe**.

Alternatively, on UNIX, you can run the installer with the following command:

```
./<installer_name> -f <Response file location>
```

On Windows, you can run the installer with the following command:

```
<installer_name> -f <Response file location>
```

In both cases, <Response file location> is the file path to the response file. If you use this alternative command, you must add the following property to the response file:

```
INSTALLER_UI=[swing | console | silent]
```

Note: To use a different response file (other than install.properties), on UNIX run the installer with the following command:

```
./<installer_name> -i silent -f <response file name>
```

On Windows, run the installer with the following command:

```
<installer_name> -i silent -f <response file name>
```

Running Extension nodes in IBM SPSS Modeler Solution Publisher and IBM SPSS Collaboration and Deployment Services

If you want to run Extension nodes (formerly R nodes) in SPSS® Modeler Solution Publisher and run the Scoring Service on the IBM® SPSS Collaboration and Deployment Services server, you must install IBM SPSS Modeler - Essentials for R and the R environment with SPSS Modeler Solution Publisher and the IBM SPSS Collaboration and Deployment Services server.

Running Extension nodes (Extension Export node, Extension Output node, Extension Model node, Extension Transform node, and Extension Import node)

1. For the Extension nodes to work with SPSS Modeler Solution Publisher, install IBM SPSS Modeler - Essentials for R and the R environment on the same machine as the IBM SPSS Collaboration and Deployment Services server. During IBM SPSS Modeler - Essentials for R installation, point to the R environment installation directory and the SPSS Modeler Solution Publisher installation directory.
2. To run the Scoring Service on the IBM SPSS Collaboration and Deployment Services server, you must also install IBM SPSS Modeler - Essentials for R and the R environment on the same machine as the IBM SPSS Collaboration and Deployment Services server. During IBM SPSS Modeler - Essentials for R installation, point to the R environment installation directory and the local IBM SPSS Modeler Server location under the IBM SPSS Collaboration and Deployment Services server installation directory.
3. For R in CDB node execution, after setting up the environment as described in the previous steps, you must also set an environment variable as follows:
 - a. On the IBM SPSS Collaboration and Deployment Services server machine and the IBM SPSS Modeler client machine, create a system environment variable called **IBM_SPSS_MODELER_EXTENSION_PATH** that points to the folder that contains the R CDB node .cdf and .cfe files.
 - b. Make sure both IBM SPSS Collaboration and Deployment Services server and IBM SPSS Modeler client can access this path.

c. Restart IBM SPSS Collaboration and Deployment Services server and IBM SPSS Modeler client.

Note: To ensure that R can launch successfully, export the library search paths that are required by libR.so to the **DLLIBPATH** variable in the modelersrv.sh file in the IBM SPSS Modeler Solution Publisher installation directory. To find all the libR.so libraries that are referenced, use the command **ldd <R_HOME>/lib/libR.so**.

Repairing an installation

If you uninstall and then reinstall the IBM® SPSS® Modeler 18.4.0 application or your R environment, then you must also uninstall and then reinstall version 18.4.0 of IBM SPSS Modeler - Essentials for R.

Uninstalling IBM® SPSS® Modeler - Essentials for R components

- [Windows](#)
 - [UNIX](#)
-

Windows

Remove the following folder and files:

- ibmspsscf84 from <R 4.0.x home directory>\\library
 - config.ini from <IBM® SPSS® Modeler location>\\ext\\bin\\pasw.rstats
 - embeded.dll from <IBM SPSS Modeler location>\\ext\\bin\\pasw.rstats
-

UNIX

Remove the following folder and files:

- ibmspsscf84 from <R home directory>/library
 - config.ini from <IBM® SPSS® Modeler location>/ext/bin/pasw.rstats
 - libembeded.so from <IBM SPSS Modeler location>/ext/bin/pasw.rstats

About IBM SPSS Modeler Server Adapter installation

This guide provides installation instructions and information relating to the products available on the IBM® SPSS® Modeler Server Adapter installation media.

The adapters enable IBM SPSS Modeler and IBM SPSS Modeler Server to interact with an IBM SPSS Collaboration and Deployment Services repository. For more information, see the *IBM SPSS Modeler User's Guide*.

System requirements

Before you can install the adapter, you must be able to connect to a fully-functioning IBM® SPSS® Collaboration and Deployment Services repository. System requirements for this are given in the *Installation and Configuration Guide* for the appropriate repository version. Kerberos credentials are supported for running jobs and managing user roles.

IBM Installation Manager **1.9.1** must be installed on the machine where the adapter will be installed, and it must be configured to use the installation files. See the following section.

Note: Installing and running the adapter will consume additional resources of the repository host, most importantly memory. It is recommended that, prior to installation, you consult the application server documentation to confirm you have sufficient memory for your selected application server.

The repository server needs to have a valid Java Runtime Environment (JRE) set up in the PATH or JAVA_HOME environment variables, otherwise installation will fail.

Make sure you have sufficient free disk space before starting installation. A minimum of 10 GB is recommended. This installation is for the **8.x** version of the adapters and uses IBM Installation Manager to install all the adapters at the same time, so the installation may take longer than in previous releases.

If not present already, the Microsoft Visual C++ 2010 runtime library will be installed on the machine where the adapter will be installed.

Installation files

Before installing, you must obtain the installation files.

To obtain the installation files do one of the following:

- Download the files from the Passport Advantage site, and use local installation: Licensed customers with a Passport Advantage ID and password can download the necessary product repositories from the Passport Advantage site.
- Access the live repositories, and use web-based installation: If you have a Passport Advantage ID and password, you can use Installation Manager to install the product directly from IBM hosted repositories.

Getting started with Installation Manager

Installing, updating, or uninstalling the product can be performed by using IBM® Installation Manager in wizard, console, or silent mode. However, you must configure an IBM Installation Manager repository or Passport Advantage preferences before performing these tasks.

For complete information about Installation Manager, see the [IBM Installation Manager documentation](#).

Wizard mode

In wizard mode, you run Installation Manager from a graphical user interface.

Most of the time, you start Installation Manager with the default shortcuts that are installed with your version of Installation Manager.

From the installation location of Installation Manager, you can run the **IBMMIM** application file to start in wizard mode manually.

The default **IBMMIM** location for the operating system varies depending on the installation type (administrator, nonadministrator, or group).

Table 1. Default installation locations for IBMMIM

Operating system	Administrator	Nonadministrator	Group
Windows 2008 and Windows 2012	C:\Program Files [(x86)]\IBM\InstallationManager\IBMMIM.exe	C:\Users\user\IBM\InstallationManager\IBMMIM.exe	
Linux® and UNIX	/opt/IBM/InstallationManager/eclipse/IBMMIM	/user_home_directory/IBM/InstallationManager/eclipse/IBMMIM	/user_home_directory/IBM/InstallationManager_Group/eclipse/IBMMIM

Console mode

Use console mode when you do not have a graphics display device available or when you want to run Installation Manager without the graphical user interface. Installation Manager supports installing in an ASCII text-based mode that is called the console mode. Console mode is interactive text-based user interface to Installation Manager. For example, use console mode for server-side deployments when no graphical user interface is present, or for running the installation from a remote host.

To start console mode:

1. Open a command line.
2. Go to the `tools` subdirectory.
3. Run the command that is appropriate for the operating system:
 - Windows: `imcl.exe -c`
 - Linux, UNIX: `./imcl -c`

The default `tools` location varies depending on the operating system and installation type (administrator, nonadministrator, or group). For more information, see the Installation Manager documentation.

Table 2. Default installation locations for the `tools` subdirectory

Operating system	Administrator	Nonadministrator	Group
Windows 2003, Windows 2008 and Windows 2012	<code>C:\Program Files [(x86)]\IBM\InstallationManager\eclipse\tools</code>	<code>C:\Users\user\IBM\InstallationManager\eclipse\tools</code>	
Linux and UNIX	<code>/opt/IBM/InstallationManager/eclipse/tools</code>	<code>/user_home_directory/IBM/InstallationManager/eclipse/tools</code>	<code>/user_home_directory/IBM/InstallationManager_Group/eclipse/tools</code>

Silent mode

Use silent installations to deploy software to multiple systems, or to an enterprise. Silent installations are defined by a response file and started from the command line or a batch file. The response file is provided with the product distribution. For more information, see [Installing silently by using a response file](#).

- [Repository preferences](#)
An IBM Installation Manager repository is a location that stores data for installing, modifying, rolling back, or updating packages.
- [Passport Advantage preferences](#)
IBM Installation Manager can access installation packages from Passport Advantage®. Passport Advantage is a centralized online location for the acquisition of IBM software offerings.

Repository preferences

An IBM Installation Manager repository is a location that stores data for installing, modifying, rolling back, or updating packages.

Before you install, modify, or update packages, obtain the installation repository location from your administrator or from IBM.

Note: To successfully access an installation repository, the repository location path must not contain an ampersand (&).

The following topics provide instructions for setting repository preferences in wizard and console mode.

- [Setting repository preferences in wizard mode](#)
You can add, edit, or remove repositories and modify the repository order in the repository table using wizard mode.
- [Setting repository preferences in console mode](#)
You can use console mode to add, remove, open, move, or close repositories.

Setting repository preferences in wizard mode

You can add, edit, or remove repositories and modify the repository order in the repository table using wizard mode.

About this task

You can clear credentials for a repository or test a connection to a repository. You might find both a `diskTag.inf` file and a `repository.config` file in the IBM® product installation files. Use the `diskTag.inf` file when you select a repository location.

Procedure

To add, edit, or remove a repository location:

1. Start Installation Manager in wizard mode by using **IBMMIM**. For more information, see [Getting started with Installation Manager](#).
2. Click **File > Preferences > Repositories**.
The Repositories page opens and shows available repositories, repository locations, and the connection status for the repositories.
3. Click **Add Repository**.
4. Enter the repository location or click **Browse**. When you browse, go to the repository location and select the **diskTag.inf** file, the **repository.config** file, the **.zip** file, or the **.jar** file as appropriate for your environment.
5. Click **OK**.
If you provided an HTTPS or restricted FTP repository location, you are prompted to enter a user ID and password.
The new repository location is added to the list. If the repository is not connected, a red box shows in the Connection column.
6. Optional: Select Search service repositories during installation and updates. Installation Manager searches the service repositories at IBM.com for updates to installed packages.
7. Click **OK** to close the Preference page.

Setting repository preferences in console mode

You can use console mode to add, remove, open, move, or close repositories.

About this task

A selected option is indicated by an **x** in brackets: **[x]**. Options that are not selected are indicated by empty brackets: **[]**. You can press **Enter** to select the default entry or select a different command. For example, **[N]** indicates that the default selection is **N** for the **Next** command.

Procedure

To add a repository:

1. Start Installation Manager in console mode by using **imcl -c**. For more information, see [Getting started with Installation Manager](#).
2. Enter **P: Preferences**.
3. Enter **1: Repositories**.
4. Enter **D: Add repository**.
5. Enter a repository location such as **C:\installation_files\repository.config**.
If you add a repository that requires credentials, you are prompted to provide the required credentials.
Use the correct case when you enter the repository location. If the correct case is not used, the package is not shown in the list of available packages for installation.
 - a. Enter **P: Provide credentials and connect**.
 - b. Enter the **user_name** and press **Enter**.
 - c. Enter the **password** and press **Enter**.
 - d. Enter **1** to save the password.
 - e. Enter **O: Ok**.
6. Enter **A: Apply Changes and Return to Preferences Menu**.
7. Enter **R: Return to Main Menu**.

Passport Advantage preferences

IBM® Installation Manager can access installation packages from Passport Advantage®. Passport Advantage is a centralized online location for the acquisition of IBM software offerings.

Before you install, modify, or update packages, obtain valid Passport Advantage credentials.

The following topics provide instructions for setting Passport Advantage preferences in wizard and console mode.

- [**Setting Passport Advantage preferences in wizard mode**](#)
You can set the Installation Manager Passport Advantage preferences to connect to Passport Advantage using wizard mode.
- [**Setting Passport Advantage preferences in console mode**](#)
You can set the Installation Manager Passport Advantage preference to connect to Passport Advantage in console mode.

Setting Passport Advantage preferences in wizard mode

You can set the Installation Manager Passport Advantage® preferences to connect to Passport Advantage using wizard mode.

About this task

Important: If you share an instance of Installation Manager with other users, see the [Installation Manager documentation](#) for information on installing as an administrator, nonadministrator, or group.

Procedure

To set Passport Advantage preferences:

1. Start Installation Manager in wizard mode by using **IBMMIM**. For more information, see [Getting started with Installation Manager](#).
2. Click **File > Preferences > Passport Advantage**.
3. Select the **Connect to Passport Advantage** check box to connect to the Passport Advantage repository.
The **Password Required** window opens.
4. Enter a user name and password for Passport Advantage.
5. Optional: Select **Save password** to save the user name and password credentials.
If you do not save the user name and password credentials, you are prompted for these credentials each time you access Passport Advantage.
6. Click **OK** to close the **Password Required** window.
7. Click **OK** to close the **Preferences** window.

What to do next

To delete saved user name and password credentials:

1. Click **File > Preferences > Passport Advantage**.
2. Click **Clear Credentials**.
3. Click **OK** in the **Confirm Clear Credentials** window.

Setting Passport Advantage preferences in console mode

You can set the Installation Manager Passport Advantage® preference to connect to Passport Advantage in console mode.

Procedure

1. Start Installation Manager in console mode by using **imcl -c**. For more information, see [Getting started with Installation Manager](#).
2. Enter **P: Preferences**.
3. Enter **6: Passport Advantage**.
4. Enter **1: Connect to Passport Advantage**.
A selected option is indicated by an **x** in brackets: **[x]**.
5. Enter **P: Provide credentials and connect**.
6. Enter the user name for the Passport Advantage account.
7. Enter the password.
If you do not save the user name and password credentials, you are prompted for these credentials each time you access Passport Advantage.
 - a. Optional: If you entered a password, enter **1: Save password if valid**.
8. Enter **O: OK** to save the credentials.

Installing IBM SPSS Modeler Adapter

You can install IBM SPSS Modeler Adapter in wizard, console, or silent mode.

You must shut down the IBM SPSS Collaboration and Deployment Services server before starting the installation, and ensure that the application server is in the following state:

- **IBM WebSphere standalone:** Server must be stopped.
- **IBM WebSphere managed:** Managed server must be stopped, Deployment Manager server must be running.
- **IBM WebSphere cluster:** Cluster members must be stopped, Deployment Manager server must be running.
- **JBoss:** Server must be stopped.

- **Oracle WebLogic standalone:** Server must be stopped.
- **Oracle WebLogic managed:** Managed server must be stopped, WebLogic administration server must be running.
- **Oracle WebLogic cluster:** Cluster members must be stopped, WebLogic administration server must be running.

- **Installing in wizard mode**

You can install IBM SPSS Modeler Adapter by using IBM Installation Manager in wizard mode.

- **Installing in console mode**

You can install IBM SPSS Modeler Adapter by using IBM Installation Manager in console mode.

- **Installing silently by using a response file**

You can use a response file to install in silent mode.

Installing in wizard mode

You can install IBM® SPSS® Modeler Adapter by using IBM Installation Manager in wizard mode.

Before you begin

Before you can install, IBM Installation Manager must have access to the repository that contains the package. You must also shut down the application server and the IBM SPSS Collaboration and Deployment Services server before starting the installation.

- If you have an IBM Passport Advantage® account, you can install packages from the Passport Advantage site. For more information about connecting to a Passport Advantage repository, see [Setting Passport Advantage preferences in wizard mode](#).
- If you are installing from a repository that is not on the Passport Advantage site, you must specify the repository in the preferences before you install. For more information, see [Setting repository preferences in wizard mode](#).

Procedure

To install IBM SPSS Modeler Adapter:

1. Start Installation Manager in wizard mode by using [IBMIM](#). For more information, see [Getting started with Installation Manager](#).
2. In Installation Manager, click Install.
Installation Manager searches the defined repositories for available packages. If no available packages are found, verify that you specified the repository correctly. See [Setting repository preferences in wizard mode](#).
3. If a new version of Installation Manager is found, you might be prompted to confirm the installation. Click Yes to proceed. Installation Manager automatically installs the new version, restarts, and resumes.
4. The Install page of Installation Manager lists all the packages that were found in the repositories that Installation Manager searched. Only the most recent version of the package is shown. To show all versions of a package that Installation Manager finds, select Show all versions.
Click a package version to show the package description in the Details pane. If more information about the package is available, a More info link is included at the end of the description text.
If you are running Installation Manager in group mode, you can install only packages that are enabled for installing in group mode. If the package is not enabled for installing in group mode, you receive an error and cannot continue with the package installation in group mode.
5. Select the IBM SPSS Modeler Adapter package. Click Next.
6. On the Licenses page, read the license agreements for the selected package. After you accept the license agreement, click Next to continue.
7. On the Location page, enter the path for the shared resources directory in the Shared Resources Directory field. The shared resources directory contains resources that can be shared by multiple package groups. Click Next.
Important: You can specify the shared resources directory only the first time that you install a package. Select the drive with enough available space to ensure adequate space for the shared resources of future packages. You cannot change the location of the shared resources directory unless you uninstall all packages.
8. On the Location page, either choose a package group into which to install the packages or create a package group.
A package group is a directory that contains resources that packages share with other packages in the same group. The first time that you install a package, you must create a package group. If you select more than one package to install, verify that the packages can be installed in the same package group by checking the documentation for the packages. For packages that cannot be installed in the same package group, install one package in one package group. After the installation completes, install the second package in a different package group.

Option	Description
Use the existing package group	Select a package group into which to install the packages. If the packages being installed are not compatible with the selected group, an alert reports the conflict. If a group is not compatible, either select a different group or create a new group.
Create a new package group	Click Browse to specify the installation directory for the packages. If you are installing on a 64-bit operating system, select the architecture for the installation as either 32-bit or 64-bit.

Click Next to continue the installation.

9. On the next Location page, select the translations to install for packages in the package group. The corresponding language translations for the graphical user interface and documentation are installed. Choices apply to all packages that are installed in this package group. This option may not apply to all product installations. Click Next to continue.
10. On the Features page, select the package features to install.
 - a. Optional: To see the dependency relationships between features, select Show Dependencies.
 - b. Optional: Click a feature to view its brief description under Details.
 - c. Select or clear features in the packages. Installation Manager automatically enforces dependencies with other features and shows updated download size and disk space requirements for the installation.

To restore the default features that are selected for the packages, click Restore Default.
11. When you are finished selecting features, click Next.
12. On the Summary page, review your choices before you install the packages.
On Windows, Installation Manager checks for running processes. If processes are blocking the installation, a list of these processes is shown in the Blocking Processes section. You must stop these processes before you continue the installation. Click Stop All Blocking Processes. If there are no processes that must be stopped, you do not see this list. The running processes lock files that must be accessed or modified by Installation Manager.
13. Click Install.

When the installation process completes, you receive a confirmation message.

Installing in console mode

You can install IBM® SPSS® Modeler Adapter by using IBM Installation Manager in console mode.

Before you begin

Before you can install, Installation Manager must have access to the repository that contains the package. You must also shut down the application server and the IBM SPSS Collaboration and Deployment Services server before starting the installation.

- If you have an IBM Passport Advantage® account, you can install packages from the Passport Advantage site. For more information about connecting to a Passport Advantage repository, see [Setting Passport Advantage preferences in console mode](#).
- If you are installing from a repository that is not on the Passport Advantage site, you must specify the repository in the preferences before you install. For more information, see [Setting repository preferences in console mode](#).

Procedure

To install in console mode:

1. Start Installation Manager in console mode by using `imcl -c`.
The default `imcl` location varies depending on the operating system and installation type (administrator, nonadministrator, or group). For more information, see [Getting started with Installation Manager](#).
2. Enter 1: Install - Install software packages.
Packages that can be installed are listed.
If you have repositories that require credentials and you did not save the credentials, you are prompted to provide these credentials
3. Enter 1: [] *package_name*.
To select a package, enter the number that is next to the package. This example selects the first package listed. If the selected package requires a later version of Installation Manager, you are prompted to install the later version.
4. On the Select screen, enter the number that is next to the package that you want to install.
 - 1: Choose version *package_version* for installation. This option shows when you chose a package that is not selected for installation.
The 1: Do NOT install version *package_version* option shows when you chose a package that is selected for installation.
 - 2: Show all available versions of the package.
5. Optional: Enter 0: Check for Other Versions, Fixes, and Extensions. Installation Manager searches available repositories for other versions, fixes, or extensions of the selected package.
 - For Installation Manager to search the default repository for the installed packages, the Search service repositories during installation and updates preference must be selected. This preference is selected by default. To access this preference, go to the Repositories preference page.
 - Typically, Internet access is required.
 - The Check for Other Versions, Fixes, and Extensions option indicates the number of other versions, fixes, or extensions found but does not list the found items. To see available versions, enter the number that is next to the package then enter 2: Show all available versions of the package.
6. Enter N: Next
7. Options for the Licenses screen:
 - 1: *product_name* - License Agreement. To view a license agreement, enter the number that is next to the product name. This example selects the first license agreement listed.

- A: [] I accept the terms in the license agreement.
 - D: [] I do not accept the terms in the license agreement. If you decline the license agreement, the installation is stopped. To continue the installation, you must accept the license agreement.
 - a. Enter A to accept the license agreement.
 - b. Enter N: Next.
8. To enter a different value for the shared resources directory, enter M: Shared Resources Directory. To accept the default value for shared resources directory or to continue after you enter a different value, enter N: Next.
Important: You can specify the shared resources directory only the first time that you install a package. Select the drive with enough available space to ensure adequate space for the shared resources of future packages. You cannot change the location of the shared resources directory unless you uninstall all packages.
9. Optional: To enter a different value for the package group location, enter M: Change Location. To accept the default values or to continue after you enter a different value, enter N: Next.
A package group is a directory that contains resources that packages share with other packages in the same group. The first time that you install a package, you must create a package group. If you select more than one package to install, verify that the packages can be installed in the same package group by checking the documentation for the packages. For packages that cannot be installed in the same package group, install one package in one package group. After the installation completes, install the second package in a different package group.
10. Enter the number that is next to the language to add or remove the language from the list of languages that are installed. You can select only one language at a time. Enter N: Next.
English is selected by default. You cannot clear the selection for the English language. Your language choices apply to all packages that are installed in the package group.
11. Enter the number that is next to the feature to add or remove the feature from the list of features that are installed. Enter N: Next.
This screen is not shown when your product does not have any features.
12. On the Summary screen, review your selections before you install the package.
Optional: To generate a response file, enter G: Generate an installation response file. Enter the name of the response file and use .xml as the file extension. Response files are XML files. You can include a directory location when you enter the response file name to save the file to a different location.
13. Enter I: Install.
14. When the installation completes, enter F: Finish.

Installing silently by using a response file

You can use a response file to install in silent mode.

Before you begin

Locate the SilentInstallOptions response file provided in the installation package. You must also shut down the application server and the IBM® SPSS® Collaboration and Deployment Services server before starting the installation.

Procedure

To install a package in silent mode:

Run the **imcl** command:

- Windows: **imcl.exe**
`input response_file -log log_file`
- Linux® and UNIX: **./imcl input response_file -log log_file**

The default **imcl** location will vary depending on the operating system and installation type (administrator, nonadministrator, or group). For more information, see [Getting started with Installation Manager](#).

Results

When the installation is complete, a status of 0 is returned. If the installation cannot be completed, a non-zero number is returned.
A log file is available. For more information, see the Installation Manager documentation.

Example

Table 1. Install commands by operating system

Operating system	Command
Windows	<code>imcl.exe input c:\response_files\install.xml -log c:\mylog\install_log.xml -acceptLicense</code>

Operating system	Command
Linux, UNIX	<code>./imcl input /response_files/install.xml -log /mylog/install_log.xml -acceptLicense</code>

Enclose file paths that include spaces with double quotation marks.

Configuring the adapter for IBM SPSS Collaboration and Deployment Services Web services on Linux

When running IBM® SPSS® Collaboration and Deployment Services Web service automations relating to SPSS Modeler on Linux, you may see the error:

```
java.io.IOException: Too many open files
```

If this occurs, increase the maximum number of open files on the Linux server by entering the command:

```
ulimit -n value
```

where *value* is the number of files that can be open. This value should be as high as possible, and depends on the amount of nodes in stream files. Default is 1024; a suggested value is 100000.

Configuring the adapter for SPSS Statistics

If you want to use the IBM® SPSS® Collaboration and Deployment Services scoring service to score an SPSS Modeler stream containing SPSS Statistics integration nodes (Statistics Transform, Statistics Model, and Statistics Output), perform the following procedure after installing the adapter.

1. On the repository host, navigate to the `/components/modeler/bin` folder.
2. Use the `statisticsutility` tool to configure the adapter to work with the SPSS Statistics server. For more information, see the section on IBM SPSS Statistics helper applications in the *IBM SPSS Modeler Source, Process and Output Nodes* guide.

Troubleshooting

IBM Installation Manager version

IBM Installation Manager version **1.9.1** is required for the installation.

Free disk space

The installation will fail if you don't have sufficient free disk space. A minimum of 10 GB is recommended.

Installation failure

IBM Installation Manager may report that installation is successful, even though the adapter is not functioning correctly. The installation consists of an *installation* process and a *configuration* process. In some cases, the installation process may succeed but configuration process may fail. Verify that the entire installation is successful before continuing.

Uninstalling IBM SPSS Modeler Server Adapter

You can uninstall IBM® SPSS® Modeler Server Adapter in wizard or console mode.

You must log in with a user account that has the same privileges as the account that was used to install IBM SPSS Modeler Server Adapter.

Important: Certain files in the IBM SPSS Modeler Server Adapter program directory (for example, program data) cannot be deleted by IBM Installation Manager. You must manually delete the program directory to completely remove all IBM SPSS Modeler Server Adapter files from the system after you uninstall it.

Uninstalling IBM SPSS Modeler Server Adapter removes the adapter files from the host file system. However, the adapter remains deployed with IBM SPSS Collaboration and Deployment Services Repository in the application server.

- [Uninstalling by using wizard mode](#)
You can use IBM Installation Manager in wizard mode to uninstall IBM SPSS Modeler Server Adapter.
- [Uninstalling by using console mode](#)
You can use IBM Installation Manager in console mode to uninstall IBM SPSS Modeler Server Adapter.

Uninstalling by using wizard mode

You can use IBM Installation Manager in wizard mode to uninstall IBM SPSS Modeler Server Adapter.

Before you begin

You must log in with a user account that has the same privileges as the account that was used to install the packages that you want to uninstall.

Procedure

To uninstall IBM SPSS Modeler Server Adapter:

1. Close programs that you installed with Installation Manager.
2. Start Installation Manager in wizard mode by using **IBMIM**.
The default **IBMIM** location will vary depending on the operating system and installation type (administrator, nonadministrator, or group). For more information, see [Getting started with Installation Manager](#).
3. In Installation Manager, click Uninstall.
4. In the Uninstall wizard, select the IBM SPSS Modeler Server Adapter package.
5. Click Next.
6. On the Summary page, review your selections. Click Back to change your selections. If you are satisfied with your choices, click Uninstall.
On Windows, Installation Manager checks for running processes. If processes are blocking the uninstall process, a list of these processes is shown in the Blocking Processes section. You must stop these processes before you continue the uninstall process. Click Stop All Blocking Processes. If there are no processes that must be stopped, you do not see this list. The running processes lock files that must be accessed or modified by Installation Manager.
7. When the uninstallation process finishes, the Complete page opens and confirms the uninstallation process.

Uninstalling by using console mode

You can use IBM Installation Manager in console mode to uninstall IBM SPSS Modeler Server Adapter.

Before you begin

You must log in with a user account that has the same privileges as the account that was used to install the packages.

About this task

A selected option is indicated by an **x** in brackets: **[x]**. Options that are not selected are indicated by empty brackets: **[]**. You can press Enter to select the default entry or select a different command. For example, **[N]** indicates that the default selection is N for the **Next** command.

Procedure

To uninstall IBM SPSS Modeler Server Adapter:

1. Close programs that you installed with Installation Manager.
2. Start Installation Manager in console mode by using **imcl -c**.
The default **imcl** location will vary depending on the operating system and installation type (administrator, nonadministrator, or group). For more information, see [Getting started with Installation Manager](#).
3. Enter 5: Uninstall - Remove the installed software packages.
4. To select the IBM SPSS Modeler Server Adapter package group, enter the number that is next to the package group.
5. Enter **N**: Next to continue.
6. To select the package, enter the number that is next to the package.
Optional: To select all packages to uninstall, enter **A**: Select all packages. The **A**: Unselect all packages option shows when all packages are selected for uninstall.

7. In the Summary panel, review your selections before you uninstall. Enter **U**: Uninstall.
 8. When the uninstall process completes, enter **F**: Finish.
-

About IBM SPSS Modeler

IBM® SPSS® Modeler is a set of data mining tools that enable you to quickly develop predictive models using business expertise and deploy them into business operations to improve decision making. Designed around the industry-standard CRISP-DM model, IBM SPSS Modeler supports the entire data mining process, from data to better business results.

IBM SPSS Modeler offers a variety of modeling methods taken from machine learning, artificial intelligence, and statistics. The methods available on the Modeling palette allow you to derive new information from your data and to develop predictive models. Each method has certain strengths and is best suited for particular types of problems.

SPSS Modeler can be purchased as a standalone product, or used as a client in combination with SPSS Modeler Server. A number of additional options are also available, as summarized in the following sections. For more information, see
<https://www.ibm.com/analytics/us/en/technology/spss/>.

IBM SPSS Modeler Products

The IBM® SPSS® Modeler family of products and associated software comprises the following.

- IBM SPSS Modeler
 - IBM SPSS Modeler Server
 - IBM SPSS Modeler Administration Console (included with IBM SPSS Deployment Manager)
 - IBM SPSS Modeler Batch
 - IBM SPSS Modeler Solution Publisher
 - IBM SPSS Modeler Server adapters for IBM SPSS Collaboration and Deployment Services
-
- [IBM SPSS Modeler](#)
 - [IBM SPSS Modeler Server](#)
 - [IBM SPSS Modeler Administration Console](#)
 - [IBM SPSS Modeler Batch](#)
 - [IBM SPSS Modeler Solution Publisher](#)
 - [IBM SPSS Modeler Server Adapters for IBM SPSS Collaboration and Deployment Services](#)
-

IBM SPSS Modeler

SPSS® Modeler is a functionally complete version of the product that you install and run on your personal computer. You can run SPSS Modeler in local mode as a standalone product, or use it in distributed mode along with IBM® SPSS Modeler Server for improved performance on large data sets.

With SPSS Modeler, you can build accurate predictive models quickly and intuitively, without programming. Using the unique visual interface, you can easily visualize the data mining process. With the support of the advanced analytics embedded in the product, you can discover previously hidden patterns and trends in your data. You can model outcomes and understand the factors that influence them, enabling you to take advantage of business opportunities and mitigate risks.

SPSS Modeler is available in two editions: SPSS Modeler Professional and SPSS Modeler Premium. See the topic [IBM SPSS Modeler Editions](#) for more information.

IBM SPSS Modeler Server

SPSS® Modeler uses a client/server architecture to distribute requests for resource-intensive operations to powerful server software, resulting in faster performance on larger data sets.

SPSS Modeler Server is a separately-licensed product that runs continually in distributed analysis mode on a server host in conjunction with one or more IBM® SPSS Modeler installations. In this way, SPSS Modeler Server provides superior performance on large data sets because memory-intensive operations can be done on the server without downloading data to the client computer. IBM SPSS Modeler Server also provides support for SQL optimization and in-database modeling capabilities, delivering further benefits in performance and automation.

Related information

-

IBM SPSS Modeler Administration Console

The Modeler Administration Console is a graphical user interface for managing many of the SPSS® Modeler Server configuration options, which are also configurable by means of an options file. The console is included in IBM® SPSS Deployment Manager, can be used to monitor and configure your SPSS Modeler Server installations, and is available free-of-charge to current SPSS Modeler Server customers. The application can be installed only on Windows computers; however, it can administer a server installed on any supported platform.

IBM® SPSS Modeler Batch

While data mining is usually an interactive process, it is also possible to run SPSS® Modeler from a command line, without the need for the graphical user interface. For example, you might have long-running or repetitive tasks that you want to perform with no user intervention. SPSS Modeler Batch is a special version of the product that provides support for the complete analytical capabilities of SPSS Modeler without access to the regular user interface. SPSS Modeler Server is required to use SPSS Modeler Batch.

IBM SPSS Modeler Solution Publisher

SPSS® Modeler Solution Publisher is a tool that enables you to create a packaged version of an SPSS Modeler stream that can be run by an external runtime engine or embedded in an external application. In this way, you can publish and deploy complete SPSS Modeler streams for use in environments that do not have SPSS Modeler installed. SPSS Modeler Solution Publisher is distributed as part of the IBM® SPSS Collaboration and Deployment Services - Scoring service, for which a separate license is required. With this license, you receive SPSS Modeler Solution Publisher Runtime, which enables you to execute the published streams.

For more information about SPSS Modeler Solution Publisher, see the IBM SPSS Collaboration and Deployment Services documentation. The IBM SPSS Collaboration and Deployment Services IBM Documentation contains sections called "IBM SPSS Modeler Solution Publisher" and "IBM SPSS Analytics Toolkit."

IBM SPSS Modeler Server Adapters for IBM SPSS Collaboration and Deployment Services

A number of adapters for IBM® SPSS® Collaboration and Deployment Services are available that enable SPSS Modeler and SPSS Modeler Server to interact with an IBM SPSS Collaboration and Deployment Services repository. In this way, an SPSS Modeler stream deployed to the repository can be shared by multiple users, or accessed from the thin-client application IBM SPSS Modeler Advantage. You install the adapter on the system that hosts the repository.

IBM SPSS Modeler Editions

SPSS® Modeler is available in the following editions.

SPSS Modeler Professional

SPSS Modeler Professional provides all the tools you need to work with most types of structured data, such as behaviors and interactions tracked in CRM systems, demographics, purchasing behavior and sales data.

SPSS Modeler Premium

SPSS Modeler Premium is a separately-licensed product that extends SPSS Modeler Professional to work with specialized data and with unstructured text data. SPSS Modeler Premium includes IBM® SPSS Modeler Text Analytics:

IBM SPSS Modeler Text Analytics uses advanced linguistic technologies and Natural Language Processing (NLP) to rapidly process a large variety of unstructured text data, extract and organize the key concepts, and group these concepts into categories. Extracted concepts and categories can be combined with existing structured data, such as demographics, and applied to modeling using the full suite of IBM SPSS Modeler data mining tools to yield better and more focused decisions.

IBM SPSS Modeler Subscription

IBM SPSS Modeler Subscription provides all the same predictive analytics capabilities as the traditional IBM SPSS Modeler client. With the Subscription edition, you can download product updates regularly.

Documentation

Documentation is available from the Help menu in SPSS® Modeler. This opens the online IBM Documentation, which is always available outside the product.

Complete documentation for each product (including installation instructions) is also available in PDF format at <https://www.ibm.com/support/pages/spss-modeler-184-documentation>.

- [SPSS Modeler Professional Documentation](#)
 - [SPSS Modeler Premium Documentation](#)
-

SPSS Modeler Professional Documentation

The SPSS® Modeler Professional documentation suite (excluding installation instructions) is as follows.

- **IBM® SPSS Modeler User's Guide.** General introduction to using SPSS Modeler, including how to build data streams, handle missing values, build CLEM expressions, work with projects and reports, and package streams for deployment to IBM SPSS Collaboration and Deployment Services or IBM SPSS Modeler Advantage.
- **IBM SPSS Modeler Source, Process, and Output Nodes.** Descriptions of all the nodes used to read, process, and output data in different formats. Effectively this means all nodes other than modeling nodes.
- **IBM SPSS Modeler Modeling Nodes.** Descriptions of all the nodes used to create data mining models. IBM SPSS Modeler offers a variety of modeling methods taken from machine learning, artificial intelligence, and statistics.
- **IBM SPSS Modeler Applications Guide.** The examples in this guide provide brief, targeted introductions to specific modeling methods and techniques. An online version of this guide is also available from the Help menu. See the topic [Application examples](#) for more information.
- **IBM SPSS Modeler Python Scripting and Automation.** Information on automating the system through Python scripting, including the properties that can be used to manipulate nodes and streams.
- **IBM SPSS Modeler Deployment Guide.** Information on running IBM SPSS Modeler streams as steps in processing jobs under IBM SPSS Deployment Manager.
- **IBM SPSS Modeler In-Database Mining Guide.** Information on how to use the power of your database to improve performance and extend the range of analytical capabilities through third-party algorithms.
- **IBM SPSS Modeler Server Administration and Performance Guide.** Information on how to configure and administer IBM SPSS Modeler Server.
- **IBM SPSS Deployment Manager User Guide.** Information on using the administration console user interface included in the Deployment Manager application for monitoring and configuring IBM SPSS Modeler Server.
- **IBM SPSS Modeler CRISP-DM Guide.** Step-by-step guide to using the CRISP-DM methodology for data mining with SPSS Modeler.
- **IBM SPSS Modeler Batch User's Guide.** Complete guide to using IBM SPSS Modeler in batch mode, including details of batch mode execution and command-line arguments. This guide is available in PDF format only.

SPSS Modeler Premium Documentation

The SPSS® Modeler Premium documentation suite (excluding installation instructions) is as follows.

- **SPSS Modeler Text Analytics User's Guide.** Information on using text analytics with SPSS Modeler, covering the text mining nodes, interactive workbench, templates, and other resources.

Application examples

While the data mining tools in SPSS® Modeler can help solve a wide variety of business and organizational problems, the application examples provide brief, targeted introductions to specific modeling methods and techniques. The data sets used here are much smaller than the enormous data stores managed by some data miners, but the concepts and methods that are involved are scalable to real-world applications.

To access the examples, click Application Examples on the Help menu in SPSS Modeler.

The data files and sample streams are installed in the Demos folder under the product installation directory. For more information, see [Demos Folder](#).

A PDF version of the Applications Guide is also available. For more information, see [Documentation](#).

Demos Folder

The data files and sample streams that are used with the application examples are installed in the Demos folder under the product installation directory (for example: C:\Program Files\IBM\SPSS\Modeler\<version>\Demos). This folder can also be accessed from the IBM SPSS® Modeler program group on the Windows Start menu, or by clicking Demos on the list of recent directories in the File...Open Stream dialog box.

License tracking

When you use SPSS® Modeler, license usage is tracked and logged at regular intervals. The license metrics that are logged are *AUTHORIZED_USER* and *CONCURRENT_USER*, and the type of metric that is logged depends on the type of license that you have for SPSS Modeler.

The log files that are produced can be processed by the IBM License Metric Tool, from which you can generate license usage reports.

The license log files are created in the same directory where SPSS Modeler Client log files are recorded (by default, %ALLUSERSPROFILE%/IBM/SPSS/Modeler/<version>/log).

What's new in version 18.4.0?

IBM® SPSS® Modeler adds the following features and enhancements in this release.

- Text Analytics flows created in Cloud Pak for Data can now be exported from Cloud Pak for Data (in JSON template format) and imported to a IBM SPSS Modeler stream.
- You can now switch Python environments via the SPSS Modeler user interface. For details, see [Switching to a different Python environment](#).
- SPSS Modeler now provides enhanced password encryption. Due to a backward compatibility issue, note the following:
 - If you run SPSS Modeler Server using a private password file to authenticate users against a private password database, you must use the **pwutil** executable to recreate the database in 18.4. For instructions, see [Configuring a private password database](#).
 - If you use an encrypted password (via the Encode Password option on the Tools menu), you must recreate it in version 18.4. For more information, see [Generating an encoded password](#).
- A new menu item is available for managing your SPSS Modeler Server connections: Tools...Manage Modeler Server Configuration. The available settings are similar to those found in the SPSS Modeler Server Configuration section of the Modeler Administration Console included with SPSS Collaboration and Deployment Services Deployment Manager. For details about the settings, see [SPSS Modeler Server Configuration](#).
- Empty passwords are no longer supported for Cognos TM1 Server connections.
- Windows 11 is now supported.
- MacOS Monterey (also known as MacOS 12) is now supported.
- Java 11 is now supported.
- CPLEX 22.1 is now supported.
- InstallAnywhere 2021 sp2 is now supported.
- SPSS Data Access Pack 8.1.1 is now supported
- Netezza Performance Server 11.x is now supported.
- Cognos Analytics Connector 11.1.7 is now supported.

- Amazon S3 is now supported through Athena (for reading data, only).
 - ClickHouse database version 22.3 is now supported with the following limitations:
 - SQL pushback isn't supported for the Merge function in the database export node (due to weak support by ClickHouse for update, delete, etc.)
 - SQL pushback isn't supported for the *time* type (due to there being no time type in ClickHouse)
 - The *date* baseline is 1970-01-01
-

Lists and geospatial data

The ability to process lists and geospatial data was added in IBM® SPSS® Modeler 17. This topic lists some of the areas where you can find further information about lists and geospatial data.

Lists

- For information about the list storage type and list depths, see [List storage and associated measurement levels](#).
- For information about creating a list from the Derive node, see [Deriving a list or geospatial field](#).
- For information about creating a list from the Merge node by merging geospatial data, see [Specifying Ranked Conditions for a Merge](#).
- For information about list values, see [Setting derived list values](#).
- For information about list icons, see [Setting Field Storage and Formatting](#).
- For information about the collection measurement level, see [Specifying Values for Collection Data](#).
- For information about one of the modeling nodes that can process non-geospatial list data, see [Association Rules node](#).

Geospatial data

- For information about importing geospatial data from a `.shp` file or a map service, see [Geospatial Source Node](#).
- For information about importing geospatial data as a flat file, see [Importing geospatial data into the Variable File Node](#).
- For information about creating a geospatial field from the Derive node, see [Deriving a list or geospatial field](#).
- For information about setting a default coordinate system for geospatial data, see [Setting geospatial options for streams](#).
- For information about changing the coordinate system for imported geospatial data, see [Reprojection Node](#).
- For information about the geospatial measurement level, see [Specifying values for geospatial data](#).
- For information about the geospatial measurement sublevels and associated restrictions, see [Geospatial measurement sublevels](#).
- For information about merging geospatial data, see [Specifying Ranked Conditions for a Merge](#).
- For an example of list depths in geospatial data, see [List storage and associated measurement levels](#).
- For a list of the geospatial functions that you can use in the Expression Builder, see [Spatial functions](#).
- For information about one of the modeling nodes that can process geospatial data, see [Spatio-Temporal Prediction modeling node](#).

Getting started

Welcome to IBM® SPSS® Modeler, a member of the modeling family of products from IBM Corp. In case you're wondering where to start, here are some suggestions.

You can...

- Try [building a stream](#).
- See [what's new in this release](#).
- Visit the IBM SPSS Modeler section of the IBM Analytics web site at <https://www.ibm.com/analytics/us/en/technology/spss/>.
- Visit the corporate Support site at <http://www.ibm.com/support>, choosing Information Management as the support type.

There's also an interactive tutorial for IBM SPSS Modeler. On the main menu, click:

Help>Application Examples

You can also learn about...

Data Mining and Modeling

Data mining is the process of digging down into your business data to discover hidden patterns and relationships. Data mining solves a common problem: the more data you have, the more difficult and time-consuming it is to analyze and draw meaning from the data effectively. What should be a gold mine often lies unexplored, owing to a lack of personnel, time, or expertise.

Data mining uses a clear business procedure and powerful analytic technologies to quickly and thoroughly explore mountains of data, pulling out and presenting you with the valuable, usable information - the business intelligence - that you need.

While those previously unknown patterns and relationships in your data are interesting in themselves, that's not the end of the story. What if you could use those patterns of past behavior to predict what might happen in the future? That's where modeling comes in - a **model** is the set of rules, formulas or equations extracted from your source data and enabling you to generate predictions against that. This is the heart of predictive analytics.

About Predictive Analytics

Predictive analytics is a business process and a set of related technologies that helps to link up your data with effective action by drawing reliable conclusions about current conditions and future events. It is a combination of:

- Advanced analytics
- Decision optimization

Advanced analytics uses a number of tools and techniques to analyze past and present events and predict future outcomes. **Decision optimization** determines which actions on your part will produce the best possible outcomes, ensuring that those recommended actions are delivered to where they can most effectively be incorporated into your business processes.

Modeling Techniques

Modeling techniques are based around the use of algorithms - sequences of instructions for solving specific problems. You use a particular algorithm to create that type of model. There are three main classes of modeling technique, and IBM® SPSS® Modeler provides several examples of each:

- Supervised
- Association
- Segmentation (sometimes known as "clustering")

Supervised models use the values of one or more **input** fields to predict the value of one or more output, or **target**, fields. Some examples of these techniques are: decision trees (C&R Tree, QUEST, CHAID and C5.0 algorithms), regression (linear, logistic, generalized linear, and Cox

regression algorithms), neural networks, support vector machines, and Bayesian networks.

Association models find patterns in your data where one or more entities (such as events, purchases, or attributes) are associated with one or more other entities. The models construct rule sets that define these relationships. Here the fields within the data can act as both inputs and targets. You could find these associations manually, but association rule algorithms do so much more quickly, and can explore more complex patterns. Apriori and Carma models are examples of the use of such algorithms. One other type of association model is a sequence detection model, which finds sequential patterns in time-structured data.

Segmentation models divide the data into segments, or clusters, of records that have similar patterns of input fields. As they are only interested in the input fields, segmentation models have no concept of output or target fields. Examples of segmentation models are Kohonen networks, K-Means clustering, two-step clustering and anomaly detection.

How Do I Know Which Technique To Use?

With such a wide variety of techniques at your disposal, it can be difficult to know where to start to solve your particular problem. Fortunately, IBM® SPSS® Modeler can make some of these decisions for you, in the form of **automated modeling**. This is a very powerful technique that estimates and compares a number of different modeling methods, ranking them in order of effectiveness. In this way you can try out a variety of approaches in a single modeling run.

As you become more familiar with the various techniques, you will learn which algorithms, and which options within those algorithms, are the most suitable for your particular problems.

How IBM SPSS Modeler Can Help You

IBM® SPSS® Modeler is a data mining, modeling and reporting tool. It gives you a unique graphical interface that enables you quickly and easily to uncover patterns and trends in your data. You can then use the statistical algorithms built into the product's advanced analytics to create data models that predict future outcomes from your current and historical data.

Where You Can Use IBM SPSS Modeler

You can use IBM® SPSS® Modeler to solve a huge variety of business problems. If you have a problem that involves data, the chances are that IBM SPSS Modeler can provide a solution. Here are just a few examples of industries and applications where IBM SPSS Modeler can make a difference.

Education. A community college wants to gain a deep understanding of student enrollment patterns and tendencies in order to improve student retention. By predicting which students are less likely to return to school, faculty and management can directly or indirectly intervene with academic counseling, financial aid packages, and curriculum offerings.

Financial. By analyzing its customer information, a mortgage lender estimates which customers are likely to move to another provider at the end of their discounted or fixed-rate period, which customers will switch to a new rate, and which ones will revert to the standard rate.

Crime detection. A local law enforcement agency analyzes a file of crime reports looking for patterns in the data. They segment the data to find clusters of crimes with similar times, locations and methods, and which therefore may have been committed by the same offender.

Non-profit organization. Taking as input a list of past donors and the amount of their donations, a charity calculates the probability of a positive response to a direct mail campaign. Using the list of likely positive responders, the charity then predicts the donation amount, calculates the probably return on the campaign, and constructs a mailing list of potential donors.

Manufacturing. An industrial manufacturing company monitors the operating condition of various pieces of machinery in order to predict possible breakdowns before they occur.

Medical. A pharmaceutical company wants to know which of several possible treatments is likely to be the most effective for a set of patients who suffer from the same disease. By analyzing which drugs show a better response rate for particular symptoms, the company builds a model that predicts which medication is best suited for a particular type of patient.

Retail. By analyzing electronic point-of-sale data from its tills, a supermarket can discover which customers with loyalty cards typically buy which combinations of products. Using the results of this market basket analysis, the retailer can target customers more accurately for promotions, improve response rates from mailshots, or adjust stock ranges for specific types of demographic populations in different branches.

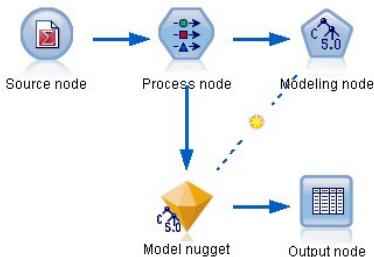

Telecommunications. As part of its efforts to reduce customer churn (loss of business), a telecommunications company is interested in modeling the "time to churn" in order to determine the factors that are associated with customers who are quick to switch to another service. To this end, a random sample of customers is selected and various data about them are pulled from the database and analyzed. The company then

models the time to churn, plotting the expected number of customers retained over the next two years, and identifying the individual customers most likely to churn in the next year.

Some of these stories, together with a number of others, are available as fully worked examples in the *IBM SPSS Modeler Applications Guide*.

How IBM SPSS Modeler works

Figure 1. Nodes in a stream

The unique graphical interface in IBM® SPSS® Modeler is based around nodes and streams. Nodes are the icons or shapes that represent individual operations on your data. The nodes are linked together in a stream to represent the flow of data through each operation.

Algorithms are represented by a special type of node known as a modeling node. There is a different modeling node for each algorithm that IBM SPSS Modeler supplies. Modeling nodes are shown as a five-sided shape.

Other types of nodes include source nodes, process nodes, and output nodes. Source nodes are the ones that bring the data into the stream, and always appear at the beginning of the stream. Process nodes perform operations on individual data records and fields, and are usually found in the middle of the stream. Output nodes produce a variety of output for data, charts and model results, or they enable you to export the results to another application, such as a database or a spreadsheet. Output nodes usually appear as the last node in a stream or a branch of a stream.

When you run a stream that contains a modeling node, the resulting model is added to stream, and is represented by a special type of node known as a model nugget--it has a shape that looks just like a gold nugget.

How to Use IBM SPSS Modeler

You can use IBM® SPSS® Modeler for ad-hoc analysis on your data to discover previous hidden patterns or trends. However, to get real value from this powerful piece of software, you need a more careful, methodical approach.

A simple, structured approach might go something like this:

- Understand your business and what you are trying to achieve with data mining
- Examine and understand your data
- Prepare the data for analysis and modeling
- Build predictive models
- Evaluate the models to verify that they are correct
- Deploy the models into your organization

This sequence is actually the basis for a more in-depth structured approach to data mining known as CRISP-DM, which stands for Cross-Industry Standard Process for Data Mining. IBM SPSS Modeler is specifically designed to work hand-in-hand with this approach.

For more information, on the main menu click:

Help > CRISP-DM Help

Starting IBM® SPSS® Modeler

To start the application, click:

Start > [All] Programs > IBM SPSS Modeler <version> > IBM SPSS Modeler <version>

The main window is displayed after a few seconds.

- [Launching from the Command Line](#)

- [Connecting to IBM SPSS Modeler Server](#)
- [Connecting to Analytic Server](#)
- [Changing the temp directory](#)
- [Starting Multiple IBM SPSS Modeler Sessions](#)

Launching from the Command Line

You can use the command line of your operating system to launch IBM® SPSS® Modeler as follows:

1. On a computer where IBM SPSS Modeler is installed, open a DOS, or command-prompt, window.
2. To launch the IBM SPSS Modeler interface in interactive mode, type the `modelerclient` command followed by the required arguments; for example:

```
modelerclient -stream report.str -execute
```

The available arguments (flags) allow you to connect to a server, load streams, run scripts, or specify other parameters as needed.

Connecting to IBM SPSS Modeler Server

IBM® SPSS® Modeler can be run as a standalone application, or as a client connected to IBM SPSS Modeler Server directly or to an IBM SPSS Modeler Server or server cluster through the Coordinator of Processes plug-in from IBM SPSS Collaboration and Deployment Services. The current connection status is displayed at the bottom left of the IBM SPSS Modeler window.

Whenever you want to connect to a server, you can manually enter the server name to which you want to connect or select a name that you have previously defined. However, if you have IBM SPSS Collaboration and Deployment Services, you can search through a list of servers or server clusters from the Server Login dialog box. The ability to browse through the Statistics services running on a network is made available through the Coordinator of Processes.

To Connect to a Server

1. On the Tools menu, click Server Login. The Server Login dialog box opens. Alternatively, double-click the connection status area of the IBM SPSS Modeler window.
2. Using the dialog box, specify options to connect to the local server computer or select a connection from the table.
 - Click Add or Edit to add or edit a connection. See the topic [Adding and Editing the IBM SPSS Modeler Server Connection](#) for more information.
 - Click Search to access a server or server cluster in the Coordinator of Processes. See the topic [Searching for Servers in IBM SPSS Collaboration and Deployment Services](#) for more information.

Server table. This table contains the set of defined server connections. The table displays the default connection, server name, description, and port number. You can manually add a new connection, as well as select or search for an existing connection. To set a particular server as the default connection, select the check box in the Default column in the table for the connection.

Default data path. Specify a path used for data on the server computer. Click the ellipsis button (...) to browse to the required location.

Set Credentials. Leave this box unchecked to enable the **single sign-on** feature, which attempts to log you in to the server using your local computer username and password details. If single sign-on is not possible, or if you check this box to disable single sign-on (for example, to log in to an administrator account), the following fields are enabled for you to enter your credentials.

User ID. Enter the user name with which to log on to the server.

Password. Enter the password associated with the specified user name.

Domain. Specify the domain used to log on to the server. A domain name is required only when the server computer is in a different Windows domain than the client computer.

3. Click OK to complete the connection.

To Disconnect from a Server

1. On the Tools menu, click Server Login. The Server Login dialog box opens. Alternatively, double-click the connection status area of the IBM SPSS Modeler window.
2. In the dialog box, select the Local Server and click OK.
 - [Adding and Editing the IBM SPSS Modeler Server Connection](#)
 - [Searching for Servers in IBM SPSS Collaboration and Deployment Services](#)
 - [Configuring single sign-on](#)
 - [Adding and Editing the IBM SPSS Modeler Server Connection](#)
 - [Searching for Servers in IBM SPSS Collaboration and Deployment Services](#)

Related information

- [Starting IBM SPSS Modeler](#)
-

Adding and Editing the IBM SPSS Modeler Server Connection

You can manually edit or add a server connection in the Server Login dialog box. By clicking Add, you can access an empty Add/Edit Server dialog box in which you can enter server connection details. By selecting an existing connection and clicking Edit in the Server Login dialog box, the Add/Edit Server dialog box opens with the details for that connection so that you can make any changes.

Note: You cannot edit a server connection that was added from IBM® SPSS® Collaboration and Deployment Services, since the name, port, and other details are defined in IBM SPSS Collaboration and Deployment Services. Best practice dictates that the same ports should be used to communicate with both IBM SPSS Collaboration and Deployment Services and SPSS Modeler Client. These can be set as `max_server_port` and `min_server_port` in the options.cfg file.

To Add Server Connections

1. On the Tools menu, click Server Login. The Server Login dialog box opens.
 2. In this dialog box, click Add. The Server Login Add/Edit Server dialog box opens.
 3. Enter the server connection details and click OK to save the connection and return to the Server Login dialog box.
- **Server.** Specify an available server or select one from the list. The server computer can be identified by an alphanumeric name (for example, *myserver*) or an IP address assigned to the server computer (for example, 202.123.456.78).
 - **Port.** Give the port number on which the server is listening. If the default does not work, ask your system administrator for the correct port number.
 - **Description.** Enter an optional description for this server connection.
 - **Ensure secure connection (use SSL).** Specifies whether an SSL (**Secure Sockets Layer**) connection should be used. SSL is a commonly used protocol for securing data sent over a network. To use this feature, SSL must be enabled on the server hosting IBM SPSS Modeler Server. If necessary, contact your local administrator for details.

To Edit Server Connections

1. On the Tools menu, click Server Login. The Server Login dialog box opens.
2. In this dialog box, select the connection you want to edit and then click Edit. The Server Login Add/Edit Server dialog box opens.
3. Change the server connection details and click OK to save the changes and return to the Server Login dialog box.

Related information

-

Searching for Servers in IBM SPSS Collaboration and Deployment Services

Instead of entering a server connection manually, you can select a server or server cluster available on the network through the Coordinator of Processes, available in IBM® SPSS® Collaboration and Deployment Services. A server cluster is a group of servers from which the Coordinator of Processes determines the server best suited to respond to a processing request.

Although you can manually add servers in the Server Login dialog box, searching for available servers lets you connect to servers without requiring that you know the correct server name and port number. This information is automatically provided. However, you still need the correct logon information, such as username, domain, and password.

Note: If you do not have access to the Coordinator of Processes capability, you can still manually enter the server name to which you want to connect or select a name that you have previously defined. See the topic [Adding and Editing the IBM SPSS Modeler Server Connection](#) for more information.

To search for servers and clusters

1. On the Tools menu, click Server Login. The Server Login dialog box opens.
2. In this dialog box, click Search to open the Search for Servers dialog box. If you are not logged on to IBM SPSS Collaboration and Deployment Services when you attempt to browse the Coordinator of Processes, you will be prompted to do so.
3. Select the server or server cluster from the list.
4. Click OK to close the dialog box and add this connection to the table in the Server Login dialog box.

Related information

-

Connecting to Analytic Server

If you have multiple Analytic Servers available, you can use the Analytic Server Connection dialog to define more than one server for use in IBM® SPSS® Modeler. Your administrator may have already set up a default Analytic Server in the <Modeler_install_path>/config/options.cfg file. But you can also use other available servers after defining them. For example, when using the Analytic Server Source and Export nodes, you may want to use different Analytic Server connections in different branches of a stream so that when each branch runs it uses its own Analytic Server and no data will be pulled to the IBM SPSS Modeler Server. Note that if a branch contains more than one Analytic Server connection, the data will be pulled from the Analytic Servers to the IBM SPSS Modeler Server.

To create a new Analytic Server connection, go to Tools > Analytic Server Connections and provide the required information in the following sections of the dialog.

Connection

URL. Type the URL for the Analytic Server in the format `https://hostname:port/contextroot`, where `hostname` is the IP address or host name of the Analytic Server, `port` is its port number, and `contextroot` is the context root of the Analytic Server.

Tenant. Type the name of the tenant that the IBM SPSS Modeler Server is a member of. Contact your administrator if you don't know the tenant.

Authentication

Mode. Select from the following authentication modes.

- Username and password requires you to enter the username and password.
- Stored credential requires you to select a credential from the IBM SPSS Collaboration and Deployment Services Repository.
- Kerberos requires you to enter the service principal name and the config file path. Contact your administrator if you don't know this information.

Username. Type the Analytic Server username.

Reams. Select the realm to use for the Analytic Server connection.

Password. Type the Analytic Server password.

Connect. Click Connect to test the new connection.

Connections

After specifying the information above and clicking Connect, the connection will be added to this Connections table. If you need to remove a connection, select it and click Remove.

If your administrator defined a default Analytic Server connection in the options.cfg file, you can click Add default connection to add it to your available connections also. You will be prompted for the username and password.

For information about setting up a default connection in options.cfg, see [Options visible in options.cfg](#).

Changing the temp directory

Some operations that are done by IBM® SPSS® Modeler Server might require temporary files to be created. By default, IBM SPSS Modeler uses the system temporary directory to create temp files. You can alter the location of the temporary directory using the following steps.

1. Create a new directory called spss and subdirectory called servertemp.
2. Edit options.cfg, located in the /config directory of your IBM SPSS Modeler installation directory. Edit the `temp_directory` parameter in this file to read: `temp_directory, "C:/spss/servertemp"`.
3. Restart the IBM SPSS Modeler Server service. You can do this by clicking the Services tab on your Windows Control Panel. Stop the service and then start it to activate the changes you made. Restarting the machine also restarts the service.

All temp files now get written to this new directory.

Note: Forward slashes must be used.

Temp directory for data view

For data view service, complete the following steps to configure the temporary directory.

1. Create the temp directory D:/SPSSTemp.
2. The data view temp files are controlled by `-Djava.io.tmpdir=D:/SPSSTemp`. Add this option to the start script for data view in the following file: \${ModelerInstallDir}/dataview/start_graph_micro_service.sh.
3. Start the IBM SPSS Modeler.

Files now get written to D:/SPSSTemp.

Starting Multiple IBM SPSS Modeler Sessions

If you need to launch more than one IBM® SPSS® Modeler session at a time, you must make some changes to your IBM SPSS Modeler and Windows settings. For example, you may need to do this if you have two separate server licenses and want to run two streams against two different servers from the same client machine.

To enable multiple IBM SPSS Modeler sessions:

1. Click:
`Start > [All] Programs > IBM SPSS Modeler`
2. On the IBM SPSS Modeler shortcut (the one with the icon), right-click and select Properties.
3. In the Target text box, add `-noshare` to the end of the string.
4. In Windows Explorer, select:
`Tools > Folder Options...`
5. On the File Types tab, select the IBM SPSS Modeler Stream option and click Advanced.
6. In the Edit File Type dialog box, select Open with IBM SPSS Modeler and click Edit.
7. In the Application used to perform action text box, add `-noshare` before the `-stream` argument.

IBM SPSS Modeler Interface at a Glance

At each point in the data mining process, the easy-to-use IBM® SPSS® Modeler interface invites your specific business expertise. Modeling algorithms, such as prediction, classification, segmentation, and association detection, ensure powerful and accurate models. Model results can easily be deployed and read into databases, IBM SPSS Statistics, and a wide variety of other applications.

Working with IBM SPSS Modeler is a three-step process of working with data.

- First, you read data into IBM SPSS Modeler.
- Next, you run the data through a series of manipulations.
- Finally, you send the data to a destination.

This sequence of operations is known as a **data stream** because the data flows record by record from the source through each manipulation and, finally, to the destination--either a model or type of data output.

IBM SPSS Modeler Stream Canvas

The stream canvas is the largest area of the IBM® SPSS® Modeler window and is where you will build and manipulate data streams.

Streams are created by drawing diagrams of data operations relevant to your business on the main canvas in the interface. Each operation is represented by an icon or **node**, and the nodes are linked together in a **stream** representing the flow of data through each operation.

You can work with multiple streams at one time in IBM SPSS Modeler, either in the same stream canvas or by opening a new stream canvas. During a session, streams are stored in the Streams manager, at the upper right of the IBM SPSS Modeler window.

Note: If using a MacBook with the built-in trackpad's Force Click and haptic feedback setting enabled, dragging and dropping nodes from the nodes palette to the stream canvas can result in duplicate nodes being added to the canvas. To avoid this issue, we recommend disabling the Force Click and haptic feedback trackpad system preference.

Nodes palette

Most of the data and modeling tools in SPSS® Modeler are available from the *Nodes Palette*, across the bottom of the window below the stream canvas.

For example, the Record Ops palette tab contains nodes that you can use to perform operations on the data *records*, such as selecting, merging, and appending.

To add nodes to the canvas, double-click icons from the Nodes Palette or drag them onto the canvas. You then connect them to create a *stream*, representing the flow of data.

Figure 1. Record Ops tab on the nodes palette

Each palette tab contains a collection of related nodes used for different phases of stream operations, such as:

- Sources nodes bring data into SPSS Modeler.
- Record Ops nodes perform operations on data *records*, such as selecting, merging, and appending.
- Field Ops nodes perform operations on data *fields*, such as filtering, deriving new fields, and determining the measurement level for given fields.
- Graphs nodes graphically display data before and after modeling. Graphs include plots, histograms, web nodes, and evaluation charts.
- Modeling nodes use the modeling algorithms available in SPSS Modeler, such as neural nets, decision trees, clustering algorithms, and data sequencing.
- Database Modeling nodes use the modeling algorithms available in Microsoft SQL Server, IBM Db2, and Oracle and Netezza databases.
- Output nodes produce various output for data, charts, and model results that can be viewed in SPSS Modeler.
- Export nodes produce various output that can be viewed in external applications, such as IBM® SPSS Data Collection or Excel.
- **IBM SPSS Statistics** nodes import data from, or export data to, IBM SPSS Statistics, as well as running IBM SPSS Statistics procedures.
- Python nodes can be used to run Python algorithms.
- Spark nodes can be used to run Spark algorithms.

As you become more familiar with SPSS Modeler, you can customize the palette contents for your own use. For more information, see [Customizing the Nodes Palette](#).

On the left side of the Nodes Palette, you can filter the nodes that display by selecting Supervised, Association, or Segmentation. For more information, see [Overview of modeling nodes](#).

Located below the Nodes Palette, a report pane provides feedback on the progress of various operations, such as when data is being read into the data stream. Also located below the Nodes Palette, a status pane provides information on what the application is currently doing, as well as indications of when user feedback is required.

Note: If using a MacBook with the built-in trackpad's Force Click and haptic feedback setting enabled, dragging and dropping nodes from the nodes palette to the stream canvas can result in duplicate nodes being added to the canvas. To avoid this issue, we recommend disabling the Force Click and haptic feedback trackpad system preference.

IBM SPSS Modeler Managers

At the top right of the window is the managers pane. This has three tabs, which are used to manage streams, output and models.

You can use the Streams tab to open, rename, save, and delete the streams created in a session.

The Outputs tab contains a variety of files, such as graphs and tables, produced by stream operations in IBM® SPSS® Modeler. You can display, save, rename, and close the tables, graphs, and reports listed on this tab.

The Models tab is the most powerful of the manager tabs. This tab contains all model **nuggets**, which contain the models generated in IBM SPSS Modeler, for the current session. These models can be browsed directly from the Models tab or added to the stream in the canvas.

IBM SPSS Modeler Projects

On the lower right side of the window is the project pane, used to create and manage data mining **projects** (groups of files related to a data mining task). There are two ways to view projects you create in IBM® SPSS® Modeler—in the Classes view and the CRISP-DM view.

The CRISP-DM tab provides a way to organize projects according to the Cross-Industry Standard Process for Data Mining, an industry-proven, nonproprietary methodology. For both experienced and first-time data miners, using the CRISP-DM tool will help you to better organize and communicate your efforts.

The Classes tab provides a way to organize your work in IBM SPSS Modeler categorically—by the types of objects you create. This view is useful when taking inventory of data, streams, and models.

IBM SPSS Modeler Toolbar

At the top of the IBM® SPSS® Modeler window, you will find a toolbar of icons that provides a number of useful functions. Following are the toolbar buttons and their functions.

	Create new stream		Open stream
	Save stream		Print current stream
	Cut & move to clipboard		Copy to clipboard
	Paste selection		Undo last action
	Redo		Search for nodes
	Edit stream properties		Preview SQL generation
	Run current stream		Run stream selection
	Stop stream (Active only while stream is running)		Add SuperNode
	Zoom in (SuperNodes only)		Zoom out (SuperNodes only)
	No markup in stream		Insert comment
	Hide stream markup (if any)		Show hidden stream markup
	Open stream in IBM SPSS Modeler Advantage		

Stream markup consists of stream comments, model links, and scoring branch indications.

Related information

- [Setting general options for streams](#)

Customizing the Toolbar

You can change various aspects of the toolbar, such as:

- Whether it is displayed
- Whether the icons have tooltips available
- Whether it uses large or small icons

To turn the toolbar display on and off:

1. On the main menu, click:
View > Toolbar > Display

To change the tooltip or icon size settings:

1. On the main menu, click:
View > Toolbar > Customize

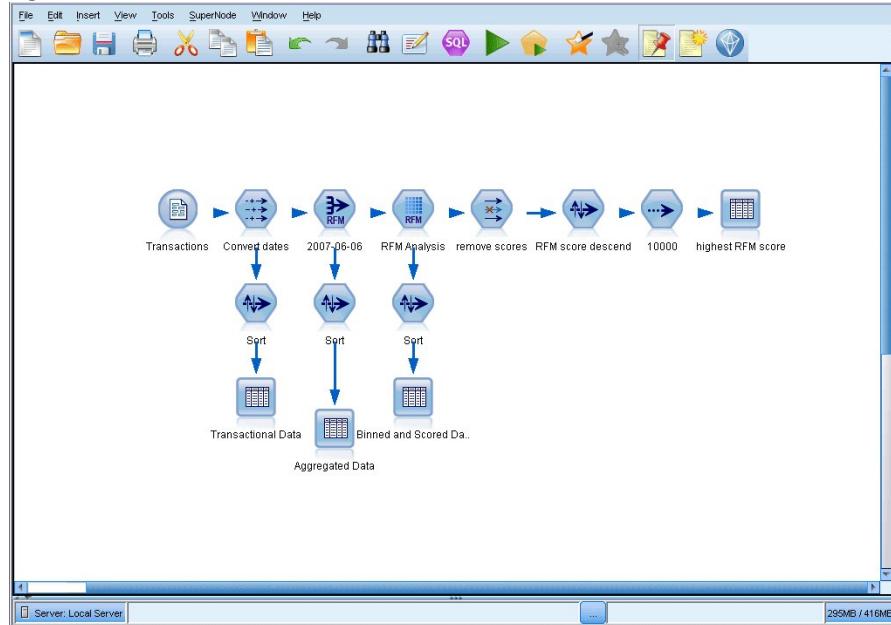

Click Show ToolTips or Large Buttons as required.

Customizing the IBM® SPSS Modeler window

Using the dividers between various portions of the SPSS® Modeler interface, you can resize or close tools to meet your preferences. For example, if you are working with a large stream, you can use the small arrows located on each divider to close the nodes palette, managers pane, and project pane. This maximizes the stream canvas, providing enough work space for large or multiple streams.

Alternatively, on the View menu, click Nodes Palette, Managers, or Project to turn the display of these items on or off.

Figure 1. Maximized stream canvas

As an alternative to closing the nodes palette, and the managers and project panes, you can use the stream canvas as a scrollable page by moving vertically and horizontally with the scrollbars at the side and bottom of the SPSS Modeler window.

You can also control the display of screen markup, which consists of stream comments, model links, and scoring branch indications. To turn this display on or off, click:

View > Stream Markup

Changing the icon size for a stream

You can change the size of the stream icons in the following ways.

- Through a stream property setting
- Through a pop-up menu in the stream
- Using the keyboard

You can scale the entire stream view to one of a number of sizes between 8% and 200% of the standard icon size.

To scale the entire stream (stream properties method)

1. From the main menu, choose Tools > Stream Properties > Options > Layout.
2. Choose the size you want from the Icon Size menu.
3. Click Apply to see the result.
4. Click OK to save the change.

To scale the entire stream (menu method)

1. Right-click the stream background on the canvas.
2. Choose Icon Size and select the size you want.

To scale the entire stream (keyboard method)

1. Press Ctrl + [-] on the main keyboard to zoom out to the next smaller size.
 2. Press Ctrl + Shift + [+] on the main keyboard to zoom in to the next larger size.
- Note that this method of zooming in may not work depending on your operating system and keyboard used.

This feature is particularly useful for gaining an overall view of a complex stream. You can also use it to minimize the number of pages needed to print a stream.

Using the Mouse in IBM SPSS Modeler

The most common uses of the mouse in IBM® SPSS® Modeler include the following:

- **Single-click.** Use either the right or left mouse button to select options from menus, open pop-up menus, and access various other standard controls and options. Click and hold the button to move and drag nodes.
- **Double-click.** Double-click using the left mouse button to place nodes on the stream canvas and edit existing nodes.
- **Middle-click.** Click the middle mouse button and drag the cursor to connect nodes on the stream canvas. Double-click the middle mouse button to disconnect a node. If you do not have a three-button mouse, you can simulate this feature by pressing the Alt key while clicking and dragging the mouse.

Related information

- [IBM SPSS Modeler Interface at a Glance](#)
- [Using shortcut keys](#)
- [Setting IBM SPSS Modeler options](#)

Using shortcut keys

Many visual programming operations in IBM® SPSS® Modeler have shortcut keys associated with them. For example, you can delete a node by clicking the node and pressing the Delete key on your keyboard. Likewise, you can quickly save a stream by pressing the S key while holding down the Ctrl key. Control commands like this one are indicated by a combination of Ctrl and another key--for example, Ctrl+S.

There are a number of shortcut keys used in standard Windows operations, such as Ctrl+X to cut. These shortcuts are supported in IBM SPSS Modeler along with the following application-specific shortcuts.

Note: In some cases, old shortcut keys used in IBM SPSS Modeler conflict with standard Windows shortcut keys. These old shortcuts are supported with the addition of the Alt key. For example, Ctrl+Alt+C can be used to toggle the cache on and off.

Table 1. Supported shortcut keys

Shortcut Key	Function
Ctrl+A	Select all
Ctrl+X	Cut

Shortcut Key	Function
Ctrl+N	New stream
Ctrl+O	Open stream
Ctrl+P	Print
Ctrl+C	Copy
Ctrl+V	Paste
Ctrl+Z	Undo
Ctrl+Q	Select all nodes downstream of the selected node
Ctrl+W	Deselect all downstream nodes (toggles with Ctrl+Q)
Ctrl+E	Run from selected node
Ctrl+S	Save current stream
Alt+Arrow keys	Move selected nodes on the stream canvas in the direction of the arrow used
Shift+F10	Open the pop-up menu for the selected node

Table 2. Supported shortcuts for old hot keys

Shortcut Key	Function
Ctrl+Alt+D	Duplicate node
Ctrl+Alt+L	Load node
Ctrl+Alt+R	Rename node
Ctrl+Alt+U	Create User Input node
Ctrl+Alt+C	Toggle cache on/off
Ctrl+Alt+F	Flush cache
Ctrl+Alt+X	Expand SuperNode
Ctrl+Alt+Z	Zoom in/zoom out
Delete	Delete node or connection

Printing

The following objects can be printed in IBM® SPSS® Modeler:

- Stream diagrams
- Graphs
- Tables
- Reports (from the Report node and Project Reports)
- Scripts (from the stream properties, Standalone Script, or SuperNode script dialog boxes)
- Models (Model browsers, dialog box tabs with current focus, tree viewers)
- Annotations (using the Annotations tab for output)

To print an object:

- To print without previewing, click the Print button on the toolbar.
- To set up the page before printing, select Page Setup from the File menu.
- To preview before printing, select Print Preview from the File menu.
- To view the standard print dialog box with options for selecting printers, and specifying appearance options, select Print from the File menu.

Automating IBM SPSS Modeler

Since advanced data mining can be a complex and sometimes lengthy process, IBM® SPSS® Modeler includes several types of coding and automation support.

- **Control Language for Expression Manipulation** (CLEM) is a language for analyzing and manipulating the data that flows along IBM SPSS Modeler streams. Data miners use CLEM extensively in stream operations to perform tasks as simple as deriving profit from cost and revenue data or as complex as transforming web log data into a set of fields and records with usable information.
- **Scripting** is a powerful tool for automating processes in the user interface. Scripts can perform the same kinds of actions that users perform with a mouse or a keyboard. You can also specify output and manipulate generated models.

Understanding data mining

- [Types of models](#)
- [Data Mining Examples](#)

Types of models

IBM® SPSS® Modeler offers a variety of modeling methods taken from machine learning, artificial intelligence, and statistics. The methods available on the Modeling palette allow you to derive new information from your data and to develop predictive models. Each method has certain strengths and is best suited for particular types of problems.

The *IBM SPSS Modeler Applications Guide* provides examples for many of these methods, along with a general introduction to the modeling process. This guide is available as an online tutorial, and also in PDF format. [More information](#).

Modeling methods are divided into these categories:

- Supervised
- Association
- Segmentation

Supervised Models

Supervised models use the values of one or more **input** fields to predict the value of one or more output, or **target**, fields. Some examples of these techniques are: decision trees (C&R Tree, QUEST, CHAID and C5.0 algorithms), regression (linear, logistic, generalized linear, and Cox regression algorithms), neural networks, support vector machines, and Bayesian networks.

Supervised models help organizations to predict a known result, such as whether a customer will buy or leave or whether a transaction fits a known pattern of fraud. Modeling techniques include machine learning, rule induction, subgroup identification, statistical methods, and multiple model generation.

Supervised nodes

	The Auto Classifier node creates and compares a number of different models for binary outcomes (yes or no, churn or do not churn, and so on), allowing you to choose the best approach for a given analysis. A number of modeling algorithms are supported, making it possible to select the methods you want to use, the specific options for each, and the criteria for comparing the results. The node generates a set of models based on the specified options and ranks the best candidates according to the criteria you specify.
	The Auto Numeric node estimates and compares models for continuous numeric range outcomes using a number of different methods. The node works in the same manner as the Auto Classifier node, allowing you to choose the algorithms to use and to experiment with multiple combinations of options in a single modeling pass. Supported algorithms include neural networks, C&R Tree, CHAID, linear regression, generalized linear regression, and support vector machines (SVM). Models can be compared based on correlation, relative error, or number of variables used.
	The Classification and Regression (C&R) Tree node generates a decision tree that allows you to predict or classify future observations. The method uses recursive partitioning to split the training records into segments by minimizing the impurity at each step, where a node in the tree is considered “pure” if 100% of cases in the node fall into a specific category of the target field. Target and input fields can be numeric ranges or categorical (nominal, ordinal, or flags); all splits are binary (only two subgroups).
	The QUEST node provides a binary classification method for building decision trees, designed to reduce the processing time required for large C&R Tree analyses while also reducing the tendency found in classification tree methods to favor inputs that allow more splits. Input fields can be numeric ranges (continuous), but the target field must be categorical. All splits are binary.
	The CHAID node generates decision trees using chi-square statistics to identify optimal splits. Unlike the C&R Tree and QUEST nodes, CHAID can generate nonbinary trees, meaning that some splits have more than two branches. Target and input fields can be numeric range (continuous) or categorical. Exhaustive CHAID is a modification of CHAID that does a more thorough job of examining all possible splits but takes longer to compute.

	The C5.0 node builds either a decision tree or a rule set. The model works by splitting the sample based on the field that provides the maximum information gain at each level. The target field must be categorical. Multiple splits into more than two subgroups are allowed.
	The Decision List node identifies subgroups, or segments, that show a higher or lower likelihood of a given binary outcome relative to the overall population. For example, you might look for customers who are unlikely to churn or are most likely to respond favorably to a campaign. You can incorporate your business knowledge into the model by adding your own custom segments and previewing alternative models side by side to compare the results. Decision List models consist of a list of rules in which each rule has a condition and an outcome. Rules are applied in order, and the first rule that matches determines the outcome.
	Linear regression models predict a continuous target based on linear relationships between the target and one or more predictors.
	The PCA/Factor node provides powerful data-reduction techniques to reduce the complexity of your data. Principal components analysis (PCA) finds linear combinations of the input fields that do the best job of capturing the variance in the entire set of fields, where the components are orthogonal (perpendicular) to each other. Factor analysis attempts to identify underlying factors that explain the pattern of correlations within a set of observed fields. For both approaches, the goal is to find a small number of derived fields that effectively summarizes the information in the original set of fields.
	The Feature Selection node screens input fields for removal based on a set of criteria (such as the percentage of missing values); it then ranks the importance of remaining inputs relative to a specified target. For example, given a data set with hundreds of potential inputs, which are most likely to be useful in modeling patient outcomes?
	Discriminant analysis makes more stringent assumptions than logistic regression but can be a valuable alternative or supplement to a logistic regression analysis when those assumptions are met.
	Logistic regression is a statistical technique for classifying records based on values of input fields. It is analogous to linear regression but takes a categorical target field instead of a numeric range.
	The Generalized Linear model expands the general linear model so that the dependent variable is linearly related to the factors and covariates through a specified link function. Moreover, the model allows for the dependent variable to have a non-normal distribution. It covers the functionality of a wide number of statistical models, including linear regression, logistic regression, loglinear models for count data, and interval-censored survival models.
	A generalized linear mixed model (GLMM) extends the linear model so that the target can have a non-normal distribution, is linearly related to the factors and covariates via a specified link function, and so that the observations can be correlated. Generalized linear mixed models cover a wide variety of models, from simple linear regression to complex multilevel models for non-normal longitudinal data.
	The Cox regression node enables you to build a survival model for time-to-event data in the presence of censored records. The model produces a survival function that predicts the probability that the event of interest has occurred at a given time (t) for given values of the input variables.
	The Support Vector Machine (SVM) node enables you to classify data into one of two groups without overfitting. SVM works well with wide data sets, such as those with a very large number of input fields.
	The Bayesian Network node enables you to build a probability model by combining observed and recorded evidence with real-world knowledge to establish the likelihood of occurrences. The node focuses on Tree Augmented Naïve Bayes (TAN) and Markov Blanket networks that are primarily used for classification.
	The Self-Learning Response Model (SLRM) node enables you to build a model in which a single new case, or small number of new cases, can be used to reestimate the model without having to retrain the model using all data.
	The Time Series node estimates exponential smoothing, univariate Autoregressive Integrated Moving Average (ARIMA), and multivariate ARIMA (or transfer function) models for time series data and produces forecasts of future performance. This Time Series node is similar to the previous Time Series node that was deprecated in SPSS Modeler version 18. However, this newer Time Series node is designed to harness the power of IBM SPSS Analytic Server to process big data, and display the resulting model in the output viewer that was added in SPSS Modeler version 17.
	The k -Nearest Neighbor (KNN) node associates a new case with the category or value of the k objects nearest to it in the predictor space, where k is an integer. Similar cases are near each other and dissimilar cases are distant from each other.
	The Spatio-Temporal Prediction (STP) node uses data that contains location data, input fields for prediction (predictors), a time field, and a target field. Each location has numerous rows in the data that represent the values of each predictor at each time of measurement. After the data is analyzed, it can be used to predict target values at any location within the shape data that is used in the analysis.

Association Models

Association models find patterns in your data where one or more entities (such as events, purchases, or attributes) are associated with one or more other entities. The models construct rule sets that define these relationships. Here the fields within the data can act as both inputs and targets. You could find these associations manually, but association rule algorithms do so much more quickly, and can explore more complex patterns. Apriori and Carma models are examples of the use of such algorithms. One other type of association model is a sequence detection model, which finds sequential patterns in time-structured data.

Association models are most useful when predicting multiple outcomes—for example, customers who bought product X also bought Y and Z. Association models associate a particular conclusion (such as the decision to buy something) with a set of conditions. The advantage of

association rule algorithms over the more standard decision tree algorithms (C5.0 and C&RT) is that associations can exist between any of the attributes. A decision tree algorithm will build rules with only a single conclusion, whereas association algorithms attempt to find many rules, each of which may have a different conclusion.

Association nodes

	The Apriori node extracts a set of rules from the data, pulling out the rules with the highest information content. Apriori offers five different methods of selecting rules and uses a sophisticated indexing scheme to process large data sets efficiently. For large problems, Apriori is generally faster to train; it has no arbitrary limit on the number of rules that can be retained, and it can handle rules with up to 32 preconditions. Apriori requires that input and output fields all be categorical but delivers better performance because it is optimized for this type of data.
	The CARMA model extracts a set of rules from the data without requiring you to specify input or target fields. In contrast to Apriori the CARMA node offers build settings for rule support (support for both antecedent and consequent) rather than just antecedent support. This means that the rules generated can be used for a wider variety of applications—for example, to find a list of products or services (antecedents) whose consequent is the item that you want to promote this holiday season.
	The Sequence node discovers association rules in sequential or time-oriented data. A sequence is a list of item sets that tends to occur in a predictable order. For example, a customer who purchases a razor and aftershave lotion may purchase shaving cream the next time he shops. The Sequence node is based on the CARMA association rules algorithm, which uses an efficient two-pass method for finding sequences.
	The Association Rules Node is similar to the Apriori Node; however, unlike Apriori, the Association Rules Node can process list data. In addition, the Association Rules Node can be used with IBM SPSS Analytic Server to process big data and take advantage of faster parallel processing.

Segmentation Models

Segmentation models divide the data into segments, or clusters, of records that have similar patterns of input fields. As they are only interested in the input fields, segmentation models have no concept of output or target fields. Examples of segmentation models are Kohonen networks, K-Means clustering, two-step clustering and anomaly detection.

Segmentation models (also known as "clustering models") are useful in cases where the specific result is unknown (for example, when identifying new patterns of fraud, or when identifying groups of interest in your customer base). Clustering models focus on identifying groups of similar records and labeling the records according to the group to which they belong. This is done without the benefit of prior knowledge about the groups and their characteristics, and it distinguishes clustering models from the other modeling techniques in that there is no predefined output or target field for the model to predict. There are no right or wrong answers for these models. Their value is determined by their ability to capture interesting groupings in the data and provide useful descriptions of those groupings. Clustering models are often used to create clusters or segments that are then used as inputs in subsequent analyses (for example, by segmenting potential customers into homogeneous subgroups).

Segmentation nodes

	The Auto Cluster node estimates and compares clustering models, which identify groups of records that have similar characteristics. The node works in the same manner as other automated modeling nodes, allowing you to experiment with multiple combinations of options in a single modeling pass. Models can be compared using basic measures with which to attempt to filter and rank the usefulness of the cluster models, and provide a measure based on the importance of particular fields.
	The K-Means node clusters the data set into distinct groups (or clusters). The method defines a fixed number of clusters, iteratively assigns records to clusters, and adjusts the cluster centers until further refinement can no longer improve the model. Instead of trying to predict an outcome, k-means uses a process known as unsupervised learning to uncover patterns in the set of input fields.
	The Kohonen node generates a type of neural network that can be used to cluster the data set into distinct groups. When the network is fully trained, records that are similar should be close together on the output map, while records that are different will be far apart. You can look at the number of observations captured by each unit in the model nugget to identify the strong units. This may give you a sense of the appropriate number of clusters.
	The TwoStep node uses a two-step clustering method. The first step makes a single pass through the data to compress the raw input data into a manageable set of subclusters. The second step uses a hierarchical clustering method to progressively merge the subclusters into larger and larger clusters. TwoStep has the advantage of automatically estimating the optimal number of clusters for the training data. It can handle mixed field types and large data sets efficiently.
	The Anomaly Detection node identifies unusual cases, or outliers, that do not conform to patterns of "normal" data. With this node, it is possible to identify outliers even if they do not fit any previously known patterns and even if you are not exactly sure what you are looking for.

In-Database Mining Models

IBM SPSS Modeler supports integration with data mining and modeling tools that are available from database vendors, including Oracle Data Miner and Microsoft Analysis Services. You can build, score, and store models inside the database—all from within the IBM SPSS Modeler application. For full details, see the *IBM SPSS Modeler In-Database Mining Guide*.

IBM SPSS Statistics Models

If you have a copy of IBM SPSS Statistics installed and licensed on your computer, you can access and run certain IBM SPSS Statistics routines from within IBM SPSS Modeler to build and score models.

Data Mining Examples

The best way to learn about data mining in practice is to start with an example. A number of application examples are available in the *IBM® SPSS® Modeler Applications Guide*, which provides brief, targeted introductions to specific modeling methods and techniques. See the topic [Application examples](#) for more information.

Building streams

- [Stream-building overview](#)
- [Building data streams](#)
- [Tips and Shortcuts](#)

Stream-building overview

Data mining using IBM® SPSS® Modeler focuses on the process of running data through a series of nodes, referred to as a **stream**. This series of nodes represents operations to be performed on the data, while links between the nodes indicate the direction of data flow. Typically, you use a data stream to read data into IBM SPSS Modeler, run it through a series of manipulations, and then send it to a destination, such as a table or a viewer.

For example, suppose that you want to open a data source, add a new field, select records based on values in the new field, and then display the results in a table. In this case, your data stream would consist of four nodes:

	A Variable File node, which you set up to read the data from the data source.
	A Derive node, which you use to add the new, calculated field to the data set.
	A Select node, which you use to set up selection criteria to exclude records from the data stream.
	A Table node, which you use to display the results of your manipulations onscreen.

Building data streams

The unique SPSS® Modeler interface lets you mine your data visually by working with diagrams of data streams. At the most basic level, you can build a data stream using the following steps:

- Add nodes to the stream canvas.
- Connect the nodes to form a stream.
- Specify any node or stream options.
- Run the stream.

This section contains more detailed information on working with nodes to create more complex data streams. It also discusses options and settings for nodes and streams. For step-by-step examples of stream building using the data shipped with SPSS Modeler (in the Demos folder of your program installation), see [Application examples](#).

Working with nodes

Nodes are used in IBM® SPSS® Modeler to help you explore data. Various nodes in the workspace represent different objects and actions. The palette at the bottom of the IBM SPSS Modeler window contains all of the possible nodes used in stream building.

There are several types of nodes. Source nodes bring data into the stream, and are located on the Sources tab of the nodes palette. Process nodes perform operations on individual data records and fields, and can be found in the Record Ops and Field Ops tabs of the palette. Output nodes produce a variety of output for data, charts and model results, and are included on the Graphs, Output and Export tabs of the nodes palette. Modeling nodes use statistical algorithms to create model nuggets, and are located on the Modeling tab, and (if activated) the Database Modeling tab, of the nodes palette. See the topic [Nodes palette](#) for more information.

You connect the nodes to form streams which, when run, let you visualize relationships and draw conclusions. Streams are like scripts--you can save them and reuse them with different data files.

A runnable node that processes stream data is known as a terminal node. A modeling or output node is a terminal node if it is located at the end of a stream or stream branch. You cannot connect further nodes to a terminal node.

Note: You can customize the Nodes palette. See the topic [Customizing the Nodes Palette](#) for more information.

Adding Nodes to a Stream

There are several ways to add nodes to a stream from the nodes palette:

- Double-click a node on the palette. *Note:* Double-clicking a node automatically connects it to the current stream. See the topic [Connecting Nodes in a Stream](#) for more information.
- Drag and drop a node from the palette to the stream canvas.
- Click a node on the palette, and then click the stream canvas.
- Select an appropriate option from the Insert menu of IBM® SPSS® Modeler.

Once you have added a node to the stream canvas, double-click the node to display its dialog box. The available options depend on the type of node that you are adding. For information about specific controls within the dialog box, click its Help button.

Removing Nodes

To remove a node from the data stream, click it and either press the Delete key, or right-click and select Delete from the menu.

Connecting Nodes in a Stream

Nodes added to the stream canvas do not form a data stream until they have been connected. Connections between the nodes indicate the direction of the data as it flows from one operation to the next. There are a number of ways to connect nodes to form a stream: double-clicking, using the middle mouse button, or manually.

To Add and Connect Nodes by Double-Clicking

The simplest way to form a stream is to double-click nodes on the palette. This method automatically connects the new node to the selected node on the stream canvas. For example, if the canvas contains a Database node, you can select this node and then double-click the next node from the palette, such as a Derive node. This action automatically connects the Derive node to the existing Database node. You can repeat this process until you have reached a terminal node, such as a Histogram or Table node, at which point any new nodes will be connected to the last non-terminal node upstream.

To Connect Nodes Using the Middle Mouse Button

On the stream canvas, you can click and drag from one node to another using the middle mouse button. (If your mouse does not have a middle button, you can simulate this by pressing the Alt key while dragging with the mouse from one node to another.)

To Manually Connect Nodes

If you do not have a middle mouse button and prefer to manually connect nodes, you can use the pop-up menu for a node to connect it to another node already on the canvas.

1. Right-click the node from which you want to start the connection. Doing so opens the node menu.
2. On the menu, click Connect.
3. A connection icon is displayed both on the start node and the cursor. Click a second node on the canvas to connect the two nodes.

When connecting nodes, there are several guidelines to follow. You will receive an error message if you attempt to make any of the following types of connections:

- A connection leading to a source node
- A connection leading from a terminal node
- A node having more than its maximum number of input connections
- Connecting two nodes that are already connected
- Circularity (data returns to a node from which it has already flowed)

Bypassing Nodes in a Stream

When you bypass a node in the data stream, all of its input and output connections are replaced by connections that lead directly from its input nodes to its output nodes. If the node does not have both input and output connections, then all of its connections are deleted rather than rerouted.

For example, you might have a stream that derives a new field, filters fields, and then explores the results in a histogram and table. If you want to also view the same graph and table for data *before* fields are filtered, you can add either new Histogram and Table nodes to the stream, or you can bypass the Filter node. When you bypass the Filter node, the connections to the graph and table pass directly from the Derive node. The Filter node is disconnected from the stream.

To Bypass a Node

1. On the stream canvas, use the middle mouse button to double-click the node that you want to bypass. Alternatively, you can use Alt+double-click.

Note: You can undo this action clicking Undo on the Edit menu or by pressing Ctrl+Z.

-

Disabling Nodes in a Stream

Process nodes with a single input within streams can be disabled, with the result that the node is ignored during running of the stream. This saves you from having to remove or bypass the node and means you can leave it connected to the remaining nodes. You can still open and edit the node settings; however, any changes will not take effect until you enable the node again.

For example, you might have a stream that filters several fields, and then builds models with the reduced data set. If you want to also build the same models *without* fields being filtered, to see if they improve the model results, you can disable the Filter node. When you disable the Filter node, the connections to the modeling nodes pass directly through from the Derive node to the Type node.

To Disable a Node

1. On the stream canvas, right-click the node that you want to disable.
2. Click Disable Node on the pop-up menu.

Alternatively, you can click Node > Disable Node on the Edit menu. When you want to include the node back in the stream, click Enable Node in the same way.

Note: You can undo this action clicking Undo on the Edit menu or by pressing Ctrl+Z.

Adding Nodes in Existing Connections

You can add a new node between two connected nodes by dragging the arrow that connects the two nodes.

1. With the middle mouse button, click and drag the connection arrow into which you want to insert the node. Alternatively, you can hold down the Alt key while clicking and dragging to simulate a middle mouse button.
2. Drag the connection to the node that you want to include and release the mouse button.

Note: You can remove new connections from the node and restore the original by **bypassing** the node.

Deleting Connections between Nodes

To delete the connection between two nodes:

1. Right-click the connection arrow.
2. On the menu, click Delete Connection.

To delete all connections to and from a node, do one of the following:

- Select the node and press F3.
- Select the node and, on the main menu, click:

Edit > Node > Disconnect

Setting options for nodes

Once you creat and connect nodes, there are several options for customizing nodes. Right-click a node and select one of the menu options.

- Click Edit to open the dialog box for the selected node.
 - Click Connect to manually connect one node to another.
 - Click Disconnect to delete all links to and from the node.
 - Click Rename and Annotate to open the Annotations tab of the editing dialog box.
 - Click New Comment to add a comment related to the node. See the topic [Adding Comments and Annotations to Nodes and Streams](#) for more information.
 - Click Disable Node to "hide" the node during processing. To make the node visible again for processing, click Enable Node. See the topic [Disabling Nodes in a Stream](#) for more information.
 - Click Cut or Delete to remove the selected node(s) from the stream canvas. *Note:* Clicking Cut allows you to paste nodes, while Delete does not.
 - Click Copy Node to make a copy of the node with no connections. This can be added to a new or existing stream.
 - Click Load Node to open a previously saved node and load its options into the currently selected node. The nodes must be of identical types.
 - Click Retrieve Node to retrieve a node from a connected IBM® SPSS® Collaboration and Deployment Services Repository.
 - Click Save Node to save the node's details in a file. You can load node details only into another node of the same type.
 - Click Store Node to store the selected node in a connected IBM SPSS Collaboration and Deployment Services Repository.
 - Click Cache to expand the menu, with options for caching the selected node.
 - Click Data Mapping to expand the menu, with options for mapping data to a new source or specifying mandatory fields.
 - Click Create SuperNode to expand the menu, with options for creating a SuperNode in the current stream.
 - Click Generate User Input Node to replace the selected node. Examples generated by this node will have the same fields as the current node.
 - Click Run From Here to run all terminal nodes downstream from the selected node.
-

Caching options for nodes

To optimize stream running, you can set up a **cache** on any nonterminal node. When you set up a cache on a node, the cache is filled with the data that passes through the node the next time you run the data stream. From then on, the data is read from the cache (which is stored on disk in a temporary directory) rather than from the data source.

Caching is most useful following a time-consuming operation such as a sort, merge, or aggregation. For example, suppose that you have a source node set to read sales data from a database and an Aggregate node that summarizes sales by location. You can set up a cache on the Aggregate node rather than on the source node because you want the cache to store the aggregated data rather than the entire data set.

Note: Caching at source nodes, which simply stores a copy of the original data as it is read into IBM® SPSS® Modeler, will not improve performance in most circumstances.

Nodes with caching enabled are displayed with a small document icon at the top right corner. When the data is cached at the node, the document icon is green.

To Enable a Cache

1. On the stream canvas, right-click the node and click Cache on the menu.
2. On the caching submenu, click Enable.
3. You can turn the cache off by right-clicking the node and clicking Disable on the caching submenu.

Caching Nodes in a Database

For streams run in a database, data can be cached midstream to a temporary table in the database rather than the file system. When combined with SQL optimization, this may result in significant gains in performance. For example, the output from a stream that merges multiple tables to create a data mining view may be cached and reused as needed. By automatically generating SQL for all downstream nodes, performance can be further improved.

To take advantage of database caching, both SQL optimization and database caching must be enabled. Note that Server optimization settings override those on the Client. See the topic [Setting optimization options for streams](#) for more information.

With database caching enabled, simply right-click any nonterminal node to cache data at that point, and the cache will be created automatically directly in the database the next time the stream is run. If database caching or SQL optimization is not enabled, the cache will be written to the file system instead.

Note: The following databases support temporary tables for the purpose of caching: Db2, Oracle, SQL Server, and Teradata. Other databases, such as Netezza, will use a normal table for database caching. The SQL code can be customized for specific databases - contact Services for assistance.

To Flush a Cache

A white document icon on a node indicates that its cache is empty. When the cache is full, the document icon becomes solid green. If you want to replace the contents of the cache, you must first flush the cache and then re-run the data stream to refill it.

1. On the stream canvas, right-click the node and click Cache on the menu.
2. On the caching submenu, click Flush.

To Save a Cache

You can save the contents of a cache as an IBM SPSS Statistics data file (*.sav). You can then either reload the file as a cache, or you can set up a node that uses the cache file as its data source. You can also load a cache that you saved from another project.

1. On the stream canvas, right-click the node and click Cache on the menu.
2. On the caching submenu, click Save Cache.
3. In the Save Cache dialog box, browse to the location where you want to save the cache file.
4. Enter a name in the File Name text box.
5. Be sure that *.sav is selected in the Files of Type list, and click Save.

To Load a Cache

If you have saved a cache file before removing it from the node, you can reload it.

1. On the stream canvas, right-click the node and click Cache on the menu.
2. On the caching submenu, click Load Cache.
3. In the Load Cache dialog box, browse to the location of the cache file, select it, and click Load.

Previewing data in nodes

To ensure that data is being changed in the way you expect as you build a stream, you could run your data through a Table node at each significant step. To save you from having to do this, you can generate a preview from each node that displays a sample of the data that will be created, thereby reducing the time it takes to build each node.

For nodes upstream of a model nugget, the preview shows the input fields; for a model nugget or nodes downstream of the nugget (except terminal nodes), the preview shows input and generated fields.

The default number of rows displayed is 10; however, you can change this in the stream properties. See the topic [Setting general options for streams](#) for more information.

From the Generate menu, you can create several types of nodes.

Note: When previewing data generated by this node, all property changes will be applied to this node and cannot be cancelled (the same behavior as clicking Apply).

Locking nodes

To prevent other users from amending the settings of one or more nodes in a stream, you can encapsulate the node or nodes in a special type of node called a SuperNode, and then lock the SuperNode by applying password protection.

Working with streams

Once you have connected source, process, and terminal nodes on the stream canvas, you have created a stream. As a collection of nodes, streams can be saved, annotated, and added to projects. You can also set numerous options for streams, such as optimization, date and time settings, parameters, and scripts. These properties are discussed in the topics that follow.

In IBM® SPSS® Modeler, you can use and modify more than one data stream in the same IBM SPSS Modeler session. The right side of the main window contains the managers pane, which helps you to navigate the streams, outputs, and models that are currently open. If you cannot see the managers pane, click Managers on the View menu, then click the Streams tab.

From this tab, you can:

- Access streams.
- Save streams.
- Save streams to the current project.
- Close streams.
- Open new streams.
- Store and retrieve streams from an IBM SPSS Collaboration and Deployment Services repository (if available at your site). See the topic [About the IBM SPSS Collaboration and Deployment Services Repository](#) for more information.

Right-click a stream on the Streams tab to access these options.

Setting options for streams

You can specify a number of options to apply to the current stream. You can also save these options as defaults to apply to all your streams. The options are as follows.

- General. Miscellaneous options such as symbols and text encoding to use in the stream. See [Setting general options for streams](#) for more information.
- Date/Time. Options relating to the format of date and time expressions. See [Setting date and time options for streams](#) for more information.

- Number formats. Options controlling the format of numeric expressions. See [Setting number format options for streams](#) for more information.
- Optimization. Options for optimizing stream performance. See [Setting optimization options for streams](#) for more information.
- Logging and Status. Options controlling SQL logging and record status. See [Setting SQL logging and record status options for streams](#) for more information.
- Layout. Options relating to the layout of the stream on the canvas. See [Setting layout options for streams](#) for more information.
- Analytic Server. Options relating to the use of Analytic Server with SPSS® Modeler. See [Analytic Server stream properties](#) for more information.
- Geospatial. Options relating to the formatting of geospatial data for use in the stream. See [Setting geospatial options for streams](#) for more information.

To set stream options

1. On the File menu, click Stream Properties (or select the stream from the Streams tab in the managers pane, right-click and then click Stream Properties on the pop-up menu).
2. Click the Options tab.

Alternatively, on the Tools menu, click:

Stream Properties > Options

- [Setting general options for streams](#)
- [Setting date and time options for streams](#)
- [Setting number format options for streams](#)
- [Setting optimization options for streams](#)
- [Setting SQL logging and record status options for streams](#)
- [Setting layout options for streams](#)
- [Analytic Server stream properties](#)
- [Setting geospatial options for streams](#)

Setting general options for streams

The general options are a set of miscellaneous options that apply to various aspects of the current stream.

The Basic section includes the following basic options:

- Decimal symbol. Select either a comma (,) or a period (.) as a decimal separator.
- Grouping symbol. For number display formats, select the symbol used to group values (for example, the comma in 3,000.00). Options include none, period, comma, space, and locale-defined (in which case the default for the current locale is used).
- Encoding. Specify the stream default method for text encoding. (Note: Applies to Var. File source node and Flat File export node only. No other nodes use this setting; most data files have embedded encoding information.) You can choose either the system default or UTF-8. The system default is specified in the Windows Control Panel or, if running in distributed mode, on the server computer. See the topic [Unicode Support in IBM SPSS Modeler](#) for more information.
- Ruleset Evaluation. Determines how rule set models are evaluated. By default, rule sets use Voting to combine predictions from individual rules and determine the final prediction. To ensure that rule sets use the first hit rule by default, select First Hit. Note that this option does not apply to Decision List models, which always use the first hit as defined by the algorithm.

Maximum number of rows to show in Data Preview. Specify the number of rows to be shown when a preview of the data is requested for a node. See the topic [Previewing data in nodes](#) for more information.

Maximum members for nominal fields. Select to specify a maximum number of members for nominal (set) fields after which the data type of the field becomes **Typeless**. This option is useful when working with large nominal fields. Note: When the measurement level of a field is set to **Typeless**, its role is automatically set to **None**. This means that the fields are not available for modeling.

Limit set size for Kohonen, and K-Means modeling. Select to specify a maximum number of members for nominal fields used in Kohonen nets and K-Means modeling. The default set size is 20, after which the field is ignored and a warning is raised, providing information on the field in question.

Note that, for compatibility, this option also applies to the old Neural Network node that was replaced in version 14 of IBM® SPSS® Modeler; some legacy streams may still contain this node.

Refresh source nodes on execution. Select to automatically refresh all source nodes when running the current stream. This action is analogous to clicking the Refresh button on a source node, except that this option automatically refreshes all source nodes (except User Input nodes) for the current stream.

Note: Selecting this option flushes the caches of downstream nodes even if the data has not changed. If you use the Run the current stream option from the toolbar, flushing occurs only once per running of the stream, though, which means that you can still use downstream caches as temporary storage for a single running. For example, say that you have set a cache midstream after a complex derive operation and that you have

several graphs and reports attached downstream of this Derive node. When running the stream, the cache at the Derive node will be flushed and refilled but only for the first graph or report. Subsequent terminal nodes will read data from the Derive node cache. Note that if you choose to execute each terminal node individually (when you have more than one terminal node), instead of using the Run the current stream option, cache flushing occurs every time you execute a terminal node.

Display field and value labels in output. Displays field and value labels in tables, charts, and other output. If labels do not exist, the field names and data values will be displayed instead. Labels are turned off by default; however, you can toggle labels on an individual basis elsewhere in IBM SPSS Modeler. You can also choose to display labels on the output window using a toggle button available on the toolbar.

Figure 1. Toolbar icon used to toggle field and value labels

Display execution times. Displays individual execution times for stream nodes on the Execution Times tab after the stream is run. See the topic [Viewing node execution times](#) for more information.

The Automatic Node Creation section includes the following options for creating nodes automatically in individual streams. These options control whether or not to insert the modeling nuggets onto the stream canvas when generating new nuggets. By default, these options only apply to streams created in version 16 or later. In IBM SPSS Modeler 16 or later, if you open a stream created in version 15 or earlier and execute a modeling node, the nugget will not be placed onto the stream canvas as it used to be in previous releases. If you create a new stream using IBM SPSS Modeler 16 or later and execute a modeling node, the nugget generated is placed onto the stream canvas. This is as designed because, for example, the Create model apply nodes for new model output option would likely break pre-16 streams that run in batch, in IBM SPSS Collaboration and Deployment Services, and in other environments where the IBM SPSS Modeler Server client user interface is not present.

- Create model apply nodes for new model output. Automatically creates model apply nodes for the new model output. If you select this option, you can also choose from the Create model update links whether to set the links as enabled, disabled, or not to create them. When a new model applier or source node is created, the link options in the drop-downs control whether the update links between the builder node and the new node are created and, if so, what mode they are in. If links are created, chances are you want them enabled, but these options provide the user with complete control.
- Create source nodes from source builders. Automatically creates source nodes from the source builders. Similar to the previous option, if you select this option you can also choose from the Create source refresh links drop-down whether to set the refresh links as enabled, disabled, or not to create them.

Save As Default. The options specified apply only to the current stream. Click this button to set these options as the default for all streams.

Setting date and time options for streams

These options specify the format to use for various date and time expressions in the current stream.

Import date/time as Select whether to use date/time storage for date/time fields or whether to import them as string variables.

Date format Select a date format to be used for date storage fields or when strings are interpreted as dates by CLEM date functions.

Time format Select a time format to be used for time storage fields or when strings are interpreted as times by CLEM time functions.

Rollover days/mins For time formats, select whether negative time differences are interpreted as referring to the previous day or hour.

Date baseline (1st Jan) Select the baseline years (always 1 January) to be used by CLEM date functions that work with a single date.

2-digit dates start from Specify the cutoff year to add century digits for years that are denoted with only 2 digits. For example, specifying 1930 as the cutoff year assumes that 05/11/02 is in the year 2002. The same setting will use the 20th century for dates after 30; thus 05/11/73 is assumed to be in 1973.

Time zone Select how the time zone is chosen for use with the datetime_now CLEM expression.

- If you select Server, the time zone depends on the following items:
 - If the current stream uses an Analytic Server data source, the datetime_now expression uses the time from the Analytic Server; by default the server uses Coordinated Universal Time time.
 - If the current stream uses a Database source node, the supported databases use SQL pushback, and the datetime_now expression uses the time of the database.
 - For all other streams, the time zone uses the time from SPSS® Modeler Server.
- If you select Modeler client the time zone reflects the time zone details from the machine on which SPSS Modeler is installed.
- Alternatively, you can select any of the Coordinated Universal Time values for the time zone.

Save As Default. The options that are specified apply only to the current stream. Click this button to set these options as the default for all streams.

-

Setting number format options for streams

These options specify the format to use for various numeric expressions in the current stream.

Number display format. You can choose from standard (####.###), scientific (#.###E+##), or currency display formats (\$##.##).

Decimal places (standard, scientific, currency). For number display formats, specifies the number of decimal places to be used when displaying or printing real numbers. This option is specified separately for each display format.

Calculations in. Select Radians or Degrees as the unit of measurement to be used in trigonometric CLEM expressions. See the topic [Trigonometric Functions](#) for more information.

Save As Default. The options specified apply only to the current stream. Click this button to set these options as the default for all streams.

Setting optimization options for streams

You can use the Optimization settings to optimize stream performance. Note that the performance and optimization settings on IBM® SPSS® Modeler Server (if used) override any equivalent settings in the client. If these settings are disabled in the server, then the client cannot enable them. But if they are enabled in the server, the client can choose to disable them.

Note: Database modeling and SQL optimization require that IBM SPSS Modeler Server connectivity be enabled on the IBM SPSS Modeler computer. With this setting enabled, you can access database algorithms, push back SQL directly from IBM SPSS Modeler, and access IBM SPSS Modeler Server. To verify the current license status, choose the following from the IBM SPSS Modeler menu.

Help>About>Additional Details

If connectivity is enabled, you see the option Server Enablement in the License Status tab.

See [Connecting to IBM SPSS Modeler Server](#) for more information.

Note: Whether SQL pushback and optimization are supported depends on the type of database in use. For the latest information on which databases and ODBC drivers are supported and tested for use with IBM SPSS Modeler, see the corporate Support site at <http://www.ibm.com/support>.

Enable stream rewriting. Select this option to enable stream rewriting in IBM SPSS Modeler. Four types of rewriting are available, and you can select one or more of them. Stream rewriting reorders the nodes in a stream behind the scenes for more efficient operation, without altering stream semantics.

- Optimize SQL generation. This option enables nodes to be reordered within the stream so that more operations can be pushed back using SQL generation for execution in the database. When it finds a node that cannot be rendered into SQL, the optimizer will look ahead to see if there are any downstream nodes that can be rendered into SQL and safely moved in front of the problem node without affecting the stream semantics. Not only can the database perform operations more efficiently than IBM SPSS Modeler, but such pushbacks act to reduce the size of the data set that is returned to IBM SPSS Modeler for processing. This, in turn, can reduce network traffic and speed stream operations. Note that the Generate SQL check box must be selected for SQL optimization to have any effect.
- Optimize CLEM expression. This option enables the optimizer to search for CLEM expressions that can be preprocessed before the stream is run, in order to increase the processing speed. As a simple example, if you have an expression such as `log(salary)`, the optimizer would calculate the actual salary value and pass that on for processing. This can be used both to improve SQL pushback and IBM SPSS Modeler Server performance.
- Optimize syntax execution. This method of stream rewriting increases the efficiency of operations that incorporate more than one node containing IBM SPSS Statistics syntax. Optimization is achieved by combining the syntax commands into a single operation, instead of running each as a separate operation.
- Optimize other execution. This method of stream rewriting increases the efficiency of operations that cannot be delegated to the database. Optimization is achieved by reducing the amount of data in the stream as early as possible. While maintaining data integrity, the

stream is rewritten to push operations closer to the data source, thus reducing data downstream for costly operations, such as joins.

Enable parallel processing. When running on a computer with multiple processors, this option allows the system to balance the load across those processors, which may result in faster performance. Use of multiple nodes or use of the following individual nodes may benefit from parallel processing: C5.0, Merge (by key), Sort, Bin (rank and tile methods), and Aggregate (using one or more key fields).

Generate SQL. Select this option to enable SQL generation, allowing stream operations to be pushed back to the database by using SQL code to generate execution processes, which may improve performance. To further improve performance, Optimize SQL generation can also be selected to maximize the number of operations pushed back to the database. When operations for a node have been pushed back to the database, the node will be highlighted in purple when the stream is run.

- Database caching. For streams that generate SQL to be executed in the database, data can be cached midstream to a temporary table in the database rather than to the file system. When combined with SQL optimization, this may result in significant gains in performance. For example, the output from a stream that merges multiple tables to create a data mining view may be cached and reused as needed. With database caching enabled, simply right-click any nonterminal node to cache data at that point, and the cache is automatically created directly in the database the next time the stream is run. This allows SQL to be generated for downstream nodes, further improving performance. Alternatively, this option can be disabled if needed, such as when policies or permissions preclude data being written to the database. If database caching or SQL optimization is not enabled, the cache will be written to the file system instead. See the topic [Caching options for nodes](#) for more information.
- Use relaxed conversion. This option enables the conversion of data from either strings to numbers, or numbers to strings, if stored in a suitable format. For example, if the data is kept in the database as a string, but actually contains a meaningful number, the data can be converted for use when the pushback occurs.

Note: Due to minor differences in SQL implementation, streams run in a database may return slightly different results from those returned when run in IBM SPSS Modeler. For similar reasons, these differences may also vary depending on the database vendor.

Save As Default. The options specified apply only to the current stream. Click this button to set these options as the default for all streams.

Setting SQL logging and record status options for streams

These settings include various options controlling the display of SQL statements generated by the stream, and the display of the number of records processed by the stream.

Display SQL in the messages log during stream execution. Specifies whether SQL generated while running the stream is passed to the message log.

Display SQL generation details in the messages log during stream preparation. During stream preview, specifies whether a preview of the SQL that would be generated is passed to the messages log.

Display SQL. Specifies whether any SQL that is displayed in the log should contain native SQL functions or standard ODBC functions of the form {fn FUNC (...)} , as generated by SPSS® Modeler. The former relies on ODBC driver functionality that may not be implemented.

Reformat SQL for improved readability. Specifies whether SQL displayed in the log should be formatted for readability.

Show status for records. Specifies when records should be reported as they arrive at terminal nodes. Specify a number that is used for updating the status every N records.

Save As Default. The options specified apply only to the current stream. Click this button to set these options as the default for all streams.

Setting layout options for streams

These settings provide a number of options relating to the display and use of the stream canvas.

Minimum stream canvas width. Specify the minimum width of the stream canvas in pixels.

Minimum stream canvas height. Specify the minimum height of the stream canvas in pixels.

Stream scroll rate. Specify the scrolling rate for the stream canvas to control how quickly the stream canvas pane scrolls when a node is being dragged from one place to another on the canvas. Higher numbers specify a faster scroll rate.

Icon name maximum. Specify a limit in characters for the names of nodes on the stream canvas.

Icon size. Select an option to scale the entire stream view to one of a number of sizes between 8% and 200% of the standard icon size.

Grid cell size. Select a grid cell size from the list. This number is used for aligning nodes on the stream canvas using an invisible grid. The default grid cell size is 0.25.

Snap to Grid. Select to align icons to an invisible grid pattern (selected by default).

Generated icon placement. Choose where on the canvas to place icons for nodes generated from model nuggets. Default is top left.

Save As Default. The options specified apply only to the current stream. Click this button to set these options as the default for all streams.

Analytic Server stream properties

These settings provide a number of options for working with Analytic Server.

Maximum number of records to process outside of Analytic Server

Specify the maximum number of records to be imported into SPSS® Modeler server from an Analytic Server data source.

Notification when a node can't be processed in Analytic Server

This setting determines what happens when a stream that would be submitted to Analytic Server contains a node that can't be processed in Analytic Server. Specify whether to issue a warning and continue processing the stream, or throw an error and stop processing.

Split Model Storage Settings

Store split models by reference on Analytic Server when model size (MB) exceeds

Model nuggets are typically stored as part of the stream. Split models with many splits can produce large nuggets, and moving the nugget back and forth between the stream and the Analytic Server can impact performance. As a solution, when a split model exceeds the specified size, it is stored on the Analytic Server, and the nugget in the SPSS Modeler contains a reference to the model.

Default folder to store models by reference on Analytic Server once execution is complete

Specify the default path where you want to store split models on Analytic Server. The path should start with a valid Analytic Server project name.

Folder to store promoted models

Specify the default path where you want to store "promoted" models. A promoted model is not cleaned up when the SPSS Modeler session is over.

Setting geospatial options for streams

Any geospatial field, whether it is a shape, coordinate, or single axis value (such as x or y, or latitude and longitude) has an associated coordinate system. This coordinate system sets attributes such as the origin point (0,0) and the units associated with the values.

There are a number of coordinate systems and there are two types: Geographic and Projected. All of the spatial functions in SPSS® Modeler can only be used with a Projected coordinate system.

Due to the nature of coordinate systems, merging or appending data from two separate geospatial data sources requires that the sources use the same coordinate system. Because of this you must specify a coordinate setting for any geospatial data used in the stream.

Data is automatically reprojected to use the chosen stream coordinate system in the following situations:

- For spatial functions (such as area, closeto, within), the parameter passed to the function is automatically reprojected; however, the original row data is left unchanged.
- When using either the build or scoring (nugget) nodes in Spatio-Temporal Prediction (STP), the location field is automatically reprojected. When scoring, the location that comes out of the nugget is the original location.
- When using the Map Visualization node.

Stream coordinate system. Only available if you select the check box. Click Change to display a list of available Projected Coordinate Systems and select the one you want to use for the current stream.

Save As Default. The coordinate system you select only applies to the current stream. To select the system as the default for all streams, click this button.

- [Selecting geospatial coordinate systems](#)

Selecting geospatial coordinate systems

All of the spatial functions in SPSS® Modeler can be used only with a Projected coordinate system.

The Select Stream Coordinate System dialog box contains a list of all the projected coordinate systems that you can select for any geospatial data that is used in a stream.

The following information is listed for each coordinate system.

- WKID The Well Known ID that is unique to each coordinate system.
- Name The name of the coordinate system.
- Units The unit of measurement that is associated with the coordinate system.

In addition to the list of all coordinate systems, the dialog box has a Filtering control. If you know all or part of the name of the coordinate system you require, type it in the Name field at the bottom of the dialog box. The list of coordinate systems from which you can choose is automatically filtered to show only the systems with names that contain the text you entered.

Viewing stream operation messages

Messages regarding stream operations, such as running, optimization, and time elapsed for model building and evaluation, can easily be viewed using the Messages tab in the stream properties dialog box. Error messages are also reported in this table.

To View Stream Messages

1. On the File menu, click Stream Properties (or select the stream from the Streams tab in the managers pane, right-click and then click Stream Properties on the pop-up menu).
2. Click the Messages tab.

Alternatively, on the Tools menu, click:

Stream Properties > Messages

In addition to messages regarding stream operations, error messages are reported here. When stream running is terminated because of an error, this dialog box will open to the Messages tab with the error message visible. Additionally, the node with errors is highlighted in red on the stream canvas.

If SQL optimization and logging options are enabled in the User Options dialog box, then information on generated SQL is also displayed. See the topic [Setting optimization options for streams](#) for more information.

You can save messages reported here for a stream by clicking Save Messages on the Save button drop-down list (on the left, just below the Messages tab).

You can clear all messages for a given stream by selecting Clear All Messages from the drop-down.

Note that CPU time is the amount of time the server process is utilizing CPU. Elapsed time is the total time between execution start and execution end, so also includes things like transferring files and rendering outputs. CPU time can be more than elapsed time when a stream is leveraging multiple CPUs (parallel execution). When a stream fully pushes back to the database being used as a data source, the CPU time will be zero.

Viewing node execution times

On the Messages tab you can choose to display Execution Times, where you can see the individual execution times for nodes in the stream that run on the IBM® SPSS® Modeler Server. Note that the times may not be accurate for streams run in other areas, such as R or Analytic Server. And the execution time of some nodes cannot be calculated.

Note: For this feature to work, the Display execution times option must be selected on the General setting of the Options tab.

In the table of node execution times, the columns are as follows. Click a column heading to sort the entries into ascending or descending order (for example, to see which nodes have the longest execution times).

Terminal Node. The identifier of the branch to which the node belongs. The identifier is the name of the terminal node at the end of the branch.

Node Label. The name of the node to which the execution time refers.

Node Id. The unique identifier of the node to which the execution time refers. This identifier is generated by the system when the node is created.

Execution Time(s). The time in seconds taken to execute this node. Note that execution time can often vary from the time you see in general messages because time is spent on preparing data and retrieving data in the output when running a stream, and this type of time cannot be calculated.

Setting Stream and Session Parameters

Parameters can be defined for use in CLEM expressions and in scripting. They are, in effect, user-defined variables that are saved and persisted with the current stream, session, or SuperNode and can be accessed from the user interface as well as through scripting. If you save a stream, for example, any parameters set for that stream are also saved. (This distinguishes them from local script variables, which can be used only in the script in which they are declared.) Parameters are often used in scripting to control the behavior of the script, by providing information about fields and values that do not need to be hard coded in the script.

The scope of a parameter depends on where it is set:

- Stream parameters can be set in a stream script or in the stream properties dialog box, and they are available to all nodes in the stream. They are displayed on the Parameters list in the Expression Builder.
- Session parameters can be set in a stand-alone script or in the session parameters dialog box. They are available to all streams used in the current session (all streams listed on the Streams tab in the managers pane).

Parameters can also be set for SuperNodes, in which case they are visible only to nodes encapsulated within that SuperNode.

To Set Stream and Session Parameters through the User Interface

1. To set stream parameters, on the main menu, click:

Tools > Stream Properties > Parameters

2. To set session parameters, click Set Session Parameters on the Tools menu.

Prompt?. Check this box if you want the user to be prompted at runtime to enter a value for this parameter.

Name. Parameter names are listed here. You can create a new parameter by entering a name in this field. For example, to create a parameter for the minimum temperature, you could type minvalue. Do not include the \$P- prefix that denotes a parameter in CLEM expressions. This name is also used for display in the CLEM Expression Builder.

Long name. Lists the descriptive name for each parameter created.

Storage. Select a storage type from the list. Storage indicates how the data values are stored in the parameter. For example, when working with values containing leading zeros that you want to preserve (such as 008), you should select String as the storage type. Otherwise, the zeros will be stripped from the value. Available storage types are string, integer, real, time, date, and timestamp. For date parameters, note that values must be specified using ISO standard notation as shown in the next paragraph.

Value. Lists the current value for each parameter. Adjust the parameter as required. Note that for date parameters, values must be specified in ISO standard notation (that is, **YYYY-MM-DD**). Dates specified in other formats are not accepted.

Type (optional). If you plan to deploy the stream to an external application, select a measurement level from the list. Otherwise, it is advisable to leave the *Type* column as is. If you want to specify value constraints for the parameter, such as upper and lower bounds for a numeric range, select Specify from the list.

Note that long name, storage, and type options can be set for parameters through the user interface only. These options cannot be set using scripts.

Click the arrows at the right to move the selected parameter further up or down the list of available parameters. Use the delete button (marked with an X) to remove the selected parameter.

-

Specifying Runtime Prompts for Parameter Values

If you have streams where you might need to enter different values for the same parameter on different occasions, you can specify runtime prompts for one or more stream or session parameter values.

Parameters. (Optional) Enter a value for the parameter, or leave the default value if there is one.

Turn off these prompts. Select this box if you do not want these prompts to be displayed when you run the stream. You can cause them to be redisplayed by selecting the Prompt? check box on the stream properties or session properties dialog box where the parameters were defined. See the topic [Setting Stream and Session Parameters](#) for more information.

Specifying Value Constraints for a Parameter Type

You can make value constraints for a parameter available during stream deployment to an external application that reads data modeling streams. This dialog box allows you to specify the values available to an external user running the stream. Depending on the data type, value constraints vary dynamically in the dialog box. The options shown here are identical to the options available for values from the Type node.

Type. Displays the currently selected measurement level. You can change this value to reflect the way that you intend to use the parameter in IBM® SPSS® Modeler.

Storage. Displays the storage type if known. Storage types are unaffected by the measurement level (continuous, nominal or flag) that you choose for work in IBM SPSS Modeler. You can alter the storage type on the main Parameters tab.

The bottom half of the dialog box dynamically changes depending on the measurement level selected in the Type field.

Continuous Measurement Levels

Lower. Specify a lower limit for the parameter values.

Upper. Specify an upper limit for the parameter values.

Labels. You can specify labels for any value of a range field. Click the Labels button to open a separate dialog box for specifying value labels.

Nominal Measurement Levels

Values. This option allows you to specify values for a parameter that will be used as a nominal field. Values will not be coerced in the IBM SPSS Modeler stream but will be used in a drop-down list for external deployment applications. Using the arrow and delete buttons, you can modify existing values as well as reorder or delete values.

Flag Measurement Levels

True. Specify a flag value for the parameter when the condition is met.

False. Specify a flag value for the parameter when the condition is not met.

Labels. You can specify labels for the values of a flag field.

Stream deployment options

The Deployment tab of the stream properties dialog box enables you to specify options for deploying the stream within IBM® SPSS® Collaboration and Deployment Services for the purposes of model refresh or automated job scheduling. All streams require a designated scoring branch before they can be deployed. See [Storing and deploying repository objects](#) for more information.

Looping Execution for Streams

Using the Execution tab in the stream properties dialog box, you can set up looping conditions to automate repetitive tasks in the current stream.

Once you set these conditions you can use it as an introduction to scripting as it populates the script window with basic scripting for your stream which you can then modify - perhaps to use as a base from which to build better scripts. See the topic [Global Functions](#) for more information.

To set Looping for a Stream

1. On the File menu, click Stream Properties (or select the stream from the Streams tab in the managers pane, right-click and then click Stream Properties on the pop-up menu).
2. Click the Execution tab.
3. Select the Looping / Conditional Execution execution mode.
4. Click the Looping tab.

Alternatively, on the Tools menu, click:

Stream Properties > Execution

As a further alternative, right click on the node and from the context menu, click:

Looping / Conditional Execution > Edit Looping Settings

Iteration. You cannot edit this row number value, but you can add, delete, or move an iteration up or down using the buttons to the right of the table.

Table headers. These reflect the iteration key and any iteration variables you created when setting up the loop.

Viewing Global Values for Streams

Using the Globals tab in the stream properties dialog box, you can view the global values set for the current stream. Global values are created using a Set Globals node to determine statistics such as mean, sum, or standard deviation for selected fields.

Once the Set Globals node is run, these values are then available for a variety of uses in stream operations. See the topic [Global Functions](#) for more information.

To View Global Values for a Stream

1. On the File menu, click Stream Properties (or select the stream from the Streams tab in the managers pane, right-click and then click Stream Properties on the pop-up menu).
2. Click the Globals tab.

Alternatively, on the Tools menu, click:

Stream Properties > Globals

Globals available. Available globals are listed in this table. You cannot edit global values here, but you can clear all global values for a stream using the Clear All Values button to the right of the table.

Searching for Nodes in a Stream

You can search for nodes in a stream by specifying a number of search criteria, such as node name, category and identifier. This feature can be especially useful for complex streams containing a large number of nodes.

To Search for Nodes in a Stream

1. On the File menu, click Stream Properties (or select the stream from the Streams tab in the managers pane, right-click and then click Stream Properties on the pop-up menu).
2. Click the Search tab.

Alternatively, on the Tools menu, click:

Stream Properties > Search

You can specify more than one option to limit the search, except that searching by node ID (using the ID equals field) excludes the other options.

Node label contains. Check this box and enter all or part of a node label to search for a particular node. Searches are not case-sensitive, and multiple words are treated as a single piece of text.

Node category. Check this box and click a category on the list to search for a particular type of node. Process Node means a node from the Record Ops or Field Ops tab of the nodes palette; Apply Model Node refers to a model nugget.

Keywords include. Check this box and enter one or more complete keywords to search for nodes having that text in the Keywords field on the Annotations tab of the node dialog box. Keyword text that you enter must be an exact match. Separate multiple keywords with semicolons to search for alternatives (for example, entering `proton;neutron` will find all nodes with either of these keywords). See the topic [Annotations](#) for more information.

Annotation contains. Check this box and enter one or more words to search for nodes that contain this text in the main text area on the Annotations tab of the node dialog box. Searches are not case-sensitive, and multiple words are treated as a single piece of text. See the topic [Annotations](#) for more information.

Generates field called. Check this box and enter the name of a generated field (for example, `$C-Drug`). You can use this option to search for modeling nodes that generate a particular field. Enter only one field name, which must be an exact match.

ID equals. Check this box and enter a node ID to search for a particular node with that identifier (selecting this option disables all the preceding options). Node IDs are assigned by the system when the node is created, and can be used to reference the node for the purposes of scripting or automation. Enter only one node ID, which must be an exact match. See the topic [Annotations](#) for more information.

Search in SuperNodes. This box is checked by default, meaning that the search is performed on nodes both inside and outside SuperNodes. Clear the box if you want to perform the search only on nodes outside SuperNodes, at the top level of the stream.

Find. When you have specified all the options you want, click this button to start the search.

Nodes that match the specified options are listed in the lower part of the dialog box. Select a node in the list to highlight it on the stream canvas.

Renaming streams

Using the Annotations tab in the stream properties dialog box, you can add descriptive annotations for a stream and create a custom name for the stream. These options are useful especially when generating reports for streams added to the project pane. See the topic [Annotations](#) for more information.

Stream descriptions

For each stream that you create, IBM® SPSS® Modeler produces a stream description containing information on the contents of the stream. This can be useful if you are trying to see what a stream does but you do not have IBM SPSS Modeler installed, for example when accessing a stream through IBM SPSS Collaboration and Deployment Services.

The stream description is displayed in the form of an HTML document consisting of a number of sections.

General Stream Information

This section contains the stream name, together with details of when the stream was created and last saved.

Description and Comments

This section includes any:

- Stream annotations (see [Annotations](#))
- Comments not connected to specific nodes
- Comments connected to nodes in both the modeling and scoring branches of the stream

Scoring Information

This section contains information under various headings relating to the scoring branch of the stream.

- **Comments.** Includes comments linked only to nodes in the scoring branch.
- **Inputs.** Lists the input fields together with their storage types (for example, string, integer, real and so on).
- **Outputs.** Lists the output fields, including the additional fields generated by the modeling node, together with their storage types.
- **Parameters.** Lists any parameters relating to the scoring branch of the stream and which can be viewed or edited each time the model is scored. These parameters are identified when you click the Scoring Parameters button on the Deployment tab of the stream properties dialog box.
- **Model Node.** Shows the model name and type (for example, Neural Net, C&R Tree and so on). This is the model nugget selected for the Model node field on the Deployment tab of the stream properties dialog box.
- **Model Details.** Shows details of the model nugget identified under the previous heading. Where possible, predictor importance and evaluation charts for the model are included.

Modeling Information

Contains information relating to the modeling branch of the stream.

- **Comments.** Lists any comments or annotations that are connected to nodes in the modeling branch.
- **Inputs.** Lists the input fields together with their role in the modeling branch (in the form of the field role value, for example, Input, Target, Split and so on).
- **Parameters.** Lists any parameters relating to the modeling branch of the stream and which can be viewed or edited each time the model is updated. These parameters are identified when you click the Model Build Parameters button on the Deployment tab of the stream properties dialog box.
- **Modeling node.** Shows the name and type of the modeling node used to generate or update the model.
- [Previewing stream descriptions](#)
- [Exporting Stream Descriptions](#)

Previewing stream descriptions

You can view the contents of a stream description in a web browser by clicking an option on the stream properties dialog box. The contents of the description depend on the options you specify on the Deployment tab of the dialog box. See the topic [Stream Deployment Options](#) for more information.

To view a stream description:

1. On the main IBM® SPSS® Modeler menu, click:
Tools > Stream Properties > Deployment
2. Set the deployment type, the designated scoring node and any scoring parameters.
3. If the deployment type is Model Refresh, you can optionally select a:
 - Modeling node and any model build parameters
 - Model nugget on the scoring branch of the stream
4. Click the Preview Stream Description button.

Exporting Stream Descriptions

You can export the contents of the stream description to an HTML file.

To export a stream description:

1. On the main menu, click:
File > Export Stream Description
2. Enter a name for the HTML file and click Save.

Running streams

Once you specify the required options for streams and connect the required nodes, you can run the stream by running the data through nodes in the stream. There are several ways to run a stream within IBM® SPSS® Modeler. You can:

- Click Run on the Tools menu.
- Click one of the Run... buttons on the toolbar. These buttons allow you to run the entire stream or simply the selected terminal node. See the topic [IBM SPSS Modeler Toolbar](#) for more information.
- Run a single data stream by right-clicking a terminal node and clicking Run on the pop-up menu.
- Run part of a data stream by right-clicking any non-terminal node and clicking Run From Here on the pop-up menu. Doing so causes only those operations after the selected node to be performed.

To halt the running of a stream in progress, you can click the red Stop button on the toolbar, or select Stop Execution from the Tools menu. Note that clicking the Stop button one time tells Modeler to have Modeler Server stop the execution. In some cases execution will stop immediately, but in other cases it must finish the current step before it can stop the entire execution. So time will vary. If you double-click the button, the server connection is dropped and a new connection is established. In most cases, this will close all server processes (and it may take some time). But in some cases, some server process won't be stopped.

If any stream takes longer than three seconds to run, the Execution Feedback dialog box is displayed to indicate the progress.

Some nodes have further displays giving additional information about stream execution. Select the corresponding row in the dialog box to see these displays. The first row is selected automatically.

Working with Models

If a stream includes a modeling node (that is, one from the Modeling or Database Modeling tab of the nodes palette), a **model nugget** is created when the stream is run. A model nugget is a container for a **model**, that is, the set of rules, formulas or equations that enables you to generate predictions against your source data, and which lies at the heart of predictive analytics.

Figure 1. Model nugget

When you successfully run a modeling node, a corresponding model nugget is placed on the stream canvas, where it is represented by a gold diamond-shaped icon (hence the name "nugget"). You can open the nugget and browse its contents to view details about the model. To view the predictions, you attach and run one or more terminal nodes, the output from which presents the predictions in a readable form.

A typical modeling stream consists of two branches. The **modeling branch** contains the modeling node, together with the source and processing nodes that precede it. The **scoring branch** is created when you run the modeling node, and contains the model nugget and the terminal node or nodes that you use to view the predictions.

For more information, see the [IBM® SPSS® Modeler Modeling Nodes](#) guide.

Adding Comments and Annotations to Nodes and Streams

You may need to describe a stream to others in your organization. To help you do this, you can attach explanatory comments to streams, nodes and model nuggets.

Others can then view these comments on-screen, or you can print out an image of the stream that includes the comments.

You can list all the comments for a stream or SuperNode, change the order of comments in the list, edit the comment text, and change the foreground or background color of a comment. See the topic [Listing Stream Comments](#) for more information.

You can also add notes in the form of text annotations to streams, nodes and nuggets by means of the Annotations tab of a stream properties dialog box, a node dialog box, or a model nugget window. These notes are visible only when the Annotations tab is open, except that stream annotations can also be shown as on-screen comments. See the topic [Annotations](#) for more information.

- [Comments](#)
- [Annotations](#)

Related information

- [Comments](#)
- [Operations Involving Comments](#)
- [Listing Stream Comments](#)
- [Converting Annotations to Comments](#)
- [Annotations](#)

Comments

Comments take the form of text boxes in which you can enter any amount of text, and you can add as many comments as you like. A comment can be freestanding (not attached to any stream objects), or it can be connected to one or more nodes or model nuggets in the stream.

Freestanding comments are typically used to describe the overall purpose of the stream; connected comments describe the node or nugget to which they are attached. Nodes and nuggets can have more than one comment attached, and the stream can have any number of freestanding comments.

Note: You can also show stream annotations as on-screen comments, though these cannot be attached to nodes or nuggets. See the topic [Converting Annotations to Comments](#) for more information.

The appearance of the text box changes to indicate the current mode of the comment (or annotation shown as a comment), as the following table shows.

Table 1. Comment and annotation text box modes

Comment text box	Annotation text box	Mode	Indicates	Obtained by...
A yellow text box with a black border and a dashed blue selection outline.	A blue text box with a black border and a dashed blue selection outline.	Edit	Comment is open for editing.	Creating a new comment or annotation, or double-clicking an existing one.
A yellow text box with a black border and a dotted blue selection outline.	A blue text box with a black border and a dotted blue selection outline.	Last selected	Comment can be moved, resized or deleted.	Clicking the stream background after editing, or single-clicking an existing comment or annotation.
A yellow text box with a solid black border and no selection outline.	A blue text box with a solid black border and no selection outline.	View	Editing is complete.	Clicking on another node, comment or annotation after editing.

When you create a new freestanding comment, it is initially displayed in the top left corner of the stream canvas.

If you are attaching a comment to a node or nugget, the comment is initially displayed above the stream object to which it is attached.

The text box is colored white to show that text can be entered. When you have entered the text, click outside the text box. The comment background changes to yellow to show that text entry is complete. The comment remains selected, enabling you to move, resize, or delete it.

When you click again, the border changes to solid lines to show that editing is complete.

Double-clicking a comment changes the text box to edit mode--the background changes to white and the comment text can be edited.

You can also attach comments to SuperNodes.

Operations Involving Comments

You can perform a number of operations on comments. You can:

- Add a freestanding comment
- Attach a comment to a node or nugget
- Edit a comment
- Resize a comment
- Move a comment
- Disconnect a comment
- Delete a comment
- Show or hide all comments for a stream

To add a freestanding comment

1. Ensure that nothing is selected on the stream.
2. Do one of the following:

- On the main menu, click:
Insert>New Comment
 - Right-click the stream background and click New Comment on the pop-up menu.
 - Click the New Comment button in the toolbar.
3. Enter the comment text (or paste in text from the clipboard).
 4. Click a node in the stream to save the comment.

To attach a comment to a node or nugget

1. Select one or more nodes or nuggets on the stream canvas.
 2. Do one of the following:
 - On the main menu, click:
Insert>New Comment
 - Right-click the stream background and click New Comment on the pop-up menu.
 - Click the New Comment button in the toolbar.
 3. Enter the comment text.
 4. Click another node in the stream to save the comment.
- Alternatively, you can:
5. Insert a freestanding comment (see previous section).
 6. Do one of the following:
 - Select the comment, press F2, then select the node or nugget.
 - Select the node or nugget, press F2, then select the comment.
 - (Three-button mice only) Move the mouse pointer over the comment, hold down the middle button, drag the mouse pointer over the node or nugget, and release the mouse button.

To attach a comment to an additional node or nugget

If a comment is already attached to a node or nugget, or if it is currently at stream level, and you want to attach it to an additional node or nugget, do one of the following:

- Select the comment, press F2, then select the node or nugget.
- Select the node or nugget, press F2, then select the comment.
- (Three-button mice only) Move the mouse pointer over the comment, hold down the middle button, drag the mouse pointer over the node or nugget, and release the mouse button.

To edit an existing comment

1. Do one of the following:
 - Double-click the comment text box.
 - Select the text box and press Enter.
 - Right-click the text box to display its menu, and click Edit.
2. Edit the comment text. You can use standard Windows shortcut keys when editing, for example Ctrl+C to copy text. Other options during editing are listed in the pop-up menu for the comment.
3. Click outside the text box once to display the resizing controls, then again to complete the comment.

To resize a comment text box

1. Select the comment to display the resizing controls.
2. Click and drag a control to resize the box.
3. Click outside the text box to save the change.

To move an existing comment

If you want to move a comment but not its attached objects (if any), do one of the following:

- Move the mouse pointer over the comment, hold down the left mouse button, and drag the comment to the new position.
- Select the comment, hold down the Alt key, and move the comment using the arrow keys.

If you want to move a comment together with any nodes or nuggets to which the comment is attached:

1. Select all the objects you want to move.
2. Do one of the following:
 - Move the mouse pointer over one of the objects, hold down the left mouse button, and drag the objects to the new position.
 - Select one of the objects, hold down the Alt key, and move the objects using the arrow keys.

To disconnect a comment from a node or nugget

1. Select one or more comments to be disconnected.
2. Do one of the following:

- Press F3.
- Right-click a selected comment and click Disconnect on its menu.

To delete a comment

1. Select one or more comments to be deleted.
2. Do one of the following:
 - Press the Delete key.
 - Right-click a selected comment and click Delete on its menu.

If the comment was attached to a node or nugget, the connection line is deleted as well.

If the comment was originally a stream or SuperNode annotation that had been converted to a freestanding comment, the comment is deleted from the canvas but its text is retained on the Annotations tab for the stream or SuperNode.

To show or hide comments for a stream

1. Do one of the following:
 - On the main menu, click:
View > Comments
 - Click the Show/hide comments button in the toolbar.

-

Listing Stream Comments

You can view a list of all the comments that have been made for a particular stream or SuperNode.

On this list, you can

- Change the order of comments
- Edit the comment text
- Change the foreground or background color of a comment

Listing Comments

To list the comments made for a stream, do one of the following:

- On the main menu, click:
Tools > Stream Properties > Comments
- Right-click a stream in the managers pane and click Stream Properties, then Comments.
- Right-click a stream background on the canvas and click Stream Properties, then Comments.

Text. The text of the comment. Double-click the text to change the field to an editable text box.

Links. The name of the node to which the comment is attached. If this field is empty, the comment applies to the stream.

Positioning buttons. These move a selected comment up or down in the list.

Comment Colors. To change the foreground or background color of a comment, select the comment, select the Custom colors check box, then select a color from the Background or Foreground list (or both). Click Apply, then click the stream background, to see the effect of the change. Click OK to save the change.

Converting Annotations to Comments

Annotations made to streams or SuperNodes can be converted into comments.

In the case of streams, the annotation is converted to a freestanding comment (that is, it is not attached to any nodes) on the stream canvas.

When a SuperNode annotation is converted to a comment, the comment is not attached to the SuperNode on the stream canvas, but is visible when you zoom in to the SuperNode.

To convert a stream annotation to a comment

1. Click Stream Properties on the Tools menu. (Alternatively, you can right-click a stream in the managers pane and click Stream Properties.)
2. Click the Annotations tab.
3. Select the Show annotation as comment check box.
4. Click OK.

To convert a SuperNode annotation to a comment

1. Double-click the SuperNode icon on the canvas.
2. Click the Annotations tab.
3. Select the Show annotation as comment check box.
4. Click OK.

Annotations

Nodes, streams, and models can be annotated in a number of ways. You can add descriptive annotations and specify a custom name. These options are useful especially when generating reports for streams added to the project pane. For nodes and model nuggets, you can also add ToolTip text to help distinguish between similar nodes on the stream canvas.

Adding annotations

Editing a node or model nugget opens a tabbed dialog box containing an Annotations tab used to set a variety of annotation options. You can also open the Annotations tab directly.

1. To annotate a node or nugget, right-click the node or nugget on the stream canvas and click Rename and Annotate. The editing dialog box opens with the Annotations tab visible.
2. To annotate a stream, click Stream Properties on the Tools menu. (Alternatively, you can right-click a stream in the managers pane and click Stream Properties.) Click the Annotations tab.

Name. Select Custom to adjust the autogenerated name or to create a unique name for the node as displayed on the stream canvas.

Tooltip text. (For nodes and model nuggets only) Enter text used as a tooltip on the stream canvas. This is particularly useful when working with a large number of similar nodes.

Keywords. Specify keywords to be used in project reports and when searching for nodes in a stream, or tracking objects stored in the repository (see [About the IBM SPSS Collaboration and Deployment Services Repository](#)). Multiple keywords can be separated by semicolons--for example, income; crop type; claim value. White spaces at the beginning and end of each keyword are trimmed--for example, income ; crop type will produce the same results as income;crop type. (White spaces within keywords are not trimmed, however. For example, crop type with one space and crop type with two spaces are not the same.)

The main text area can be used to enter lengthy annotations regarding the operations of the node or decisions made in the node. For example, when you are sharing and reusing streams, it is helpful to take notes on decisions such as discarding a field with numerous blanks using a Filter node. Annotating the node stores this information with the node. You can also choose to include these annotations in a project report created from the project pane. See the topic [Introduction to Projects](#) for more information.

Show annotation as comment. (For stream and SuperNode annotations only) Check this box to convert the annotation to a freestanding comment that will be visible on the stream canvas. See the topic [Adding Comments and Annotations to Nodes and Streams](#) for more information.

ID. Displays a unique ID that can be used to reference the node for the purpose of scripting or automation. This value is automatically generated when the node is created and will not change. Also note that to avoid confusion with the letter "O," zeros are not used in node IDs. Use the copy button at the right to copy and paste the ID into scripts or elsewhere as needed.

Saving data streams

After you create a stream, you can save it for future reuse.

To save a stream

1. On the File menu, click Save Stream or Save Stream As.
2. In the Save dialog box, browse to the folder in which you want to save the stream file.
3. Enter a name for the stream in the File Name text box.
4. Select Add to project if you would like to add the saved stream to the current project.

Clicking Save stores the stream with the extension *.str in the specified directory.

Automatic backup files. Each time a stream is saved, the previously saved version of the file is automatically preserved as a backup, with a hyphen appended to the filename (for example mystream.str-). To restore the backed-up version, simply delete the hyphen and reopen the file.

- [Saving States](#)
- [Saving Nodes](#)
- [Saving multiple stream objects](#)
- [Saving Output](#)
- [Encrypting and Decrypting Information](#)

Saving States

In addition to streams, you can save **states**, which include the currently displayed stream diagram and any model nuggets that you have created (listed on the Models tab in the managers pane).

To Save a State

1. On the File menu, click:
State... Save State or Save State As
2. In the Save dialog box, browse to the folder in which you want to save the state file.

Clicking Save stores the state with the extension *.cst in the specified directory.

Saving Nodes

You can also save an individual node by right-clicking the node on the stream canvas and clicking Save Node on the pop-up menu. Use the file extension *.nod.

Saving multiple stream objects

When you exit IBM® SPSS® Modeler with multiple unsaved objects, such as streams, projects, or model nuggets, you will be prompted to save before completely closing the software. If you choose to save items, a dialog box displays options for saving each object.

1. Simply select the check boxes for the objects that you want to save.
2. Click OK to save each object in the required location.

You will then be prompted with a standard Save dialog box for each object. After you finish saving, the application will close.

Saving Output

Tables, graphs, and reports generated from IBM® SPSS® Modeler output nodes can be saved in output object (*.cou) format.

1. When viewing the output you want to save, on the output window menus click:
`File > Save`
2. Specify a name and location for the output file.
3. Optionally, select Add file to project in the Save dialog box to include the file in the current project. See the topic [Introduction to Projects](#) for more information.

Alternatively, you can right-click any output object listed in the managers pane and select Save from the pop-up menu.

Encrypting and Decrypting Information

When you save a stream, node, project, output file, or model nugget, you can encrypt it to prevent its unauthorized use. To do this, you select an extra option when saving, and add a password to the item being saved. This encryption can be set for any of the items that you save and adds extra security to them; it is not the same as the SSL encryption used if you are passing files between IBM® SPSS® Modeler and IBM SPSS Modeler Server.

When you try to open an encrypted item, you are prompted to enter the password. After you enter the correct password, the item is decrypted automatically and opens as usual.

To Encrypt an Item

1. In the Save dialog box, for the item to be encrypted, click Options. The Encryption Options dialog box opens.
2. Select Encrypt this file.
3. Optionally, for further security, select Mask password. This displays anything you enter as a series of dots.
4. Enter the password. *Warning:* If you forget the password, the file or model cannot be opened.
5. If you selected Mask password, re-enter the password to confirm that you entered it correctly.
6. Click OK to return to the Save dialog box.

Note: If you save a copy of any encryption-protected item, the new item is automatically saved in an encrypted format using the original password unless you change the settings in the Encryption Options dialog box.

Loading files

You can reload a number of saved objects in IBM® SPSS® Modeler:

- Streams (.str)
- States (.cst)
- Models (.gm)
- Models palette (.gen)
- Nodes (.nod)
- Output (.cou)
- Projects (.cpj)

Opening new files

Streams can be loaded directly from the File menu.

- On the File menu, click Open Stream.

All other file types can be opened using the submenu items available on the File menu. For example, to load a model, on the File menu click:

`Models > Open Model` or `Load Models Palette`

Opening recently used files

For quick loading of recently used files, you can use the options at the bottom of the File menu.

Select Recent Streams, Recent Projects, or Recent States to expand a list of recently used files.

Mapping Data Streams

Using the mapping tool, you can connect a new data source to a preexisting stream. The mapping tool will not only set up the connection but it will also help you to specify how fields in the new source will replace those in the existing stream. Instead of re-creating an entire data stream for a new data source, you can simply connect to an existing stream.

The data mapping tool allows you to join together two stream fragments and be sure that all of the (essential) field names match up properly. In essence, mapping data results simply in the creation of a new Filter node, which matches up the appropriate fields by renaming them.

There are two equivalent ways to map data:

Select replacement node. This method starts with the node to be replaced. First, you right-click the node to replace; then, using the Data Mapping > Select Replacement Node option from the pop-up menu, select the node with which to replace it.

Map to. This method starts with the node to be introduced to the stream. First, right-click the node to introduce; then, using the Data Mapping > Map To option from the pop-up menu, select the node to which it should join. This method is particularly useful for mapping to a terminal node. Note: You cannot map to Merge or Append nodes. Instead, you should simply connect the stream to the Merge node in the normal manner.

Data mapping is tightly integrated into stream building. If you try to connect to a node that already has a connection, you will be offered the option of replacing the connection or mapping to that node.

- [Examining Mapped Fields](#)

Related information

- [Mapping Data to a Template](#)
- [Mapping between Streams](#)
- [Specifying Essential Fields](#)
- [Examining Mapped Fields](#)

Mapping Data to a Template

To replace the data source for a template stream with a new source node bringing your own data into IBM® SPSS® Modeler, you should use the Select Replacement Node option from the Data Mapping pop-up menu. This option is available for all nodes except Merge, Aggregate, and all terminal nodes. Using the data mapping tool to perform this action helps ensure that fields are matched properly between the existing stream operations and the new data source. The following steps provide an overview of the data mapping process.

Step 1: Specify essential fields in the original source node. In order for stream operations to run properly, essential fields should be specified. See the topic [Specifying Essential Fields](#) for more information.

Step 2: Add new data source to the stream canvas. Using one of the source nodes, bring in the new replacement data.

Step 3: Replace the template source node. Using the Data Mapping option on the pop-up menu for the template source node, click Select Replacement Node, then select the source node for the replacement data.

Step 4: Check mapped fields. In the dialog box that opens, check that the software is mapping fields properly from the replacement data source to the stream. Any unmapped essential fields are displayed in red. These fields are used in stream operations and must be replaced with a similar field in the new data source in order for downstream operations to function properly. See the topic [Examining Mapped Fields](#) for more information.

After using the dialog box to ensure that all essential fields are properly mapped, the old data source is disconnected and the new data source is connected to the stream using a Filter node called *Map*. This Filter node directs the actual mapping of fields in the stream. An *Unmap* Filter node is also included on the stream canvas. The *Unmap* Filter node can be used to reverse field name mapping by adding it to the stream. It will undo the mapped fields, but note that you will have to edit any downstream terminal nodes to reselect the fields and overlays.

Related information

- [Mapping Data Streams](#)
- [Mapping between Streams](#)
- [Specifying Essential Fields](#)
- [Examining Mapped Fields](#)

Mapping between Streams

Similar to connecting nodes, this method of data mapping does not require you to set essential fields beforehand. With this method, you simply connect from one stream to another using Map to from the Data Mapping pop-up menu. This type of data mapping is useful for mapping to terminal nodes and copying and pasting between streams. *Note:* Using the Map to option, you cannot map to Merge, Append, and all types of source nodes.

To Map Data between Streams

1. Right-click the node that you want to use for connecting to the new stream.
2. On the menu, click:
 Data Mapping > Map to
3. Use the cursor to select a destination node on the target stream.
4. In the dialog box that opens, ensure that fields are properly matched and click OK.

Related information

- [Mapping Data Streams](#)
- [Mapping Data to a Template](#)
- [Specifying Essential Fields](#)
- [Examining Mapped Fields](#)

Specifying Essential Fields

When mapping to an existing stream, essential fields will typically be specified by the stream author. These essential fields indicate whether a particular field is used in downstream operations. For example, the existing stream may build a model that uses a field called *Churn*. In this stream, *Churn* is an essential field because you could not build the model without it. Likewise, fields used in manipulation nodes, such as a Derive node, are necessary to derive the new field. Explicitly setting such fields as essential helps to ensure that the proper fields in the new source node are mapped to them. If mandatory fields are not mapped, you will receive an error message. If you decide that certain manipulations or output nodes are unnecessary, you can delete the nodes from the stream and remove the appropriate fields from the Essential Fields list.

To Set Essential Fields

1. Right-click the source node of the template stream that will be replaced.
2. On the menu, click:
 Data Mapping > Specify Essential Fields
3. Using the Field Chooser, you can add or remove fields from the list. To open the Field Chooser, click the icon to the right of the fields list.

Related information

- [Mapping Data Streams](#)
- [Mapping Data to a Template](#)
- [Mapping between Streams](#)
- [Examining Mapped Fields](#)

Examining Mapped Fields

Once you have selected the point at which one data stream or data source will be mapped to another, a dialog box is displayed for you to select fields for mapping or to ensure that the system default mapping is correct. If essential fields have been set for the stream or data source and they are unmatched, these fields are displayed in red. Any unmapped fields from the data source will pass through the Filter node unaltered, but note that you can map non-essential fields as well.

Original. Lists all fields in the template or existing stream—all of the fields that are present further downstream. Fields from the new data source will be mapped to these fields.

Mapped. Lists the fields selected for mapping to template fields. These are the fields whose names may have to change to match the original fields used in stream operations. Click in the table cell for a field to activate a list of available fields.

If you are unsure of which fields to map, it may be useful to examine the source data closely before mapping. For example, you can use the Types tab in the source node to review a summary of the source data.

Tips and Shortcuts

Work quickly and easily by familiarizing yourself with the following shortcuts and tips:

- **Build streams quickly by double-clicking.** Simply double-click a node on the palette to add and connect it to the current stream.
- **Use key combinations to select downstream nodes.** Press Ctrl+Q and Ctrl+W to toggle the selection of all nodes downstream.
- **Use shortcut keys to connect and disconnect nodes.** When a node is selected in the canvas, press F2 to begin a connection, press Tab to move to the required node, and press Shift+Spacebar to complete the connection. Press F3 to disconnect all inputs and outputs to the selected node.
- **Customize the Nodes Palette tab with your favorite nodes.** On the Tools menu, click Manage Palettes to open a dialog box for adding, removing, or moving the nodes shown on the Nodes Palette.
- **Rename nodes and add ToolTips.** Each node dialog box includes an Annotations tab on which you can specify a custom name for nodes on the canvas as well as add ToolTips to help organize your stream. You can also include lengthy annotations to track progress, save process details, and denote any business decisions required or achieved.
- **Insert values automatically into a CLEM expression.** Using the Expression Builder, accessible from a variety of dialog boxes (such as those for Derive and Filler nodes), you can automatically insert field values into a CLEM expression. Click the values button on the Expression Builder to choose from existing field values.

Figure 1. Values button

- **Browse for files quickly.** When browsing for files on an Open dialog box, use the File list (click the yellow diamond button at the top of the dialog box, next to the Look In field) to access previously used directories as well as IBM® SPSS® Modeler default directories. Use the forward and back buttons to scroll through accessed directories.
- **Minimize output window clutter.** You can close and delete output quickly using the red X button at the top right corner of all output windows. This enables you to keep only promising or interesting results on the Outputs tab of the managers pane.

A full range of keyboard shortcuts is available for the software. See the topic [Keyboard Accessibility](#) for more information.

Did you know that you can...

- Drag and select a group of nodes on the stream canvas using your mouse.
- Copy and paste nodes from one stream to another.
- Access Help from every dialog box and output window.
- Get Help on CRISP-DM, the Cross-Industry Standard Process for Data Mining. (On the Help menu, click CRISP-DM Help.)

Building charts

Required service

Watson Studio

Data format

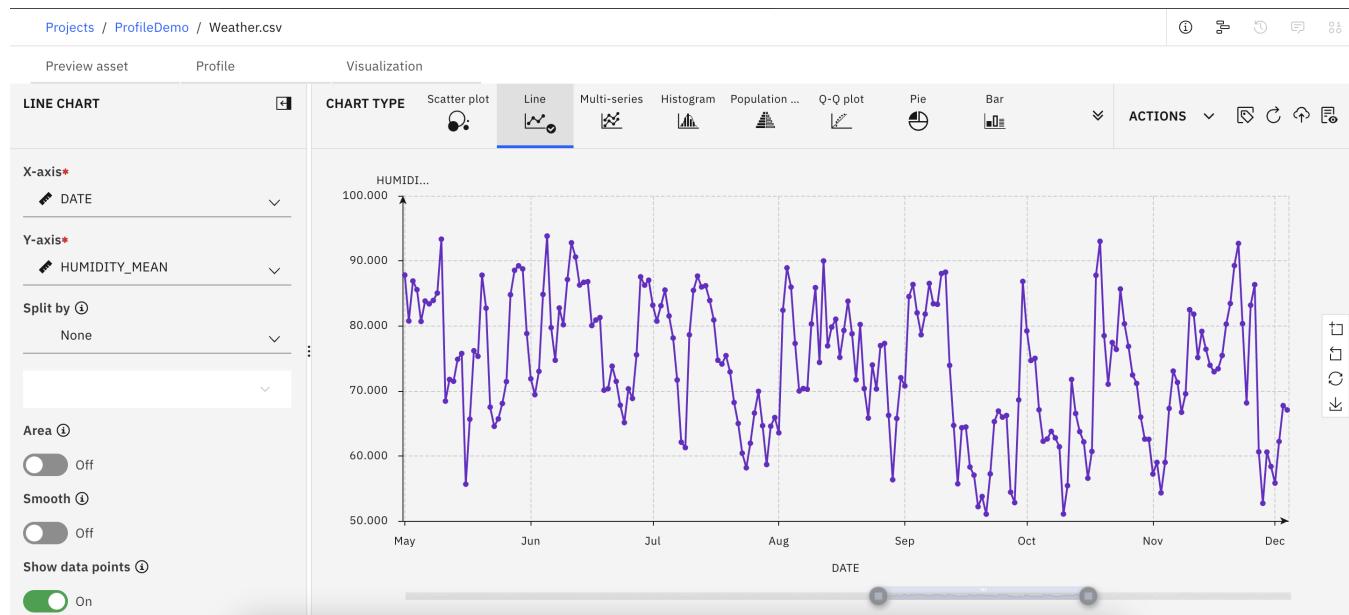

Tabular: Avro, CSV, JSON, Parquet, TSV, SAV, Microsoft Excel .xls and .xlsx files, SAS, delimited text files, and connected data.

For more information on supported data sources, see [Connection types](#).

Data size

No limit

You can create graphics similar to the following example that shows how humidity values over time.

Starting the Chart builder

- Right-click the data node that you want to work with and then select View Data.
- [Chart catalog](#)
- [Layout and terms](#)
- [Building a chart from the chart type gallery](#)
- [Chart types](#)
- [Global visualization preferences](#)

Chart catalog

The Chart catalog provides options for finding suitable charts by browsing chart categories, using keyword search, or filtering by chart characteristics. The Chart catalog can be accessed from any active dataset tab.

From any active dataset tab click the Chart builder control that is available in the toolbar. Alternately, access the catalog through Visualize > Chart builder.... There are various methods you can use to search for suitable chart types.

- The Find chart type field can be used to search for specific charts and keywords. As you enter a chart name or keywords, the number of available chart tiles filters to provide results for only the specified chart names or keywords.
Note: You can use the tile view and list view icons next to the Find chart type field to control how chart types are presented in the Chart catalog.
- The Chart catalog tiles are grouped according to the their corresponding categories. You can scroll through the available tiles until you locate the desired chart type.
- The Filter pane provides options for filtering charts according to their corresponding categories, purpose, dependent variables, and statistics.
Notes:
 - The number next to each Filter pane heading identifies the number of filters that are currently selected for each section.
 - Click Reset filter to clear the Filter pane settings.

Layout and terms

Canvas

The canvas is the area of the Chart Builder dialog where you build the chart.

Chart type

Lists the available chart types. The graphic elements are the items in the chart that represent data (bars, points, lines, and so on).

Details pane

The Details pane provides the basic chart building blocks.

Chart settings

Provides options for selecting which variables are used to build the chart, distribution method, title and subtitle fields, and so on. Depending on the selected chart type, the Details pane options might vary. For more information, see [Chart types](#).

Actions

Provides options for downloading chart configuration files, downloading charts as image files, resetting charts, and setting the global chart preferences.

Building a chart from the chart type gallery

Use chart type gallery for building charts. Following are general steps for building a chart from the gallery. For more information, see [Chart types](#).

1. In the Chart Type section, select a chart category. A preview version of the selected chart type is shown on the chart canvas.
2. If the canvas already displays a chart, the new chart replaces the chart's axis set and graphic elements.
 - a. Depending on the selected chart type, the available variables are presented under a number of different headings in the Details pane (for example, Category for bar charts, X-axis and Y-axis for line charts). Select the appropriate variables for the selected chart type.

Chart types

The gallery contains a collection of the most commonly used charts.

3D charts

3D charts are commonly used to represent multiple-variable functions and include a z-axis variable that is a function of both the x and y-axis variables.

Creating a simple 3D chart

1. In the Chart Type section, click the 3D icon.

3D

The canvas updates to display a 3D chart template.

2. Select the chart Type from the drop-down list.
3. Select an X-axis variable from the drop-down list.
4. Select an Y-axis variable from the drop-down list.
5. Select an Z-axis variable from the drop-down list.

Options

Type

Lists the chart types that are available to represent the data.

X-axis

Lists variables that are available for the chart's X-axis.

Y-axis

Lists variables that are available for the chart's Y-axis.

Z-axis

Lists variables that are available for the chart's Z-axis.

Tooltip info

Lists the variables that can be used to generate tooltip information when the cursor hovers over a data point.

Color map

Lists available color map variables. These variables use color progression, based on the range of values in the specified column, to represent themselves in the plot points. Color maps are also known as choropleth maps.

Size map

Lists available size map variables. These variables use differing sizes to represent themselves in the plot points.

Z ratio

Sets the scale of the Z-axis data values, relative to the X and Y axes.

Rotate

Enables and disables chart rotation.

Data point tooltips

Controls where the data point tooltips display (right of data points, top-right of chart, or hide).

Primary title

The chart title.

Subtitle

The chart subtitle, which is placed directly beneath the chart title.

Footnote

The chart footnote, which is placed beneath the chart.

Bar charts

Bar charts are useful for summarizing categorical variables. For example, you can use a bar chart to show the number of men and the number of women who participated in a survey. You can also use a bar chart to show the mean salary for men and the mean salary for women.

Creating a simple bar chart

1. In the Chart Type section, click the Bar icon.

Bar

The canvas updates to display a bar chart template.

2. Select a categorical (nominal or ordinal) variable as the Category variable. You can use a scale variable, but the results are useful in only a few special cases. A bar chart looks best with a limited number of distinct values. If you create a bar chart with a scale Category axis, the bars are thin because each bar is drawn at an exact value, and the bar cannot overlap other continuous values.
3. Select a statistic from the Summary list. The result of any statistic determines the height of the bars. If the statistic you want does not appear in the Summary list, it might require a variable. Select a variable from the Value list and check if the statistic is now available. Other chart type limitations might exist. For example, error bar charts can be calculated only for specific statistics.

Options

Category

Lists variables that are available for the chart's X-axis.

Order based on

Select a sorting option for the categories within the variable.

Category name

Use the category labels for sorting the variable's categories. The labels appear in the chart, usually as tick or legend labels.

Category value

Use the value that is stored in the data set for sorting the variable's categories. The category's value is what identifies the category in the data set. It often differs from its label and is not necessarily descriptive. For example, the value might be a number (for example, 1), while the label is a text description of the category (for example, *Female*).

Category order

Select the order in which variable categories are sorted.

As read

Variable categories are presented as they appear in the data set.

Ascending

Sort variable categories in ascending order.

Descending

Sort variable categories in descending order.

Summary

Select a statistical summary function for the graphic element. The result of the statistic determines the position of the graphic elements on the Y-axis. In a 2-D chart, the statistic is calculated for each value on the X-axis. In a 3-D chart, it is calculated for the intersection of values on the X-axis and Z-axis.

Two types of statistical summary functions are available. The distinction is important because it determines whether you need to specify a Value variable.

- **Functions that do not require a value variable.** Functions that do not require a variable. All count and percentage statistics are in this category. These statistics are available when the Value variable is not defined.
- **Functions that do require a value variable.** Functions that do require a Value variable. For example, the **Mean** function requires a variable on which the mean is calculated. These statistics are available when the Value variable is not defined.

Value

This field displays when a Summary function that requires a value variable, is selected. Select a variable to serve as the value.

Split by

Select a categorical variable that creates a table of charts, with a cell for each category in the Split by variable. Like grouping, split by variables essentially add more dimensions to your chart by displaying information for each variable category. For more information, see [Adding Split by variables](#).

Split type

When a Split by variable is selected, you can choose to display the resulting category bars as either stacked or clustered. Clustering and stacking add dimensionality within the chart. Clustering splits one bar into multiple bars, and stacking creates segments in each bar. Be careful that you choose the right statistic for stacking. When the values are added (stacked), the result must make sense. For example, adding and stacking mean (averaged) values is not usually meaningful.

Bar type

Select the bar chart type from the provided options.

- X-axis
- Y-axis
- X-axis inverse
- Y-axis inverse
- Polar-angle axis
- Polar-radius axis
- Polar-rainbow

Label position

Select the chart's label position from the drop-down menu.

- none
- top
- left
- right
- bottom
- inside
- insideLeft
- insideRight
- insideTop
- insideBottom
- insideTopLeft
- insideBottomLeft

- insideTopRight
- insideBottomRight

Show reference line

The toggle control enables and disables the display of reference lines in the chart. Available options are Min, Max, and Average, which display reference lines at the chart's minimum, maximum and average values.

Enter a reference line value

When Show reference line is enabled, this setting provides the option of specifying a reference line value. Click Add another column to specify more reference line values.

Transpose

When enabled, the chart's X and Y axes are transposed.

Primary title

The chart title.

Subtitle

The chart subtitle, which is placed directly beneath the chart title.

Footnote

The chart footnote, which is placed beneath the chart.

XAxis label

The x-axis label, which is placed beneath the x-axis.

YAxis label

The y-axis label, which is placed above the y-axis.

Box plots

A box plot chart shows the five statistics (minimum, first quartile, median, third quartile, and maximum). It is useful for displaying the distribution of a scale variable and pinpointing outliers.

Creating a simple box plot

1. In the Chart Type section, click the Box plot icon.

Box plot

The canvas updates to display a box plot chart template.

2. Select one or more scale variables as the Columns variable.

Note: The statistic for a dot plot is Box plot. You cannot change this setting.

Options

Columns

Lists variables that are available for the chart's X-axis.

Click Add another column to add more columns.

Split by

Select a categorical variable that creates a table of charts, with a cell for each category in the Split by variable. Like grouping, split by variables essentially add more dimensions to your chart by displaying information for each variable category. For more information, see [Adding Split by variables](#).

Category order

Select the order in which variable categories are sorted.

As read

Variable categories are presented as they appear in the data set.

Ascending

Sort variable categories in ascending order.

Descending

Sort variable categories in descending order.

Strength holder of IQR

The strength holder of the inter-quartile range (**N*IQR**). The **N** default value is 1.5.

Normalize data

When enabled, this setting transforms data into a normal distribution compares data from multiple data sets or multiple columns. This setting creates 100% stacking for counts and converts statistics to percents.

Transpose

When enabled, the chart's X and Y axes are transposed.

Show the outlier

When enabled, outliers display on the chart.

Show extreme outlier style
When enabled, extreme outlier style displays on the chart.

Show label
When enabled, column labels display on the chart. Only scatter series data is supported.

Primary title
The chart title.

Subtitle
The chart subtitle, which is placed directly beneath the chart title.

Footnote
The chart footnote, which is placed beneath the chart.

XAxis label
The x-axis label, which is placed beneath the x-axis.

YAxis label
The y-axis label, which is placed above the y-axis.

Bubble charts

Bubble charts display categories in your groups as nonhierarchical packed circles. The size of each circle (bubble) is proportional to its value. Bubble charts are useful for comparing relationships in your data.

Creating a simple bubble chart

1. In the Chart Type section, click the Bubble icon.

Bubble

The canvas updates to display a bubble chart template.

2. Select a Columns variable from the drop-down list.
Note: Click Add another column to include more column variables.

Options

Columns
Lists variables that are available for the chart.
Click Add another column to add more columns.

Group color
Turn on or off color groupings.

Primary title
The chart title.

Subtitle
The chart subtitle, which is placed directly beneath the chart title.

Footnote
The chart footnote, which is placed beneath the chart.

Candlestick charts

Candlestick charts are a style of financial charts that are used to describe price movements of a security, derivative, or currency. Each candlestick element typically shows one day. A one-month chart might show the 20 trading days as 20 candlesticks elements. Candlestick charts are most often used in the analysis of equity and currency price patterns and are similar to box plots.

The data set that is used to create a candlestick chart must contain open, high, low, and close values for each time period you want to display.

Creating a simple Candlestick chart

1. In the Chart Type section, click the Candlestick icon.

Candlestick

The canvas updates to display a Candlestick chart template.

2. Select a variable as the X-axis variable.
3. Select a variable as the High variable.
4. Select a variable as the Low variable.

Options

X-axis

Lists variables that are available for the chart's X-axis.

Summary

When enabled, summary calculations for available for the following options.

High

Lists variables that are available for the chart's high price value.

High field summary

Select a statistical summary function for the selected high variable.

Low

Lists variables that are available for the chart's low price value.

Open

Lists variables that are available for the chart's opening price value.

Close

Lists variables that are available for the chart's closing price value.

Volume

Lists variables that are available for the chart's volume bars.

Category order

Select the order in which variable categories are sorted.

As read

Variable categories are presented as they appear in the data set.

Ascending

Sort variable categories in ascending order.

Descending

Sort variable categories in descending order.

Candlestick

Toggles the chart data to display as either candlestick or line.

Primary title

The chart title.

Subtitle

The chart subtitle, which is placed directly beneath the chart title.

Footnote

The chart footnote, which is placed beneath the chart.

XAxis label

The x-axis label, which is placed beneath the x-axis.

YAxis label

The y-axis label, which is placed above the y-axis.

Circle packing charts

Circle packing charts display hierarchical data as a set of nested areas to visualize a large amount of hierarchically structured data. It's similar to a treemap, but uses circles instead of rectangles. Circle packing charts use containment (nesting) to display hierarchy data.

Creating a simple circle packing chart

1. In the Chart Type section, click the Time plot icon.

Circle packing

The canvas updates to display a circle packing chart template.

2. Select a Columns variable from the drop-down list.

Note: Click Add another column to include more column variables.

Options

Columns

Lists variables that are available for the chart.

Click Add another column to add more columns.

Group color

Turn on or off color groupings.

Summary

Select a statistical summary function (the method that is used for summarizing each category).

Two types of statistical summary functions are available. The distinction is important because it determines whether you need to specify a Value variable.

- **Functions that do not require a value variable.** Functions that do not require a variable. All count and percentage statistics are in this category. These statistics are available when the Value variable is not defined.
- **Functions that do require a value variable.** Functions that do require a Value variable. For example, the **Mean** function requires a variable on which the mean is calculated. These statistics are available when the Value variable is not defined.

Value

This field displays when a Summary function that requires a value variable, is selected. Select a variable to serve as the value.

Primary title

The chart title.

Subtitle

The chart subtitle, which is placed directly beneath the chart title.

Footnote

The chart footnote, which is placed beneath the chart.

Custom charts

The custom charts option provides options for pasting or editing JSON code to create the wanted chart.

Creating a custom chart

1. In the Chart Type section, click the Customized icon.

Customized

2. Paste the JSON code that contains the chart specifications into the provided JSON script field in the Details pane.

Dendrogram charts

Dendrogram charts are similar to tree charts and are typically used to illustrate a network structure (for example, a hierarchical structure). Dendrogram charts consist of a root node that is connected to subordinate nodes through edges or branches. The last nodes in the hierarchy are called leaves.

Creating a simple dendrogram chart

1. In the Chart Type section, click the Dendrogram icon.

Dendrogram

The canvas updates to display a Dendrogram chart template.

2. Select at least two variables from the Field name list. You can select SELECT ALL to select all available variables. A maximum number 300 variables are recommended.

Options

Field name

The list provides all available variables that represent the leave nodes. You must select at least two variables.

Show axis

The toggle control enables or disables the display of the distance value axis.

Linkage

The linkage criterion determines the distance between sets of observations as a function of the pairwise distances between observations.

Select Average distance, Min distance, or Max distance.

Tree layout

Left to right

The root node displays on the left and the leaf nodes display on the right.

Right to left

The root node displays on the right and the leaf nodes display on the left.

Top to bottom

The root node displays on the top and the leaf nodes display on the bottom.

Bottom to top

The root node displays on the bottom and the leaf nodes display on the top.

Radial

The root node displays in the middle and the leaf nodes radiate from the root.

Primary title

The chart title.

Subtitle

The chart subtitle, which is placed directly beneath the chart title.

Footnote

The chart footnote, which is placed beneath the chart.

Dual Y-axes charts

A dual Y-axes chart summarizes or plots two Y-axes variables that have different domains. For example, you can plot the number of cases on one axis and the mean salary on another. This chart can also be a mix of different graphic elements so that the dual Y-axes chart encompasses several of the different chart types. Dual Y-axes charts can display the counts as a line and the mean of each category as a bar.

Creating a simple Dual Y-axes chart

1. In the Chart Type section, click the Dual Y-axes icon.

Dual Y-axes

The canvas updates to display a Dual Y-axes chart template.

2. Select a variable as the X-axis variable.
 3. Select variable for the first Y-axis variable and then select a chart type to represent the variable (Bar, Line, or Scatter plot).
 4. Select variable for the second Y-axis variable and then select a chart type to represent the variable (Bar, Line, or Scatter plot).
- Note: You can use the up and down arrow controls to change the Y-axes order.

Options

X-axis

Lists variables that are available for the chart's X-axis.

Y-axis

Lists variables that are available for the chart's dual Y-axes.

Summary

When enabled, options for selecting the method that is used for summarizing each category are displayed.

Left Y-axis summary

Sets the summary method for the Y-axis that displays on the left side of the chart. Options include Sum, Mean, Maximum, and Minimum.

Right Y-axis summary

Sets the summary method for the Y-axis that displays on the right side of the chart. Options include Sum, Mean, Maximum, and Minimum.

Normalize data

When enabled, data is transformed into a normal distribution, which allows data from multiple data sets or columns to be easily compared.

Second axis lines

When enabled, the chart's second axis line is shown.

Reorder

When enabled, the chart's data is reordered based on the X and Y axis values.
Legend orient
Sets the chart legend orientation. Available options are Horizontal, Vertical, and Vertical bottom.
Primary title
The chart title.
Subtitle
The chart subtitle, which is placed directly beneath the chart title.
Footnote
The chart footnote, which is placed beneath the chart.
XAxis label
The x-axis label, which is placed beneath the x-axis.
YAxis label
The y-axis label, which is placed above the y-axis.

Error bar charts

Error bar charts represent the variability of data and indicate the error (or uncertainty) in a reported measurement. Error bars help determine whether differences are statistically significant. Error bars can also suggest goodness of fit for a specific function.

Creating a simple error bar chart

1. In the Chart Type section, click the Error bar icon.

Error bar

The canvas updates to display an error bar chart template.

2. Select a scale variable as the Category variable (the variable whose data is represented on the X-axis).
3. Select a variable as the Y-axis variable (the variable whose data is represented on the Y-axis).

Options

Category	Lists variables that are available for the chart's X-axis.
Y-axis	Lists variables that are available for the chart's Y-axis.
Category order	Select the order in which variable categories are sorted.
As read	Variable categories are presented as they appear in the data set.
Ascending	Sort variable categories in ascending order.
Descending	Sort variable categories in descending order.
Split by	Select a categorical variable that creates a table of charts, with a cell for each category in the Split by variable. Like grouping, split by variables essentially add more dimensions to your chart by displaying information for each variable category. For more information, see Adding Split by variables .
Reference line	When enabled, displays a reference line on the chart. The reference line correlates with the selected Statistical method.
Error bars	When enabled, the lines that represent the range of error are displayed in the chart.
Measure	Select the measure type that is represented by the error bars:
Confidence intervals	Sets the confidence intervals for the selected variables. The default value is 0.95 (95%), as reflected in the Represent value field.
Standard error	Measures the standard error of the selected variables.
Standard deviation	Measures the standard deviations of the selected variables.
Confidence level	This value represents the confidence intervals for the selected Measure. The default value is 0.95 (95%).

Statistical method

Select the method for describing the central tendency:

Mean

The result of summing the ratios and dividing the result by the total number ratios.

Median

The value such that number of ratios less than this value and the number of ratios greater than this value are the same.

Display mode

Select how the Statistical method selection displays (bar, line, or circle).

Legend orient

Sets the chart legend orientation. Available options are Horizontal, Vertical, and Vertical bottom.

Primary title

The chart title.

Subtitle

The chart subtitle, which is placed directly beneath the chart title.

Footnote

The chart footnote, which is placed beneath the chart.

XAxis label

The x-axis label, which is placed beneath the x-axis.

YAxis label

The y-axis label, which is placed above the y-axis.

Evaluation charts

Evaluation charts are similar to histograms or collection graphs. Evaluation charts show how accurate models are in predicting particular outcomes. They work by sorting records based on the predicted value and confidence of the prediction, splitting the records into groups of equal size (quantiles), and then plotting the value of the criterion for each quantile, from highest to lowest. Multiple models are shown as separate lines in the plot.

Outcomes are handled by defining a specific value or range of values as a "hit". Hits usually indicate success of some sort (such as a sale to a customer) or an event of interest (such as a specific medical diagnosis).

Flag

Output fields are straightforward; hits correspond to `true` values.

Nominal

For nominal output fields, the first value in the set defines a hit.

Continuous

For continuous output fields, hits equal values greater than the midpoint of the field's range.

Evaluation charts can also be cumulative so that each point equals the value for the corresponding quantile plus all higher quantiles. Cumulative charts usually convey the overall performance of models better, whereas noncumulative charts often excel at indicating particular problem areas for models.

Creating a simple Evaluation chart

1. In the Chart Type section, click the Evaluation icon.

Evaluation

The canvas updates to display an Evaluation chart template.

2. Set the Target field, Predict field and Confidence field variables. The target field can be any instantiated flag or nominal field with two or more values. The predict field defines the variable that is used as the predicted value. The confidence field defines the variable that is used to establish the confidence of the prediction.

Note: The Predict field variable type must match the variable type that is selected for the Target field.

3. Specify a custom condition used to indicate the User defined hit. This option is useful for defining the outcome of interest rather than deducing it from the type of target field and the order of values.

You must specify a CLEM expression for a hit condition. For example, `@TARGET = "YES"` is a valid condition that indicates a value of `Yes` for the target field is counted as a hit in the evaluation. The specified condition is used for all target fields.

Options

Target field

Lists instantiated flag or nominal field variables with two or more values.

User defined hit

Specify a hit value. Hits indicate events of interest (for example, a specific medical diagnosis).

Predict field

Lists variables that can be used as the predicted value.

Confidence field

Lists variables that can establish the confidence of the prediction.

Cumulative plot

Create a cumulative chart when enabled. Values in cumulative charts are plotted for each quantile plus all higher quantiles.

Display mode

The settings control which charts display in preview mode and in the output.

Single mode

When selected, the Model Classification Tuning chart is in the only chart that displays in preview mode and in the output.

Classical mode

When selected, the Model Classification Tuning, Cutoff, Matrix Bar, ROC, Gains, ROI, and Profit charts display in preview mode and in the output.

Full mode

When selected, the Model Classification Tuning, Cutoff, Matrix Bar, ROC, Gains, ROI, Profit, GINI, Lift, and Response charts display in preview mode and in the output.

Evaluation charts

Cutoff

The cutoff chart shows the predicted versus actual values for selected variables for a specified cutoff value.

Matrix Bar

Matrix Bar charts are a good way to determine whether linear correlations exist between multiple variables.

ROC

ROC (Receiver Operating Characteristic) evaluates the performance of classification schemes where subjects are classified for one variable with two categories.

Gains

Gains are defined as the proportion of total hits that occurs in each quantile. Gains are computed as `(number of hits in quantile / total number of hits) × 100%`.

ROI

ROI (return on investment) is similar to profit in that it involves defining revenues and costs. ROI compares profits to costs for the quantile. ROI is computed as `(profits for quantile / costs for quantile) × 100%`.

Profit

Profit equals the revenue for each record minus the cost for the record. Profits for a quantile are the sum of profits for all records in the quantile. Revenues are assumed to apply only to hits, but costs apply to all records. Profits and costs can be fixed or can be defined by fields in the data. Profits are computed as `(sum of revenue for records in quantile – sum of costs for records in quantile)`.

Kolmogorov-Smirnov

Compares the observed cumulative distribution function for a variable with a specified theoretical distribution, which can be normal, uniform, exponential, or Poisson.

GINI

GINI measures statistical dispersion and is intended to represent the income or wealth distribution. It is the most commonly used measurement of inequality.

Lift

Lift compares the percentage of records in each quantile that are hits with the overall percentage of hits in the training data. It is computed as `(hits in quantile / records in quantile) / (total hits / total records)`.

Response

Response is the percentage of records in the quantile that are hits. Response is computed as `(hits in quantile / records in quantile) × 100%`.

Evaluation chart settings

The following settings apply only to profit and ROI charts.

Costs

Specify the fixed cost associated with each record.

Revenue

Specify the fixed revenue associated with each record that represents a hit.

Weight

If the records in your data represent more than one unit, you can use frequency weights to adjust the results. Specify the fixed weight associated with each record.

Heat map charts

Heat map charts present data where the individual values that are contained in a matrix are represented as colors.

Creating a simple heat map chart

1. In the Chart Type section, click the Heat map icon.

Heat map

The canvas updates to display a heat map chart template.

2. Select a variable as the Column variable. Each variable category is represented as an individual chart column.

3. Select a variable as the Row variable. Each variable category is represented as an individual chart row.

Options

Column

Lists variables that are available for the chart's columns. Each variable category is represented as an individual chart column.

Row

Lists variables that are available for the chart's rows. Each variable category is represented as an individual chart row.

Category order

Select the order in which variable categories are sorted.

As read

Variable categories are presented as they appear in the data set.

Ascending

Sort variable categories in ascending order.

Descending

Sort variable categories in descending order.

Summary

Select a statistical summary function for the graphic element. The result of the statistic determines the position of the graphic elements on the Y-axis. In a 2-D chart, the statistic is calculated for each value on the X-axis. In a 3-D chart, it is calculated for the intersection of values on the X-axis and Z-axis.

Two types of statistical summary functions are available. The distinction is important because it determines whether you need to specify a Value variable.

- **Functions that do not require a value variable.** Functions that do not require a variable. All count and percentage statistics are in this category. These statistics are available when the Value variable is not defined.
- **Functions that do require a value variable.** Functions that do require a Value variable. For example, the **Mean** function requires a variable on which the mean is calculated. These statistics are available when the Value variable is not defined.

Value

This field displays when a Summary function that requires a value variable, is selected. Select a variable to serve as the value.

Primary title

The chart title.

Subtitle

The chart subtitle, which is placed directly beneath the chart title.

Footnote

The chart footnote, which is placed beneath the chart.

XAxis label

The x-axis label, which is placed beneath the x-axis.

YAxis label

The y-axis label, which is placed above the y-axis.

Histogram charts

A histogram is similar in appearance to a bar chart, but instead of comparing categories or looking for trends over time, each bar represents how data is distributed in a single category. Each bar represents a continuous range of data or the number of frequencies for a specific data point. Histograms are useful for showing the distribution of a single scale variable. Data are binned and summarized by using a count or percentage statistic. A variation of a histogram is a frequency polygon, which is like a typical histogram except that the area graphic element is used instead of the bar graphic element.

Another variation of the histogram is the population pyramid. Its name is derived from its most common use: summarizing population data. When used with population data, it is split by gender to provide two back-to-back, horizontal histograms of age data. In countries with a young population, the shape of the resulting graph resembles a pyramid.

Creating a histogram chart

1. In the Chart Type section, click the Histogram icon.

Histogram *

The canvas updates to display a histogram chart template.

2. Select a scale variable as the X-axis variable.

Note: The statistic for a histogram is Histogram or Histogram Percent. These statistics bin the data and calculate a count for each bin.

Options

X-axis

Lists variables that are available for the chart's X-axis.

Split by

Select a categorical variable that creates a table of charts, with a cell for each category in the Split by variable. Like grouping, split by variables essentially add more dimensions to your chart by displaying information for each variable category. For more information, see [Adding Split by variables](#).

Bin method

Specify a bin method that is used to create the chart bars. Available options include Auto bin, By bin width, and By bin num.

Show kde curve

When enabled, the kernel density estimate curve is shown on the chart.

Show distribution curve

When enabled, the distribution fitting curve is shown on the chart.

Distribution

The drop-down list provides the following distribution options.

Auto fit distribution

Automatically fits the distribution (the default setting).

Beta

Returns the value from a Beta distribution with specified shape parameters.

Exponential

Returns the value from an exponential distribution.

Gamma

Returns the value from the Gamma distribution, with the specified shape and scale parameters.

Log-normal

Returns the value from a log-normal distribution with specified parameters.

Normal

Returns the value from a normal distribution with specified mean and standard deviation.

Triangular

Returns the value from a triangular distribution with specified parameters.

Uniform

Returns the value from the uniform distribution between the minimum and maximum.

Weibull

Returns the value from a Weibull distribution with specified parameters.

Bin width

The slider controls the size of the interval that is used to split the data into groups.

Primary title

The chart title.

Subtitle

The chart subtitle, which is placed directly beneath the chart title.

Footnote

The chart footnote, which is placed beneath the chart.

XAxis label

The x-axis label, which is placed beneath the x-axis.

YAxis label

The y-axis label, which is placed above the y-axis.

Line charts

A line chart plots a series of data points on a graph and connects them with lines. A line chart is useful for showing trend lines with subtle differences, or with data lines that cross one another. You can use a line chart to summarize categorical variables, in which case it is similar to a bar chart (see [Bar charts](#)). Line charts are also useful for time-series data.

Creating a simple time-series line chart

1. In the Chart Type section, click the Line icon.

Line •

The canvas updates to display a line chart template.

2. Select a date variable as the X-axis variable.

3. Select a scale variable as the Y-axis variable (the variable whose values were recorded over time).

Options

X-axis

Lists variables that are available for the chart's X-axis.

Y-axis

Lists variables that are available for the chart's Y-axis.

Split by

Select a categorical variable that creates a table of charts, with a cell for each category in the Split by variable. Like grouping, split by variables essentially add more dimensions to your chart by displaying information for each variable category. For more information, see [Adding Split by variables](#).

Area

When enabled, the area beneath the line is shown in a different color.

Smooth

When enabled, the chart shows a smooth curve.

Show data points

When enabled, the data point is shown in the chart.

Reorder

The toggle control reorders data based on X and Y-axis values.

Fit line

In a fit line, the data points are fitted to a line that usually does not pass through all of the data points. The fit line represents the trend of the data. Some fits lines are regression-based. Others are based on iterative weighted least squares. Select a fit line option from the drop-down list.

Show reference line

When enabled, the option shows a reference line on the chart that is based on the specified xAxiS and yAxiS values.

Enter a reference line value on xAxiS

When Show reference line is enabled, this setting provides the option of specifying a specific reference line value for the X-axis.
Click Add another column to specify more reference line values.

Enter a reference line value on yAxiS

When Show reference line is enabled, this setting provides the option of specifying a specific reference line value for the Y-axis.
Click Add another column to specify more reference line values.

Primary title

The chart title.

Subtitle

The chart subtitle, which is placed directly beneath the chart title.

Footnote

The chart footnote, which is placed beneath the chart.

XAxis label

The x-axis label, which is placed beneath the x-axis.

YAxis label

The y-axis label, which is placed above the y-axis.

Map charts

Map charts are commonly used to compare values and show categories across geographical regions. Map charts are most beneficial when the data contains geographic information (countries, regions, states, counties, postal codes, and so on).

Creating a simple map chart

1. In the Chart Type section, click the Map icon.

Map

The canvas updates to display a map chart template.

2. Select a service to use for serving map images from the Map service drop-down list. The list provides options that cover specific global regions.
3. Select a map chart Type from the drop-down menu. The following options are available, dependent on the selected chart type:

Longitude

Select a variable to serve as the longitudinal value from the drop-down list.

Latitude

Select a variable to serve as the latitudinal value from the drop-down list.

Group

Select a variable that groups the data point locations from the drop-down menu.

Category

Select a column variable that you want to visualize.

Summary

Select a statistical summary function (the method that is used for summarizing each category).

Two types of statistical summary functions are available. The distinction is important because it determines whether you need to specify a Value variable.

- **Functions that do not require a value variable.** Functions that do not require a variable. All count and percentage statistics are in this category. These statistics are available when the Value variable is not defined.
- **Functions that do require a value variable.** Functions that do require a Value variable. For example, the **Mean** function requires a variable on which the mean is calculated. These statistics are available when the Value variable is not defined.

Value

This field displays when a Summary function that requires a value variable, is selected. Select a variable to serve as the value.

Options

Map service

Lists the services that are available for providing map images. See [Map service options](#).

Type

Lists the chart types that are available to represent the data.

Longitude

Lists the variables that are available to serve as the longitudinal value.

Latitude

Lists the variables that are available to serve as the latitudinal value.

Group

Lists the variables that can be used to group the data point locations.

Category

Lists column variables.

Summary

Select a statistical summary function (the method that is used for summarizing each category).

Two types of statistical summary functions are available. The distinction is important because it determines whether you need to specify a Value variable.

- **Functions that do not require a value variable.** Functions that do not require a variable. All count and percentage statistics are in this category. These statistics are available when the Value variable is not defined.
- **Functions that do require a value variable.** Functions that do require a Value variable. For example, the **Mean** function requires a variable on which the mean is calculated. These statistics are available when the Value variable is not defined.

Value

This field displays when a Summary function that requires a value variable, is selected. Select a variable to serve as the value.

Tooltip info

Lists the variables that can be used to generate tooltip information when the cursor hovers over a data point.

Size map

Lists available size map variables. These variables use differing sizes to represent themselves in the plot points.

Primary title

The chart title.

Subtitle

The chart subtitle, which is placed directly beneath the chart title.

Footnote

The chart footnote, which is placed beneath the chart.

- [Map service options](#)
-

Map service options

On the Details pane for Map charts, you can select the map service to use for providing map images.

Configuring map service options

1. Stop the IBM® SPSS® Modeler Server.
2. If you're going to apply local geojson formatted map files, put them in the directory <Modeler_installation_directory>/dataview/conf/public/mapfiles. If the directory doesn't exist, create it.
3. Open the file <Modeler_installation_directory>/dataview/conf/application.conf in a text editor and add the following options to the `map.resources` section. In this example, two new maps named `World - Local Map` and `World - Online Map` are added.

```
map.resources {
    "mapservices" :
    [
        {
            "type"      : "geojson",
            "name"      : "World (Built-in)",
            "location"  : "built_in_world",
            "id"        : "built_in_world"
        },
        {
            "type"      : "geojson",
            "name"      : "Blank (Built-in)",
            "location"  : "built_in_blank",
            "id"        : "built_in_blank"
        },
        {
            "type"      : "geojson",
            "name"      : "World - Local Map",
            "location"  : "/mapfiles/world.json",
            "useProxy"   : "false",
            "id"        : "world_local"
        },
        {
            "type"      : "geojson",
            "name"      : "World - Online Map",
            "location"  : "http://map.example.com/map/world.json",
            "useProxy"   : "true",
            "id"        : "world_online"
        }
    ]
}
```

The following parameters are available for the map options:

Table 1. Map service parameters

Option	Value	Type	Required?	Description
<code>type</code>	<code>geojson</code>	String	Yes	Currently, only the value <code>geojson</code> is supported for this option.
<code>name</code>	Map name	String	Yes	Enter a name for the map. This name is shown in the Map service drop-down on the Details pane for map charts.
<code>location</code>	Map location	String	Yes	Enter the URL or local file location of the map. For URL, it must begin with <code>http://</code> or <code>https://</code> . For local file, it must begin with the path <code>/mapfiles/</code> .
<code>useProxy</code>	<code>true</code> or <code>false</code>	String	Yes	Use <code>true</code> if the map location is a URL. Use <code>false</code> if the map location is a local file.
<code>id</code>	Map ID	String	Yes	Use an unique ID for each map.

Note:

- Don't remove the default World (Built-in) and Blank (Built-in) options.
- Remember to use a comma between the content blocks as shown in the example, and be sure your new `map.resources` section is valid JSON formatted content.
- The IBM SPSS Modeler Server (or the standalone SPSS Modeler Client without Server) must be able to access the map location.

4. Start the IBM SPSS Modeler Server.

Now while working with map charts, on the Details pane, you'll see the new map service you added.

Math curve charts

A math curve chart plots mathematical equation curves that are based on user-entered expressions.

Creating a simple math curve chart

1. In the Chart Type section, click the Math curve icon.

Math curve

The canvas updates to display a math curve chart template.

2. Enter a starting value for the X-axis in the X value starts from field.
3. Enter an ending value for the X-axis in the X value ends with field.
4. Enter an equation that plots the graph curve in the equations field. Click Add another column to include more equations. Each equation treats **x** as an independent variable. The following equations are allowed.

- +, -, *, /, %, and ^
- abs(x)
- ceil(x)
- floor(x)
- log(x)
- max(a,b,c...)
- min(a,b,c...)
- random()
- round(x)
- sqrt(x)
- sin
- cos
- exp
- tan
- atan
- atan2
- asin
- acos

Options

X value starts from

The X-axis starting value.

X value ends with

The X-axis ending value.

equations

User-entered equations that plot the graph curve.

Primary title

The chart title.

Subtitle

The chart subtitle, which is placed directly beneath the chart title.

Footnote

The chart footnote, which is placed beneath the chart.

XAxis label

The x-axis label, which is placed beneath the x-axis.

YAxis label

The y-axis label, which is placed above the y-axis.

Multi-chart charts

Multi-chart charts provide options for creating multiple charts. The charts can be of the same or different types, and can include different variables from the same data set.

Creating a simple multi-chart chart

1. In the Chart Type section, click the Multi-chart icon.

Multi-chart

The canvas updates to display a multi-chart chart template.

2. Click Add another sub-chart to add a subchart.
3. Select a chart type from the Type drop-down list.
4. Depending on the selected chart type, the following options are available:

Bar and Pie charts

Select a Category variable from the drop-down list.

Line and Scatter plot charts

Select an X-axis variable from the drop-down list.

Select an Y-axis variable from the drop-down list.

5. Click Add another sub-chart to include more charts types.

Options

Title

The subchart title.

Primary title

The chart title.

Subtitle

The chart subtitle, which is placed directly beneath the chart title.

Footnote

The chart footnote, which is placed beneath the chart.

Multiple series charts

Multiple series charts are similar to line charts, with the exception that you can chart multiple variables on the Y-axis.

Creating a simple multiple series chart

1. In the Chart Type section, click the Multi-series icon.

Multi-series

The canvas updates to display a multiple series chart template.

2. Select a variable as the X-axis variable.
3. Select at least two scale variables as the Y-axis variables.

Options

X-axis

Lists variables that are available for the chart's X-axis.

Y-axis

Lists variables that are available for the chart's Y-axes.

Select the chart type (bar, line, or scatter) from the drop-down list.

Click Add another column to include more columns on the chart.

Series style

Provides options for defining the Y-axes orientation. The following options are available.

- Default
- Separate Y axes
- Show a secondary Y axis
- Dual Y axes

Secondary Y-axis

Lists variables that are available for the chart's secondary Y-axes.

Select the chart type (bar, line, or scatter) from the drop-down list.

Click Add another column to include more columns on the chart.

Normalize data

When enabled, this setting transforms data into a normal distribution compares data from multiple data sets or multiple columns. This setting creates 100% stacking for counts and converts statistics to percents.

Reorder

When enabled, the chart's data is reordered based on the X and Y axis values.

Show label

When enabled, column labels display on the chart. Only scatter series data is supported.

Label field

The field menu provides variables to display as chart labels.

Legend orient

Sets the chart legend orientation. Available options are Horizontal, Vertical, and Vertical bottom.

Primary title

The chart title.

Subtitle

The chart subtitle, which is placed directly beneath the chart title.

Footnote

The chart footnote, which is placed beneath the chart.

XAxis label

The x-axis label, which is placed beneath the x-axis.

YAxis label

The y-axis label, which is placed above the y-axis.

Parallel charts

Parallel charts are useful for visualizing high dimensional geometry and for analyzing multivariate data. Parallel charts resemble line charts for time-series data, but the axes do not correspond to points in time (a natural order is not present).

Creating a simple parallel chart

1. In the Chart Type section, click the Parallel icon.

Parallel

The canvas updates to display a parallel chart template.

2. Select at least two variables as the Columns variables. Each column represents a vertical, parallel axis in the chart.

Note: The column order is important for finding features. In a typical data analysis, you might need to reorder the columns numerous times.

Options

Columns

Lists variables that are available for the chart's Y-axes.

Click Add another column to add more columns.

Color map

Lists available color map variables. These variables use color progression, based on the range of values in the specified column, to represent themselves in the plot points. Color maps are also known as choropleth maps.

Primary title

The chart title.

Subtitle

The chart subtitle, which is placed directly beneath the chart title.

Footnote

The chart footnote, which is placed beneath the chart.

Pareto charts

Pareto charts contain both bars and a line graph. The bars represent individual variable categories and the line graph represents the cumulative total.

Creating a simple Pareto chart

1. In the Chart Type section, click the Pareto icon.

Pareto

The canvas updates to display a Pareto chart template.

2. Select a variable as the Category variable. The selected variable categories are drawn on the chart's X-axis.

Options

Category

Lists variables that are available for the chart's X-axis.

YAxis align

The toggle control enables and disables the alignment of the two Y-axes on the chart.

Gradient bar

The toggle control enables and disables the display of color gradients in the chart bars.

Highlight vital few

The toggle control enables and disables the highlighting of variable categories that are considered vital.

Primary title

The chart title.

Subtitle

The chart subtitle, which is placed directly beneath the chart title.

Footnote

The chart footnote, which is placed beneath the chart.

Pie charts

A pie chart is useful for comparing proportions. For example, you can use a pie chart to demonstrate that a greater proportion of Europeans is enrolled in a certain class.

Creating a simple pie chart

1. In the Chart Type section, click the Pie icon.

Pie •

The canvas updates to display a pie chart template.

2. Select a categorical (nominal or ordinal) variable from the Category list. The categories in this variable determine the number of slices in the pie chart.
3. Select a statistical summary function for the graphic element. For pie charts, you typically want a count-based statistic or a sum. The result of the statistic determines the size of each slice.

Options

Category

Select a categorical (nominal or ordinal) variable that determines the number of slices in the pie chart.

Summary

Select a statistical summary function for the graphic element. For pie charts, you typically want a count-based statistic or a sum. The result of the statistic determines the size of each slice.

Two types of statistical summary functions are available. The distinction is important because it determines whether you need to specify a Value variable.

- **Functions that do not require a value variable.** Functions that do not require a variable. All count and percentage statistics are in this category. These statistics are available when the Value variable is not defined.
- **Functions that do require a value variable.** Functions that do require a Value variable. For example, the **Mean** function requires a variable on which the mean is calculated. These statistics are available when the Value variable is not defined.

Value

This field displays when a Summary function that requires a scale variable, is selected. Select a variable to serve as the scale variable.

Pie type

The following styles are available.

Normal

The pie segments display as normal slices.

Ring

The pie segments display as a ring. This style is also known as a doughnut chart.

Rose

Unlike the normal pie chart, which uses a common radius, the pie segment sizes vary depending on their value.

Rose area

Unlike the normal pie chart, which uses a common radius, the pie segment sizes vary depending on their area.

Rose ring

Unlike the normal pie chart, which uses a common radius, the pie segment sizes vary depending on their value and the segments display as a ring.

Half rose

Same as Rose, except the chart is represented as one-half of a pie.

Show value

When enabled, the pie slice values display in the legend.

Outer field

The list provides variables that can be used as the count value of the outer ring.

Outer label angle

The value specifies the location of the outer field variable value on the outer ring.

Legend orient

Sets the chart legend orientation. Available options are Horizontal, Vertical, and Vertical bottom.

Primary title

The chart title.

Subtitle

The chart subtitle, which is placed directly beneath the chart title.

Footnote

The chart footnote, which is placed beneath the chart.

Population pyramid charts

Population pyramid charts (also known as "age-sex pyramids") are commonly used to present and analyze population information based on age and gender.

Creating a simple Population pyramid chart

1. In the Chart Type section, click the Population pyramid icon.

Population ...

The canvas updates to display a Population pyramid chart template.

2. Select a Y-axis variable from the drop-down list.
3. Select a Split by variable from the drop-down list.

Options

Y-axis

Lists variables that are available for the chart's Y-axis.

Split by

Select a categorical variable that creates a table of charts, with a cell for each category in the Split by variable. Like grouping, split by variables essentially add more dimensions to your chart by displaying information for each variable category. For more information, see [Adding Split by variables](#).

Bin width

The slider controls the size of the interval that is used to split the data into groups.

Show distribution curve

When enabled, the distribution fitting curve is shown on the chart.

Primary title

The chart title.

Subtitle

The chart subtitle, which is placed directly beneath the chart title.

Footnote

The chart footnote, which is placed beneath the chart.

Q-Q plots

Q-Q (quantile-quantile) plots compare two probability distributions by plotting their quantiles against each other. A Q-Q plot is used to compare the shapes of distributions, providing a graphical view of how properties such as location, scale, and skewness are similar or different in the two distributions.

Creating a simple Q-Q plot chart

1. In the Chart Type section, click the Q-Q plot icon.

Q-Q plot

The canvas updates to display a Q-Q plot chart template.

2. Select a variable as the X-axis variable.

Options

X-axis

Lists variables that are available for the chart's X-axis.

Distribution

The drop-down list provides all available distribution methods.

Auto fit distribution

Automatically fits the distribution (the default setting).

Beta

Returns the value from a Beta distribution with specified shape parameters.

Exponential

Returns the value from an exponential distribution.

Gamma

Returns the value from the Gamma distribution, with the specified shape and scale parameters.

Log-normal

Returns the value from a log-normal distribution with specified parameters.

Normal

Returns the value from a normal distribution with specified mean and standard deviation.

Uniform

Returns the value from the uniform distribution between the minimum and maximum.

Student t

Returns the value from Student's t distribution, with specified degrees of freedom.

Plot type

Select either a Q-Q (quantile-quantile) plot or a P-P (percent-percent) plot.

Auto fit

When enabled, data parameters for the selected Distribution are automatically estimated. When not selected, the Shape and Scale distribution values display.

Shape1

Sets the shape1 value for the Beta distribution. This setting is available only when Auto fit is not enabled and Beta is selected as the Distribution.

Shape2

Sets the shape2 value for the Beta distribution. This setting is available only when Auto fit is not enabled and Beta is selected as the Distribution.

Shape

Sets the shape value for the selected distribution. This setting is available only when Auto fit is not enabled and Gamma or Log-normal is selected as the Distribution.

Scale

Sets the scale value for the selected distribution. This setting is available only when Auto fit is not enabled and Exponential, Gamma, or Log-normal is selected as the Distribution.

Mean

Sets the means value for the Normal distribution. This setting is available only when Auto fit is not enabled and Normal is selected as the Distribution.

Std. dev.

Sets the standard deviation value for the Normal distribution. This setting is available only when Normal is selected as the Distribution.

Min

Sets the minimum value for the Uniform distribution. This setting is available only when Auto fit is not enabled and Uniform is selected as the Distribution.

Max

Sets the maximum value for the Uniform distribution. This setting is available only when Auto fit is not enabled and Uniform is selected as the Distribution.

Degrees of freedom(df)

Set the degrees of freedom value for the Student t distribution. This setting is available only when Auto fit is not enabled and Student t is selected as the Distribution.

Detrend

When enabled, detrended plots display on the chart.

Primary title

The chart title.

Subtitle

The chart subtitle, which is placed directly beneath the chart title.

Footnote

- The chart footnote, which is placed beneath the chart.
- XAxis label
 - The x-axis label, which is placed beneath the x-axis.
- YAxis label
 - The y-axis label, which is placed above the y-axis.

Radar charts

Radar charts compare multiple quantitative variables and are useful for visualizing which variables have similar values, or if outliers exist among the variables. Radar charts consists of a sequence of spokes, with each spoke representing a single variable. Radar Charts are also useful for determining which variables are scoring high or low within a data set.

Creating a simple radar chart

- In the Chart Type section, click the Radar icon.

Radar

The canvas updates to display a radar chart template.

- Select a Columns variable from the drop-down list.

Note: Click Add another column to include more columns. At least three columns variables must be defined.

Options

Category

Select a categorical (nominal or ordinal) variable. If you select None as the category values, all values are shown separately, and no summary method is applied.

Summary

When a categorical variable is selected, the following summary statistics are available.

Count

Total number of cases.

Sum

Sum of the values.

Mean

Arithmetic average; the sum divided by the number of cases.

Maximum

Largest (highest) value.

Minimum

Smallest (lowest) value.

Radar Layout

Determines the background image layout for the radar chart:

Circle

When selected, the radar chart is drawn over a circular layout.

Polygon

When selected, the radar chart is drawn over a polygonal layout.

Split by

Select a categorical variable that creates a table of charts, with a cell for each category in the Split by variable. Like grouping, split by variables essentially add more dimensions to your chart by displaying information for each variable category. For more information, see [Adding Split by variables](#).

Primary title

The chart title.

Subtitle

The chart subtitle, which is placed directly beneath the chart title.

Footnote

The chart footnote, which is placed beneath the chart.

Relationship charts

A relationship chart is useful for determining how variables relate to each other.

Creating a simple relationship chart

1. In the Chart Type section, click the Relationship icon.

Relationship

The canvas updates to display a relational chart template.

2. Select at least two variables as Columns variables.

Note: Click Add another column to include more column variables.

Options

Columns

Lists the available variables.

Click Add another column to add more columns.

Line style

Controls the line style between related data points.

Curve

When selected, curved lines are drawn between related data points.

Straight

When selected, straight lines are drawn between related data points.

Label threshold

Displays labels for data points whose values exceed the defined value.

Legend orient

Sets the chart legend orientation. Available options are Horizontal, Vertical, and Vertical bottom.

Primary title

The chart title.

Subtitle

The chart subtitle, which is placed directly beneath the chart title.

Footnote

The chart footnote, which is placed beneath the chart.

Scatter plots and dot plots

Several broad categories of charts are created with the point graphic element.

Scatter plots

Scatter plots are useful for plotting multivariate data. They can help you determine potential relationships among scale variables. A simple scatter plot uses a 2-D coordinate system to plot two variables. A 3-D scatter plot uses a 3-D coordinate system to plot three variables. When you need to plot more variables, you can try overlay scatter plots and scatter plot matrices (SPLOMs). An overlay scatter plot displays overlaid pairs of X-Y variables, with each pair distinguished by color or shape. A SPLOM creates a matrix of 2-D scatter plots, with each variable plotted against every other variable in the SPLOM.

Dot plots

Like histograms, dot plots are useful for showing the distribution of a single scale variable. The data are binned, but, instead of one value for each bin (like a count), all of the points in each bin are displayed and stacked. These graphs are sometimes called density plots.

Summary point plots

Summary point plots are similar to bar charts, except that points are drawn in place of the top of the bars. For more information, see [Bar charts](#).

Drop-line charts

Drop-line charts are a special type of summary point plot. The points are grouped and a line is drawn through the points in each category. The drop-line chart is useful for comparing a statistic across categorical variables.

Creating a simple scatter plot

1. In the Chart Type section, click the Scatter plot icon.

Scatter plot

The canvas updates to display a scatter plot chart template.

2. Select a scale variable as the X-axis variable.
3. Select a scale variable as the Y-axis variable. You do not need to specify a statistic because scatter plots typically show raw values.

Options

- X-axis
Lists variables that are available for the chart's X-axis.
- Y-axis
Lists variables that are available for the chart's Y-axis.
- Color map
Lists available color map variables. These variables use color progression, based on the range of values in the specified column, to represent themselves in the plot points. Color maps are also known as choropleth maps.
- Size map
Lists available size map variables. These variables use differing sizes to represent themselves in the plot points.
- Shape map
Lists available shape map variables. These variables use differing shapes to represent themselves in the plot points.
- Fit line
In a fit line, the data points are fitted to a line that usually does not pass through all of the data points. The fit line represents the trend of the data. Some fits lines are regression-based. Others are based on iterative weighted least squares. Select a fit line option from the drop-down list.
- Gradient bubble
The toggle control enables and disables the display of color gradients and 3D effects in the chart bubbles. The setting is not available when a Color map variable is selected.
- Minimum bubble size
Sets the minimum bubble size. Enter a value in the range 5 - 20.
- Maximum bubble size
Sets the maximum bubble size. Enter a value in the range 20 - 80.
- Show reference line
When enabled, the option shows a reference line on the chart that is based on the specified xAixs and yAixs values.
- Enter a reference line value on xAixs
When Show reference line is enabled, this setting provides the option of specifying a specific reference line value for the X-axis.
Click Add another column to specify more reference line values.
- Enter a reference line value on yAixs
When Show reference line is enabled, this setting provides the option of specifying a specific reference line value for the Y-axis.
Click Add another column to specify more reference line values.
- Show label
When enabled, column labels display on the chart. Only scatter series data is supported.
- Label field
The field menu provides variables to display as chart labels.
- Primary title
The chart title.
- Subtitle
The chart subtitle, which is placed directly beneath the chart title.
- Footnote
The chart footnote, which is placed beneath the chart.
- XAxis label
The x-axis label, which is placed beneath the x-axis.
- YAxis label
The y-axis label, which is placed above the y-axis.

Scatter matrix charts

Scatter plot matrices are a good way to determine whether linear correlations exist between multiple variables.

Creating a scatter matrix chart

1. In the Chart Type section, click the Scatter matrix icon.

Scatterplot matrix

The canvas updates to display a scatter matrix chart template.

2. Select at least two scale Columns variables.

Note: Click Add another column to include more column variables.

Each selected variable is plotted against every other variable to create a matrix of individual scatter plots.

Options

Columns

Select at least two matrix variables. The variables must be numeric (but not date format).

Click Add another column to add more columns.

Color map

Lists available color map variables. These variables use color progression, based on the range of values in the specified column, to represent themselves in the plot points. Color maps are also known as choropleth maps.

Correlation

When enabled, linear correlation information (Strong, Medium, Weak) is shown for the selected variables.

Show kde curve

When enabled, the kernel density estimate curve is shown on the chart.

Show histogram

When enabled, histogram charts display for the selected column variables.

Gradient bubble

The toggle control enables and disables the display of color gradients and 3D effects in the chart bubbles. The setting is not available when a Color map variable is selected.

Minimum bubble size

Sets the minimum bubble size. Enter a value in the range 5 - 20.

Maximum bubble size

Sets the maximum bubble size. Enter a value in the range 20 - 80.

Show label

When enabled, column labels display on the chart. Only scatter series data is supported.

Primary title

The chart title.

Subtitle

The chart subtitle, which is placed directly beneath the chart title.

Footnote

The chart footnote, which is placed beneath the chart.

Series array charts

Series array charts include individual sub charts and display the Y-axis for all sub charts in the legend.

Creating a series array chart

1. In the Chart Type section, click the Series array icon.

Series array

The canvas updates to display a series array chart template.

2. Click Add another sub-chart to define the first series array sub chart.
3. Select a variable as the X-axis variable.
4. Select a variable as the Y-axis variable.
5. Click Add another sub-chart to define more series array sub charts.

Options

X-axis

Lists variables that are available for the sub chart's x-axis.

Y-axis

Lists variables that are available for the sub chart's y-axis.

Split by

Select a categorical variable that creates a table of charts, with a cell for each category in the Split by variable. Like grouping, split by variables essentially add more dimensions to your chart by displaying information for each variable category. For more information, see [Adding Split by variables](#).

Legend label

	Specify a sub-chart legend title.
Title	Specify a sub-chart title.
Type	Select a sub-chart type. Available options are line, bar, and scatter.
Smooth	When enabled, the chart shows a smooth curve.
Show data points	When enabled, the data point is shown in the chart.
Primary title	The chart title.
Subtitle	The chart subtitle, which is placed directly beneath the chart title.
Footnote	The chart footnote, which is placed beneath the chart.
XAxis label	The x-axis label, which is placed beneath the x-axis.
YAxis label	The y-axis label, which is placed above the y-axis.

Sunburst charts

A sunburst chart is useful for visualizing hierarchical data structures. A sunburst chart consists of an inner circle that is surrounded by rings of deeper hierarchy levels. The angle of each segment proportional to either a value or divided equally under its inner segment. The chart segments are colored based on the category or hierarchical level to which they belong.

Creating a simple sunburst chart

1. In the Chart Type section, click the Sunburst icon.

Sunburst

The canvas updates to display a sunburst chart template.

2. Select a categorical (nominal or ordinal) variable from the Columns list. The categories in this variable determine the number of segments in the chart.
3. Click Add another column and select another categorical (nominal or ordinal) variable from the Columns list. The categories in this variable determine the number of segments in the chart's second ring and represent a hierarchical level.
4. Select a statistical summary function for the graphic element (count-based statistic or a sum). The result of the statistic determines the size of each segment. When Sum is selected, choose a scale variable from the Value list to represent the value in the data set to summarize.
5. Select a Sunburst layout option (either Traditional or Divergent).

Options

Columns

Select a categorical (nominal or ordinal) variable that determines the number of segments in the chart.

Summary

Select a statistical summary function for the graphic element (count-based statistic or a sum). The result of the statistic determines the size of each slice.

Two types of statistical summary functions are available. The distinction is important because it determines whether you need to specify a Value variable.

Functions that do not require a value variable

All count and percentage statistics are in this category. These statistics are available when there is no defined Value variable.

Functions that do require a value variable

For example, the **Sum** function requires a variable on which the summary is calculated.

Value

This field displays when a Summary function that requires a scale variable, is selected. Select a variable to serve as the scale variable.

Sunburst layout

Available options are Traditional and Divergent.

Primary title

- The chart title.
Subtitle
The chart subtitle, which is placed directly beneath the chart title.
Footnote
The chart footnote, which is placed beneath the chart.
-

t-SNE charts

T-distributed Stochastic Neighbor Embedding (t-SNE) is a machine learning algorithm for visualization. t-SNE charts model each high-dimensional object by a two-or-three dimensional point in such a way that similar objects are modeled by nearby points and dissimilar objects are modeled by distant points with high probability.

Creating a simple t-SNE chart

1. In the Chart Type section, click the t-SNE icon.

The canvas updates to display a t-SNE chart template.
2. Set the Perplexity, Learning rate, and Maximum iterations values.
3. Optional: Select a Color map variable.

Options

- Perplexity
Sets a number that establishes an educated guess as to the number of close neighbors for each data point. The purpose is to balance the local and global aspects for your data.
- Learning rate
This value affects the speed of learning by specifying the weight size changes at each iteration.
- Maximum iterations
The maximum number of iterations to run.
- Color map
Lists available color map variables. These variables use color progression, based on the range of values in the specified column, to represent themselves in the plot points. Color maps are also known as choropleth maps.
- Primary title
The chart title.

Time plots

Time plots illustrate data points at successive intervals of time. The time series you plot must contain numeric values and are assumed to occur over a range of time in which the periods are uniform. Time plots provide a preliminary analysis of the characteristics of time series data on basic statistics and test, and thus generate useful insights about your data before modeling. Time plots include analysis methods such as decomposition, augmented Dickey-Fuller test (ADF), correlations (ACF/PACF), and spectral analysis.

Creating a simple time plot

1. In the Chart Type section, click the Time plot icon.

The canvas updates to display a time plot chart template.
2. From the Values drop-down, select a value for the y-axis.

Options

Values

Lists variables that are available for the time plot values.

Date

Select a date from the drop-down, if applicable. Each observation is separated by the same time interval. If you select a date variable, a resample option is shown. You can use this option to aggregate value fields to match the specified interval.

Time plot algorithm

The time plot algorithm to use for analyzing the time series data.

Decomposition

Decompose a time series as three components (trend-cycle, seasonal, and irregular). Decomposition is run in an additive fashion.

ADF test

Augmented Dickey–Fuller (ADF) tests the null hypothesis that a unit root exists in the series and the series is not stationary. If the test result rejects the null hypothesis, the series is stationary, or can be represented to be stationary with a difference model.

ACF/PACF

Correlations of series.

Spectral analysis

An analytic tool in the frequency domain. The highest frequency is marked as diamond.

Swap chart position

Reverses the positions of the charts on the planimetric rectangular coordinate system and the polar coordinate system.

Show the turning point

Shows or hides the turning points in the charts. The series is explored to determine whether it has an overall trend or has some turning points that change the direction of the trend pattern.

Show the outlier

Shows or hides any outliers. The outliers of the time series are analyzed from the irregular component of time series decomposition.

Primary title

The chart title.

Subtitle

The chart subtitle, which is placed directly beneath the chart title.

Footnote

The chart footnote, which is placed beneath the chart.

XAxis label

The x-axis label, which is placed beneath the x-axis.

YAxis label

The y-axis label, which is placed above the y-axis.

Theme River charts

A theme river is a specialized flow graph that shows changes over time.

Creating a simple theme river chart

1. In the Chart Type section, click the Theme River icon.

Theme River

The canvas updates to display a theme river chart template.

2. Select an X-axis variable.
3. Select a Category variable.

Restriction: If a category field has more than 50 distinct categories, only the first 50 maximum categories are used as events in the chart.

Options

X-axis

Lists variables that are available for the X-axis.

Order based on

Depending on the X-axis value you select, you might be able to specify whether the category order is based on category name or category value.

Category order

Depending on the X-axis value you select, you might be able to specify whether the category order is ascending, descending, or as read from the data set.

Category

Lists variables that are available as categories.

Summary

Select a statistical summary function (the method that is used for summarizing each category).

Two types of statistical summary functions are available. The distinction is important because it determines whether you need to specify a Value variable.

- **Functions that do not require a value variable.** Functions that do not require a variable. All count and percentage statistics are in this category. These statistics are available when the Value variable is not defined.
- **Functions that do require a value variable.** Functions that do require a Value variable. For example, the **Mean** function requires a variable on which the mean is calculated. These statistics are available when the Value variable is not defined.

Value

This field displays when a Summary function that requires a value variable, is selected. Select a variable to serve as the value.

Legend orient

Sets the chart legend orientation. Available options are Horizontal, Vertical, and Vertical bottom.

Primary title

The chart title.

Subtitle

The chart subtitle, which is placed directly beneath the chart title.

Footnote

The chart footnote, which is placed beneath the chart.

Tree charts

Tree charts represent hierarchy in a tree-like structure. The structure of a Tree chart consists of a root node (has no parent node), line connections (named branches), and leaf nodes (have no child nodes). Line connections represent the relationships and connections between the members.

Creating a simple tree chart

1. In the Chart Type section, click the Tree icon.

The canvas updates to display a Tree chart template.

2. Select a Columns variable from the drop-down list.

Note: Click Add another column to include more column variables.

Options

Columns

Lists variables that are available to represent chart columns.

Summary

Select a statistical summary function for the graphic element. The result of the statistic determines the position of the graphic elements.

Two types of statistical summary functions are available. The distinction is important because it determines whether you need to specify a Value variable.

Functions that do not require a value variable

All count and percentage statistics are in this category. These statistics are available when there is no defined Value variable.

Functions that do require a value variable

For example, the **Mean** function requires a variable on which the mean is calculated. These statistics are available when there is a defined Value variable.

Value

This field displays when a Summary function that requires a value variable, is selected. Select a variable to serve as the basis for the summary value.

Tree layout

Left to right

The root node displays on the left and the leaf nodes display on the right.

Right to left

The root node displays on the right and the leaf nodes display on the left.

Top to bottom

The root node displays on the top and the leaf nodes display on the bottom.

Bottom to top

The root node displays on the bottom and the leaf nodes display on the top.

Radial

The root node displays in the middle and the leaf nodes radiate from the root.

Leaf depth

Sets the drill-down level value for the leaf nodes.

Show leaves label

When enabled, labels display for each leaf node.

Primary title

The chart title.

Subtitle

The chart subtitle, which is placed directly beneath the chart title.

Footnote

The chart footnote, which is placed beneath the chart.

Treemap charts

Treemap charts are an alternative method for visualizing the hierarchical structure of tree diagrams while also displaying quantities for each category. Treemap charts are useful for identifying patterns in data. Tree branches are represented by rectangles, with each sub branch represented by smaller rectangles.

Creating a simple Treemap chart

1. In the Chart Type section, click the Treemap icon.

Treemap

The canvas updates to display a Treemap chart template.

2. Select a Columns variable from the drop-down list.

Note: Click Add another column to include more column variables.

Options

Columns

Lists variables that are available to represent chart columns.

Summary

Select a statistical summary function for the graphic element. The result of the statistic determines the position of the graphic elements.

Two types of statistical summary functions are available. The distinction is important because it determines whether you need to specify a Value variable.

Functions that do not require a value variable

All count and percentage statistics are in this category. These statistics are available when there is no defined Value variable.

Functions that do require a value variable

For example, the **Mean** function requires a variable on which the mean is calculated. These statistics are available when there is a defined Value variable.

Value

This field displays when a Summary function that requires a value variable is selected. Select a variable to serve as the basis for the summary value.

Leaf depth

Sets the drill-down level value for the leaf nodes.

Primary title

The chart title.

Subtitle

The chart subtitle, which is placed directly beneath the chart title.

Footnote

The chart footnote, which is placed beneath the chart.

Word cloud charts

Word cloud charts present data as words, where the size and placement of any individual word is determined by how it is weighted.

Creating a simple word cloud chart

1. In the Chart Type section, click the Word cloud icon.

Word cloud

The canvas updates to display a word cloud chart template.

2. Select a variable as the Source variable. Each variable category is represented in the chart based on its weight value.
3. Select a Shape value for the chart. The chart data is presented in the selected shape.

Options

Source

Lists variables that are available as the chart's source. Each variable category is represented in the chart based on its weight value.

Shape

Lists the available chart shapes. The chart data is presented in the selected shape.

Primary title

The chart title.

Subtitle

The chart subtitle, which is placed directly beneath the chart title.

Footnote

The chart footnote, which is placed beneath the chart.

Global visualization preferences

You can override the default settings for titles, range slider, grid lines, and mouse tracking. You can also specify a different color scheme template.

1. After right-clicking a data node and selecting View Data, click the Global visualization preferences control in the Actions section.

Figure 1. Global visualization preferences control

The Global visualization preferences dialog provides the following settings.

Titles

Provides global chart title settings.

Global titles

Enables or disables the global titles for all charts.

Global primary title

Enables or disables the display of global, primary chart titles. When enabled, the top-level chart title that you enter here is applied to all chart's, effectively overriding each chart's individual Primary title setting.

Global subtitle

Enables or disables the display of global chart subtitles. When enabled, the chart subtitle that you enter here is applied to all chart's, effectively overriding each chart's individual Subtitle setting.

Default titles

Enables or disables the default titles for all charts.

Title alignment

Provides the title alignment options Left, Center (the default setting), and Right.

Tools

Provides options that control chart behavior.

Range slider

Enables or disables the range slider for each chart. When enabled, you can control the amount of chart data that displays with a range slider that is provided for each chart.

Grid lines

Controls the display of X axis (vertical) and Y axis (horizontal) grid lines.

Mouse tracker

When enabled, the mouse cursor location, in relation to the chart data, is tracked and displayed when placed anywhere over the chart.

Toolbox

Enables or disables the toolbox for each chart. Depending on the chart type, the toolbox on the right of the screen provides tools such as zoom, save as image, restore, select data, and clear selection.

ARIA

When enabled, web content and web applications are more accessible to users with disabilities.

Filter out null

Enables or disables the filtering of null chart data.

X axis on zero

When enabled, the X axis lies on the other's origin position. When not enabled, the X axis always starts at 0.

Y axis on zero

When enabled, the Y axis lies on the other's origin position. When not enabled, the Y axis always starts at 0.

Show xAxis Label

Enables or disables the xAxis label.

Show yAxis Label

Enables or disables the yAxis label.

Show xAxis Line

Enables or disables the xAxis line.

Show yAxis Line

Enables or disables the yAxis line.

Show xAxis Name

Enables or disables the xAxis name.

Show yAxis Name

Enables or disables the yAxis name.

yAxis Name Location

The drop-down list provides options for specifying the yAxis name location. Options include Start, Middle, and End.

Truncation length

The specified value sets the string length. Strings that are longer than the specified length are truncated. The default value is 10. When 0 is specified, truncation is turned off.

xAxis tick label decimal

Sets the tick label decimal value for the xAxis. The default value is 3.

yAxis tick label decimal

Sets the tick label decimal value for the yAxis. The default value is 3.

xAxis tick label rotate

Sets the xAxis tick label rotation value. The default value is 0 (no rotation). You can specify value in the range -90 to 90 degrees.

Theme

Select a template to change the colors that are used in charts that have a grouping or stacking variable. Any element attributes defined in the selected template file override the default template settings for those element attributes.

2. Click Apply to save your settings or Cancel to disregard the changes.

Dashboard

You can create a chart dashboard layout for viewing several charts at a time. Save layouts as templates and drag-and-drop your saved charts to the positions in your layout.

1. After right-clicking a data node and selecting View Data, click the Dashboard control in the Actions section.

Figure 1. Dashboard control

The Dashboard displays and provides the following settings.

Template

In this section, you can create new layout templates or choose from predefined templates or from your saved templates.

Choose a layout template

Choose from available layout templates or start with a new template.

Actions

Click the Edit the layout icon to edit the layout template you selected. You can also import a dashboard file. When finished, save your template.

Click the Leave layout edit mode icon when you're finished.

Content

Use this section to drag-and-drop items to your dashboard layout.

Choose a saved chart

This section provides a list of your saved charts. Drag-and-drop charts to the desired position on your dashboard layout.

Choose an object

You can also drag HTML text or images to your dashboard layout.

Working with output

When you run some streams, the results are available in the Viewer via the Model tab or the Advanced tab of model nugget nodes. In the Viewer, you can easily navigate to the output that you want to see. You can also manipulate the output and create a document that contains precisely the output that you want. Some graph output also uses the Viewer.

The Viewer is used for the following output in IBM® SPSS® Modeler:

- TCM model nuggets
 - STP model nuggets
 - TwoStep-AS Cluster model nuggets
 - GSAR model nuggets
 - Map Visualization graph node
- [Viewer](#)
 - [Copying output into other applications](#)
 - [Interactive output](#)
 - [Export output](#)
 - [Viewer printing](#)
 - [Saving output](#)
 - [Pivot tables](#)
 - [Options](#)
-

Viewer

Results are displayed in the Viewer. You can use the Viewer to:

- Browse results
- Show or hide selected tables and charts
- Change the display order of results by moving selected items
- Move items between the Viewer and other applications

The Viewer is divided into two panes:

- The left pane contains an outline view of the contents.
- The right pane contains statistical tables, charts, and text output.

You can click an item in the outline to go directly to the corresponding table or chart. You can click and drag the right border of the outline pane to change the width of the outline pane.

- [Showing and hiding results](#)
 - [Moving, deleting, and copying output](#)
 - [Changing initial alignment](#)
 - [Changing alignment of output items](#)
 - [Viewer outline](#)
 - [Editing and adding items to the Viewer](#)
 - [Finding and replacing information in the Viewer](#)
-

Showing and hiding results

In the Viewer, you can selectively show and hide individual tables or results from an entire procedure. This process is useful when you want to shorten the amount of visible output in the contents pane.

- [To hide tables and charts](#)
- [To hide procedure results](#)

Related information

- [Controlling the initial display state for new output](#)
 - [Viewer](#)
-

To hide tables and charts

1. Double-click the item's book icon in the outline pane of the Viewer.
or
2. Click the item to select it.
3. From the menus choose:
View > Hide
4. Click the closed book (Hide) icon on the Outlining toolbar.

The open book (Show) icon becomes the active icon, indicating that the item is now hidden.

Related information

- [Showing and hiding results](#)
 - [To hide procedure results](#)
 - [Controlling the initial display state for new output](#)
-

To hide procedure results

1. Click the box to the left of the procedure name in the outline pane.

This hides all results from the procedure and collapses the outline view.

Related information

- [Showing and hiding results](#)
 - [To hide tables and charts](#)
 - [Controlling the initial display state for new output](#)
-

Moving, deleting, and copying output

You can rearrange the results by copying, moving, or deleting an item or a group of items.

- [Moving output in the Viewer](#)
 - [Deleting output in the Viewer](#)
-

Moving output in the Viewer

1. Select the items in the outline or contents pane.
2. Drag and drop the selected items into a different location.

The item you cut in step 1, is moved to the selected location.

Related information

- [Moving, deleting, and copying output](#)
 - [Deleting output in the Viewer](#)
-

Deleting output in the Viewer

1. Select the items in the outline or contents pane.
2. Press the Delete key.
or
3. From the menus choose:
`Edit > Delete`

Related information

- [Moving, deleting, and copying output](#)
 - [Moving output in the Viewer](#)
-

Changing initial alignment

By default, all results are initially left-aligned. To change the initial alignment of new output items:

1. From the menus choose:
`Edit > Options`
 2. Click the Viewer tab.
 3. In the Initial Output State group, select the item type (for example, pivot table, chart, text output).
 4. Select the alignment option you want.
-

Changing alignment of output items

1. In the outline or contents pane, select the items that you want to align.
2. From the menus choose:
`Format > Align Left`
or
`Format > Center`
or
`Format > Align Right`

Viewer outline

The outline pane provides a table of contents of the Viewer document. You can use the outline pane to navigate through your results and control the display. Most actions in the outline pane have a corresponding effect on the contents pane.

- Selecting an item in the outline pane displays the corresponding item in the contents pane.
- Moving an item in the outline pane moves the corresponding item in the contents pane.
- Collapsing the outline view hides the results from all items in the collapsed levels.

Controlling the outline display

To control the outline display, you can:

- Expand and collapse the outline view
- Change the outline level for selected items
- Change the size of items in the outline display
- Change the font that is used in the outline display
- [Collapsing and expanding the outline view](#)
- [Changing the outline level](#)

- [To change the size of outline items](#)
 - [To change the font in the outline](#)
-

Collapsing and expanding the outline view

1. Click the box to the left of the outline item that you want to collapse or expand.
or
 2. Click the item in the outline.
 3. From the menus choose:
`View > Collapse`
or
`View > Expand`
-

Changing the outline level

1. Click the item in the outline pane.
2. From the menus choose:
`Edit > Outline > Promote`
or
`Edit > Outline > Demote`

Related information

- [Collapsing and expanding the outline view](#)
-

To change the size of outline items

1. From the menus choose:
`View > Outline Size`
2. Select the outline size (Small, Medium, or Large).

-

To change the font in the outline

1. From the menus choose:
`View > Outline Font...`
2. Select a font.

Related information

- [Viewer outline](#)
 - [To change the size of outline items](#)
-

Editing and adding items to the Viewer

In the Viewer, you can edit and add items such as titles, new text, charts, or material from other applications.

- [Adding a title or text](#)
 - [To add a text file](#)
 - [Pasting objects into the Viewer](#)
-

Adding a title or text

Text items that are not connected to a table or chart can be added to the Viewer.

1. Click the table, chart, or other object that will precede the title or text.
2. From the menus choose:
`Insert > New Title`
or
`Insert > New Text`
3. Double-click the new object.
4. Enter the text.

Related information

- [To add a text file](#)
-

To add a text file

1. In the outline pane or contents pane of the Viewer, click the table, chart, or other object that will precede the text.
2. From the menus choose:
`Insert > Text File...`
3. Select a text file.

To edit the text, double-click it.

Related information

- [Adding a title or text](#)
-

Pasting objects into the Viewer

Objects from other applications can be pasted into the Viewer. You can use either Paste After or Paste Special. Either type of pasting puts the new object after the currently selected object in the Viewer. Use Paste Special when you want to choose the format of the pasted object.

Finding and replacing information in the Viewer

1. To find or replace information in the Viewer, from the menus choose:
`Edit > Find`
or
`Edit > Replace`

You can use Find and Replace to:

- Search the entire document or just the selected items.
- Search down or up from the current location.
- Search both panes or restrict the search to the contents or outline pane.

- Search for hidden items. These include any items hidden in the contents pane (for example, Notes tables, which are hidden by default) and hidden rows and columns in pivot tables.
- Restrict the search criteria to case-sensitive matches.
- Restrict the search criteria in pivot tables to matches of the entire cell contents.
- Restrict the search criteria in pivot tables to footnote markers only. This option is not available if the selection in the Viewer includes anything other than pivot tables.

Hidden Items and Pivot Table Layers

- Layers beneath the currently visible layer of a multidimensional pivot table are not considered hidden and will be included in the search area even when hidden items are not included in the search.
- Hidden items include hidden items in the contents pane (items with closed book icons in the outline pane or included within collapsed blocks of the outline pane) and rows and columns in pivot tables either hidden by default (for example, empty rows and columns are hidden by default) or manually hidden by editing the table and selectively hiding specific rows or columns. Hidden items are only included in the search if you explicitly select **Include hidden items**.
- In both cases, the hidden or nonvisible element that contains the search text or value is displayed when it is found, but the item is returned to its original state afterward.

Finding a range of values in pivot tables

To find values that fall within a specified range of values in pivot tables:

1. Activate a pivot table or select one or more pivot tables in the Viewer. Make sure that only pivot tables are selected. If any other objects are selected, the Range option is not available.
2. From the menus choose:
Edit > Find
3. Click the Range tab.
4. Select the type of range: Between, Greater than or equal to, or Less than or equal to.
5. Select the value or values that define the range.
 - If either value contains non-numeric characters, both values are treated as strings.
 - If both values are numbers, only numeric values are searched.
 - You cannot use the Range tab to replace values.

This feature is not available for legacy tables. See the topic [Legacy tables](#) for more information.

Copying output into other applications

Output objects can be copied and pasted into other applications, such as a word-processing program or a spreadsheet. You can paste output in a variety of formats. Depending on the target application and the selected output objects, some or all of the following formats may be available:

Metafile. WMF and EMF metafile format. These formats are available only on Windows operating systems.

RTF (rich text format). Multiple selected objects, text output, and pivot tables can be copied and pasted in RTF format. For pivot tables, in most applications this means that the tables are pasted as tables that can then be edited in the other application. Pivot tables that are too wide for the document width will either be wrapped, scaled down to fit the document width, or left unchanged, depending on the pivot table options settings. See the topic [Pivot table options](#) for more information.

Note: Microsoft Word may not display extremely wide tables properly.

Image. JPG and PNG image formats.

BIFF. Pivot tables and text output can be pasted into a spreadsheet in BIFF format. Numbers in pivot tables retain numeric precision. This format is available only on Windows operating systems.

Text. Pivot tables and text output can be copied and pasted as text. This process can be useful for applications such as e-mail, where the application can accept or transmit only text.

Microsoft Office Graphic Object. Charts that support this format can be copied to Microsoft Office applications and edited in those applications as native Microsoft Office charts. Because of differences between SPSS® Statistics/SPSS Modeler charts and Microsoft Office charts, some features of SPSS Statistics/SPSS Modeler charts are not retained in the copied version. Copying multiple selected charts in Microsoft Office Graphic Object format is not supported.

If the target application supports multiple available formats, it may have a Paste Special menu item that allows you to select the format, or it may automatically display a list of available formats.

Note: Microsoft Office version 16 (or higher) is required when copying and pasting Boxplots and Histograms.

Copying and pasting multiple output objects

The following limitations apply when pasting multiple output objects into other applications:

- RTF format. In most applications, pivot tables are pasted as tables that can be edited in that application. Charts, trees, and model views are pasted as images.
- Metafile and image formats. All the selected output objects are pasted as a single object in the other application.
- BIFF format. Charts, trees, and model views are excluded.

Copy special

When copying and pasting large amounts of output, particularly very large pivot tables, you can improve the speed of the operation by using Edit > Copy Special to limit the number of formats copied to the clipboard.

You can also save the selected formats as the default set of formats to copy to the clipboard. This setting persists across sessions.

Copy as

You can right-click a selected object in the Output Viewer and select Edit > Copy as to copy to the most popular formats (for example, All, Image, or Microsoft Office Graphic Object). Selecting Edit > Copy copies All. Note that if Copy as is grayed out or not present for a selected object, this copy format is not available for that particular object.

Interactive output

Interactive output objects contain multiple, related output objects. The selection in one object can change what is displayed or highlighted in the other object. For example, selecting a row in a table might highlight an area in a map or display a chart for a different category.

Interactive output objects do not support editing features, such as changing text, colors, fonts, or table borders. The individual objects can be copied from the interactive object to the Viewer. Tables copied from interactive output can be edited in the pivot table editor.

Copying objects from interactive output

File>Copy to Viewer copies individual output objects to the Viewer window.

- The available options depend on the contents of the interactive output.
- Chart and Map create chart objects.
- Table creates a pivot table that can be edited in the pivot table editor.
- Snapshot creates an image of the current view.
- Model creates a copy of the current interactive output object.

Edit>Copy Object copies individual output objects to the clipboard.

- Pasting the copied object into the Viewer is equivalent to File>Copy to Viewer.
- Pasting the object into another application pastes the object as an image.

Zoom and Pan

For maps, you can use View>Zoom to zoom the view of the map. Within a zoomed map view, you can use View>Pan to move the view.

Print settings

File>Print Settings controls how interactive objects are printed.

- Print visible view only. Prints only the view that is currently displayed. This option is the default setting.
- Print all views. Prints all views contained in the interactive output.
- The selected option also determines the default action for exporting the output object.

Export output

Export Output saves Viewer output in HTML, text, Word/RTF, Excel, PowerPoint (requires PowerPoint 97 or later), and PDF formats. Charts can also be exported in a number of different graphics formats.

Note: Export to PowerPoint is available only on Windows operating systems.

Exporting Output

1. Make the Viewer the active dialog (click anywhere in the dialog).
2. Click the Export button on the toolbar or right-click in the output window and select Export.
3. Enter a file name (or prefix for charts) and select an export format.

Objects to Export. You can export all objects in the Viewer, all visible objects, or only selected objects.

Document Type. The available options are:

- Word/RTF (*.doc). Pivot tables are exported as Word tables with all formatting attributes intact (for example, cell borders, font styles, and background colors). Text output is exported as formatted RTF. Charts, tree diagrams, and model views are included in PNG format. Note that Microsoft Word might not display extremely wide tables properly.
- Excel 97-2004 (*.xls)/Excel 2007 and Higher (*.xlsx). Pivot table rows, columns, and cells are exported as Excel rows, columns, and cells, with all formatting attributes intact (for example, cell borders, font styles, and background colors). Text output is exported with all font attributes intact. Each line in the text output is a row in the Excel file, with the entire contents of the line in a single cell. Charts, tree diagrams, and model views are included in PNG format. Output can be exported as *Excel 97-2004* or *Excel 2007 and higher*.
- HTML (*.htm). Pivot tables are exported as HTML tables. Text output is exported as preformatted HTML. Charts, tree diagrams, and model views are embedded in the document in the selected graphic format. A browser compatible with HTML 5 is required for viewing output that is exported in HTML format.
- Portable Document Format (*.pdf). All output is exported as it appears in Print Preview, with all formatting attributes intact.
- Text - Plain/UTF8/UTF16 (*.txt). Text output formats include plain text, UTF-8, and UTF-16. Pivot tables can be exported in tab-separated or space-separated format. All text output is exported in space-separated format. For charts, tree diagrams, and model views, a line is inserted in the text file for each graphic, indicating the image file name.
- None (Graphics Only). Available export formats include: EPS, JPEG, TIFF, PNG, and BMP. On Windows operating systems, EMF (enhanced metafile) format is also available.

Open the containing folder. Opens the folder that contains the files that are created by the export.

-

HTML options

HTML export requires a browser that is compatible with HTML 5.

The following options are available for exporting output in HTML format:

Layers in pivot tables. By default, inclusion or exclusion of pivot table layers is controlled by the table properties for each pivot table. You can override this setting and include all layers or exclude all but the currently visible layer. See the topic [Table properties: printing](#) for more information.

Export layered tables as interactive. Layered tables are displayed as they appear in the Viewer, and you can interactively change the displayed layer in the browser. If this option is not selected, each table layer is displayed as a separate table.

Tables as HTML. This controls style information included for exported pivot tables.

- **Export with styles and fixed column width.** All pivot table style information (font styles, background colors, etc.) and column widths are preserved.
- **Export without styles.** Pivot tables are converted to default HTML tables. No style attributes are preserved. Column width is determined automatically.

Include footnotes and captions. Controls the inclusion or exclusion of all pivot table footnotes and captions.

Views of Models. By default, inclusion or exclusion of model views is controlled by the model properties for each model. You can override this setting and include all views or exclude all but the currently visible view. See the topic [Model properties](#) for more information. (Note: all model views, including tables, are exported as graphics.)

Note: For HTML, you can also control the image file format for exported charts. See the topic [Graphics format options](#) for more information.

To set HTML export options

1. Make the Viewer the active window (click anywhere in the window).
 2. From the menus choose:
File > Export...
 3. Select HTML as the export format.
 4. Click Change Options.
-

Web report options

A web report is an interactive document that is compatible with most browsers. Many of the interactive features of pivot tables available in the Viewer are also available in web reports.

Report Title. The title that is displayed in the header of the report. By default, the file name is used. You can specify a custom title to use instead of the file name.

Format. There are two options for report format:

- SPSS Web Report (HTML 5). This format requires a browser that is compatible with HTML 5.
- Cognos Active Report (mht). This format requires a browser that supports MHT format files or the Cognos Active Report application.

Exclude Objects. You can exclude selected object types from the report:

- Text. Text objects that are not logs. This option includes text objects that contain information about the active dataset.
- Logs. Text objects that contain a listing of the command syntax that was run. Log items also include warnings and error messages that are encountered by commands that do not produce any Viewer output.
- Notes Tables. Output from statistical and charting procedures includes a Notes table. This table contains information about the dataset that was used, missing values, and the command syntax that was used to run the procedure.
- Warnings and Error Messages. Warnings and error messages from statistical and charting procedures.

Restyle the tables and charts to match the Web Report. This option applies the standard web report style to all tables and charts. This setting overrides any fonts, colors, or other styles in the output as displayed in the Viewer. You cannot modify the standard web report style.

Web Server Connection. You can include the URL location of one or more application servers that are running the IBM® SPSS® Statistics Web Report Application Server. The web application server provides features to pivot tables, edit charts, and save modified web reports.

- Select Use for each application server that you want to include in the web report.
- If a web report contains a URL specification, the web report connects to that application server to provide the additional editing features.
- If you specify multiple URLs, the web report attempts to connect to each server in the order in which they are specified.

The IBM SPSS Statistics Web Report Application Server can be downloaded from <http://www.ibm.com/developerworks/spssdevcentral>.

-

Word options

The following options are available for exporting output in Word format:

Preserve break points. If you have defined break points, these settings will be preserved in the Word tables.

Include footnotes and captions. Controls the inclusion or exclusion of all pivot table footnotes and captions.

Views of Models. By default, inclusion or exclusion of model views is controlled by the model properties for each model. You can override this setting and include all views or exclude all but the currently visible view. See the topic [Model properties](#) for more information. (Note: all model views, including tables, are exported as graphics.)

Page Setup for Export. This opens a dialog where you can define the page size and margins for the exported document. The document width used to determine wrapping and shrinking behavior is the page width minus the left and right margins.

To set Word export options

1. Make the Viewer the active window (click anywhere in the window).
 2. From the menus choose:
File > Export...
 3. Select Word/RTF as the export format.
 4. Click Change Options.
-

Excel options

The following options are available for exporting output in Excel format:

Create a worksheet or workbook or modify an existing worksheet. By default, a new workbook is created. If a file with the specified name already exists, it will be overwritten. If you select the option to create a worksheet, if a worksheet with the specified name already exists in the specified file, it will be overwritten. If you select the option to modify an existing worksheet, you must also specify the worksheet name. (This is optional for creating a worksheet.) Worksheet names cannot exceed 31 characters and cannot contain forward or back slashes, square brackets, question marks, or asterisks.

When exporting to Excel 97-2004, if you modify an existing worksheet, charts, model views, and tree diagrams are not included in the exported output.

Location in worksheet. Controls the location within the worksheet for the exported output. By default, exported output will be added after the last column that has any content, starting in the first row, without modifying any existing contents. This is a good choice for adding new columns to an existing worksheet. Adding exported output after the last row is a good choice for adding new rows to an existing worksheet. Adding exported output starting at a specific cell location will overwrite any existing content in the area where the exported output is added.

Layers in pivot tables. By default, inclusion or exclusion of pivot table layers is controlled by the table properties for each pivot table. You can override this setting and include all layers or exclude all but the currently visible layer. See the topic [Table properties: printing](#) for more information.

Include footnotes and captions. Controls the inclusion or exclusion of all pivot table footnotes and captions.

Views of Models. By default, inclusion or exclusion of model views is controlled by the model properties for each model. You can override this setting and include all views or exclude all but the currently visible view. See the topic [Model properties](#) for more information. (Note: all model views, including tables, are exported as graphics.)

To set Excel export options

1. Make the Viewer the active window (click anywhere in the window).
 2. From the menus choose:
File > Export...
 3. Select Excel as the export format.
 4. Click Change Options.
-

PowerPoint options

The following options are available for PowerPoint:

Layers in pivot tables. By default, inclusion or exclusion of pivot table layers is controlled by the table properties for each pivot table. You can override this setting and include all layers or exclude all but the currently visible layer. See the topic [Table properties: printing](#) for more information.

Wide Pivot Tables. Controls the treatment of tables that are too wide for the defined document width. By default, the table is wrapped to fit. The table is divided into sections, and row labels are repeated for each section of the table. Alternatively, you can shrink wide tables or make no changes to wide tables and allow them to extend beyond the defined document width.

Include footnotes and captions. Controls the inclusion or exclusion of all pivot table footnotes and captions.

Use Viewer outline entries as slide titles. Includes a title on each slide that is created by the export. Each slide contains a single item that is exported from the Viewer. The title is formed from the outline entry for the item in the outline pane of the Viewer.

Views of Models. By default, inclusion or exclusion of model views is controlled by the model properties for each model. You can override this setting and include all views or exclude all but the currently visible view. See the topic [Model properties](#) for more information. (Note: all model views, including tables, are exported as graphics.)

Page Setup for Export. This opens a dialog where you can define the page size and margins for the exported document. The document width used to determine wrapping and shrinking behavior is the page width minus the left and right margins.

To set PowerPoint export options

1. Make the Viewer the active window (click anywhere in the window).
2. From the menus choose:
File > *Export...*
3. Select PowerPoint as the export format.
4. Click Change Options.

Note: Export to PowerPoint is available only on Windows operating systems.

PDF options

The following options are available for PDF:

Embed bookmarks. This option includes bookmarks in the PDF document that correspond to the Viewer outline entries. Like the Viewer outline pane, bookmarks can make it much easier to navigate documents with a large number of output objects.

Embed fonts. Embedding fonts ensures that the PDF document will look the same on all computers. Otherwise, if some fonts used in the document are not available on the computer being used to view (or print) the PDF document, font substitution may yield suboptimal results.

Layers in pivot tables. By default, inclusion or exclusion of pivot table layers is controlled by the table properties for each pivot table. You can override this setting and include all layers or exclude all but the currently visible layer. See the topic [Table properties: printing](#) for more information.

Views of Models. By default, inclusion or exclusion of model views is controlled by the model properties for each model. You can override this setting and include all views or exclude all but the currently visible view. See the topic [Model properties](#) for more information. (Note: all model views, including tables, are exported as graphics.)

To set PDF export options

1. Make the Viewer the active window (click anywhere in the window).
2. From the menus choose:
File > *Export...*
3. Select Portable Document Format as the export format.
4. Click Change Options.

Other Settings That Affect PDF Output

Page Setup/Page Attributes. Page size, orientation, margins, content and display of page headers and footers, and printed chart size in PDF documents are controlled by page setup and page attribute options.

Table Properties/TableLooks. Scaling of wide and/or long tables and printing of table layers are controlled by table properties for each table. These properties can also be saved in TableLooks.

Default/Current Printer. The resolution (DPI) of the PDF document is the current resolution setting for the default or currently selected printer (which can be changed using Page Setup). The maximum resolution is 1200 DPI. If the printer setting is higher, the PDF document resolution will be 1200 DPI.

Note: High-resolution documents may yield poor results when printed on lower-resolution printers.

Text options

Setting text output options

The following options are available for text export:

Pivot Table Format. Pivot tables can be exported in tab-separated or space-separated format. For space-separated format, you can also control:

- **Column Width.** Autofit does not wrap any column contents, and each column is as wide as the widest label or value in that column.
Custom sets a maximum column width that is applied to all columns in the table, and values that exceed that width wrap onto the next line in that column.
- **Row/Column Border Character.** Controls the characters used to create row and column borders. To suppress display of row and column borders, enter blank spaces for the values.

Layers in pivot tables. By default, inclusion or exclusion of pivot table layers is controlled by the table properties for each pivot table. You can override this setting and include all layers or exclude all but the currently visible layer. See the topic [Table properties: printing](#) for more information.

Include footnotes and captions. Controls the inclusion or exclusion of all pivot table footnotes and captions.

Views of Models. By default, inclusion or exclusion of model views is controlled by the model properties for each model. You can override this setting and include all views or exclude all but the currently visible view. See the topic [Model properties](#) for more information. (Note: all model views, including tables, are exported as graphics.)

To set text export options

1. Make the Viewer the active window (click anywhere in the window).
2. From the menus choose:
File > Export...
3. Select Text as the export format.
4. Click Change Options.

Images only options

The following options are available for exporting images only:

1. Make the Workbook tab the active tab (click anywhere in the tab).
2. Select the items that you want to export, click the vertical ellipsis control, and then select Export from the menu. You can also click the Export button on the toolbar. The Export workbook dialog displays.

Document setting

Type

Select Images only as the document Type.

Image format

Select an image format for exported images.

PNG

When selected, images are exported in Portable Network Graphics (*.png) format. The setting provides options for selecting the image Scale (%) and Color depth.

JPG

When selected, images are exported in Joint Photographic Experts Group (*.jpg) format. The setting provides options for selecting the image Scale (%) and Convert to grayscale.

TIFF

When selected, images are exported in Tag Image File Format (*.tiff) format. The setting provides options for selecting the image Scale (%).

BMP

When selected, images are exported in bitmap (*.bmp) format. The setting provides options for selecting the image Scale (%) and Compress image to reduce file size.

Open the containing folder

Optionally, select the setting to open the export save file location folder after export.

Objects to export

Objects to include

Select to export All or Selected (the default setting) output objects.

3. Click Export after specifying the image only export settings.
-

Graphics format options

For HTML and text documents and for exporting charts only, you can select the graphic format, and for each graphic format you can control various optional settings.

To select the graphic format and options for exported charts:

1. Make the Viewer the active window (click anywhere in the window).
2. From the menus choose:
File > Export...
3. Select HTML, Text, or None (Graphics only) as the document type.
4. Select the graphic file format from the drop-down list.
5. Click Change Options to change the options for the selected graphic file format.
 - [JPEG chart export options](#)
 - [BMP chart export options](#)
 - [PNG chart export options](#)
 - [EMF and TIFF chart export options](#)
 - [EPS chart export options](#)

JPEG chart export options

Image size(%)

Percentage of original chart size, up to 200 percent.

Convert to grayscale

Converts colors to shades of gray.

BMP chart export options

Image size(%)

Percentage of original chart size, up to 200 percent.

Compress image to reduce file size

A lossless compression technique that creates smaller files without affecting image quality.

PNG chart export options

Image size(%)

Percentage of original chart size, up to 200 percent.

Color Depth

Determines the number of colors in the exported chart. A chart that is saved under any depth will have a minimum of the number of colors that are actually used and a maximum of the number of colors that are allowed by the depth. For example, if the chart contains three colors (red, white, and black) and you save it as 16 colors, the chart will remain as three colors.

Note: If the number of colors in the chart exceeds the number of colors for that depth, the colors will be dithered to replicate the colors in the chart.

EMF and TIFF chart export options

Image size. Percentage of original chart size, up to 200 percent.

Note: EMF (enhanced metafile) format is available only on Windows operating systems.

EPS chart export options

Image size. You can specify the size as a percentage of the original image size (up to 200 percent), or you can specify an image width in pixels (with height determined by the width value and the aspect ratio). The exported image is always proportional to the original.

Include TIFF preview image. Saves a preview with the EPS image in TIFF format for display in applications that cannot display EPS images on screen.

Fonts. Controls the treatment of fonts in EPS images.

- **Use font references.** If the fonts that are used in the chart are available on the output device, the fonts are used. Otherwise, the output device uses alternate fonts.
- **Replace fonts with curves.** Turns fonts into PostScript curve data. The text itself is no longer editable as text in applications that can edit EPS graphics. This option is useful if the fonts that are used in the chart are not available on the output device.

Viewer printing

There are two options for printing the contents of the Viewer window:

All visible output. Prints only items that are currently displayed in the contents pane. Hidden items (items with a closed book icon in the outline pane or hidden in collapsed outline layers) are not printed.

Selection. Prints only items that are currently selected in the outline and/or contents panes.

-

Print Preview

Print Preview shows you what will print on each page for Viewer documents. It is a good idea to check Print Preview before actually printing a Viewer document, because Print Preview shows you items that may not be visible by looking at the contents pane of the Viewer, including:

- Page breaks
- Hidden layers of pivot tables
- Breaks in wide tables
- Headers and footers that are printed on each page

If any output is currently selected in the Viewer, the preview displays only the selected output. To view a preview for all output, make sure nothing is selected in the Viewer.

Related information

- [Viewer printing](#)
-

Page Attributes: Headers and Footers

Headers and footers are the information that is printed at the top and bottom of each page. You can enter any text that you want to use as headers and footers. You can also use the toolbar in the middle of the dialog box to insert:

- Date and time
 - Page numbers
 - Viewer filename
 - Outline heading labels
 - Page titles and subtitles
 - Make Default uses the settings specified here as the default settings for new Viewer documents. (Note: this makes the current settings on both the Header/Footer tab and the Options tab the default settings.)
 - Outline heading labels indicate the first-, second-, third-, and/or fourth-level outline heading for the first item on each page.
 - Page titles and subtitles print the current page titles and subtitles. These can be created with New Page Title on the Viewer Insert menu or with the **TITLE** and **SUBTITLE** commands. If you have not specified any page titles or subtitles, this setting is ignored.
- Note:* Font characteristics for new page titles and subtitles are controlled on the Viewer tab of the Options dialog box (accessed by choosing Options on the Edit menu). Font characteristics for existing page titles and subtitles can be changed by editing the titles in the Viewer.

To see how your headers and footers will look on the printed page, choose Print Preview from the File menu.

- [To insert page headers and footers](#)

Related information

-

To insert page headers and footers

1. Make the Viewer the active window (click anywhere in the window).
 2. From the menus, choose:
File > Header and Footer...
 3. Enter the header and/or footer that you want to appear on each page.
-

Page Attributes: Options

This dialog box controls the printed chart size, the space between printed output items, and page numbering.

- Printed Chart Size. Controls the size of the printed chart relative to the defined page size. The chart's aspect ratio (width-to-height ratio) is not affected by the printed chart size. The overall printed size of a chart is limited by both its height and width. When the outer borders of a chart reach the left and right borders of the page, the chart size cannot increase further to fill more page height.
- Space between items. Controls the space between printed items. Each pivot table, chart, and text object is a separate item. This setting does not affect the display of items in the Viewer.
- Number pages starting with. Numbers pages sequentially, starting with the specified number.
- Make Default. This option uses the settings that are specified here as the default settings for new Viewer documents. (Note that this option makes the current Header/Footer settings and Options settings the default.)

-

To change printed chart size, page numbering, and space between printed Items

1. Make the Viewer the active window (click anywhere in the window).
 2. From the menus choose:
File > Page Attributes...
 3. Click the Options tab.
 4. Change the settings and click OK.
-

Saving output

The contents of the Viewer can be saved.

- Output object (*.cou). This format saves the entire output container, including the graph, tabs, annotations, and so on. This format can be opened and viewed in IBM® SPSS® Modeler, added to projects, and published and tracked using the IBM SPSS Collaboration and Deployment Services Repository. This format is not compatible with IBM SPSS Statistics.
- Viewer files (*.spv). The format that is used to display files in the Viewer window. When you save to this format from a model nugget in IBM SPSS Modeler, only the content of the Viewer from the Model tab is saved.

To control options for saving web reports or save results in other formats (for example, text, Word, Excel), use Export on the File menu.

- [Saving a Viewer document](#)

Related information

- [Export output](#)
 - [Publish to Web](#)
 - [Viewer](#)
-

Saving a Viewer document

1. From the Viewer window menus choose:

File > Save

2. Enter the name of the document, and then click Save.

Optionally, you can do the following:

Lock files to prevent editing in IBM® SPSS® Smartreader

If a Viewer document is locked, you can manipulate pivot tables (swap rows and columns, change the displayed layer, etc.) but you cannot edit any output or save any changes to the Viewer document in IBM SPSS Smartreader (a separate product for working with Viewer documents). This setting has no effect on Viewer documents opened in IBM SPSS Statistics or IBM SPSS Modeler.

Encrypt files with a password

You can protect confidential information stored in a Viewer document by encrypting the document with a password. Once encrypted, the document can only be opened by providing the password. IBM SPSS Smartreader users will also be required to provide the password in order to open the file.

To encrypt a Viewer document:

- a. Select Encrypt file with password in the Save Output As dialog box.
- b. Click Save.
- c. In the Encrypt File dialog box, provide a password and re-enter it in the Confirm password text box. Passwords are limited to 10 characters and are case-sensitive.

Note: Passwords cannot be recovered if they are lost. If the password is lost the file cannot be opened.

Creating strong passwords

- Use eight or more characters.
- Include numbers, symbols and even punctuation in your password.
- Avoid sequences of numbers or characters, such as "123" and "abc", and avoid repetition, such as "111aaa".
- Do not create passwords that use personal information such as birthdays or nicknames.
- Periodically change the password.

Note: Storing encrypted files to an IBM SPSS Collaboration and Deployment Services Repository is not supported.

Modifying encrypted files

- If you open an encrypted file, make modifications to it and choose File > Save, the modified file will be saved with the same password.
- You can change the password on an encrypted file by opening the file, repeating the steps for encrypting it, and specifying a different password in the Encrypt File dialog box.
- You can save an unencrypted version of an encrypted file by opening the file, choosing File > Save As and deselecting Encrypt file with password in the Save Output As dialog box.

Note: Encrypted data files and output documents cannot be opened in versions of IBM SPSS Statistics prior to version 21.

Encrypted syntax files cannot be opened in versions prior to version 22.

Store required model information with the output document

This option applies only when there are model viewer items in the output document that require auxiliary information to enable some of the interactive features. Click More Info to display a list of these model viewer items and the interactive features that require auxiliary information. Storing this information with the output document might substantially increase the document size. If you choose not to store this information, you can still open these output items but the specified interactive features will not be available.

Pivot tables

Many results are presented in tables that can be pivoted interactively. That is, you can rearrange the rows, columns, and layers.

Manipulating a pivot table

Options for manipulating a pivot table include:

- Transposing rows and columns
 - Moving rows and columns
 - Creating multidimensional layers
 - Grouping and ungrouping rows and columns
 - Showing and hiding rows, columns, and other information
 - Rotating row and column labels
 - Finding definitions of terms
 - [Activating a pivot table](#)
 - [Pivoting a table](#)
 - [Changing display order of elements within a dimension](#)
 - [Moving rows and columns within a dimension element](#)
 - [Transposing rows and columns](#)
 - [Grouping rows or columns](#)
 - [Ungrouping rows or columns](#)
 - [Rotating row or column labels](#)
 - [Sorting rows](#)
 - [Inserting rows and columns](#)
 - [Controlling display of variable and value labels](#)
 - [Changing the output language](#)
 - [Navigating large tables](#)
 - [Undoing changes](#)
-

Activating a pivot table

Before you can manipulate or modify a pivot table, you need to **activate** the table. To activate a table:

1. Double-click the table.
or
 2. Right-click the table and from the pop-up menu choose Edit Content.
 3. From the sub-menu choose either In Viewer or In Separate Window.
-

Pivoting a table

A table has three dimensions: rows, columns, and layers. A dimension can contain multiple elements (or none at all). You can change the organization of the table by moving elements between or within dimensions. To move an element, just drag and drop it where you want it.

Related information

- [Activating a pivot table](#)
 - [Changing display order of elements within a dimension](#)
 - [Moving rows and columns within a dimension element](#)
 - [Transposing rows and columns](#)
-

Changing display order of elements within a dimension

To change the display order of elements within a table dimension (row, column, or layer):

1. Activate the pivot table.
 2. If pivoting trays are not already on, from the Pivot Table menu choose:
Pivot > Pivoting Trays
 3. Drag and drop the elements within the dimension in the pivoting tray.
-

Moving rows and columns within a dimension element

1. Activate the pivot table.
2. In the table itself (not the pivoting trays), click the label for the row or column you want to move.
3. Drag the label to the new position.

Related information

- [Activating a pivot table](#)
-

Transposing rows and columns

1. Activate the pivot table.
2. From the menus choose:
Pivot > Transpose Rows and Columns

This has the same effect as dragging all of the row elements into the column dimension and dragging all of the column elements into the row dimension.

Grouping rows or columns

1. Activate the pivot table.
2. Select the labels for the rows or columns that you want to group together (click and drag or Shift+click to select multiple labels).
3. From the menus choose:
Edit > Group

A group label is automatically inserted. Double-click the group label to edit the label text.

Note: To add rows or columns to an existing group, you must first ungroup the items that are currently in the group. Then you can create a new group that includes the additional items.

Related information

- [Manipulating a pivot table](#)
- [Activating a pivot table](#)
- [Pivoting a table](#)
- [Changing display order of elements within a dimension](#)
- [Moving rows and columns within a dimension element](#)
- [Transposing rows and columns](#)
- [Ungrouping rows or columns](#)
- [Rotating row or column labels](#)
- [Undoing changes](#)

Ungrouping rows or columns

Ungrouping automatically deletes the group label.

Related information

- [Manipulating a pivot table](#)
- [Activating a pivot table](#)
- [Pivoting a table](#)
- [Changing display order of elements within a dimension](#)
- [Moving rows and columns within a dimension element](#)
- [Transposing rows and columns](#)
- [Grouping rows or columns](#)
- [Rotating row or column labels](#)
- [Undoing changes](#)

Rotating row or column labels

You can rotate labels between horizontal and vertical display for the innermost column labels and the outermost row labels in a table.

1. Activate the pivot table.
2. From the menus choose:
Format > Rotate Inner Column Labels
or
Format > Rotate Outer Row Labels

Only the innermost column labels and the outermost row labels can be rotated.

Related information

- [Manipulating a pivot table](#)

- [Grouping rows or columns](#)
- [Ungrouping rows or columns](#)
- [Undoing changes](#)

Sorting rows

To sort the rows of a pivot table:

1. Activate the table.
2. Select any cell in the column you want to use to sort on. To sort just a selected group of rows, select two or more contiguous cells in the column you want to use to sort on.
3. From the menus, choose:
Edit > Sort rows
4. Select Ascending or Descending from the submenu.
 - If the row dimension contains groups, sorting affects only the group that contains the selection.
 - You cannot sort across group boundaries.
 - You cannot sort tables with more than one item in the row dimension.

Inserting rows and columns

To insert a row or column in a pivot table:

1. Activate the table.
2. Select any cell in the table.
3. From the menus, choose:

Insert Before

or

Insert After

From the submenu, choose:

Row

or

Column

- A plus sign (+) is inserted in each cell of the new row or column to prevent the new row or column from being automatically hidden because it is empty.
 - In a table with nested or layered dimensions, a column or row is inserted at every corresponding dimension level.
-

Controlling display of variable and value labels

If variables contain descriptive variable or value labels, you can control the display of variable names and labels and data values and value labels in pivot tables.

1. Activate the pivot table.
2. From the menus, choose:

View > Variable labels

or

View > Value labels

3. Select one of the follow options from the submenu:

- Name or Value. Only variable names (or values) are displayed. Descriptive labels are not displayed.
 - Label. Only descriptive labels are displayed. Variable names (or values) are not displayed.
 - Both. Both names (or values) and descriptive labels are displayed.
-

Changing the output language

To change the output language in a pivot table:

1. Activate the table
2. From the menus, choose:

View > Language

3. Select one of the available languages.

Changing the language affects only text that is generated by the application, such as table titles, row and column labels, and footnote text. Variable names and descriptive variable and value labels are not affected.

Navigating large tables

To use the navigation window to navigate large tables:

1. Activate the table.
2. From the menus choose:

View > Navigation

Undoing changes

You can undo the most recent change or all changes to an activated pivot table. Both actions apply only to changes made since the most recent activation of the table.

To undo the most recent change:

1. From the menus, choose:
Edit > Undo

To undo all changes:

2. From the menus, choose:
Edit > Restore

Working with layers

You can display a separate two-dimensional table for each category or combination of categories. The table can be thought of as stacked in layers, with only the top layer visible.

- [Creating and displaying layers](#)
- [Go to layer category](#)

Creating and displaying layers

To create layers:

1. If pivoting trays are not already on, from the Pivot Table menu, choose:
Pivot > Pivoting Trays
2. Drag an element from the row or column dimension into the layer dimension.

Moving elements to the layer dimension creates a multidimensional table, but only a single two-dimensional "slice" is displayed. The visible table is the table for the top layer. For example, if a yes/no categorical variable is in the layer dimension, then the multidimensional table has two layers: one for the "yes" category and one for the "no" category.

Changing the displayed layer

1. Choose a category from the drop-down list of layers (in the pivot table itself, not the pivoting tray).
or
2. From the menus, choose:
Pivot > Go to Layer...

Go to layer category

Go to Layer Category allows you to change layers in a pivot table. This dialog box is particularly useful when there are many layers or the selected layer has many categories.

Hiding rows and columns in a table

Showing hidden rows and columns in a table

1. Activate the pivot table.
2. From the menus choose:
View > Show All Categories

This displays all hidden rows and columns in the table. (If Hide empty rows and columns is selected in Table Properties for this table, a completely empty row or column remains hidden.)

TableLooks

A TableLook is a set of properties that define the appearance of a table. You can select a previously defined TableLook or create your own TableLook.

- Before or after a TableLook is applied, you can change cell formats for individual cells or groups of cells by using cell properties. The edited cell formats remain intact, even when you apply a new TableLook.
 - Optionally, you can reset all cells to the cell formats that are defined by the current TableLook. This option resets any cells that were edited. If As Displayed is selected in the TableLook Files list, any edited cells are reset to the current table properties.
 - Only table properties that are defined in the Table Properties dialog are saved in TableLooks. TableLooks do not include individual cell modifications.
- [To apply a TableLook](#)
[To edit or create a TableLook](#)
-

To apply a TableLook

1. Activate a pivot table.
2. From the menus, choose:
Format > TableLooks...
3. Select a TableLook from the list of files. To select a file from another directory, click Browse.
4. Click OK to apply the TableLook to the selected pivot table.

You can also edit TableLooks and create new ones.

To edit or create a TableLook

1. Activate a pivot table.
 2. From the menus, choose:
Format > TableLooks...
 3. In the TableLooks dialog box, select a TableLook from the list of files.
 4. Click Edit Look.
 5. Adjust the table properties for the attributes that you want, and then click OK.
 6. Click Save Look to save the edited TableLook, or click Save As to save it as a new TableLook.
- Editing a TableLook affects only the selected pivot table. An edited TableLook is not applied to any other tables that use that TableLook unless you select those tables and reapply the TableLook. For information on setting the default TableLook applied to all new tables, see [Setting the TableLook for new pivot tables](#).
 - Only table properties that are defined in the Table Properties dialog are saved in TableLooks. TableLooks do not include individual cell modifications.
-

Table properties

Table Properties allows you to set general properties of a table, and set cell styles for various parts of a table. You can:

- Control general properties, such as hiding empty rows or columns and adjusting printing properties.
 - Control the format and position of footnote markers.
 - Determine specific formats for cells in the data area, for row and column labels, and for other areas of the table.
 - Control the width and color of the lines that form the borders of each area of the table.
- [To change pivot table properties](#)
[Table properties: general](#)
[Table properties: notes](#)
[Table properties: cell formats](#)
[Table properties: borders](#)

- [Table properties: printing](#)

- [Footnotes and captions](#)
- [Data cell widths](#)
- [Changing column width](#)
- [Selecting rows, columns, and cells in a pivot table](#)
- [Printing pivot tables](#)
- [Set rows to display](#).

To change pivot table properties

1. From the menus choose:
Format > Table Properties...
2. Select a tab (General, Footnotes, Cell Formats, Borders, or Printing).
3. Select the options that you want.
4. Click OK or Apply.

The new properties are applied to the selected pivot table.

Table properties: general

Several properties apply to the table as a whole. You can:

- Show or hide empty rows and columns. (An empty row or column has nothing in any of the data cells.)
- Control the placement of row labels, which can be in the upper left corner or nested.
- Control maximum and minimum column width (expressed in points).

To change general table properties:

1. From the menus, choose:
Format > Table Properties...
2. Click the General tab.
3. Select the options that you want.
4. Click OK or Apply.

The new properties are applied to the selected pivot table.

- [Set rows to display](#)

Set rows to display

Note: This feature only applies to legacy tables.

By default, tables with many rows are displayed in sections of 100 rows. To control the number of rows displayed in a table:

1. Activate the table.
2. From the menus choose:
Table Properties > General
3. Select Display table by rows.
4. Click Set Rows to Display.
or

5. From the View menu of an activated pivot table, choose Display table by rows and Set Rows to Display.

Rows to display. Controls the maximum number of rows to display at one time. Navigation controls allow you move to different sections of the table. The minimum value is 10. The default is 100.

Widow/orphan tolerance. Controls the maximum number of rows of the inner most row dimension of the table to split across displayed views of the table. For example, if there are six categories in each group of the inner most row dimension, specifying a value of six would prevent any group from splitting across displayed views. This setting can cause the total number of rows in a displayed view to exceed the specified maximum number of rows to display.

Table properties: notes

The Notes tab of the Table Properties dialog controls footnote formatting and table comment text.

Footnotes. The properties of footnote markers include style and position in relation to text.

- The style of footnote markers is either numbers (1, 2, 3, ...) or letters (a, b, c, ...).
- The footnote markers can be attached to text as superscripts or subscripts.

Comment Text. You can add comment text to each table.

- Comment text is displayed in a tooltip when you hover over a table in the Viewer.
- Screen readers read the comment text when the table has focus.
- The tooltip in the Viewer displays only the first 200 characters of the comment, but screen readers read the entire text.
- When you export output to HTML, the comment text is used as alt text.

The new properties are applied to the selected pivot table. To apply new table properties to a TableLook instead of just the selected table, edit the TableLook (Format menu, TableLooks).

Table properties: cell formats

For formatting, a table is divided into areas: title, layers, corner labels, row labels, column labels, data, caption, and footnotes. For each area of a table, you can modify the associated cell formats. Cell formats include text characteristics (such as font, size, color, and style), horizontal and vertical alignment, background colors, and inner cell margins.

Cell formats are applied to areas (categories of information). They are not characteristics of individual cells. This distinction is an important consideration when pivoting a table.

For example,

- If you specify a bold font as a cell format of column labels, the column labels will appear bold no matter what information is currently displayed in the column dimension. If you move an item from the column dimension to another dimension, it does not retain the bold characteristic of the column labels.
- If you make column labels bold simply by highlighting the cells in an activated pivot table and clicking the Bold button on the toolbar, the contents of those cells will remain bold no matter what dimension you move them to, and the column labels will not retain the bold characteristic for other items moved into the column dimension.

To change cell formats:

1. From the menus choose:
Format > Table Properties...
2. Select the Cell Formats tab.
3. Select an Area from the drop-down list or click an area of the sample.
4. Select characteristics for the area. Your selections are reflected in the sample.
5. Click OK or Apply.

The new properties are applied to the selected pivot table.

Alternating row colors

To apply a different background and/or text color to alternate rows in the Data area of the table:

1. Select Data from the Area drop-down list.
2. Select (check) Alternate row color in the Background Color group.
3. Select the colors to use for the alternate row background and text.

Alternate row colors affect only the Data area of the table. They do not affect row or column label areas.

Table properties: borders

For each border location in a table, you can select a line style and a color. If you select None as the style, there will be no line at the selected location.

To change table borders:

1. From the menus choose:
Format > Table Properties...
2. Click the Borders tab.
3. Select a border location, either by clicking its name in the list or by clicking a line in the Sample area.
4. Select a line style or select None.
5. Select a color.
6. Click OK or Apply.

The new properties are applied to the selected pivot table.

Table properties: printing

You can control the following properties for printed pivot tables:

- Print all layers or only the top layer of the table, and print each layer on a separate page.
- Shrink a table horizontally or vertically to fit the page for printing.
- Control widow/orphan lines by controlling the minimum number of rows and columns that will be contained in any printed section of a table if the table is too wide and/or too long for the defined page size.
Note: If a table is too long to fit on the current page because there is other output above it, but it will fit within the defined page length, the table is automatically printed on a new page, regardless of the widow/orphan setting.
- Include continuation text for tables that don't fit on a single page. You can display continuation text at the bottom of each page and at the top of each page. If neither option is selected, the continuation text will not be displayed.

To control pivot table printing properties:

1. From the menus choose:
Format > Table Properties...
2. Click the Printing tab.
3. Select the printing options that you want.
4. Click OK or Apply.

The new properties are applied to the selected pivot table.

Cell properties

Cell properties are applied to a selected cell. You can change the font, value format, alignment, margins, and colors. Cell properties override table properties; therefore, if you change table properties, you do not change any individually applied cell properties.

To change cell properties:

1. Select the cells in the table.
2. From the Format menu or the pop-up menu choose Cell Properties.

- [Cell properties: Font and background](#)
 - [Cell properties: Format value](#)
 - [Cell properties: Alignment and margins](#)
-

Cell properties: Font and background

The Font and Background tab controls the font style and color and background color for the selected cells in the table.

To change font and background settings for selected cells in a pivot table:

Related information

-

To hide or show a footnote in a table

To hide a footnote:

1. Activate the pivot table.
2. Right-click the cell that contains the footnote reference and select Hide Footnotes from the pop-up menu
or

3. Select the footnote in the footnote area of the table and select Hide from the pop-up menu.

Note: For legacy tables, select the footnote area of the table, select Edit Footnote from the pop-up menu, and then deselect (clear) the Visible property for any footnotes you want to hide.

If a cell contains multiple footnotes, use the latter method to selectively hide footnotes.

To hide all footnotes in the table:

1. Select all of the footnotes in the footnote area of the table (use click and drag or Shift+click to select the footnotes) and select Hide from the View menu.

To show hidden footnotes:

1. Select Show All Footnotes from the View menu.

-

Footnote marker

Footnote Marker changes the characters that can be used to mark a footnote. By default, standard footnote markers are sequential letters or numbers, depending on the table properties settings. You can also assign a special marker. Special markers are not affected when you renumber footnotes or switch between numbers and letters for standard markers. The display of numbers or letters for standard markers and the subscript or superscript position of footnote markers are controlled by the Footnotes tab of the Table Properties dialog.

To change footnote markers:

1. Select a footnote.
2. From the Format menu, choose Footnote Marker.

Special markers are limited to 2 characters. Footnotes with special markers precede footnotes with sequential letters or numbers in the footnote area of the table; so changing to a special marker can reorder the footnote list.

Editing footnotes in legacy tables

For legacy tables, you can use the Edit Footnotes dialog to enter and modify footnote text and font settings, change footnote markers, and selectively hide or delete footnotes.

When you insert a new footnote in a legacy table, the Edit Footnotes dialog automatically opens. To use the Edit Footnotes dialog to edit existing footnotes (without creating a new footnote):

Marker. By default, standard footnote markers are sequential letters or numbers, depending on the table properties settings. To assign a special marker, simply enter the new marker value in the Marker column. Special markers are not affected when you renumber footnotes or switch between numbers and letters for standard markers. The display of numbers or letters for standard markers and the subscript or superscript position of footnote markers are controlled by the Footnotes tab of the Table Properties dialog. See the topic [Table properties: notes](#) for more information.

To change a special marker back to a standard marker, right-click on the marker in the Edit Footnotes dialog, select Footnote Marker from the pop-up menu, and select Standard marker in the Footnote Marker dialog box.

Footnote. The content of the footnote. The display reflects the current font and background settings. The font settings can be changed for individual footnotes using the Format subdialog. See the topic [Footnote font and color settings](#) for more information. A single background color is applied to all footnotes and can be changed in the Font and Background tab of the Cell Properties dialog. See the topic [Cell properties: Font and background](#) for more information.

Visible. All footnotes are visible by default. Deselect (clear) the Visible checkbox to hide a footnote.

Footnote font and color settings

For legacy tables, you can use the Format dialog to change the font family, style, size and color for one or more selected footnotes:

1. Double-click the footnote area of the table or from the menus choose: Format > Edit Footnotes.
2. In the Edit Footnotes dialog, select (click) one or more footnotes in the Footnotes grid.
3. Click the **Format** button.

The selected font family, style, size, and colors are applied to all the selected footnotes.

Background color, alignment, and margins can be set in the Cell Properties dialog and apply to all footnotes. You cannot change these settings for individual footnotes. See the topic [Cell properties: Font and background](#) for more information.

Printing pivot tables

Several factors can affect the way that printed pivot tables look, and these factors can be controlled by changing pivot table attributes.

- For multidimensional pivot tables (tables with layers), you can either print all layers or print only the top (visible) layer. See the topic [Table properties: printing](#) for more information.
- For long or wide pivot tables, you can automatically resize the table to fit the page or control the location of table breaks and page breaks. See the topic [Table properties: printing](#) for more information.

Use Print Preview on the File menu to see how printed pivot tables will look.

- [Controlling table breaks for wide and long tables](#)

Related information

 - [Data cell widths](#)
 - [Changing column width](#)
 - [Selecting rows, columns, and cells in a pivot table](#)
 - [Table properties: printing](#)
 - [Controlling table breaks for wide and long tables](#)
-

Controlling table breaks for wide and long tables

Pivot tables that are either too wide or too long to print within the defined page size are automatically split and printed in multiple sections. You can:

- Control the row and column locations where large tables are split.
- Specify rows and columns that should be kept together when tables are split.
- Rescale large tables to fit the defined page size.

To specify row and column breaks for printed pivot tables:

1. Activate the pivot table.
 2. Click any cell in the column to the left of where you want to insert the break, or click any cell in the row before the row where you want to insert the break.
 3. From the menus, choose:
`Format > Breakpoints > Vertical Breakpoint`
or
`Format > Breakpoints > Horizontal Breakpoint`
1. Activate the pivot table.
 2. Click any cell in the column to the left of where you want to insert the break, or click any cell in the row before the row where you want to insert the break.

- From the menus, choose:
Format > Breakpoints > Vertical Breakpoint

or

- Format > Breakpoints > Horizontal Breakpoint

To specify rows or columns to keep together:

- Select the labels of the rows or columns that you want to keep together. Click and drag or Shift+click to select multiple row or column labels.
- From the menus, choose:
Format > Breakpoints > Keep Together

To view breakpoints and keep together groups:

- From the menus, choose:

Format > Breakpoints > Display Breakpoints

Breakpoints are shown as vertical or horizontal lines. Keep together groups appear as grayed out rectangular regions that are enclosed by a darker border.

Note: Displaying breakpoints and keep together groups is not supported for legacy tables.

To clear breakpoints and keep together groups

To clear a breakpoint:

- Click any cell in the column to the left of a vertical breakpoint, or click any cell in the row above a horizontal breakpoint.
- From the menus, choose:
Format > Breakpoints > Clear Breakpoint or Group

To clear a keep together group:

- Select the column or row labels that specify the group.
- From the menus, choose:
Format > Breakpoints > Clear Breakpoint or Group

All breakpoints and keep together groups are automatically cleared when you pivot or reorder any row or column. This behavior does not apply to legacy tables.

Creating a chart from a pivot table

- Double-click the pivot table to activate it.
 - Select the rows, columns, or cells you want to display in the chart.
 - Right-click anywhere in the selected area.
 - Choose Create Graph from the pop-up menu and select a chart type.
-

Legacy tables

You can choose to render tables as legacy tables (referred to as full-featured tables in release 19) which are then fully compatible with IBM® SPSS® Statistics releases prior to 20. Legacy tables may render slowly and are only recommended if compatibility with releases prior to 20 is required. For information on how to create legacy tables, see [Pivot table options](#).

Options

- [General options](#)

- [Viewer options](#)
 - [Pivot table options](#)
 - [Output options](#)
-

General options

Maximum Number of Threads

The number of threads that multithreaded procedures use when calculating results. The Automatic setting is based on the number of available processing cores. Specify a lower value if you want to make more processing resources available to other applications while multithreaded procedures are running. This option is disabled in distributed analysis mode.

Output

Display a leading zero for decimal values. Displays leading zeros for numeric values that consist only of a decimal part. For example, when leading zeros are displayed, the value .123 is displayed as 0.123. This setting does not apply to numeric values that have a currency or percent format. Except for fixed ASCII files (*.dat), leading zeros are not included when the data are saved to an external file.

Measurement System. The measurement system used (points, inches, or centimeters) for specifying attributes such as pivot table cell margins, cell widths, and space between tables for printing.

- [Setting general options](#)
-

Setting general options

1. From the menus choose:
`Edit > Options...`
 2. Click the General tab.
 3. Select the settings that you want.
 4. Click OK or Apply.
-

Viewer options

Viewer output display options affect only new output that is produced after you change the settings. Output that is already displayed in the Viewer is not affected by changes in these settings.

Initial Output State

Controls which items are automatically displayed or hidden each time that you run a procedure and how items are initially aligned. You can control the display of the following items: log, warnings, notes, titles, pivot tables, charts, tree diagrams, and text output. You can also turn the display of commands in the log on or off. You can copy command syntax from the log and save it in a syntax file.

Note: All output items are displayed left-aligned in the Viewer. Only the alignment of printed output is affected by the justification settings. Centered and right-aligned items are identified by a small symbol.

Title

Controls the font style, size, and color for new output titles. The font Size list provides a set of predefined sizes, but you can manually enter other, supported size values.

Page Title

Controls the font style, size, and color for new page titles and page titles that are generated by **TITLE** and **SUBTITLE** command syntax or created by New Page Title on the Insert menu. The font Size list provides a set of predefined sizes, but you can manually enter other, supported size values.

Text Output

Font that is used for text output. Text output is designed for use with a monospaced (fixed-pitch) font. If you select a proportional font, tabular output does not align properly. The font Size list provides a set of predefined sizes, but you can manually enter other, supported size values.

Default Page Setup

Controls the default options for orientation and margins for printing.

- [Setting Viewer options](#)
- [Controlling the initial display state for new output](#)

Changing the initial alignment of new results

1. From the menus choose:
Edit>Options...
2. Click the Viewer tab and select the alignment (justification) in the Initial Output State group.

Pivot table options

Pivot Table options set various options for the display of pivot tables.

TableLook

Select a TableLook from the list of files and click OK or Apply. You can use one of the TableLooks provided with IBM® SPSS® Statistics, or you can create your own in the Pivot Table Editor (choose TableLooks from the Format menu).

- Browse. Allows you to select a TableLook from another directory.
- Set TableLook Directory. Allows you to change the default TableLook directory. Use Browse to navigate to the directory you want to use, select a TableLook in that directory, and then select Set TableLook Directory.

Note: TableLooks created in earlier versions of IBM SPSS Statistics cannot be used in version 16.0 or later.

Column Widths

These options control the automatic adjustment of column widths in pivot tables.

- Adjust for labels only. Adjusts column width to the width of the column label. This produces more compact tables, but data values wider than the label may be truncated.
- Adjust for labels and data for all tables. Adjusts column width to whichever is larger: the column label or the largest data value. This produces wider tables, but it ensures that all values will be displayed.

Default Editing Mode

This option controls activation of pivot tables in the Viewer window or in a separate window. By default, double-clicking a pivot table activates all but very large tables in the Viewer window. You can choose to activate pivot tables in a separate window or select a size setting that will open smaller pivot tables in the Viewer window and larger pivot tables in a separate window.

Copying wide tables to the clipboard in rich text format

When pivot tables are pasted in Word/RTF format, tables that are too wide for the document width will either be wrapped, scaled down to fit the document width, or left unchanged.

- [Setting the TableLook for new pivot tables](#)
 - [Controlling column width for new pivot tables](#)
 - [Creating a custom default TableLook](#)
-

Setting the TableLook for new pivot tables

1. From the menus choose:
Edit > Options...
2. Click the Pivot Tables tab.
3. Select the TableLook that you want.
4. Click OK or Apply.

Note: TableLooks created in earlier versions of IBM® SPSS® Statistics cannot be used in version 16.0 or later.

Controlling column width for new pivot tables

1. From the menus choose:
Edit > Options...
 2. Click the Pivot Tables tab.
 3. Select the option you want for Column Widths.
 4. Click OK or Apply.
- **Adjust for labels and data except for extremely large tables.** For tables that don't exceed 10,000 cells, adjusts column width to whichever is larger—the column label or the largest data value. For tables with more than 10,000 cells, adjusts column width to the width of the column label.
 - **Adjust for labels only.** Adjusts column width to the width of the column label. This produces more compact tables, but data values wider than the label may be truncated.
 - **Adjust for labels and data.** Adjusts column width to whichever is larger: the column label or the largest data value. This produces wider tables, but it ensures that all values will be displayed.

Related information

-

Creating a custom default TableLook

1. Activate a pivot table (double-click anywhere in the table).
2. From the menus choose:
Format > TableLooks...
3. Select a TableLook from the list and click Edit Look.
4. Adjust the table properties for the attributes that you want.
5. Click Save Look or Save As to save the TableLook and click OK.
6. Deselect the pivot table.
7. From the menus choose:
Edit > Options...

8. Click the Pivot Tables tab.
9. Select the TableLook from the list and click OK.

Note: TableLooks created in earlier versions of IBM® SPSS® Statistics cannot be used in version 16.0 or later.

Output options

Output options control the default setting for a number of output options.

Screen Reader Accessibility. Controls how pivot table row and column labels are read by screen readers. You can read full row and column labels for each data cell or read only the labels that change as you move between data cells in the table.

- [Setting output options](#)
-

Setting output options

1. From the menus choose:
Edit > Options...
2. Click the Output tab.
3. Select the settings that you want.
4. Click OK or Apply.

Viewer output display options affect only new output produced after you change the settings. Output already displayed in the Viewer is not affected by changes in these settings.

Handling missing values

- [Overview of Missing Values](#)
 - [Handling Missing Values](#)
 - [Imputing or Filling Missing Values](#)
 - [CLEM Functions for Missing Values](#)
-

Overview of Missing Values

During the Data Preparation phase of data mining, you will often want to replace missing values in the data. **Missing values** are values in the data set that are unknown, uncollected, or incorrectly entered. Usually, such values are invalid for their fields. For example, the field Sex should contain the values M and F. If you discover the values Y or Z in the field, you can safely assume that such values are invalid and should therefore be interpreted as blanks. Likewise, a negative value for the field Age is meaningless and should also be interpreted as a blank. Frequently, such obviously wrong values are purposely entered, or fields left blank, during a questionnaire to indicate a nonresponse. At times, you may want to examine these blanks more closely to determine whether a nonresponse, such as the refusal to give one's age, is a factor in predicting a specific outcome.

Some modeling techniques handle missing data better than others. For example, C5.0 and Apriori cope well with values that are explicitly declared as "missing" in a Type node. Other modeling techniques have trouble dealing with missing values and experience longer training times, resulting in less-accurate models.

There are several types of missing values recognized by IBM® SPSS® Modeler:

- Null or system-missing values. These are nonstring values that have been left blank in the database or source file and have not been specifically defined as "missing" in a source or Type node. System-missing values are displayed as \$null\$. Note that empty strings are not considered nulls in IBM SPSS Modeler, although they may be treated as nulls by certain databases.
- Empty strings and white space. Empty string values and white space (strings with no visible characters) are treated as distinct from null values. Empty strings are treated as equivalent to white space for most purposes. For example, if you select the option to treat white space as blanks in a source or Type node, this setting applies to empty strings as well.
- Blank or user-defined missing values. These are values such as **unknown**, **99**, or **-1** that are explicitly defined in a source node or Type node as missing. Optionally, you can also choose to treat nulls and white space as blanks, which allows them to be flagged for special treatment and to be excluded from most calculations. For example, you can use the **@BLANK** function to treat these values, along with other types of missing values, as blanks.

Reading in mixed data. Note that when you are reading in fields with numeric storage (either integer, real, time, timestamp, or date), any non-numeric values are set to *null* or *system missing*. This is because, unlike some applications, does not allow mixed storage types within a field. To avoid this, any fields with mixed data should be read in as strings by changing the storage type in the source node or external application as necessary.

Reading empty strings from Oracle. When reading from or writing to an Oracle database, be aware that, unlike IBM SPSS Modeler and unlike most other databases, Oracle treats and stores empty string values as equivalent to null values. This means that the same data extracted from an Oracle database may behave differently than when extracted from a file or another database, and the data may return different results.

-

Handling Missing Values

You should decide how to treat missing values in light of your business or domain knowledge. To ease training time and increase accuracy, you may want to remove blanks from your data set. On the other hand, the presence of blank values may lead to new business opportunities or additional insights. In choosing the best technique, you should consider the following aspects of your data:

- Size of the data set
- Number of fields containing blanks
- Amount of missing information

In general terms, there are two approaches you can follow:

- You can exclude fields or records with missing values
- You can impute, replace, or coerce missing values using a variety of methods

Both of these approaches can be largely automated using the Data Audit node. For example, you can generate a Filter node that excludes fields with too many missing values to be useful in modeling, and generate a Supernode that imputes missing values for any or all of the fields that remain. This is where the real power of the audit comes in, allowing you not only to assess the current state of your data, but to take action based on the assessment.

- [Handling Records with Missing Values](#)
- [Handling Fields with Missing Values](#)
- [Handling Records with System Missing Values](#)

Related information

- [Overview of Missing Values](#)
 - [CLEM Functions for Missing Values](#)
-

Handling Records with Missing Values

If the majority of missing values is concentrated in a small number of records, you can just exclude those records. For example, a bank usually keeps detailed and complete records on its loan customers. If, however, the bank is less restrictive in approving loans for its own staff members, data gathered for staff loans is likely to have several blank fields. In such a case, there are two options for handling these missing values:

- You can use a Select node to remove the staff records.
- If the data set is large, you can discard all records with blanks.

Related information

- [Handling Fields with Missing Values](#)
-

Handling Fields with Missing Values

If the majority of missing values is concentrated in a small number of fields, you can address them at the field level rather than at the record level. This approach also allows you to experiment with the relative importance of particular fields before deciding on an approach for handling missing values. If a field is unimportant in modeling, it probably is not worth keeping, regardless of how many missing values it has.

For example, a market research company may collect data from a general questionnaire containing 50 questions. Two of the questions address age and political persuasion, information that many people are reluctant to give. In this case, *Age* and *Political_persuasion* have many missing values.

Field Measurement Level

In determining which method to use, you should also consider the measurement level of fields with missing values.

Numeric fields. For numeric field types, such as *Continuous*, you should always eliminate any non-numeric values before building a model, because many models will not function if blanks are included in numeric fields.

Categorical fields. For categorical fields, such as *Nominal* and *Flag*, altering missing values is not necessary but will increase the accuracy of the model. For example, a model that uses the field *Sex* will still function with meaningless values, such as *Y* and *Z*, but removing all values other than *M* and *F* will increase the accuracy of the model.

Screening or Removing Fields

To screen out fields with too many missing values, you have several options:

- You can use a Data Audit node to filter fields based on quality.
- You can use a Feature Selection node to screen out fields with more than a specified percentage of missing values and to rank fields based on importance relative to a specified target.
- Instead of removing the fields, you can use a Type node to set the field role to None. This will keep the fields in the data set but exclude them from the modeling processes.

Related information

-

Handling Records with System Missing Values

What are system missing values?

System missing values represent data values that are not known or not applicable. In databases, these values are often referred to as *NULL* values.

System missing values are different from blank values. Blank values are typically defined in the Type node as particular values, or ranges of values, which can be regarded as user-defined-missing. Blank values are handled differently in the context of modeling.

Constructing system missing values

System missing values might be present in data that is read from a data source (for example, database tables might contain *NULL* values).

System missing values can be constructed by using the value *undef* in expressions. For example, the following CLEM expression returns the *Age*, if less than or equal to 30, or a missing value if greater than 30:

```
if Age > 30 then undef else Age endif
```

Missing values can also be created when an outer join is carried out, when a number is divided by zero, when the square root of a negative number is computed, and in other situations.

Displaying system missing values

System missing values are displayed in tables and other output as `$null$`.

Testing for system missing values

Use the special function `@NULL` to return `true` if the argument value is a system missing value, for example:

```
if @NULL(MyFieldName) then 'It is null' else 'It is not null' endif
```

System missing values passed to functions

System missing values that are passed to functions usually propagate missing values to the output. For example, if the value of field `f1` is a system missing value in a particular row, then the expression `log(f1)` also evaluates to a system missing value for that row. An exception is the `@NULL` function.

System missing values in expressions that involve arithmetic operators

Applying arithmetic operators to values that include a system missing value results in a system missing value. For example, if the value of field `f1` is a system missing value in a particular row, then the expression `f1 + 10` also evaluates to a system missing value for that row.

System missing values in expressions that involve logical operators

When you work with system missing values in expressions that involve logical operators, the rules of three valued logic (*true*, *false*, and *missing*) apply and can be described in truth tables. The truth tables for the common logical operators of *not*, *and*, and *or* are shown in the following tables.

Table 1. Truth table for NOT

Operand	NOT Operand
true	false
false	true
missing	missing

Table 2. Truth table for AND

Operand1	Operand2	Operand1 AND Operand2
true	true	true
true	false	false
true	missing	missing
false	true	false
false	false	false
false	missing	false
missing	true	missing
missing	false	false
missing	missing	missing

Table 3. Truth table for OR

Operand1	Operand2	Operand1 OR Operand2
true	true	true
true	false	true
true	missing	true
false	true	true
false	false	false
false	missing	missing
missing	true	true
missing	false	missing
missing	missing	missing

System missing values in expressions that involve comparison operators

When you compare a system missing value and a non-system-missing value, the outcome evaluates to a system missing value rather than a true or false result. System missing values can be compared with each other; two system missing values are considered to be equal.

System missing values in if/then/else/endif expressions

When you use conditional expressions, and the conditional expression returns a system missing value, the value from the `else` clause is returned from the conditional expression.

System missing values in the Select node

When, for a particular record, the selection expression evaluates to a missing value, the record is not output from the Select node (this action applies to both Include and Discard modes).

System missing values in the Merge node

When you merge by using a key, any records that have system missing values in a key field are not merged.

System missing values in aggregation

When aggregating data on columns, missing values are not included in the calculation. For example, in a column with three values { 1, 2, and `undef` }, the sum of the values in the column is computed as 3; the mean value is computed as 1.5.

- [Handling Records with Missing Values](#)

Imputing or Filling Missing Values

In cases where there are only a few missing values, it may be useful to insert values to replace the blanks. You can do this from the Data Audit report, which allows you to specify options for specific fields as appropriate and then generate a SuperNode that imputes values using a number of methods. This is the most flexible method, and it also allows you to specify handling for large numbers of fields in a single node.

The following methods are available for imputing missing values:

Fixed. Substitutes a fixed value (either the field mean, midpoint of the range, or a constant that you specify).

Random. Substitutes a random value based on a normal or uniform distribution.

Expression. Allows you to specify a custom expression. For example, you could replace values with a global variable created by the Set Globals node.

Algorithm. Substitutes a value predicted by a model based on the C&RT algorithm. For each field imputed using this method, there will be a separate C&RT model, along with a Filler node that replaces blanks and nulls with the value predicted by the model. A Filter node is then used to remove the prediction fields generated by the model.

Alternatively, to coerce values for specific fields, you can use a Type node to ensure that the field types cover only legal values and then set the *Check* column to Coerce for the fields whose blank values need replacing.

CLEM Functions for Missing Values

There are several functions used to handle missing values. The following functions are often used in Select and Filler nodes to discard or fill missing values:

- `count_nulls(LIST)`
- `@BLANK(FIELD)`
- `@NULL(FIELD)`
- `undef`

The @ functions can be used in conjunction with the `@FIELD` function to identify the presence of blank or null values in one or more fields. The fields can simply be flagged when blank or null values are present, or they can be filled with replacement values or used in a variety of other operations.

You can count nulls across a list of fields, as follows:

```
count_nulls(['cardtenure' 'card2tenure' 'card3tenure'])
```

When using any of the functions that accept a list of fields as input, the special functions `@FIELDS_BETWEEN` and `@FIELDS_MATCHING` can be used, as shown in the following example:

```
count_nulls(@FIELDS_MATCHING('card*'))
```

You can use the `undef` function to fill fields with the system-missing value, displayed as `$null$`. For example, to replace any numeric value, you could use a conditional statement, such as:

```
if not(Age > 17) or not(Age < 66) then undef else Age endif
```

This replaces anything that is not in the range with a system-missing value, displayed as `$null$`. By using the `not()` function, you can catch all other numeric values, including any negatives. See the topic [Functions Handling Blanks and Null Values](#) for more information.

Note on Discarding Records

When using a Select node to discard records, note that syntax uses three-valued logic and automatically includes null values in select statements. To exclude null values (system-missing) in a select expression, you must explicitly specify this by using **and** **not** in the expression. For example, to select and include all records where the type of prescription drug is Drug C, you would use the following select statement:

```
Drug = 'drugC' and not (@NULL(Drug))
```

Earlier versions of excluded null values in such situations.

About CLEM

The Control Language for Expression Manipulation (CLEM) is a powerful language for analyzing and manipulating the data that flows along IBM® SPSS® Modeler streams. Data miners use CLEM extensively in stream operations to perform tasks as simple as deriving profit from cost and revenue data or as complex as transforming web log data into a set of fields and records with usable information.

CLEM is used within IBM SPSS Modeler to:

- Compare and evaluate conditions on record fields.
- Derive values for new fields.
- Derive new values for existing fields.
- Reason about the sequence of records.
- Insert data from records into reports.

CLEM expressions are indispensable for data preparation in IBM SPSS Modeler and can be used in a wide range of nodes—from record and field operations (Select, Balance, Filler) to plots and output (Analysis, Report, Table). For example, you can use CLEM in a Derive node to create a new field based on a formula such as ratio.

CLEM expressions can also be used for global search and replace operations. For example, the expression `@NULL(@FIELD)` can be used in a Filler node to replace **system-missing values** with the integer value 0. (To replace **user-missing values**, also called blanks, use the `@BLANK` function.)

CLEM Examples

To illustrate correct syntax as well as the types of expressions possible with CLEM, example expressions follow.

Simple Expressions

Formulas can be as simple as this one, which derives a new field based on the values of the fields *After* and *Before*:

```
(After - Before) / Before * 100.0
```

Notice that field names are unquoted when referring to the values of the field.

Similarly, the following expression simply returns the log of each value for the field *salary*.

```
log(salary)
```

Complex Expressions

Expressions can also be lengthy and more complex. The following expression returns *true* if the value of two fields (*\$KX-Kohonen* and *\$KY-Kohonen*) fall within the specified ranges. Notice that here the field names are single-quoted because the field names contain special characters.

```
('$KX-Kohonen' >= -0.2635771036148072 and '$KX-Kohonen' <= 0.3146203637123107  
and '$KY-Kohonen' >= -0.18975617885589602 and  
'$KY-Kohonen' <= 0.17674794197082522) -> T
```

Several functions, such as string functions, require you to enter several parameters using correct syntax. In the following example, the function **subscr**s is used to return the first character of a *produce_ID* field, indicating whether an item is organic, genetically modified, or conventional. The results of an expression are described by -> `result`.

```
subscr(1,produce_ID) -> `c`
```

Similarly, the following expression is:

```
stripchar(`3`,`123`) -> `12`
```

It is important to note that characters are always encapsulated within single backquotes.

Combining Functions in an Expression

Frequently, CLEM expressions consist of a combination of functions. The following function combines **subscr** and **lowertoupper** to return the first character of *produce_ID* and convert it to upper case.

```
lowertoupper(subscr(1,produce_ID)) -> `C`
```

This same expression can be written in shorthand as:

```
lowertoupper(produce_ID(1)) -> `C`
```

Another commonly used combination of functions is:

```
locchar_back(`n`, (length(web_page)), web_page)
```

This expression locates the character `n` within the values of the field *web_page* reading backward from the last character of the field value. By including the **length** function as well, the expression dynamically calculates the length of the current value rather than using a static number, such as 7, which will be invalid for values with less than seven characters.

Special Functions

Numerous special functions (preceded with an @ symbol) are available. Commonly used functions include:

```
@BLANK('referrer ID') -> T
```

Frequently, special functions are used in combination, which is a commonly used method of flagging blanks in more than one field at a time.

```
@BLANK(@FIELD) -> T
```

Additional examples are discussed throughout the CLEM documentation. See the topic [CLEM Reference Overview](#) for more information.

Values and Data Types

CLEM expressions are similar to formulas constructed from values, field names, operators, and functions. The simplest valid CLEM expression is a value or a field name. Examples of valid values are:

```
3  
1.79  
'banana'
```

Examples of field names are:

```
Product_ID  
'$P-NextField'
```

where *Product* is the name of a field from a market basket data set, '*\$P-NextField*' is the name of a parameter, and the value of the expression is the value of the named field. Typically, field names start with a letter and may also contain digits and underscores (_). You can use names that do not follow these rules if you place the name within quotation marks. CLEM values can be any of the following:

- Strings--for example, "c1", "Type 2", "a piece of free text"
- Integers--for example, 12, 0, -189
- Real numbers--for example, 12.34, 0.0, -0.0045
- Date/time fields--for example, 05/12/2002, 12/05/2002, 12/05/02

It is also possible to use the following elements:

- Character codes--for example, `a` or 3
- Lists of items--for example, [1 2 3], ['Type 1'
'Type 2']

Character codes and lists do not usually occur as field values. Typically, they are used as arguments of CLEM functions.

Quoting Rules

Although the software is flexible when determining the fields, values, parameters, and strings used in a CLEM expression, the following general rules provide a list of "best practices" to use when creating expressions:

- **Strings**--Always use double quotes when writing strings ("Type 2" or "value"). Single quotes can be used instead but at the risk of confusion with quoted fields.
- **Characters**--Always use single backquotes like this `. For example, note the character d in the function `stripchar('d', "drugA")`. The only exception to this is when you are using an integer to refer to a specific character in a string. For example, note the character 5 in the function `lowertoupper("drugA"(5))`
→ "A". Note: On a standard U.K. and U.S. keyboard, the key for the backquote character (grave accent, Unicode 0060) can be found just below the Esc key.
- **Fields**--Fields are typically unquoted when used in CLEM expressions (`subscr(2, arrayID)`) → CHAR). You can use single quotes when necessary to enclose spaces or other special characters ('Order Number'). Fields that are quoted but undefined in the data set will be misread as strings.
- **Parameters**--Always use single quotes ('\$P-threshold').

Related information

- [About CLEM](#)
- [The Expression Builder](#)

Expressions and Conditions

CLEM expressions can return a result (used when deriving new values)--for example:

```
Weight * 2.2  
Age + 1  
sqrt(Signal-Echo)
```

Or, they can evaluate *true* or *false* (used when selecting on a condition)--for example:

```
Drug = "drugA"  
Age < 16  
not(PowerFlux) and Power > 2000
```

You can combine operators and functions arbitrarily in CLEM expressions--for example:

```
sqrt(abs(Signal)) * max(T1, T2) + Baseline
```

Brackets and operator precedence determine the order in which the expression is evaluated. In this example, the order of evaluation is:

- `abs(Signal)` is evaluated, and `sqrt` is applied to its result.
- `max(T1, T2)` is evaluated.
- The two results are multiplied: `*` has higher precedence than `+`.
- Finally, `Baseline` is added to the result.

The descending order of precedence (that is, operations that are performed first to operations that are performed last) is as follows:

- Function arguments
- Function calls

- xx
- x / mod div rem
- + -
- > < >= <= /== == = /=

If you want to override precedence, or if you are in any doubt of the order of evaluation, you can use parentheses to make it explicit--for example,

```
sqrt(abs(Signal)) * (max(T1, T2) + Baseline)
```

Stream, Session, and SuperNode Parameters

Parameters can be defined for use in CLEM expressions and in scripting. They are, in effect, user-defined variables that are saved and persisted with the current stream, session, or SuperNode and can be accessed from the user interface as well as through scripting. If you save a stream, for example, any parameters set for that stream are also saved. (This distinguishes them from local script variables, which can be used only in the script in which they are declared.) Parameters are often used in scripting to control the behavior of the script, by providing information about fields and values that do not need to be hard coded in the script.

The scope of a parameter depends on where it is set:

- Stream parameters can be set in a stream script or in the stream properties dialog box, and they are available to all nodes in the stream. They are displayed on the Parameters list in the Expression Builder.
- Session parameters can be set in a stand-alone script or in the session parameters dialog box. They are available to all streams used in the current session (all streams listed on the Streams tab in the managers pane).

Parameters can also be set for SuperNodes, in which case they are visible only to nodes encapsulated within that SuperNode.

Using Parameters in CLEM Expressions

Parameters are represented in CLEM expressions by `$P-pname`, where `pname` is the name of the parameter. When used in CLEM expressions, parameters must be placed within single quotes—for example, '`$P-scale`'.

Available parameters are easily viewed using the Expression Builder. To view current parameters:

1. In any dialog box accepting CLEM expressions, click the Expression Builder button.
2. From the Fields list, select Parameters.

You can select parameters from the list for insertion into the CLEM expression. See the topic [Selecting fields, parameters, and global variables](#) for more information.

- [Lists](#)
- [Fields](#)
- [CLEM Operators](#)
- [Conventions in Function Descriptions](#)

Working with Strings

There are a number of operations available for strings, including:

- Converting a string to upper case or lower case—`uppertolower(CHAR)`.
- Removing specified characters, such as `ID_` or `\$_`, from a string variable—`stripchar(CHAR, STRING)`.
- Determining the length (number of characters) for a string variable—`length(STRING)`.
- Checking the alphabetical ordering of string values—`alphabefore(STRING1, STRING2)`.
- Removing leading or trailing white space from values—`trim(STRING)`, `trim_start(STRING)`, or `trimend(STRING)`.
- Extract the first or last *n* characters from a string—`startstring(LENGTH, STRING)` or `endstring(LENGTH, STRING)`. For example, suppose you have a field named *item* that combines a product name with a four-digit ID code (`ACME CAMERA-D109`). To create a new field

that contains only the four-digit code, specify the following formula in a Derive node:

```
endstring(4, item)
```

- Matching a specific pattern—**STRING matches PATTERN**. For example, to select persons with "market" anywhere in their job title, you could specify the following in a Select node:

```
job_title matches "*market*"
```

- Replacing all instances of a substring within a string—**replace(SUBSTRING, NEWSUBSTRING, STRING)**. For example, to replace all instances of an unsupported character, such as a vertical pipe (|), with a semicolon prior to text mining, use the **replace** function in a Filler node. Under Fill in fields:, select all fields where the character may occur. For the Replace: condition, select Always, and specify the following condition under Replace with:

```
replace(' | ', ';' ,@FIELD)
```

- Deriving a flag field based on the presence of a specific substring. For example, you could use a string function in a Derive node to generate a separate flag field for each response with an expression such as:

```
hassubstring(museums, "museum_of_design")
```

See the topic [String Functions](#) for more information.

Handling Blanks and Missing Values

Replacing blanks or missing values is a common data preparation task for data miners. CLEM provides you with a number of tools to automate blank handling. The Filler node is the most common place to work with blanks; however, the following functions can be used in any node that accepts CLEM expressions:

- @BLANK(FIELD)** can be used to determine records whose values are blank for a particular field, such as **Age**.
- @NULL(FIELD)** can be used to determine records whose values are system-missing for the specified field(s). In IBM® SPSS® Modeler, system-missing values are displayed as \$null\$ values.

See the topic [Functions Handling Blanks and Null Values](#) for more information.

Related information

- [CLEM Reference Overview](#)
- [Working with Strings](#)
- [Working with Numbers](#)
- [Working with Times and Dates](#)

Working with Numbers

Numerous standard operations on numeric values are available in IBM® SPSS® Modeler, such as:

- Calculating the sine of the specified angle—**sin(NUM)**
- Calculating the natural log of numeric fields—**log(NUM)**
- Calculating the sum of two numbers—**NUM1 + NUM2**

See the topic [Numeric Functions](#) for more information.

Related information

Working with Times and Dates

Time and date formats may vary depending on your data source and locale. The formats of date and time are specific to each stream and are set in the stream properties dialog box. The following examples are commonly used functions for working with date/time fields.

Calculating Time Passed

You can easily calculate the time passed from a baseline date using a family of functions similar to the following one. This function returns the time in months from the baseline date to the date represented by the date string **DATE** as a real number. This is an approximate figure, based on a month of 30.0 days.

```
date_in_months(Date)
```

Comparing Date/Time Values

Values of date/time fields can be compared across records using functions similar to the following one. This function returns a value of *true* if the date string **DATE1** represents a date prior to that represented by the date string **DATE2**. Otherwise, this function returns a value of 0.

```
date_before(Date1, Date2)
```

Calculating Differences

You can also calculate the difference between two times and two dates using functions, such as:

```
date_weeks_difference(Date1, Date2)
```

This function returns the time in weeks from the date represented by the date string **DATE1** to the date represented by the date string **DATE2** as a real number. This is based on a week of 7.0 days. If **DATE2** is prior to **DATE1**, this function returns a negative number.

Today's Date

The current date can be added to the data set using the function **@TODAY**. Today's date is added as a string to the specified field or new field using the date format selected in the stream properties dialog box. See the topic [Date and Time Functions](#) for more information.

Summarizing Multiple Fields

The CLEM language includes a number of functions that return summary statistics across multiple fields. These functions may be particularly useful in analyzing survey data, where multiple responses to a question may be stored in multiple fields. See the topic [Working with Multiple-Response Data](#) for more information.

Comparison Functions

You can compare values across multiple fields using the **min_n** and **max_n** functions—for example:

```
max_n(['card1fee' 'card2fee' 'card3fee' 'card4fee'])
```

You can also use a number of counting functions to obtain counts of values that meet specific criteria, even when those values are stored in multiple fields. For example, to count the number of cards that have been held for more than five years:

```
count_greater_than(5, ['cardtenure' 'card2tenure' 'card3tenure'])
```

To count null values across the same set of fields:

```
count_nulls(['cardtenure' 'card2tenure' 'card3tenure'])
```

Note that this example counts the number of cards being held, not the number of people holding them. See the topic [Comparison Functions](#) for more information.

To count the number of times a specified value occurs across multiple fields, you can use the **count_equal** function. The following example counts the number of fields in the list that contain the value **Y**.

```
count_equal("Y", [Answer1, Answer2, Answer3])
```

Given the following values for the fields in the list, the function returns the results for the value **x** as shown.

Table 1. Function values

Answer1	Answer2	Answer3	Count
Y	N	Y	2
Y	N	N	1

Numeric Functions

You can obtain statistics across multiple fields using the **sum_n**, **mean_n**, and **sdev_n** functions—for example:

```
sum_n(['card1bal' 'card2bal' 'card3bal'])  
mean_n(['card1bal' 'card2bal' 'card3bal'])
```

See the topic [Numeric Functions](#) for more information.

Generating Lists of Fields

When using any of the functions that accept a list of fields as input, the special functions **@FIELDS_BETWEEN(start, end)** and **@FIELDS_MATCHING(pattern)** can be used as input. For example, assuming the order of fields is as shown in the **sum_n** example earlier, the following would be equivalent:

```
sum_n(@FIELDS_BETWEEN(card1bal, card3bal))
```

Alternatively, to count the number of null values across all fields beginning with "card":

```
count_nulls(@FIELDS_MATCHING('card*'))
```

See the topic [Special Fields](#) for more information.

Related information

- [Functions reference](#)

Working with Multiple-Response Data

A number of comparison functions can be used to analyze multiple-response data, including:

- **value_at**
- **first_index / last_index**
- **first_non_null / last_non_null**
- **first_non_null_index / last_non_null_index**
- **min_index / max_index**

For example, suppose a multiple-response question asked for the first, second, and third most important reasons for deciding on a particular purchase (for example, price, personal recommendation, review, local supplier, other). In this case, you might determine the importance of price by deriving the index of the field in which it was first included:

```
first_index("price", [Reason1 Reason2 Reason3])
```

Similarly, suppose you have asked customers to rank three cars in order of likelihood to purchase and coded the responses in three separate fields, as follows:

Table 1. Car ranking example

customer id	car1	car2	car3
101	1	3	2
102	3	2	1
103	2	3	1

In this case, you could determine the index of the field for the car they like most (ranked #1, or the lowest rank) using the **min_index** function:

```
min_index(['car1' 'car2' 'car3'])
```

See the topic [Comparison Functions](#) for more information.

Referencing Multiple-Response Sets

The special **@MULTI_RESPONSE_SET** function can be used to reference all of the fields in a multiple-response set. For example, if the three **car** fields in the previous example are included in a multiple-response set named **car_rankings**, the following would return the same result:

```
max_index(@MULTI_RESPONSE_SET("car_rankings"))
```

The Expression Builder

You can type CLEM expressions manually or use the Expression Builder, which displays a complete list of CLEM functions and operators as well as data fields from the current stream, allowing you to quickly build expressions without memorizing the exact names of fields or functions. In addition, the Builder controls automatically add the proper quotes for fields and values, making it easier to create syntactically correct expressions.

Note: The Expression Builder is not supported in scripting or parameter settings.

Note: If you want to change your datasource, before changing the source you should check that the Expression Builder can still support the functions you have selected. Because not all databases support all functions, you may encounter an error if you run against a new datasource.

Accessing the Expression Builder

The Expression Builder is available in all nodes where CLEM expressions are used, including Select, Balance, Derive, Filler, Analysis, Report, and Table nodes. You can open it by clicking the calculator button just to the right of the formula field.

Related information

- [The Expression Builder](#)
 - [Creating Expressions](#)
 - [Checking CLEM expressions](#)
 - [Find and Replace](#)
-

Creating Expressions

The Expression Builder provides not only complete lists of fields, functions, and operators but also access to data values if your data is instantiated.

To Create an Expression Using the Expression Builder

1. Type in the expression field, using the function and field lists as references.
or
2. Select the required fields and functions from the scrolling lists.
3. Double-click or click the yellow arrow button to add the field or function to the expression field.
4. Use the operand buttons in the center of the dialog box to insert the operations into the expression.

Related information

- [The Expression Builder](#)
 - [Accessing the Expression Builder](#)

-

Selecting functions

The function list displays all available CLEM functions and operators. Scroll to select a function from the list, or, for easier searching, use the drop-down list to display a subset of functions or operators. Available functions are grouped into categories for easier searching.

Most of these categories are described in the Reference section of the CLEM language description. For more information, see [Functions reference](#).

The other categories are as follows.

- General Functions contains a selection of some of the most commonly-used functions.
- Recently Used contains a list of CLEM functions used within the current session.
- @ Functions contains a list of all the special functions, which have their names preceded by an "@" sign.
Note: The `@DIFF1(FIELD1, FIELD2)` and `@DIFF2(FIELD1, FIELD2)` functions require that the two field types are the same (for example, both Integer or both Long or both Real).
- Database Functions. If the stream includes a database connection (by means of a Database source node), this selection lists the functions available from within that database, including user-defined functions (UDFs). For more information, see [Database functions](#).
- Database Aggregates. If the stream includes a database connection (by means of a Database source node), this selection lists the aggregation options available from within that database. These options are available in the Expression Builder of the Aggregate node.
- Database Window Aggregates. If the stream includes a database connection (by means of a Database source node), this selection lists the window aggregation options that you can use within that database. These options are available in the Expression Builder within nodes in the Field Operations palette only.
Note: Because SPSS® Modeler obtains the Window Aggregate Functions from the Database System View, the available options are dependent on Database behavior.
Although called "aggregates" these options are not designed for use in the Aggregate node; they are more applicable to nodes such as Derive or Select. This is because their output is scalar instead of a true aggregate; that is, they do not reduce the amount of data shown in the output in the same way that the Aggregate node does. For example, you could use this sort of aggregation to provide a moving average down through rows of data, such as "average of the current row and all previous rows".
- Built-In Aggregates. Contains a list of the possible modes of aggregation that can be used.
- Operators lists all the operators you can use when building expressions. Operators are also available from the buttons in the center of the dialog box.
- All Functions contains a complete list of available CLEM functions.

After you have selected a group of functions, double-click to insert the functions into the expression field at the point indicated by the position of the cursor.

- [Database functions](#)
-

Database functions

Database functions can be listed in many different locations; the following table shows the locations that SPSS® Modeler searches when looking for function details. This table can be used by database administrators to ensure that users have access privileges to the required areas to be able to use the different functions.

In addition, the table lists the conditions that are used to filter when a function is available for use, based on the database and function type.

Note: If using database functions from Amazon Redshift, your database administrator may need to grant you permissions to the following six database objects. The first four are system catalog tables, and the last two are schemas.

- pg_type
- pg_proc
- pg_namespace
- pg_aggregate
- information_schema
- pg_catalog

Table 1. Database functions in the Expression Builder

Database	Function type	Where to find functions	Conditions used to filter functions

- UDF User Defined Function
- UDA User Defined Aggregate Function
- WUDA User Defined Window Aggregate Function
- ##### the database that you are currently connected to.

Selecting fields, parameters, and global variables

The field list displays all fields available at this point in the data stream. Scroll to select a field from the list. Double-click or click the yellow arrow button to add a field to the expression.

See the topic [Stream, Session, and SuperNode Parameters](#) for more information.

In addition to fields, you can also choose from the following items:

Multiple-response sets. For more information, see the *IBM SPSS Modeler Source, Process, and Output Nodes* guide.

Recently used contains a list of fields, multiple-response sets, parameters, and global values used within the current session.

Parameters. See the topic [Stream, Session, and SuperNode Parameters](#) for more information.

Global values. For more information, see the *IBM SPSS Modeler Source, Process, and Output Nodes* guide.

Viewing or selecting values

Field values can be viewed from a number of places in the system, including the Expression Builder, data audit reports, and when editing future values in a Time Intervals node. Note that data must be fully instantiated in a source or Type node to use this feature, so that storage, types, and values are known.

To view values for a field from the Expression Builder or a Time Intervals node, select the required field and click the value picker button to open a dialog box listing values for the selected field. You can then select a value and click Insert to paste the value into the current expression or list.

Figure 1. Value picker button

To view values for a field from a Data Audit report, click on the Type cell or the Unique cell for the required field.

For flag and nominal fields, all defined values are listed. For continuous (numeric range) fields, the minimum and maximum values are displayed.

Related information

 - [Selecting functions](#)
 - [Selecting fields, parameters, and global variables](#)
-

Checking CLEM expressions

Click Check in the Expression Builder (lower right corner) to validate the expression. Expressions that have not been checked are displayed in red. If errors are found, a message indicating the cause is displayed.

The following items are checked:

- Correct quoting of values and field names
- Correct usage of parameters and global variables
- Valid usage of operators
- Existence of referenced fields
- Existence and definition of referenced globals

If you encounter errors in syntax, try creating the expression using the lists and operator buttons rather than typing the expression manually. This method automatically adds the proper quotes for fields and values.

Note: Field names that contain separators must be surrounded by single quotes. To automatically add quotes, you can create expressions using the lists and operator buttons rather than typing expressions manually. The following characters in field names may cause errors: • ! "# \$% & ' () = ~ | - ^ ¥ @ " + * " <> ? . , / : ; → (arrow mark), □ Δ (graphic mark, etc.)

Find and Replace

The Find/Replace dialog box is available in places where you edit script or expression text, including the script editor, CLEM expression builder, or when defining a template in the Report node. When editing text in any of these areas, press **Ctrl+F** to access the dialog box, making sure cursor has focus in a text area. If working in a Filler node, for example, you can access the dialog box from any of the text areas on the Settings tab, or from the text field in the Expression Builder.

1. With the cursor in a text area, press **Ctrl+F** to access the Find/Replace dialog box.
2. Enter the text you want to search for, or choose from the drop-down list of recently searched items.
3. Enter the replacement text, if any.
4. Click Find Next to start the search.
5. Click Replace to replace the current selection, or Replace All to update all or selected instances.
6. The dialog box closes after each operation. Press **F3** from any text area to repeat the last find operation, or press **Ctrl+F** to access the dialog box again.

Search Options

Match case. Specifies whether the find operation is case-sensitive; for example, whether *myvar* matches *myVar*. Replacement text is always inserted exactly as entered, regardless of this setting.

Whole words only. Specifies whether the find operation matches text embedded within words. If selected, for example, a search on *spider* will not match *spiderman* or *spider-man*.

Regular expressions. Specifies whether regular expression syntax is used (see next section). When selected, the Whole words only option is disabled and its value is ignored.

Selected text only. Controls the scope of the search when using the Replace All option.

Regular Expression Syntax

Regular expressions allow you to search on special characters such as tabs or newline characters, classes or ranges of characters such as *a* through *d*, any digit or non-digit, and boundaries such as the beginning or end of a line. The following types of expressions are supported.

Table 1. Character matches

Characters	Matches
x	The character x
\\	The backslash character
\0n	The character with octal value 0n (0 <= n <= 7)
\0nn	The character with octal value 0nn (0 <= n <= 7)
\0mnn	The character with octal value 0mnn (0 <= m <= 3, 0 <= n <= 7)
\xhh	The character with hexadecimal value 0xhh

Characters	Matches
\uhhhh	The character with hexadecimal value 0xhhhh
\t	The tab character ('\u0009')
\n	The newline (line feed) character ('\u000A')
\r	The carriage-return character ('\u000D')
\f	The form-feed character ('\u000C')
\a	The alert (bell) character ('\u0007')
\e	The escape character ('\u001B')
\cx	The control character corresponding to x

Table 2. Matching character classes

Character classes	Matches
[abc]	a, b, or c (simple class)
[^abc]	Any character except a, b, or c (subtraction)
[a-zA-Z]	a through z or A through Z, inclusive (range)
[a-d[m-p]]	a through d, or m through p (union). Alternatively this could be specified as [a-dm-p]
[a-z&&[def]]	a through z, and d, e, or f (intersection)
[a-z&&[^bc]]	a through z, except for b and c (subtraction). Alternatively this could be specified as [ad-z]
[a-z&&[^m-p]]	a through z, and not m through p (subtraction). Alternatively this could be specified as [a-lq-z]

Table 3. Predefined character classes

Predefined character classes	Matches
.	Any character (may or may not match line terminators)
\d	Any digit: [0-9]
\D	A non-digit: [^0-9]
\s	A white space character: [\t\n\x0B\f\r]
\S	A non-white space character: [^\s]
\w	A word character: [a-zA-Z_0-9]
\W	A non-word character: [^\w]

Table 4. Boundary matches

Boundary matchers	Matches
^	The beginning of a line
\$	The end of a line
\b	A word boundary
\B	A non-word boundary
\A	The beginning of the input
\Z	The end of the input but for the final terminator, if any
\z	The end of the input

CLEM Reference Overview

This section describes the Control Language for Expression Manipulation (CLEM), which is a powerful tool used to analyze and manipulate the data used in IBM® SPSS® Modeler streams. You can use CLEM within nodes to perform tasks ranging from evaluating conditions or deriving values to inserting data into reports.

CLEM expressions consist of values, field names, operators, and functions. Using the correct syntax, you can create a wide variety of powerful data operations.

Related information

- [CLEM Datatypes](#)

- [Strings](#)
 - [Lists](#)
 - [Fields](#)
 - [CLEM Operators](#)
 - [Conventions in Function Descriptions](#)
-

CLEM Datatypes

CLEM datatypes can be made up of any of the following:

- Integers
- Reals
- Characters
- Strings
- Lists
- Fields
- Date/Time

Rules for Quoting

Although IBM® SPSS® Modeler is flexible when you are determining the fields, values, parameters, and strings used in a CLEM expression, the following general rules provide a list of "good practices" to use in creating expressions:

- Strings—Always use double quotes when writing strings, such as "`Type` `2`". Single quotes can be used instead but at the risk of confusion with quoted fields.
- Fields—Use single quotes only where necessary to enclose spaces or other special characters, such as '`Order Number`'. Fields that are quoted but undefined in the data set will be misread as strings.
- Parameters—Always use single quotes when using parameters, such as '`$P-threshold`'.
- Characters—Always use single backquotes (`), such as `stripchar(`d`, "drugA")`.

These rules are covered in more detail in the following topics.

- [Integers](#)
- [Reals](#)
- [Characters](#)
- [Strings](#)
- [Lists](#)
- [Fields](#)
- [Dates](#)
- [Time](#)

Related information

 - [Strings](#)
 - [Lists](#)
 - [Fields](#)
 - [CLEM Reference Overview](#)
 - [Stream, Session, and SuperNode Parameters](#)
 - [CLEM Operators](#)
 - [Conventions in Function Descriptions](#)
-

Integers

Integers are represented as a sequence of decimal digits. Optionally, you can place a minus sign (–) before the integer to denote a negative number—for example, `1234`, `999`, `-77`.

The CLEM language handles integers of arbitrary precision. The maximum integer size depends on your platform. If the values are too large to be displayed in an integer field, changing the field type to `Real` usually restores the value.

Related information

- [CLEM Datatypes](#)
-

Reals

Real refers to a floating-point number. Reals are represented by one or more digits followed by a decimal point followed by one or more digits. CLEM reals are held in double precision.

Optionally, you can place a minus sign (–) before the real to denote a negative number—for example, `1.234`, `0.999`, `-77.001`. Use the form `<number> e <exponent>` to express a real number in exponential notation—for example, `1234.0e5`, `1.7e-2`. When the IBM® SPSS® Modeler application reads number strings from files and converts them automatically to numbers, numbers with no leading digit before the decimal point or with no digit after the point are accepted—for example, `999.` or `.11`. However, these forms are illegal in CLEM expressions.

Note: When referencing real numbers in CLEM expressions, a period must be used as the decimal separator, regardless of any settings for the current stream or locale. For example, specify

`Na > 0.6`

rather than

`Na > 0,6`

This applies even if a comma is selected as the decimal symbol in the stream properties dialog box and is consistent with the general guideline that code syntax should be independent of any specific locale or convention.

Related information

- [CLEM Datatypes](#)
-

Characters

Characters (usually shown as **CHAR**) are typically used within a CLEM expression to perform tests on strings. For example, you can use the function **isuppercode** to determine whether the first character of a string is upper case. The following CLEM expression uses a character to indicate that the test should be performed on the first character of the string:

`isuppercode (subscrs (1, "MyString"))`

To express the code (in contrast to the location) of a particular character in a CLEM expression, use single backquotes of the form ``<character>``—for example, ``A``, ``Z``.

Note: There is no **CHAR** storage type for a field, so if a field is derived or filled with an expression that results in a **CHAR**, then that result will be converted to a string.

Related information

- [CLEM Datatypes](#)
-

Strings

Generally, you should enclose strings in double quotation marks. Examples of strings are `"c35product2"` and `"referrerID"`. To indicate special characters in a string, use a backslash—for example, `"\$65443"`. (To indicate a backslash character, use a double backslash, `\\"`.) You can use single quotes around a string, but the result is indistinguishable from a quoted field (`'referrerID'`). See the topic [String Functions](#) for more information.

Related information

- [CLEM Datatypes](#)
 - [CLEM Reference Overview](#)
 - [Lists](#)
 - [Fields](#)
 - [CLEM Operators](#)
 - [Conventions in Function Descriptions](#)
-

Lists

A list is an ordered sequence of elements, which may be of mixed type. Lists are enclosed in square brackets ([]). Examples of lists are [1 2 4 16] and ["abc" "def"]. Lists are not used as the value of IBM® SPSS® Modeler fields. They are used to provide arguments to functions, such as `member` and `oneof`.

Note: Lists can be composed only of static objects (for example, a string, number, or field name) and not calls to functions.

Related information

- [CLEM Datatypes](#)
- [CLEM Reference Overview](#)
- [Strings](#)
- [Fields](#)
- [CLEM Operators](#)
- [Conventions in Function Descriptions](#)

Fields

Names in CLEM expressions that are not names of functions are assumed to be field names. You can write these simply as `Power`, `val27`, `state_flag`, and so on, but if the name begins with a digit or includes non-alphabetic characters, such as spaces (with the exception of the underscore), place the name within single quotation marks—for example, '`Power Increase`', '`2nd answer`', '`#101`', '`$P-NextField`'.

Note: Fields that are quoted but undefined in the data set will be misread as strings.

Related information

- [CLEM Datatypes](#)
- [CLEM Reference Overview](#)
- [Strings](#)
- [Lists](#)
- [CLEM Operators](#)
- [Conventions in Function Descriptions](#)

Dates

Date calculations are based on a "baseline" date, which is specified in the stream properties dialog box. The default baseline date is 1 January 1900.

The CLEM language supports the following date formats.

Table 1. CLEM language date formats

Format	Examples
DDMMYY	150163
MMDDYY	011563
YYMMDD	630115
YYYYMMDD	19630115
YYYYDDD	Four-digit year followed by a three-digit number representing the day of the year—for example, 2000032 represents the 32nd day of 2000, or 1 February 2000.
DAY	Day of the week in the current locale—for example, <code>Monday</code> , <code>Tuesday</code> , ..., in English.
MONTH	Month in the current locale—for example, <code>January</code> , <code>February</code> ,
DD/MM/YY	15/01/63
DD/MM/YYYY	15/01/1963
MM/DD/YY	01/15/63
MM/DD/YYYY	01/15/1963
DD-MM-YY	15-01-63
DD-MM-YYYY	15-01-1963
MM-DD-YY	01-15-63
MM-DD-YYYY	01-15-1963

Format	Examples
DD.MM.YY	15.01.63
DD.MM.YYYY	15.01.1963
MM.DD.YY	01.15.63
MM.DD.YYYY	01.15.1963
DD-MON-YY	15-JAN-63, 15-jan-63, 15-Jan-63
DD/MON/YY	15/JAN/63, 15/jan/63, 15/Jan/63
DD.MON.YY	15.JAN.63, 15.jan.63, 15.Jan.63
DD-MON-YYYY	15-JAN-1963, 15-jan-1963, 15-Jan-1963
DD/MON/YYYY	15/JAN/1963, 15/jan/1963, 15/Jan/1963
DD.MON.YYYY	15.JAN.1963, 15.jan.1963, 15.Jan.1963
MON YYYY	Jan 2004
q Q YYYY	Date represented as a digit (1–4) representing the quarter followed by the letter Q and a four-digit year—for example, 25 December 2004 would be represented as 4 Q 2004.
ww WK YYYY	Two-digit number representing the week of the year followed by the letters WK and then a four-digit year. The week of the year is calculated assuming that the first day of the week is Monday and there is at least one day in the first week.

Time

The CLEM language supports the following time formats.

Table 1. CLEM language time formats

Format	Examples
HHMMSS	120112, 010101, 221212
HHMM	1223, 0745, 2207
MMSS	5558, 0100
HH:MM:SS	12:01:12, 01:01:01, 22:12:12
HH:MM	12:23, 07:45, 22:07
MM:SS	55:58, 01:00
(H) H: (M) M: (S) S	12:1:12, 1:1:1, 22:12:12
(H) H: (M) M	12:23, 7:45, 22:7
(M) M: (S) S	55:58, 1:0
HH.MM.SS	12.01.12, 01.01.01, 22.12.12
HH.MM	12.23, 07.45, 22.07
MM.SS	55.58, 01.00
(H) H. (M) M. (S) S	12.1.12, 1.1.1, 22.12.12
(H) H. (M) M	12.23, 7.45, 22.7
(M) M. (S) S	55.58, 1.0

CLEM Operators

The following operators are available.

Table 1. CLEM language operators

Operation	Comments	Precedence (see next section)
or	Used between two CLEM expressions. Returns a value of true if either is true or if both are true.	10
and	Used between two CLEM expressions. Returns a value of true if both are true.	9
=	Used between any two comparable items. Returns true if ITEM1 is equal to ITEM2.	7
==	Identical to =.	7

Operation	Comments	Precedence (see next section)
<code>/=</code>	Used between any two comparable items. Returns true if ITEM1 is <i>not</i> equal to ITEM2.	7
<code>/==</code>	Identical to <code>/=</code> .	7
<code>></code>	Used between any two comparable items. Returns true if ITEM1 is strictly greater than ITEM2.	6
<code>>=</code>	Used between any two comparable items. Returns true if ITEM1 is greater than or equal to ITEM2.	6
<code><</code>	Used between any two comparable items. Returns true if ITEM1 is strictly less than ITEM2	6
<code><=</code>	Used between any two comparable items. Returns true if ITEM1 is less than or equal to ITEM2.	6
<code>&&_0</code>	Used between two integers. Equivalent to the Boolean expression INT1 && INT2 = 0.	6
<code>&&/=_0</code>	Used between two integers. Equivalent to the Boolean expression INT1 && INT2 /= 0.	6
<code>+</code>	Adds two numbers: NUM1 + NUM2.	5
<code>>x</code>	Concatenates two strings; for example, <code>STRING1 >x STRING2</code> .	5
<code>-</code>	Subtracts one number from another: NUM1 - NUM2. Can also be used in front of a number: - NUM.	5
<code>*</code>	Used to multiply two numbers: NUM1 * NUM2.	4
<code>&&</code>	Used between two integers. The result is the bitwise 'and' of the integers INT1 and INT2.	4
<code>&&~~</code>	Used between two integers. The result is the bitwise 'and' of INT1 and the bitwise complement of INT2.	4
<code> </code>	Used between two integers. The result is the bitwise 'inclusive or' of INT1 and INT2.	4
<code>~~</code>	Used in front of an integer. Produces the bitwise complement of INT.	4
<code> /&</code>	Used between two integers. The result is the bitwise 'exclusive or' of INT1 and INT2.	4
<code>INT1 << N</code>	Used between two integers. Produces the bit pattern of INT shifted left by N positions.	4
<code>INT1 >> N</code>	Used between two integers. Produces the bit pattern of INT shifted right by N positions.	4
<code>/</code>	Used to divide one number by another: NUM1 / NUM2.	4
<code>**</code>	Used between two numbers: BASE ** POWER. Returns BASE raised to the power POWER.	3
<code>rem</code>	Used between two integers: INT1 rem INT2. Returns the remainder, INT1 - (INT1 div INT2) * INT2.	2
<code>div</code>	Used between two integers: INT1 div INT2. Performs integer division.	2

Operator Precedence

Precedences determine the parsing of complex expressions, especially unbracketed expressions with more than one infix operator. For example,

`3 + 4 * 5`

parses as `3 + (4 * 5)` rather than `(3 + 4) *`

because the relative precedences dictate that `*` is to be parsed before `+`. Every operator in the CLEM language has a precedence value associated with it; the lower this value, the more important it is on the parsing list, meaning that it will be processed sooner than other operators with higher precedence values.

Functions reference

The following CLEM functions are available for working with data in IBM® SPSS® Modeler. You can enter these functions as code in various dialog boxes, such as Derive and Set To Flag nodes, or you can use the Expression Builder to create valid CLEM expressions without memorizing function lists or field names.

Table 1. CLEM functions for use with IBM SPSS Modeler data

Function Type	Description
Information	Used to gain insight into field values. For example, the function <code>is_string</code> returns true for all records whose type is a string.
Conversion	Used to construct new fields or convert storage type. For example, the function <code>to_timestamp</code> converts the selected field to a timestamp.

Function Type	Description
Comparison	Used to compare field values to each other or to a specified string. For example, <code><=</code> is used to compare whether the values of two fields are lesser or equal.
Logical	Used to perform logical operations, such as <code>if, then, else</code> operations.
Numeric	Used to perform numeric calculations, such as the natural log of field values.
Trigonometric	Used to perform trigonometric calculations, such as the arccosine of a specified angle.
Probability	Returns probabilities that are based on various distributions, such as probability that a value from Student's <i>t</i> distribution is less than a specific value.
Spatial	Used to perform spatial calculations on geospatial data.
Bitwise	Used to manipulate integers as bit patterns.
Random	Used to randomly select items or generate numbers.
String	Used to perform various operations on strings, such as <code>stripchar</code> , which allows you to remove a specified character.
SoundEx	Used to find strings when the precise spelling is not known; based on phonetic assumptions about how certain letters are pronounced.
Date and time	Used to perform various operations on date, time, and timestamp fields.
Sequence	Used to gain insight into the record sequence of a data set or perform operations that are based on that sequence.
Global	Used to access global values that are created by a Set Globals node. For example, <code>@MEAN</code> is used to refer to the mean average of all values for a field across the entire data set.
Blanks and null	Used to access, flag, and frequently fill user-specified blanks or system-missing values. For example, <code>@BLANK (FIELD)</code> is used to raise a true flag for records where blanks are present.
Special fields	Used to denote the specific fields under examination. For example, <code>@FIELD</code> is used when deriving multiple fields.

Conventions in Function Descriptions

The following conventions are used throughout this guide when referring to items in a function.

Table 1. Conventions in function descriptions

Convention	Description
<code>BOOL</code>	A Boolean, or flag, such as true or false.
<code>NUM, NUM1, NUM2</code>	Any number.
<code>REAL, REAL1, REAL2</code>	Any real number, such as <code>1.234</code> or <code>-77.01</code> .
<code>INT, INT1, INT2</code>	Any integer, such as <code>1</code> or <code>-77</code> .
<code>CHAR</code>	A character code, such as <code>'A'</code> .
<code>STRING</code>	A string, such as <code>"referrerID"</code> .
<code>LIST</code>	A list of items, such as <code>["abc" "def"]</code> .
<code>ITEM</code>	A field, such as <code>Customer</code> or <code>extract_concept</code> .
<code>DATE</code>	A date field, such as <code>start_date</code> , where values are in a format such as <code>DD-MON-YYYY</code> .
<code>TIME</code>	A time field, such as <code>power_flux</code> , where values are in a format such as <code>HHMMSS</code> .

Functions in this guide are listed with the function in one column, the result type (integer, string, and so on) in another, and a description (where available) in a third column. For example, the following is the description of the `rem` function.

Table 2. rem function description

Function	Result	Description
<code>INT1 rem INT2</code>	Number	Returns the remainder of <code>INT1</code> divided by <code>INT2</code> . For example, <code>INT1 - (INT1 div INT2) * INT2</code> .

Details on usage conventions, such as how to list items or specify characters in a function, are described elsewhere. See the topic [CLEM Datatypes](#) for more information.

Information Functions

Information functions are used to gain insight into the values of a particular field. They are typically used to derive flag fields. For example, you can use the `@BLANK` function to create a flag field indicating records whose values are blank for the selected field. Similarly, you can check the storage type for a field using any of the storage type functions, such as `is_string`.

Table 1. CLEM information functions

Function	Result	Description
<code>@BLANK(FIELD)</code>	Boolean	Returns true for all records whose values are blank according to the blank-handling rules set in an upstream Type node or source node (Types tab).
<code>@NULL(ITEM)</code>	Boolean	Returns true for all records whose values are undefined. Undefined values are system null values, displayed in IBM® SPSS® Modeler as <code>\$null\$</code> .
<code>is_date(ITEM)</code>	Boolean	Returns true for all records whose type is a date.
<code>is_datetime(ITEM)</code>	Boolean	Returns true for all records whose type is a date, time, or timestamp.
<code>is_integer(ITEM)</code>	Boolean	Returns true for all records whose type is an integer.
<code>is_number(ITEM)</code>	Boolean	Returns true for all records whose type is a number.
<code>is_real(ITEM)</code>	Boolean	Returns true for all records whose type is a real.
<code>is_string(ITEM)</code>	Boolean	Returns true for all records whose type is a string.
<code>is_time(ITEM)</code>	Boolean	Returns true for all records whose type is a time.
<code>is_timestamp(ITEM)</code>	Boolean	Returns true for all records whose type is a timestamp.

-

Conversion Functions

Conversion functions allow you to construct new fields and convert the storage type of existing files. For example, you can form new strings by joining strings together or by taking strings apart. To join two strings, use the operator `><`. For example, if the field `site` has the value `"BRAMLEY"`, then `"xx"` `>< site` returns `"xxBRAMLEY"`. The result of `><` is always a string, even if the arguments are not strings. Thus, if field `v1` is 3 and field `v2` is 5, then `v1 >< v2` returns `"35"` (a string, not a number).

Conversion functions (and any other functions that require a specific type of input, such as a date or time value) depend on the current formats specified in the Stream Options dialog box. For example, if you want to convert a string field with values `Jan 2003`, `Feb 2003`, and so on, select the matching date format `MON YYYY` as the default date format for the stream.

Table 1. CLEM conversion functions

Function	Result	Description
----------	--------	-------------

Function	Result	Description
<code>ITEM1 <> ITEM2</code>	<code>String</code>	Concatenates values for two fields and returns the resulting string as <code>ITEM1ITEM2</code> .
<code>to_integer(ITEM)</code>	<code>Integer</code>	Converts the storage of the specified field to an integer.
<code>to_real(ITEM)</code>	<code>Real</code>	Converts the storage of the specified field to a real.
<code>to_number(ITEM)</code>	<code>Number</code>	Converts the storage of the specified field to a number.
<code>to_string(ITEM)</code>	<code>String</code>	Converts the storage of the specified field to a string. When a real is converted to string using this function, it returns a value with 6 digits after the radix point.
<code>to_time(ITEM)</code>	<code>Time</code>	Converts the storage of the specified field to a time.
<code>to_date(ITEM)</code>	<code>Date</code>	Converts the storage of the specified field to a date.
<code>to_timestamp(ITEM)</code>	<code>Timestamp</code>	Converts the storage of the specified field to a timestamp.
<code>to_datetime(ITEM)</code>	<code>Datetime</code>	Converts the storage of the specified field to a date, time, or timestamp value.
<code>datetime_date(ITEM)</code>	<code>Date</code>	Returns the date value for a <i>number</i> , <i>string</i> , or <i>timestamp</i> . Note this is the only function that allows you to convert a number (in seconds) back to a date. If <code>ITEM</code> is a string, creates a date by parsing a string in the current date format. The date format specified in the stream properties dialog box must be correct for this function to be successful. If <code>ITEM</code> is a number, it is interpreted as a number of seconds since the base date (or epoch). Fractions of a day are truncated. If <code>ITEM</code> is a timestamp, the date part of the timestamp is returned. If <code>ITEM</code> is a date, it is returned unchanged.
<code>stb_centroid_latitude(ITEM)</code>	<code>Integer</code>	Returns an integer value for latitude corresponding to centroid of the geohash argument.
<code>stb_centroid_longitude(ITEM)</code>	<code>Integer</code>	Returns an integer value for longitude corresponding to centroid of the geohash argument.
<code>to_geohash(ITEM)</code>	<code>String</code>	Returns the geohashed string corresponding to the latitude and longitude using the specified number of bits for the density. A geohash is a code used to identify a set of geographic coordinates based on the latitude and longitude details. The three parameters for <code>to_geohash</code> are: <ul style="list-style-type: none"> • <i>latitude</i>: Range (-180, 180), and units are degrees in the WGS84 coordinate system • <i>longitude</i>: Range (-90, 90), and units are degrees in the WGS84 coordinate system • <i>bits</i>: The number of bits to use to store the hash. Range [1,75]. This affects both the length of the returned string (1 character is used for every 5 bits), and the accuracy of the hash. For example, 5 bits (1 character) represents approximately 2500 kilometers, or 45 bits (9 characters), represents approximately 2.3 meters.

Comparison Functions

Comparison functions are used to compare field values to each other or to a specified string. For example, you can check strings for equality using `=`. An example of string equality verification is: `Class = "class 1"`.

For purposes of numeric comparison, *greater* means closer to positive infinity, and *lesser* means closer to negative infinity. That is, all negative numbers are less than any positive number.

Table 1. CLEM comparison functions

Function	Result	Description
<code>count_equal(ITEM1, LIST)</code>	<code>Integer</code>	Returns the number of values from a list of fields that are equal to <code>ITEM1</code> or null if <code>ITEM1</code> is null.
<code>count_greater_than(ITEM1, LIST)</code>	<code>Integer</code>	Returns the number of values from a list of fields that are greater than <code>ITEM1</code> or null if <code>ITEM1</code> is null.
<code>count_less_than(ITEM1, LIST)</code>	<code>Integer</code>	Returns the number of values from a list of fields that are less than <code>ITEM1</code> or null if <code>ITEM1</code> is null.

Function	Result	Description
<code>count_not_equal(ITEM1, LIST)</code>	<code>Integer</code>	Returns the number of values from a list of fields that are not equal to <i>ITEM1</i> or null if <i>ITEM1</i> is null.
<code>count_nulls(LIST)</code>	<code>Integer</code>	Returns the number of null values from a list of fields.
<code>count_non_nulls(LIST)</code>	<code>Integer</code>	Returns the number of non-null values from a list of fields.
<code>date_before(DATE1, DATE2)</code>	<code>Boolean</code>	Used to check the ordering of date values. Returns a true value if <i>DATE1</i> is before <i>DATE2</i> .
<code>first_index(ITEM, LIST)</code>	<code>Integer</code>	Returns the index of the first field containing <i>ITEM</i> from a <i>LIST</i> of fields or 0 if the value is not found. Supported for string, integer, and real types only.
<code>first_non_null(LIST)</code>	<code>Any</code>	Returns the first non-null value in the supplied list of fields. All storage types supported.
<code>first_non_null_index(LIST)</code>	<code>Integer</code>	Returns the index of the first field in the specified <i>LIST</i> containing a non-null value or 0 if all values are null. All storage types are supported.
<code>ITEM1 = ITEM2</code>	<code>Boolean</code>	Returns true for records where <i>ITEM1</i> is equal to <i>ITEM2</i> .
<code>ITEM1 /= ITEM2</code>	<code>Boolean</code>	Returns true if the two strings are not identical or 0 if they are identical.
<code>ITEM1 < ITEM2</code>	<code>Boolean</code>	Returns true for records where <i>ITEM1</i> is less than <i>ITEM2</i> .
<code>ITEM1 <= ITEM2</code>	<code>Boolean</code>	Returns true for records where <i>ITEM1</i> is less than or equal to <i>ITEM2</i> .
<code>ITEM1 > ITEM2</code>	<code>Boolean</code>	Returns true for records where <i>ITEM1</i> is greater than <i>ITEM2</i> .
<code>ITEM1 >= ITEM2</code>	<code>Boolean</code>	Returns true for records where <i>ITEM1</i> is greater than or equal to <i>ITEM2</i> .
<code>last_index(ITEM, LIST)</code>	<code>Integer</code>	Returns the index of the last field containing <i>ITEM</i> from a <i>LIST</i> of fields or 0 if the value is not found. Supported for string, integer, and real types only.
<code>last_non_null(LIST)</code>	<code>Any</code>	Returns the last non-null value in the supplied list of fields. All storage types supported.
<code>last_non_null_index(LIST)</code>	<code>Integer</code>	Returns the index of the last field in the specified <i>LIST</i> containing a non-null value or 0 if all values are null. All storage types are supported.
<code>max(ITEM1, ITEM2)</code>	<code>Any</code>	Returns the greater of the two items-- <i>ITEM1</i> or <i>ITEM2</i> .
<code>max_index(LIST)</code>	<code>Integer</code>	Returns the index of the field containing the maximum value from a list of numeric fields or 0 if all values are null. For example, if the third field listed contains the maximum, the index value 3 is returned. If multiple fields contain the maximum value, the one listed first (leftmost) is returned.
<code>max_n(LIST)</code>	<code>Number</code>	Returns the maximum value from a list of numeric fields or null if all of the field values are null.
<code>member(ITEM, LIST)</code>	<code>Boolean</code>	Returns true if <i>ITEM</i> is a member of the specified <i>LIST</i> . Otherwise, a false value is returned. A list of field names can also be specified.
<code>min(ITEM1, ITEM2)</code>	<code>Any</code>	Returns the lesser of the two items-- <i>ITEM1</i> or <i>ITEM2</i> .
<code>min_index(LIST)</code>	<code>Integer</code>	Returns the index of the field containing the minimum value from a list of numeric fields or 0 if all values are null. For example, if the third field listed contains the minimum, the index value 3 is returned. If multiple fields contain the minimum value, the one listed first (leftmost) is returned.
<code>min_n(LIST)</code>	<code>Number</code>	Returns the minimum value from a list of numeric fields or null if all of the field values are null.
<code>time_before(TIME1, TIME2)</code>	<code>Boolean</code>	Used to check the ordering of time values. Returns a true value if <i>TIME1</i> is before <i>TIME2</i> .
<code>value_at(INT, LIST)</code>		Returns the value of each listed field at offset <i>INT</i> or NULL if the offset is outside the range of valid values (that is, less than 1 or greater than the number of listed fields). All storage types supported.

Logical Functions

CLEM expressions can be used to perform logical operations.

Table 1. CLEM logical functions

Function	Result	Description
----------	--------	-------------

Function	Result	Description
<code>COND1 and COND2</code>	<code>Boolean</code>	This operation is a logical conjunction and returns a true value if both <code>COND1</code> and <code>COND2</code> are true. If <code>COND1</code> is false, then <code>COND2</code> is not evaluated; this makes it possible to have conjunctions where <code>COND1</code> first tests that an operation in <code>COND2</code> is legal. For example, <code>length(Label) >=6 and Label(6) = 'x'</code> .
<code>COND1 or COND2</code>	<code>Boolean</code>	This operation is a logical (inclusive) disjunction and returns a true value if either <code>COND1</code> or <code>COND2</code> is true or if both are true. If <code>COND1</code> is true, <code>COND2</code> is not evaluated.
<code>not(COND)</code>	<code>Boolean</code>	This operation is a logical negation and returns a true value if <code>COND</code> is false. Otherwise, this operation returns a value of 0.
<code>if COND then EXPR1 else EXPR2 endif</code>	<code>Any</code>	This operation is a conditional evaluation. If <code>COND</code> is true, this operation returns the result of <code>EXPR1</code> . Otherwise, the result of evaluating <code>EXPR2</code> is returned.
<code>if COND1 then EXPR1 elseif COND2 then EXPR2 else EXPR_N endif</code>	<code>Any</code>	This operation is a multibranch conditional evaluation. If <code>COND1</code> is true, this operation returns the result of <code>EXPR1</code> . Otherwise, if <code>COND2</code> is true, this operation returns the result of evaluating <code>EXPR2</code> . Otherwise, the result of evaluating <code>EXPR_N</code> is returned.

Related information

- [Functions reference](#)

Numeric Functions

CLEM contains a number of commonly used numeric functions.

Table 1. CLEM numeric functions

Function	Result	Description
<code>-NUM</code>	<code>Number</code>	Used to negate <code>NUM</code> . Returns the corresponding number with the opposite sign.
<code>NUM1 + NUM2</code>	<code>Number</code>	Returns the sum of <code>NUM1</code> and <code>NUM2</code> .
<code>NUM1 - NUM2</code>	<code>Number</code>	Returns the value of <code>NUM2</code> subtracted from <code>NUM1</code> .
<code>NUM1 * NUM2</code>	<code>Number</code>	Returns the value of <code>NUM1</code> multiplied by <code>NUM2</code> .
<code>NUM1 / NUM2</code>	<code>Number</code>	Returns the value of <code>NUM1</code> divided by <code>NUM2</code> .
<code>INT1 div INT2</code>	<code>Number</code>	Used to perform integer division. Returns the value of <code>INT1</code> divided by <code>INT2</code> .
<code>INT1 rem INT2</code>	<code>Number</code>	Returns the remainder of <code>INT1</code> divided by <code>INT2</code> . For example, <code>INT1 - (INT1 div INT2) * INT2</code> .
<code>INT1 mod INT2</code>	<code>Number</code>	This function has been deprecated. Use the <code>rem</code> function instead.
<code>BASE ** POWER</code>	<code>Number</code>	Returns <code>BASE</code> raised to the power <code>POWER</code> , where either may be any number (except that <code>BASE</code> must not be zero if <code>POWER</code> is zero of any type other than integer 0). If <code>POWER</code> is an integer, the computation is performed by successively multiplying powers of <code>BASE</code> . Thus, if <code>BASE</code> is an integer, the result will be an integer. If <code>POWER</code> is integer 0, the result is always a 1 of the same type as <code>BASE</code> . Otherwise, if <code>POWER</code> is not an integer, the result is computed as <code>exp(POWER * log(BASE))</code> .
<code>abs(NUM)</code>	<code>Number</code>	Returns the absolute value of <code>NUM</code> , which is always a number of the same type.
<code>exp(NUM)</code>	<code>Real</code>	Returns e raised to the power <code>NUM</code> , where e is the base of natural logarithms.
<code>fracof(NUM)</code>	<code>Real</code>	Returns the fractional part of <code>NUM</code> , defined as <code>NUM - intof(NUM)</code> .
<code>intof(NUM)</code>	<code>Integer</code>	Truncates its argument to an integer. It returns the integer of the same sign as <code>NUM</code> and with the largest magnitude such that <code>abs(INT) <= abs(NUM)</code> .
<code>log(NUM)</code>	<code>Real</code>	Returns the natural (base e) logarithm of <code>NUM</code> , which must not be a zero of any kind.
<code>log10(NUM)</code>	<code>Real</code>	Returns the base 10 logarithm of <code>NUM</code> , which must not be a zero of any kind. This function is defined as <code>log(NUM) / log(10)</code> .
<code>negate(NUM)</code>	<code>Number</code>	Used to negate <code>NUM</code> . Returns the corresponding number with the opposite sign.
<code>round(NUM)</code>	<code>Integer</code>	Used to round <code>NUM</code> to an integer by taking <code>intof(NUM+0.5)</code> if <code>NUM</code> is positive or <code>intof(NUM-0.5)</code> if <code>NUM</code> is negative.
<code>sign(NUM)</code>	<code>Number</code>	Used to determine the sign of <code>NUM</code> . This operation returns -1, 0, or 1 if <code>NUM</code> is an integer. If <code>NUM</code> is a real, it returns -1.0, 0.0, or 1.0, depending on whether <code>NUM</code> is negative, zero, or positive.
<code>sqrt(NUM)</code>	<code>Real</code>	Returns the square root of <code>NUM</code> . <code>NUM</code> must be positive.
<code>sum_n(LIST)</code>	<code>Number</code>	Returns the sum of values from a list of numeric fields or null if all of the field values are null.
<code>mean_n(LIST)</code>	<code>Number</code>	Returns the mean value from a list of numeric fields or null if all of the field values are null.
<code>sdev_n(LIST)</code>	<code>Number</code>	Returns the standard deviation from a list of numeric fields or null if all of the field values are null.

Trigonometric Functions

All of the functions in this section either take an angle as an argument or return one as a result. In both cases, the units of the angle (radians or degrees) are controlled by the setting of the relevant stream option.

Table 1. CLEM trigonometric functions

Function	Result	Description
<code>arccos (NUM)</code>	<i>Real</i>	Computes the arccosine of the specified angle.
<code>arccosh (NUM)</code>	<i>Real</i>	Computes the hyperbolic arccosine of the specified angle.
<code>arcsin (NUM)</code>	<i>Real</i>	Computes the arcsine of the specified angle.
<code>arcsinh (NUM)</code>	<i>Real</i>	Computes the hyperbolic arcsine of the specified angle.
<code>arctan (NUM)</code>	<i>Real</i>	Computes the arctangent of the specified angle.
<code>arctan2 (NUM_Y, NUM_X)</code>	<i>Real</i>	Computes the arctangent of <code>NUM_Y / NUM_X</code> and uses the signs of the two numbers to derive quadrant information. The result is a real in the range <code>- pi < ANGLE <= pi (radians) - 180 < ANGLE <= 180 (degrees)</code>
<code>arctanh (NUM)</code>	<i>Real</i>	Computes the hyperbolic arctangent of the specified angle.
<code>cos (NUM)</code>	<i>Real</i>	Computes the cosine of the specified angle.
<code>cosh (NUM)</code>	<i>Real</i>	Computes the hyperbolic cosine of the specified angle.
<code>pi</code>	<i>Real</i>	This constant is the best real approximation to pi.
<code>sin (NUM)</code>	<i>Real</i>	Computes the sine of the specified angle.
<code>sinh (NUM)</code>	<i>Real</i>	Computes the hyperbolic sine of the specified angle.
<code>tan (NUM)</code>	<i>Real</i>	Computes the tangent of the specified angle.
<code>tanh (NUM)</code>	<i>Real</i>	Computes the hyperbolic tangent of the specified angle.

Probability Functions

Probability functions return probabilities based on various distributions, such as the probability that a value from Student's *t* distribution will be less than a specific value.

Table 1. CLEM probability functions

Function	Result	Description
<code>cdf_chisq (NUM, DF)</code>	<i>Real</i>	Returns the probability that a value from the chi-square distribution with the specified degrees of freedom will be less than the specified number.
<code>cdf_f (NUM, DF1, DF2)</code>	<i>Real</i>	Returns the probability that a value from the <i>F</i> distribution, with degrees of freedom <i>DF1</i> and <i>DF2</i> , will be less than the specified number.
<code>cdf_normal (NUM, MEAN, STDDEV)</code>	<i>Real</i>	Returns the probability that a value from the normal distribution with the specified mean and standard deviation will be less than the specified number.
<code>cdf_t (NUM, DF)</code>	<i>Real</i>	Returns the probability that a value from Student's <i>t</i> distribution with the specified degrees of freedom will be less than the specified number.

Spatial functions

Spatial functions can be used with geospatial data. For example, they allow you to calculate the distances between two points, the area of a polygon, and so on. There can also be situations that require a merge of multiple geospatial data sets that are based on a spatial predicate (within, close to, and so on), which can be done through a merge condition.

These spatial functions work in conjunction with the coordinate system specified in Tools > Stream Properties > Options > Geospatial.

Note: These spatial functions do not apply to three-dimensional data. If three-dimensional data is imported into the stream, only the first two dimensions are used by these functions. The z-axis values are ignored.

Table 1. CLEM spatial functions

Function	Result	Description
<code>close_to(SHAPE, SHAPE, NUM)</code>	Boolean	Tests whether 2 shapes are within a certain DISTANCE of each other. If a projected coordinate system is used, DISTANCE is in meters. If no coordinate system is used, it is an arbitrary unit.
<code>crosses(SHAPE, SHAPE)</code>	Boolean	Tests whether 2 shapes cross each other. This function is suitable for 2 linestring shapes, or 1 linestring and 1 polygon.
<code>overlap(SHAPE, SHAPE)</code>	Boolean	Tests whether there is an intersection between 2 polygons and that the intersection is interior to both shapes.
<code>within(SHAPE, SHAPE)</code>	Boolean	Tests whether the entirety of SHAPE1 is contained within a POLYGON.
<code>area(SHAPE)</code>	Real	Returns the area of the specified POLYGON. If a projected system is used, the function returns meters squared. If no coordinate system is used, it is an arbitrary unit. The shape must be a POLYGON or a MULTIPOLYGON.
<code>num_points(SHAPE, LIST)</code>	Integer	Returns the number of points from a point field (MULTIPOINT) which are contained within the bounds of a POLYGON. SHAPE1 must be a POLYGON or a MULTIPOLYGON.
<code>distance(SHAPE, SHAPE)</code>	Real	Returns the distance between SHAPE1 and SHAPE2. If a projected coordinate system is used, the function returns meters. If no coordinate system is used, it is an arbitrary unit. SHAPE1 and SHAPE2 can be any geo measurement type.

Bitwise Integer Operations

These functions enable integers to be manipulated as bit patterns representing two's-complement values, where bit position **N** has weight 2^{**N} . Bits are numbered from 0 upward. These operations act as though the sign bit of an integer is extended indefinitely to the left. Thus, everywhere above its most significant bit, a positive integer has 0 bits and a negative integer has 1 bit.

Table 1. CLEM bitwise integer operations

Function	Result	Description
<code>~~ INT1</code>	Integer	Produces the bitwise complement of the integer INT1. That is, there is a 1 in the result for each bit position for which INT1 has 0. It is always true that <code>~~ INT = -(INT + 1)</code> .
<code>INT1 INT2</code>	Integer	The result of this operation is the bitwise "inclusive or" of INT1 and INT2. That is, there is a 1 in the result for each bit position for which there is a 1 in either INT1 or INT2 or both.
<code>INT1 /& INT2</code>	Integer	The result of this operation is the bitwise "exclusive or" of INT1 and INT2. That is, there is a 1 in the result for each bit position for which there is a 1 in either INT1 or INT2 but not in both.
<code>INT1 && INT2</code>	Integer	Produces the bitwise "and" of the integers INT1 and INT2. That is, there is a 1 in the result for each bit position for which there is a 1 in both INT1 and INT2.
<code>INT1 && ~~ INT2</code>	Integer	Produces the bitwise "and" of INT1 and the bitwise complement of INT2. That is, there is a 1 in the result for each bit position for which there is a 1 in INT1 and a 0 in INT2. This is the same as <code>INT1 && (~~INT2)</code> and is useful for clearing bits of INT1 set in INT2.
<code>INT << N</code>	Integer	Produces the bit pattern of INT1 shifted left by N positions. A negative value for N produces a right shift.
<code>INT >> N</code>	Integer	Produces the bit pattern of INT1 shifted right by N positions. A negative value for N produces a left shift.
<code>INT1 &&= _0 INT2</code>	Boolean	Equivalent to the Boolean expression <code>INT1 && INT2 /== 0</code> but is more efficient.
<code>INT1 &&/_= _0 INT2</code>	Boolean	Equivalent to the Boolean expression <code>INT1 && INT2 == 0</code> but is more efficient.
<code>integer_bitcount(INT)</code>	Integer	Counts the number of 1 or 0 bits in the two's-complement representation of INT. If INT is non-negative, N is the number of 1 bits. If INT is negative, it is the number of 0 bits. Owing to the sign extension, there are an infinite number of 0 bits in a non-negative integer or 1 bits in a negative integer. It is always the case that <code>integer_bitcount(INT) = integer_bitcount(- (INT+1))</code> .

Function	Result	Description
<code>integer_leastbit(INT)</code>	<code>Integer</code>	Returns the bit position N of the least-significant bit set in the integer INT . N is the highest power of 2 by which INT divides exactly.
<code>integer_length(INT)</code>	<code>Integer</code>	Returns the length in bits of INT as a two's-complement integer. That is, N is the smallest integer such that $INT < (1 \ll N) \text{ if } INT \geq 0 \text{ INT } \geq (-1 \ll N) \text{ if } INT < 0$. If INT is non-negative, then the representation of INT as an unsigned integer requires a field of at least N bits. Alternatively, a minimum of $N+1$ bits is required to represent INT as a signed integer, regardless of its sign.
<code>testbit(INT, N)</code>	<code>Boolean</code>	Tests the bit at position N in the integer INT and returns the state of bit N as a Boolean value, which is true for 1 and false for 0.

Random Functions

The following functions are used to randomly select items or randomly generate numbers.

Table 1. CLEM random functions

Function	Result	Description
<code>oneof(LIST)</code>	<code>Any</code>	Returns a randomly chosen element of $LIST$. List items should be entered as <code>[ITEM1, ITEM2, ..., ITEM_N]</code> . Note that a list of field names can also be specified.
<code>random(NUM)</code>	<code>Number</code>	Returns a uniformly distributed random number of the same type (INT or $REAL$), starting from 1 to NUM . If you use an integer, then only integers are returned. If you use a real (decimal) number, then real numbers are returned (decimal precision determined by the stream options). The largest random number returned by the function could equal NUM .
<code>random0(NUM)</code>	<code>Number</code>	This has the same properties as <code>random(NUM)</code> , but starting from 0. The largest random number returned by the function will never equal NUM .

String Functions

In CLEM, you can perform the following operations with strings:

- Compare strings
- Create strings
- Access characters

In CLEM, a string is any sequence of characters between matching double quotation marks ("string quotes"). Characters (**CHAR**) can be any single alphanumeric character. They are declared in CLEM expressions using single backquotes in the form of `<character>`, such as `z`, `A`, or `2`. Characters that are out-of-bounds or negative indices to a string will result in undefined behavior.

Note: Comparisons between strings that do and do not use SQL pushback may generate different results where trailing spaces exist.

Table 1. CLEM string functions

Function	Result	Description
<code>allbutfirst(N, STRING)</code>	<code>String</code>	Returns a string, which is $STRING$ with the first N characters removed.
<code>allbutlast(N, STRING)</code>	<code>String</code>	Returns a string, which is $STRING$ with the last characters removed.
<code>alphabefore(STRING1, STRING2)</code>	<code>Boolean</code>	Used to check the alphabetical ordering of strings. Returns true if $STRING1$ precedes $STRING2$.
<code>endstring(LENGTH, STRING)</code>	<code>String</code>	Extracts the last N characters from the specified string. If the string length is less than or equal to the specified length, then it is unchanged.

Function	Result	Description
<code>hasendstring(STRING, SUBSTRING)</code>	<code>Integer</code>	This function is the same as <code>isendstring(SUBSTRING, STRING)</code> .
<code>hasmidstring(STRING, SUBSTRING)</code>	<code>Integer</code>	This function is the same as <code>ismidstring(SUBSTRING, STRING)</code> (embedded substring).
<code>hasstartswith(STRING, SUBSTRING)</code>	<code>Integer</code>	This function is the same as <code>isstartswith(SUBSTRING, STRING)</code> .
<code>hassubstring(STRING, N, SUBSTRING)</code>	<code>Integer</code>	This function is the same as <code>issubstring(SUBSTRING, N, STRING)</code> , where <code>N</code> defaults to 1.
<code>count_substring(STRING, SUBSTRING)</code>	<code>Integer</code>	Returns the number of times the specified substring occurs within the string. For example, <code>count_substring("foooo.txt", "oo")</code> returns 3.
<code>hassubstring(STRING, SUBSTRING)</code>	<code>Integer</code>	This function is the same as <code>issubstring(SUBSTRING, 1, STRING)</code> , where <code>N</code> defaults to 1.
<code>isalphacode(CHAR)</code>	<code>Boolean</code>	Returns a value of true if <code>CHAR</code> is a character in the specified string (often a field name) whose character code is a letter. Otherwise, this function returns a value of 0. For example, <code>isalphacode(produce_num(1))</code> .
<code>isendstring(SUBSTRING, STRING)</code>	<code>Integer</code>	If the string <code>STRING</code> ends with the substring <code>SUBSTRING</code> , then this function returns the integer subscript of <code>SUBSTRING</code> in <code>STRING</code> . Otherwise, this function returns a value of 0.
<code>islowercode(CHAR)</code>	<code>Boolean</code>	Returns a value of true if <code>CHAR</code> is a lowercase letter character for the specified string (often a field name). Otherwise, this function returns a value of 0. For example, both <code>islowercode(``)</code> and <code>islowercode(country_name(2))</code> are valid expressions.
<code>ismidstring(SUBSTRING, STRING)</code>	<code>Integer</code>	If <code>SUBSTRING</code> is a substring of <code>STRING</code> but does not start on the first character of <code>STRING</code> or end on the last, then this function returns the subscript at which the substring starts. Otherwise, this function returns a value of 0.
<code>isnumbercode(CHAR)</code>	<code>Boolean</code>	Returns a value of true if <code>CHAR</code> for the specified string (often a field name) is a character whose character code is a digit. Otherwise, this function returns a value of 0. For example, <code>isnumbercode(product_id(2))</code> .
<code>isstartswith(SUBSTRING, STRING)</code>	<code>Integer</code>	If the string <code>STRING</code> starts with the substring <code>SUBSTRING</code> , then this function returns the subscript 1. Otherwise, this function returns a value of 0.
<code>issubstring(SUBSTRING, N, STRING)</code>	<code>Integer</code>	Searches the string <code>STRING</code> , starting from its <code>N</code> th character, for a substring equal to the string <code>SUBSTRING</code> . If found, this function returns the integer subscript at which the matching substring begins. Otherwise, this function returns a value of 0. If <code>N</code> is not given, this function defaults to 1.
<code>issubstring(SUBSTRING, STRING)</code>	<code>Integer</code>	Searches the string <code>STRING</code> , starting from its <code>N</code> th character, for a substring equal to the string <code>SUBSTRING</code> . If found, this function returns the integer subscript at which the matching substring begins. Otherwise, this function returns a value of 0. If <code>N</code> is not given, this function defaults to 1.
<code>issubstring_count(SUBSTRING, N, STRING) :</code>	<code>Integer</code>	Returns the index of the <code>N</code> th occurrence of <code>SUBSTRING</code> within the specified <code>STRING</code> . If there are fewer than <code>N</code> occurrences of <code>SUBSTRING</code> , 0 is returned.
<code>issubstring_lim(SUBSTRING, N, STARTLIM, ENDLIM, STRING)</code>	<code>Integer</code>	This function is the same as <code>issubstring</code> , but the match is constrained to start on or before the subscript <code>STARTLIM</code> and to end on or before the subscript <code>ENDLIM</code> . The <code>STARTLIM</code> or <code>ENDLIM</code> constraints may be disabled by supplying a value of false for either argument—for example, <code>issubstring_lim(SUBSTRING, N, false, false, STRING)</code> is the same as <code>issubstring</code> .
<code>isuppercode(CHAR)</code>	<code>Boolean</code>	Returns a value of true if <code>CHAR</code> is an uppercase letter character. Otherwise, this function returns a value of 0. For example, both <code>isuppercode(``)</code> and <code>isuppercode(country_name(2))</code> are valid expressions.
<code>last(CHAR)</code>	<code>String</code>	Returns the last character <code>CHAR</code> of <code>STRING</code> (which must be at least one character long).
<code>length(STRING)</code>	<code>Integer</code>	Returns the length of the string <code>STRING</code> —that is, the number of characters in it.
<code>locchar(CHAR, N, STRING)</code>	<code>Integer</code>	Used to identify the location of characters in symbolic fields. The function searches the string <code>STRING</code> for the character <code>CHAR</code> , starting the search at the <code>N</code> th character of <code>STRING</code> . This function returns a value indicating the location (starting at <code>N</code>) where the character is found. If the character is not found, this function returns a value of 0. If the function has an invalid offset (<code>N</code>) (for example, an offset that is beyond the length of the string), this function returns <code>\$null\$</code> . For example, <code>locchar(`n`, 2, web_page)</code> searches the field called <code>web_page</code> for the <code>`n`</code> character beginning at the second character in the field value. Note: Be sure to use single backquotes to encapsulate the specified character.

Function	Result	Description
<code>locchar_back(CHAR, N, STRING)</code>	<code>Integer</code>	Similar to <code>locchar</code> , except that the search is performed backward starting from the <i>N</i> th character. For example, <code>locchar_back(`n`, 9, web_page)</code> searches the field <code>web_page</code> starting from the ninth character and moving backward toward the start of the string. If the function has an invalid offset (for example, an offset that is beyond the length of the string), this function returns <code>\$null\$</code> . Ideally, you should use <code>locchar_back</code> in conjunction with the function <code>length(<field>)</code> to dynamically use the length of the current value of the field. For example, <code>locchar_back(`n`, (length(web_page)), web_page)</code> .
<code>lowertoupper(CHAR)</code> <code>lowertoupper(STRING)</code>	<code>CHAR or String</code>	Input can be either a string or character, which is used in this function to return a new item of the same type, with any lowercase characters converted to their uppercase equivalents. For example, <code>lowertoupper(`a`)</code> , <code>lowertoupper("My string")</code> , and <code>lowertoupper(field_name(2))</code> are all valid expressions.
<code>matches</code>	<code>Boolean</code>	Returns true if a string matches a specified pattern. The pattern must be a string literal; it cannot be a field name containing a pattern. A question mark (?) can be included in the pattern to match exactly one character; an asterisk (*) matches zero or more characters. To match a literal question mark or asterisk (rather than using these as wildcards), a backslash (\) can be used as an escape character.
<code>replace(SUBSTRING, NEWSUBSTRING, STRING)</code>	<code>String</code>	Within the specified <code>STRING</code> , replace all instances of <code>SUBSTRING</code> with <code>NEWSUBSTRING</code> .
<code>replicate(COUNT, STRING)</code>	<code>String</code>	Returns a string that consists of the original string copied the specified number of times.
<code>stripchar(CHAR, STRING)</code>	<code>String</code>	Enables you to remove specified characters from a string or field. You can use this function, for example, to remove extra symbols, such as currency notations, from data to achieve a simple number or name. For example, using the syntax <code>stripchar(`\$`, 'Cost')</code> returns a new field with the dollar sign removed from all values. Note: Be sure to use single backquotes to encapsulate the specified character.
<code>skipchar(CHAR, N, STRING)</code>	<code>Integer</code>	Searches the string <code>STRING</code> for any character other than <code>CHAR</code> , starting at the <i>N</i> th character. This function returns an integer substring indicating the point at which one is found or 0 if every character from the <i>N</i> th onward is a <code>CHAR</code> . If the function has an invalid offset (for example, an offset that is beyond the length of the string), this function returns <code>\$null\$</code> . <code>locchar</code> is often used in conjunction with the <code>skipchar</code> functions to determine the value of <i>N</i> (the point at which to start searching the string). For example, <code>skipchar(`s`, (locchar(`s`, 1, "MyString")), "MyString")</code> .
<code>skipchar_back(CHAR, N, STRING)</code>	<code>Integer</code>	Similar to <code>skipchar</code> , except that the search is performed backward , starting from the <i>N</i> th character.
<code>startstring(LENGTH, STRING)</code>	<code>String</code>	Extracts the first <i>N</i> characters from the specified string. If the string length is less than or equal to the specified length, then it is unchanged.
<code>strmember(CHAR, STRING)</code>	<code>Integer</code>	Equivalent to <code>locchar(CHAR, 1, STRING)</code> . It returns an integer substring indicating the point at which <code>CHAR</code> first occurs, or 0. If the function has an invalid offset (for example, an offset that is beyond the length of the string), this function returns <code>\$null\$</code> .
<code>subscr(N, STRING)</code>	<code>CHAR</code>	Returns the <i>N</i> th character <code>CHAR</code> of the input string <code>STRING</code> . This function can also be written in a shorthand form as <code>STRING(N)</code> . For example, <code>lowertoupper("name"(1))</code> is a valid expression.
<code>substring(N, LEN, STRING)</code>	<code>String</code>	Returns a string <code>SUBSTRING</code> , which consists of the <i>LEN</i> characters of the string <code>STRING</code> , starting from the character at subscript <i>N</i> .
<code>substring_between(N1, N2, STRING)</code>	<code>String</code>	Returns the substring of <code>STRING</code> , which begins at subscript <i>N1</i> and ends at subscript <i>N2</i> .
<code>trim(STRING)</code>	<code>String</code>	Removes leading and trailing white space characters from the specified string.
<code>trim_start(STRING)</code>	<code>String</code>	Removes leading white space characters from the specified string.
<code>trimend(STRING)</code>	<code>String</code>	Removes trailing white space characters from the specified string.
<code>unicode_char(NUM)</code>	<code>CHAR</code>	Input must be decimal, not hexadecimal values. Returns the character with Unicode value <i>NUM</i> .
<code>unicode_value(CHAR)</code>	<code>NUM</code>	Returns the Unicode value of <code>CHAR</code>
<code>uppertolower(CHAR)</code> <code>uppertolower(STRING)</code>	<code>CHAR or String</code>	Input can be either a string or character and is used in this function to return a new item of the same type with any uppercase characters converted to their lowercase equivalents. Note: Remember to specify strings with double quotes and characters with single backquotes. Simple field names should be specified without quotes.

SoundEx Functions

SoundEx is a method used to find strings when the sound is known but the precise spelling is not. Developed in 1918, it searches out words with similar sounds based on phonetic assumptions about how certain letters are pronounced. It can be used to search names in a database, for example, where spellings and pronunciations for similar names may vary. The basic SoundEx algorithm is documented in a number of sources and, despite known limitations (for example, leading letter combinations such as **ph** and **f** will not match even though they sound the same), is supported in some form by most databases.

Table 1. CLEM soundex functions

Function	Result	Description
soundex (STRING)	<i>Integer</i>	Returns the four-character SoundEx code for the specified <i>STRING</i> .
soundex_difference (STRING1, STRING2)	<i>Integer</i>	Returns an integer between 0 and 4 that indicates the number of characters that are the same in the SoundEx encoding for the two strings, where 0 indicates no similarity and 4 indicates strong similarity or identical strings.

Date and Time Functions

CLEM includes a family of functions for handling fields with datetime storage of string variables representing dates and times. The formats of date and time used are specific to each stream and are specified in the stream properties dialog box. The date and time functions parse date and time strings according to the currently selected format.

When you specify a year in a date that uses only two digits (that is, the century is not specified), IBM® SPSS® Modeler uses the default century that is specified in the stream properties dialog box.

Note: If the data function is pushed back to SQL or IBM SPSS Analytic Server, in a branch that follows an Analytic Server data source, any date format strings (*to_date*) within that data must match the date format specified in the SPSS Modeler stream.

Table 1. CLEM date and time functions

Function	Result	Description
@TODAY	<i>String</i>	If you select Rollover days/mins in the stream properties dialog box, this function returns the current date as a string in the current date format. If you use a two-digit date format and do not select Rollover days/mins, this function returns \$null\$ on the current server.
to_time (ITEM)	<i>Time</i>	Converts the storage of the specified field to a time.
to_date (ITEM)	<i>Date</i>	Converts the storage of the specified field to a date.
to_timestamp (ITEM)	<i>Timestamp</i>	Converts the storage of the specified field to a timestamp.
to_datetime (ITEM)	<i>Datetime</i>	Converts the storage of the specified field to a date, time, or timestamp value.
datetime_date (ITEM)	<i>Date</i>	Returns the date value for a <i>number</i> , <i>string</i> , or <i>timestamp</i> . Note this is the only function that allows you to convert a number (in seconds) back to a date. If <i>ITEM</i> is a string, creates a date by parsing a string in the current date format. The date format specified in the stream properties dialog box must be correct for this function to be successful. If <i>ITEM</i> is a number, it is interpreted as a number of seconds since the base date (or epoch). Fractions of a day are truncated. If <i>ITEM</i> is timestamp, the date part of the timestamp is returned. If <i>ITEM</i> is a date, it is returned unchanged.
date_before (DATE1, DATE2)	<i>Boolean</i>	Returns a value of true if <i>DATE1</i> represents a date or timestamp before that represented by <i>DATE2</i> . Otherwise, this function returns a value of 0.
date_days_difference (DATE1, DATE2)	<i>Integer</i>	Returns the time in days from the date or timestamp represented by <i>DATE1</i> to that represented by <i>DATE2</i> , as an integer. If <i>DATE2</i> is before <i>DATE1</i> , this function returns a negative number.
date_in_days (DATE)	<i>Integer</i>	Returns the time in days from the baseline date to the date or timestamp represented by <i>DATE</i> , as an integer. If <i>DATE</i> is before the baseline date, this function returns a negative number. You must include a valid date for the calculation to work appropriately. For example, you should not specify 29 February 2001 as the date. Because 2001 is not a leap year, this date does not exist.
date_in_months (DATE)	<i>Real</i>	Returns the time in months from the baseline date to the date or timestamp represented by <i>DATE</i> , as a real number. This is an approximate figure based on a month of 30.4375 days. If <i>DATE</i> is before the baseline date, this function returns a negative number. You must include a valid date for the calculation to work appropriately. For example, you should not specify 29 February 2001 as the date. Because 2001 is not a leap year, this date does not exist.

Function	Result	Description
<code>date_in_weeks(DATE)</code>	<code>Real</code>	Returns the time in weeks from the baseline date to the date or timestamp represented by <code>DATE</code> , as a real number. This is based on a week of 7.0 days. If <code>DATE</code> is before the baseline date, this function returns a negative number. You must include a valid date for the calculation to work appropriately. For example, you should not specify 29 February 2001 as the date. Because 2001 is not a leap year, this date does not exist.
<code>date_in_years(DATE)</code>	<code>Real</code>	Returns the time in years from the baseline date to the date or timestamp represented by <code>DATE</code> , as a real number. This is an approximate figure based on a year of 365.25 days. If <code>DATE</code> is before the baseline date, this function returns a negative number. You must include a valid date for the calculation to work appropriately. For example, you should not specify 29 February 2001 as the date. Because 2001 is not a leap year, this date does not exist.
<code>date_months_difference(DATE1, DATE2)</code>	<code>Real</code>	Returns the time in months from the date or timestamp represented by <code>DATE1</code> to that represented by <code>DATE2</code> , as a real number. This is an approximate figure based on a month of 30.4375 days. If <code>DATE2</code> is before <code>DATE1</code> , this function returns a negative number.
<code>datetime_date(YEAR, MONTH, DAY)</code>	<code>Date</code>	Creates a date value for the given <code>YEAR</code> , <code>MONTH</code> , and <code>DAY</code> . The arguments must be integers.
<code>datetime_day(DATE)</code>	<code>Integer</code>	Returns the day of the month from a given <code>DATE</code> or timestamp. The result is an integer in the range 1 to 31.
<code>datetime_day_name(DAY)</code>	<code>String</code>	Returns the full name of the given <code>DAY</code> . The argument must be an integer in the range 1 (Sunday) to 7 (Saturday).
<code>datetime_hour(TIME)</code>	<code>Integer</code>	Returns the hour from a <code>TIME</code> or timestamp. The result is an integer in the range 0 to 23.
<code>datetime_in_seconds(TIME)</code>	<code>Real</code>	Returns the seconds portion stored in <code>TIME</code> .
<code>datetime_in_seconds(DATE), datetime_in_seconds(DATETIME)</code>	<code>Real</code>	Returns the accumulated number, converted into seconds, from the difference between the current <code>DATE</code> or <code>DATETIME</code> and the baseline date (1900-01-01).
<code>datetime_minute(TIME)</code>	<code>Integer</code>	Returns the minute from a <code>TIME</code> or timestamp. The result is an integer in the range 0 to 59.
<code>datetime_month(DATE)</code>	<code>Integer</code>	Returns the month from a <code>DATE</code> or timestamp. The result is an integer in the range 1 to 12.
<code>datetime_month_name(MONTH)</code>	<code>String</code>	Returns the full name of the given <code>MONTH</code> . The argument must be an integer in the range 1 to 12.
<code>datetime_now</code>	<code>Timestamp</code>	Returns the current time as a timestamp.
<code>datetime_second(TIME)</code>	<code>Integer</code>	Returns the second from a <code>TIME</code> or timestamp. The result is an integer in the range 0 to 59.
<code>datetime_day_short_name(DAY)</code>	<code>String</code>	Returns the abbreviated name of the given <code>DAY</code> . The argument must be an integer in the range 1 (Sunday) to 7 (Saturday).
<code>datetime_month_short_name(MONTH)</code>	<code>String</code>	Returns the abbreviated name of the given <code>MONTH</code> . The argument must be an integer in the range 1 to 12.
<code>datetime_time(HOUR, MINUTE, SECOND)</code>	<code>Time</code>	Returns the time value for the specified <code>HOUR</code> , <code>MINUTE</code> , and <code>SECOND</code> . The arguments must be integers.
<code>datetime_time(ITEM)</code>	<code>Time</code>	Returns the time value of the given <code>ITEM</code> .
<code>datetime_timestamp(YEAR, MONTH, DAY, HOUR, MINUTE, SECOND)</code>	<code>Timestamp</code>	Returns the timestamp value for the given <code>YEAR</code> , <code>MONTH</code> , <code>DAY</code> , <code>HOUR</code> , <code>MINUTE</code> , and <code>SECOND</code> .
<code>datetime_timestamp(DATE, TIME)</code>	<code>Timestamp</code>	Returns the timestamp value for the given <code>DATE</code> and <code>TIME</code> .
<code>datetime_timestamp(NUMBER)</code>	<code>Timestamp</code>	Returns the timestamp value of the given number of seconds.
<code>datetime_weeekday(DATE)</code>	<code>Integer</code>	Returns the day of the week from the given <code>DATE</code> or timestamp.
<code>datetime_year(DATE)</code>	<code>Integer</code>	Returns the year from a <code>DATE</code> or timestamp. The result is an integer such as 2002.

Function	Result	Description
<code>date_weeks_difference(DATE1, DATE2)</code>	Real	Returns the time in weeks from the date or timestamp represented by <i>DATE1</i> to that represented by <i>DATE2</i> , as a real number. This is based on a week of 7.0 days. If <i>DATE2</i> is before <i>DATE1</i> , this function returns a negative number.
<code>date_years_difference(DATE1, DATE2)</code>	Real	Returns the time in years from the date or timestamp represented by <i>DATE1</i> to that represented by <i>DATE2</i> , as a real number. This is an approximate figure based on a year of 365.25 days. If <i>DATE2</i> is before <i>DATE1</i> , this function returns a negative number.
<code>date_from_ywd(YEAR, WEEK, DAY)</code>	Integer	Converts the year, week in year, and day in week, to a date using the ISO 8601 standard.
<code>date_iso_day(DATE)</code>	Integer	Returns the day in the week from the date using the ISO 8601 standard.
<code>date_iso_week(DATE)</code>	Integer	Returns the week in the year from the date using the ISO 8601 standard.
<code>date_iso_year(DATE)</code>	Integer	Returns the year from the date using the ISO 8601 standard.
<code>time_before(TIME1, TIME2)</code>	Boolean	Returns a value of true if <i>TIME1</i> represents a time or timestamp before that represented by <i>TIME2</i> . Otherwise, this function returns a value of 0.
<code>time_hours_difference(TIME1, TIME2)</code>	Real	Returns the time difference in hours between the times or timestamps represented by <i>TIME1</i> and <i>TIME2</i> , as a real number. If you select Rollover days/mins in the stream properties dialog box, a higher value of <i>TIME1</i> is taken to refer to the previous day. If you do not select the rollover option, a higher value of <i>TIME1</i> causes the returned value to be negative.
<code>time_in_hours(TIME)</code>	Real	Returns the time in hours represented by <i>TIME</i> , as a real number. For example, under time format <code>HHMM</code> , the expression <code>time_in_hours('0130')</code> evaluates to 1.5. <i>TIME</i> can represent a time or a timestamp.
<code>time_in_mins(TIME)</code>	Real	Returns the time in minutes represented by <i>TIME</i> , as a real number. <i>TIME</i> can represent a time or a timestamp.
<code>time_in_secs(TIME)</code>	Integer	Returns the time in seconds represented by <i>TIME</i> , as an integer. <i>TIME</i> can represent a time or a timestamp.
<code>time_mins_difference(TIME1, TIME2)</code>	Real	Returns the time difference in minutes between the times or timestamps represented by <i>TIME1</i> and <i>TIME2</i> , as a real number. If you select Rollover days/mins in the stream properties dialog box, a higher value of <i>TIME1</i> is taken to refer to the previous day (or the previous hour, if only minutes and seconds are specified in the current format). If you do not select the rollover option, a higher value of <i>TIME1</i> will cause the returned value to be negative.
<code>time_secs_difference(TIME1, TIME2)</code>	Integer	Returns the time difference in seconds between the times or timestamps represented by <i>TIME1</i> and <i>TIME2</i> , as an integer. If you select Rollover days/mins in the stream properties dialog box, a higher value of <i>TIME1</i> is taken to refer to the previous day (or the previous hour, if only minutes and seconds are specified in the current format). If you do not select the rollover option, a higher value of <i>TIME1</i> causes the returned value to be negative.

Converting Date and Time Values

Note that conversion functions (and any other functions that require a specific type of input, such as a date or time value) depend on the current formats specified in the Stream Options dialog box. For example, if you have a field named *DATE* that is stored as a string with values *Jan 2003*, *Feb 2003*, and so on, you could convert it to date storage as follows:

`to_date(DATE)`

For this conversion to work, select the matching date format `MON YYYY` as the default date format for the stream.

For an example that converts string values to dates using a Filler node, see the stream `broadband_create_models.str`, installed in the `|Demos` folder under the `streams` subfolder.

Dates stored as numbers. Note that *DATE* in the previous example is the name of a field, while `to_date` is a CLEM function. If you have dates stored as numbers, you can convert them using the `datetime_date` function, where the number is interpreted as a number of seconds since the base date (or epoch).

`datetime_date(DATE)`

By converting a date to a number of seconds (and back), you can perform calculations such as computing the current date plus or minus a fixed number of days, for example:

```
datetime_date((date_in_days(DATE)-7)*60*60*24)
```

Sequence functions

For some operations, the sequence of events is important. The application allows you to work with the following record sequences:

- Sequences and time series
- Sequence functions
- Record indexing
- Averaging, summing, and comparing values
- Monitoring change--differentiation
- `@SINCE`
- Offset values
- Additional sequence facilities

For many applications, each record passing through a stream can be considered as an individual case, independent of all others. In such situations, the order of records is usually unimportant.

For some classes of problems, however, the record sequence is very important. These are typically time series situations, in which the sequence of records represents an ordered sequence of events or occurrences. Each record represents a snapshot at a particular instant in time; much of the richest information, however, might be contained not in instantaneous values but in the way in which such values are changing and behaving over time.

Of course, the relevant parameter may be something other than time. For example, the records could represent analyses performed at distances along a line, but the same principles would apply.

Sequence and special functions are immediately recognizable by the following characteristics:

- They are all prefixed by `@`.
- Their names are given in upper case.

Sequence functions can refer to the record currently being processed by a node, the records that have already passed through a node, and even, in one case, records that have yet to pass through a node. Sequence functions can be mixed freely with other components of CLEM expressions, although some have restrictions on what can be used as their arguments.

Examples

You may find it useful to know how long it has been since a certain event occurred or a condition was true. Use the function `@SINCE` to do this—for example:

```
@SINCE(Income > Outgoings)
```

This function returns the offset of the last record where this condition was true—that is, the number of records before this one in which the condition was true. If the condition has never been true, `@SINCE` returns `@INDEX + 1`.

Sometimes you may want to refer to a value of the current record in the expression used by `@SINCE`. You can do this using the function `@THIS`, which specifies that a field name always applies to the current record. To find the offset of the last record that had a `Concentration` field value more than twice that of the current record, you could use:

```
@SINCE(Concentration > 2 * @THIS(Concentration))
```

In some cases the condition given to `@SINCE` is true of the current record by definition—for example:

```
@SINCE(ID == @THIS(ID))
```

For this reason, `@SINCE` does not evaluate its condition for the current record. Use a similar function, `@SINCE0`, if you want to evaluate the condition for the current record as well as previous ones; if the condition is true in the current record, `@SINCE0` returns 0.

Table 1. CLEM sequence functions

Function	Result	Description
----------	--------	-------------

Function	Result	Description
MEAN (FIELD)	<i>Real</i>	Returns the mean average of values for the specified <i>FIELD</i> or <i>FIELDS</i> .
@MEAN (FIELD , EXPR)	<i>Real</i>	Returns the mean average of values for <i>FIELD</i> over the last <i>EXPR</i> records received by the current node, including the current record. <i>FIELD</i> must be the name of a numeric field. <i>EXPR</i> may be any expression evaluating to an integer greater than 0. If <i>EXPR</i> is omitted or if it exceeds the number of records received so far, the average over all of the records received so far is returned.
@MEAN (FIELD , EXPR , INT)	<i>Real</i>	Returns the mean average of values for <i>FIELD</i> over the last <i>EXPR</i> records received by the current node, including the current record. <i>FIELD</i> must be the name of a numeric field. <i>EXPR</i> may be any expression evaluating to an integer greater than 0. If <i>EXPR</i> is omitted or if it exceeds the number of records received so far, the average over all of the records received so far is returned. <i>INT</i> specifies the maximum number of values to look back. This is far more efficient than using just two arguments.
@DIFF1 (FIELD)	<i>Real</i>	Returns the first differential of <i>FIELD</i> . The single-argument form thus simply returns the difference between the current value and the previous value of the field. Returns \$null\$ if the relevant previous records do not exist.
@DIFF1 (FIELD 1 , FIELD2)	<i>Real</i>	The two-argument form gives the first differential of <i>FIELD1</i> with respect to <i>FIELD2</i> . Returns \$null\$ if the relevant previous records do not exist. It is calculated as $\text{@DIFF1}(\text{FIELD1}) / \text{@DIFF1}(\text{FIELD2})$.
@DIFF2 (FIELD)	<i>Real</i>	Returns the second differential of <i>FIELD</i> . The single-argument form thus simply returns the difference between the current value and the previous value of the field. Returns \$null\$ if the relevant previous records do not exist. @DIFF2 is calculated as $\text{@DIFF}(\text{@DIFF}(\text{FIELD}))$.
@DIFF2 (FIELD 1 , FIELD2)	<i>Real</i>	The two-argument form gives the second differential of <i>FIELD1</i> with respect to <i>FIELD2</i> . Returns \$null\$ if the relevant previous records do not exist. This is a complex calculation -- $\text{@DIFF1}(\text{FIELD1}) / \text{@DIFF1}(\text{FIELD2}) - \text{@OFFSET}(\text{@DIFF1}(\text{FIELD1}), 1) / \text{@OFFSET}(\text{@DIFF1}(\text{FIELD2})) / \text{@DIFF1}(\text{FIELD2})$.
@INDEX	<i>Integer</i>	Returns the index of the current record. Indices are allocated to records as they arrive at the current node. The first record is given index 1, and the index is incremented by 1 for each subsequent record.
@LAST_NON_BLANK (FIELD)	<i>Any</i>	Returns the last value for <i>FIELD</i> that was not blank, as defined in an upstream source or Type node. If there are no nonblank values for <i>FIELD</i> in the records read so far, \$null\$ is returned. Note that blank values, also called user-missing values, can be defined separately for each field.
@MAX (FIELD)	<i>Number</i>	Returns the maximum value for the specified <i>FIELD</i> .
@MAX (FIELD , EXPR)	<i>Number</i>	Returns the maximum value for <i>FIELD</i> over the last <i>EXPR</i> records received so far, including the current record. <i>FIELD</i> must be the name of a numeric field. <i>EXPR</i> may be any expression evaluating to an integer greater than 0.
@MAX (FIELD , EXPR , INT)	<i>Number</i>	Returns the maximum value for <i>FIELD</i> over the last <i>EXPR</i> records received so far, including the current record. <i>FIELD</i> must be the name of a numeric field. <i>EXPR</i> may be any expression evaluating to an integer greater than 0. If <i>EXPR</i> is omitted, or if it exceeds the number of records received so far, the maximum value over all of the records received so far is returned. <i>INT</i> specifies the maximum number of values to look back. This is far more efficient than using just two arguments.
@MIN (FIELD)	<i>Number</i>	Returns the minimum value for the specified <i>FIELD</i> .
@MIN (FIELD , EXPR)	<i>Number</i>	Returns the minimum value for <i>FIELD</i> over the last <i>EXPR</i> records received so far, including the current record. <i>FIELD</i> must be the name of a numeric field. <i>EXPR</i> may be any expression evaluating to an integer greater than 0.
@MIN (FIELD , EXPR , INT)	<i>Number</i>	Returns the minimum value for <i>FIELD</i> over the last <i>EXPR</i> records received so far, including the current record. <i>FIELD</i> must be the name of a numeric field. <i>EXPR</i> may be any expression evaluating to an integer greater than 0. If <i>EXPR</i> is omitted, or if it exceeds the number of records received so far, the minimum value over all of the records received so far is returned. <i>INT</i> specifies the maximum number of values to look back. This is far more efficient than using just two arguments.

Function	Result	Description
<code>@OFFSET(FIELD, EXPR)</code>	Any	<p>Returns the value of <i>FIELD</i> in the record offset from the current record by the value of <i>EXPR</i>. A positive offset refers to a record that has already passed (a "lookback"), while a negative one specifies a "lookahead" to a record that has yet to arrive. For example, <code>@OFFSET(Status, 1)</code> returns the value of the <i>Status</i> field in the previous record, while <code>@OFFSET(Status, -4)</code> "looks ahead" four records in the sequence (that is, to records that have not yet passed through this node) to obtain the value. <i>Note that a negative (look ahead) offset must be specified as a constant.</i> For positive offsets only, <i>EXPR</i> may also be an arbitrary CLEM expression, which is evaluated for the current record to give the offset. In this case, the three-argument version of this function should improve performance (see next function). If the expression returns anything other than a non-negative integer, this causes an error—that is, it is not legal to have calculated lookahead offsets. <i>Note: A self-referential @OFFSET function cannot use literal lookahead.</i> For example, in a Filler node, you cannot replace the value of <i>field1</i> using an expression such as <code>@OFFSET(field1, -2)</code>. <i>Note: In the Filler node, when filling a field, there are effectively two different values of that field, namely the pre-filled value and the post-filled value. When @OFFSET refers to itself it refers to the post-filled value. This post-filled value only exists for past rows so self referential @OFFSET can only refer to past rows. Since self referential @OFFSET cannot refer to the future it carries out the following checks of the offset:</i></p> <ul style="list-style-type: none"> • If the offset is literal, and into the future, an error is reported before execution begins. • If the offset is an expression and evaluates to the future at runtime then @OFFSET returns \$null\$. <p><i>Note: Using both "lookahead" and "lookback" within one node is not supported.</i></p>
<code>@OFFSET(FIELD, EXPR, INT)</code>	Any	Performs the same operation as the <code>@OFFSET</code> function with the addition of a third argument, <i>INT</i> , which specifies the maximum number of values to look back. In cases where the offset is computed from an expression, this third argument should improve performance. For example, in an expression such as <code>@OFFSET(Foo, Month, 12)</code> , the system knows to keep only the last twelve values of <i>Foo</i> ; otherwise, it has to store every value just in case. In cases where the offset value is a constant—including negative "lookahead" offsets, which must be constant—the third argument is pointless and the two-argument version of this function should be used. See also the note about self-referential functions in the two-argument version described earlier. <i>Note: Using both "lookahead" and "lookback" within one node is not supported.</i>
<code>@SDEV(FIELD)</code>	Real	Returns the standard deviation of values for the specified <i>FIELD</i> or <i>FIELDS</i> .
<code>@SDEV(FIELD, EXPR)</code>	Real	Returns the standard deviation of values for <i>FIELD</i> over the last <i>EXPR</i> records received by the current node, including the current record. <i>FIELD</i> must be the name of a numeric field. <i>EXPR</i> may be any expression evaluating to an integer greater than 0. If <i>EXPR</i> is omitted, or if it exceeds the number of records received so far, the standard deviation over all of the records received so far is returned.
<code>@SDEV(FIELD, EXPR, INT)</code>	Real	Returns the standard deviation of values for <i>FIELD</i> over the last <i>EXPR</i> records received by the current node, including the current record. <i>FIELD</i> must be the name of a numeric field. <i>EXPR</i> may be any expression evaluating to an integer greater than 0. If <i>EXPR</i> is omitted, or if it exceeds the number of records received so far, the standard deviation over all of the records received so far is returned. <i>INT</i> specifies the maximum number of values to look back. This is far more efficient than using just two arguments.
<code>@SINCE(EXPR)</code>	Any	Returns the number of records that have passed since <i>EXPR</i> , an arbitrary CLEM expression, was true.
<code>@SINCE(EXPR, INT)</code>	Any	Adding the second argument, <i>INT</i> , specifies the maximum number of records to look back. If <i>EXPR</i> has never been true, <i>INT</i> is <code>@INDEX+1</code> .
<code>@SINCE0(EXPR)</code>	Any	Considers the current record, while <code>@SINCE</code> does not; <code>@SINCE0</code> returns 0 if <i>EXPR</i> is true for the current record.
<code>@SINCE0(EXPR, INT)</code>	Any	Adding the second argument, <i>INT</i> specifies the maximum number of records to look back.
<code>@SUM(FIELD)</code>	Number	Returns the sum of values for the specified <i>FIELD</i> or <i>FIELDS</i> .
<code>@SUM(FIELD, EXPR)</code>	Number	Returns the sum of values for <i>FIELD</i> over the last <i>EXPR</i> records received by the current node, including the current record. <i>FIELD</i> must be the name of a numeric field. <i>EXPR</i> may be any expression evaluating to an integer greater than 0. If <i>EXPR</i> is omitted, or if it exceeds the number of records received so far, the sum over all of the records received so far is returned.
<code>@SUM(FIELD, EXPR, INT)</code>	Number	Returns the sum of values for <i>FIELD</i> over the last <i>EXPR</i> records received by the current node, including the current record. <i>FIELD</i> must be the name of a numeric field. <i>EXPR</i> may be any expression evaluating to an integer greater than 0. If <i>EXPR</i> is omitted, or if it exceeds the number of records received so far, the sum over all of the records received so far is returned. <i>INT</i> specifies the maximum number of values to look back. This is far more efficient than using just two arguments.
<code>@THIS(FIELD)</code>	Any	Returns the value of the field named <i>FIELD</i> in the current record. Used only in <code>@SINCE</code> expressions.

Global Functions

The functions @MEAN, @SUM, @MIN, @MAX, and @SDEV work on, at most, all of the records read up to and including the current one. In some cases, however, it is useful to be able to work out how values in the current record compare with values seen in the entire data set. Using a Set Globals node to generate values across the entire data set, you can access these values in a CLEM expression using the global functions.

For example,

`@GLOBAL_MAX(Age)`

returns the highest value of `Age` in the data set, while the expression

`(Value - @GLOBAL_MEAN(Value)) / @GLOBAL_SDEV(Value)`

expresses the difference between this record's `Value` and the global mean as a number of standard deviations. You can use global values only after they have been calculated by a Set Globals node. All current global values can be canceled by clicking the Clear Global Values button on the Globals tab in the stream properties dialog box.

Table 1. CLEM global functions

Function	Result	Description
<code>@GLOBAL_MAX(FIELD)</code>	Number	Returns the maximum value for <i>FIELD</i> over the whole data set, as previously generated by a Set Globals node. <i>FIELD</i> must be the name of a numeric, date/time/datetime, or string field. If the corresponding global value has not been set, an error occurs.
<code>@GLOBAL_MIN(FIELD)</code>	Number	Returns the minimum value for <i>FIELD</i> over the whole data set, as previously generated by a Set Globals node. <i>FIELD</i> must be the name of a numeric, date/time/datetime, or string field. If the corresponding global value has not been set, an error occurs.
<code>@GLOBAL_SDEV(FIELD)</code>	Number	Returns the standard deviation of values for <i>FIELD</i> over the whole data set, as previously generated by a Set Globals node. <i>FIELD</i> must be the name of a numeric field. If the corresponding global value has not been set, an error occurs.
<code>@GLOBAL_MEAN(FIELD)</code>	Number	Returns the mean average of values for <i>FIELD</i> over the whole data set, as previously generated by a Set Globals node. <i>FIELD</i> must be the name of a numeric field. If the corresponding global value has not been set, an error occurs.
<code>@GLOBAL_SUM(FIELD)</code>	Number	Returns the sum of values for <i>FIELD</i> over the whole data set, as previously generated by a Set Globals node. <i>FIELD</i> must be the name of a numeric field. If the corresponding global value has not been set, an error occurs.

Functions Handling Blanks and Null Values

Using CLEM, you can specify that certain values in a field are to be regarded as "blanks," or missing values. The following functions work with blanks.

Table 1. CLEM blank and null value functions

Function	Result	Description
<code>@BLANK(FIELD)</code>	Boolean	Returns true for all records whose values are blank according to the blank-handling rules set in an upstream Type node or source node (Types tab).
<code>@LAST_NON_BLANK(FIELD)</code>	Any	Returns the last value for <i>FIELD</i> that was not blank, as defined in an upstream source or Type node. If there are no nonblank values for <i>FIELD</i> in the records read so far, <code>\$null\$</code> is returned. Note that blank values, also called user-missing values, can be defined separately for each field.
<code>@NULL(FIELD)</code>	Boolean	Returns true if the value of <i>FIELD</i> is the system-missing <code>\$null\$</code> . Returns false for all other values, including user-defined blanks. If you want to check for both, use <code>@BLANK(FIELD)</code> and <code>@NULL(FIELD)</code> .
<code>undef</code>	Any	Used generally in CLEM to enter a <code>\$null\$</code> value—for example, to fill blank values with nulls in the Filler node.

Blank fields may be "filled in" with the Filler node. In both Filler and Derive nodes (multiple mode only), the special CLEM function `@FIELD` refers to the current field(s) being examined.

Related information

- [Functions reference](#)

Special Fields

Special functions are used to denote the specific fields under examination, or to generate a list of fields as input. For example, when deriving multiple fields at once, you should use `@FIELD` to denote "perform this derive action on the selected fields." Using the expression `log(@FIELD)` derives a new log field for each selected field.

Table 1. CLEM special fields

Function	Result	Description
<code>@FIELD</code>	Any	Performs an action on all fields specified in the expression context.
<code>@TARGET</code>	Any	When a CLEM expression is used in a user-defined analysis function, <code>@TARGET</code> represents the target field or "correct value" for the target/predicted pair being analyzed. This function is commonly used in an Analysis node.
<code>@PREDICTED</code>	Any	When a CLEM expression is used in a user-defined analysis function, <code>@PREDICTED</code> represents the predicted value for the target/predicted pair being analyzed. This function is commonly used in an Analysis node.
<code>@PARTITION_FIELD</code>	Any	Substitutes the name of the current partition field.
<code>@TRAINING_PARTITION</code>	Any	Returns the value of the current training partition. For example, to select training records using a Select node, use the CLEM expression: <code>@PARTITION_FIELD = @TRAINING_PARTITION</code> This ensures that the Select node will always work regardless of which values are used to represent each partition in the data.
<code>@TESTING_PARTITION</code>	Any	Returns the value of the current testing partition.
<code>@VALIDATION_PARTITION</code>	Any	Returns the value of the current validation partition.
<code>@FIELDS_BETWEEN(start, end)</code>	Any	Returns the list of field names between the specified start and end fields (inclusive) based on the natural (that is, insert) order of the fields in the data.
<code>@FIELDS_MATCHING(pattern)</code>	Any	Returns a list of field names matching a specified pattern. A question mark (?) can be included in the pattern to match exactly one character; an asterisk (*) matches zero or more characters. To match a literal question mark or asterisk (rather than using these as wildcards), a backslash (\) can be used as an escape character. Note: This requires a string literal as an argument; it cannot use a nested expression to generate the argument.
<code>@MULTI_RESPONSE_SET</code>	Any	Returns the list of fields in the named multiple response set.

- [Deploying streams](#)

About the IBM SPSS Collaboration and Deployment Services Repository

SPSS® Modeler can be used in conjunction with an IBM® SPSS Collaboration and Deployment Services repository, enabling you to manage the life cycle of data mining models and related predictive objects, and enabling these objects to be used by enterprise applications, tools, and solutions.

IBM SPSS Modeler objects that can be shared in this way include streams, nodes, stream outputs, projects, and models. Objects are stored in the central repository, from where they can be shared with other applications and tracked using extended versioning, metadata, and search capabilities.

Before you can use SPSS Modeler with the repository, you need to install an adapter at the repository host. Without this adapter, you may see the following message when attempting to access repository objects from certain SPSS Modeler nodes or models:

The repository may need updating to support new node, model and output types.

For instructions on installing the adapter, see the *SPSS Modeler Deployment Installation* guide, available as a PDF file as part of your product download. Details of how to access IBM SPSS Modeler repository objects from IBM SPSS Deployment Manager are given in the *SPSS Modeler Deployment Guide*.

The following sections provide information on accessing the repository from within SPSS Modeler.

Extensive Versioning and Search Support

The repository provides comprehensive object versioning and search capabilities. For example, suppose that you create a stream and store it in the repository where it can be shared with researchers from other divisions. If you later update the stream in SPSS Modeler, you can add the updated version to the repository without overwriting the previous version. All versions remain accessible and can be searched by name, label, fields used, or other attributes. You could, for example, search for all model versions that use net revenue as an input, or all models created by a particular author. (To do this with a traditional file system, you would have to save each version under a different filename, and the relationships between versions would be unknown to the software.)

Single Sign-On

The single sign-on feature enables users to connect to the repository without having to enter username and password details each time. The user's existing local network login details provide the necessary authentication to IBM SPSS Collaboration and Deployment Services. This feature depends on the following:

- IBM SPSS Collaboration and Deployment Services must be configured to use a single sign-on provider.
- The user must be logged in to a host that is compatible with the provider.

For more information, see [Connecting to the Repository](#).

Storing and deploying repository objects

Streams created in IBM® SPSS® Modeler can be **stored** in the repository just as they are, as files with the extension .str. In this way, a single stream can be accessed by multiple users throughout the enterprise. See the topic [Storing Objects in the Repository](#) for more information.

It is also possible to deploy a stream in the repository. A deployed stream is stored as a file with additional metadata. A deployed stream can take full advantage of the enterprise-level features of IBM SPSS Collaboration and Deployment Services, such as automated scoring and model refresh. For example, a model can be automatically updated at regularly-scheduled intervals as new data becomes available. Alternatively, a set of streams can be deployed for Champion Challenger analysis, in which streams are compared to determine which one contains the most effective predictive model.

Note: The Association Rules, STP, and TCM modeling nodes do not support the Model Evaluation or Champion Challenger steps in IBM SPSS Collaboration and Deployment Services.

You can deploy a stream (with the extension .str). Deployment as a stream enables the stream to be used by the thin-client application IBM SPSS Modeler Advantage. See the topic [Opening a Stream in IBM SPSS Modeler Advantage](#) for more information.

For more information, see [Stream Deployment Options](#).

Other Deployment Options

While IBM SPSS Collaboration and Deployment Services offers the most extensive features for managing enterprise content, a number of other mechanisms for deploying or exporting streams are also available, including:

- Export the stream and model for later use with IBM SPSS Modeler Solution Publisher Runtime.
- Export one or more models in PMML, an XML-based format for encoding model information. See the topic [Importing and exporting models as PMML](#) for more information.

Connecting to the Repository

1. To connect to the repository, on the IBM® SPSS® Modeler main menu, click:
Tools > Repository > Options...
2. In the RepositoryURL. field, enter or select the directory path to, or URL of, the repository installation you want to access. You can connect to only one repository at a time.
Settings are specific to each site or installation. For specific login details, contact your local system administrator.

Set Credentials. Leave this box unchecked to enable the *single sign-on* feature, which attempts to log you in using your local computer username and password details. If single sign-on is not possible, or if you select this option to disable single sign-on (for example, to log in to an administrator account), a screen is displayed for you to enter your credentials.

- [Entering Credentials for the Repository](#)
- [Browse for repository credentials](#)

- [Searching for objects in the repository](#)
- [Creating, Renaming, and Deleting Folders](#)
- [Viewing Folder Properties](#)
- [Viewing and Editing Object Properties](#)

Entering Credentials for the Repository

Depending on your settings, the following fields may be required in the Repository: Credentials dialog box:

User ID and password. Specify a valid user name and password for logging on. If necessary, contact your local administrator for more information.

Provider. Choose a security provider for authentication. The repository can be configured to use different security providers; if necessary, contact your local administrator for more information.

Remember repository and user ID. Saves the current settings as the default so that you do not have to reenter them each time you want to connect.

Browse for repository credentials

When you connect to a repository from an Analytic Server, Cognos, ODBC, or TM1 source node, you can select previously recorded credentials to connect to a repository. These credentials are listed in the Select Repository Credential dialog box. To select this dialog box, click Browse next to the Credential field.

In the Select Repository Credential dialog box, highlight the credentials in the list supplied and click OK. If the list is too large, use the Filter field to enter the name, or part of the name, to find the credentials you require.

Browsing the Repository Contents

The repository allows you to browse stored content in a manner similar to Windows Explorer; you can also browse *versions* of each stored object.

1. To open the IBM® SPSS® Collaboration and Deployment Services Repository window, on the SPSS Modeler menus click:

Tools > Repository > Explore...

1. Specify connection settings to the repository if necessary. See the topic [Connecting to the Repository](#) for more information. For specific port, password, and other connection details, contact your local system administrator.

The explorer window initially displays a tree view of the folder hierarchy. Click a folder name to display its contents.

Objects that match the current selection or search criteria are listed in the right pane, with detailed information on the selected version displayed in the lower right pane. The attributes displayed apply to the most recent version.

Storing Objects in the Repository

You can store streams, nodes, models, model palettes, projects, and output objects in the repository, from where they can be accessed by other users and applications.

You can also publish stream output to the repository in a format that enables other users to view it over the Internet using the IBM® SPSS® Collaboration and Deployment Services Deployment Portal.

Setting Object Properties

When you store an object, the Repository: Store dialog box is displayed, enabling you to set the values of a number of properties for the object. You can:

- Choose the name and repository folder under which the object is to be stored
- Add information about the object such as the version label and other searchable properties
- Assign one or more classification topics to the object
- Set security options for the object

The following sections describe the properties you can set.

- [Choosing the Location for Storing Objects](#)
 - [Adding Information About Stored Objects](#)
 - [Assigning Topics to a Stored Object](#)
 - [Setting Security Options for Stored Objects](#)
-

Choosing the Location for Storing Objects

In the Repository: Store dialog box, enter the following.

Save in. Shows the current folder--the location where the object will be stored. Double-click a folder name in the list to set that folder as the current folder. Use the Up Folder button to navigate to the parent folder. Use the New Folder button to create a folder at the current level.

File name. The name under which the object will be stored.

Store. Stores the object at the current location.

Adding Information About Stored Objects

All of the fields on the Information tab of the Repository: Store dialog box are optional.

Author. The username of the user creating the object in the repository. By default, this shows the username used for the repository connection, but you can change this name here.

Version Label. Select a label from the list to indicate the object version, or click Add to create a new label. Avoid using the "[" character in the label. Ensure that no boxes are checked if you do not want to assign a label to this object version. See the topic [Viewing and Editing Object Properties](#) for more information.

Description. A description of the object. Users can search for objects by description (see note).

Keywords. One or more keywords that relate to the object and which can be used for search purposes (see note).

Expiration. A date after which the object is no longer visible to general users, although it can still be seen by its owner and by the repository administrator. To set an expiration date, select the Date option and enter the date, or choose one using the calendar button.

Store. Stores the object at the current location.

Note: Information in the Description and Keywords fields is treated as distinct from anything entered in SPSS® Modeler on the Annotations tab of the object. A repository search by description or keyword does not return information from the Annotations tab. See the topic [Searching for objects in the repository](#) for more information.

Assigning Topics to a Stored Object

Topics are a hierarchical classification system for the content stored in the repository. You can choose from the available topics when storing objects, and users can also search for objects by topic. The list of available topics is set by repository users with the appropriate privileges (for more information, see the *Deployment Manager User's Guide*).

To assign a topic to the object, on the Topics tab of the Repository: Store dialog box:

1. Click the Add button.
2. Click a topic name from the list of available topics.
3. Click OK.

To remove a topic assignment:

4. Select the topic in the list of assigned topics.
5. Click Delete.

Setting Security Options for Stored Objects

You can set or change a number of security options for a stored object on the Security tab of the Repository: Store dialog box. For one or more **principals** (that is, users or groups of users), you can:

- Assign access rights to the object
- Modify access rights to the object
- Remove access rights to the object

Principal. The repository username of the user or group who has access rights on this object.

Permissions. The access rights that this user or group has for the object.

Add. Enables you to add one or more users or groups to the list of those with access rights on this object. See the topic [Adding a User to the Permissions List](#) for more information.

Modify. Enables you to modify the access rights of the selected user or group for this object. Read access is granted by default. This option enables you to grant additional access rights, namely Owner, Write, Delete, and Modify Permissions.

Delete. Deletes the selected user or group from the permissions list for this object.

- [Adding a User to the Permissions List](#)
- [Modifying Access Rights for an Object](#)

Adding a User to the Permissions List

The following fields are available when you select Add on the Security tab of the Repository: Store dialog box:

Select provider. Choose a security provider for authentication. The repository can be configured to use different security providers; if necessary, contact your local administrator for more information.

Find. Enter the repository username of the user or group you want to add, and click Search to display that name in the user list. To add more than one username at a time, leave this field blank and just click Search to display a list of all the repository usernames.

User list. Select one or more usernames from the list and click OK to add them to the permissions list.

Modifying Access Rights for an Object

The following fields are available when you select Modify on the Security tab of the Repository: Store dialog box:

Owner. Select this option to give this user or group owner access rights to the object. The owner has full control over the object, including Delete and Modify access rights.

Read. By default, a user or group that is not the object owner has only Read access rights to the object. Select the appropriate check boxes to add Write, Delete, and Modify Permissions access rights for this user or group.

Storing Streams

You can store a stream as a .str file in the repository, from where it can be accessed by other users.

Note: For information on deploying a stream, to take advantage of additional repository features, see [Deploying streams](#).

To store the current stream:

1. On the main menu, click:
`File > Store > Store as Stream...`
2. Specify connection settings to the repository if necessary. See the topic [Connecting to the Repository](#) for more information. For specific port, password, and other connection details, contact your local system administrator.
3. In the Repository: Store dialog box, choose the folder where you want to store the object, specify any other information you want to record, and click the Store button. See the topic [Setting Object Properties](#) for more information.

Storing Projects

You can store a complete IBM® SPSS® Modeler project as a .cpj file in the repository so that it can be accessed by other users.

Because a project file is a container for other IBM SPSS Modeler objects, you need to tell IBM SPSS Modeler to store the project's objects in the repository. You do this using a setting in the Project Properties dialog box. See the topic [Setting Project Properties](#) for more information.

Once you configure a project to store objects in the repository, whenever you add a new object to the project, IBM SPSS Modeler automatically prompts you to store the object.

When you have finished your IBM SPSS Modeler session, you must store a new version of the project file so that it remembers your additions. The project file automatically contains (and retrieves) the latest versions of its objects. If you did not add any objects to a project during an IBM SPSS Modeler session, then you do not have to re-store the project file. You must, however, store new versions for the project objects (streams, output, and so forth) that you changed.

To store a project

1. Select the project on the CRISP-DM or Classes tab in the managers pane in IBM SPSS Modeler, and on the main menu click:
`File > Project > Store Project...`
2. Specify connection settings to the repository if necessary. See the topic [Connecting to the Repository](#) for more information. For specific port, password, and other connection details, contact your local system administrator.
3. In the Repository: Store dialog box, choose the folder where you want to store the object, specify any other information you want to record, and click the Store button. See the topic [Setting Object Properties](#) for more information.

Storing Nodes

You can store an individual node definition from the current stream as a .nod file in the repository, from where it can be accessed by other users.

To store a node:

1. Right-click the node in the stream canvas and click Store Node.
2. Specify connection settings to the repository if necessary. See the topic [Connecting to the Repository](#) for more information. For specific port, password, and other connection details, contact your local system administrator.
3. In the Repository: Store dialog box, choose the folder where you want to store the object, specify any other information you want to record, and click the Store button. See the topic [Setting Object Properties](#) for more information.

Storing Output Objects

You can store an output object from the current stream as a .cou file in the repository, from where it can be accessed by other users.

To store an output object:

1. Click the object on the Outputs tab of the managers pane in SPSS® Modeler, and on the main menu click:
File->Outputs->Store Output...
2. Alternatively, right-click an object in the Outputs tab and click Store.
3. Specify connection settings to the repository if necessary. See the topic [Connecting to the Repository](#) for more information. For specific port, password, and other connection details, contact your local system administrator.
4. In the Repository: Store dialog box, choose the folder where you want to store the object, specify any other information you want to record, and click the Store button. See the topic [Setting Object Properties](#) for more information.

Storing Models and Model Palettes

You can store an individual model as a .gm file in the repository, from where it can be accessed by other users. You can also store the complete contents of the Models palette as a .gen file in the repository.

Storing a model:

1. Click the object on the Models palette in SPSS® Modeler, and on the main menu click:
File->Models->Store Model...
2. Alternatively, right-click an object in the Models palette and click Store Model.
3. Continue from "Completing the storage procedure".

Storing a Models palette:

1. Right-click the background of the Models palette.
2. On the pop-up menu, click Store Palette.
3. Continue from "Completing the storage procedure".

Completing the storage procedure:

1. Specify connection settings to the repository if necessary. See the topic [Connecting to the Repository](#) for more information. For specific port, password, and other connection details, contact your local system administrator.
2. In the Repository: Store dialog box, choose the folder where you want to store the object, specify any other information you want to record, and click the Store button. See the topic [Setting Object Properties](#) for more information.

Retrieving Objects from the Repository

You can retrieve streams, models, model palettes, nodes, projects, and output objects that have been stored in the repository.

Note: Besides using the menu options as described here, you can also retrieve streams, output objects, models and model palettes by right-clicking in the appropriate tab of the managers pane at the top right of the SPSS® Modeler window.

1. To retrieve a stream, on the IBM® SPSS Modeler main menu click:
File->Retrieve Stream...
2. To retrieve a model, model palette, project, or output object, on the IBM SPSS Modeler main menu click:
File->Models->Retrieve Model...
or
File->Models->Retrieve Models Palette...
or
File->Projects->Retrieve Project...
or
File->Outputs->Retrieve Output...

3. Alternatively, right-click in the managers or project pane and click Retrieve on the pop-up menu.
4. To retrieve a node, on the IBM SPSS Modeler main menu click:
Insert > Node (or SuperNode) from Repository...
 - a. Specify connection settings to the repository if necessary. See the topic [Connecting to the Repository](#) for more information. For specific port, password, and other connection details, contact your local system administrator.
5. In the Repository: Retrieve dialog box, browse to the object, select it and click the Retrieve button. See the topic [Choosing an Object to Retrieve](#) for more information.
 - [Choosing an Object to Retrieve](#)
 - [Selecting an Object Version](#)

-

Choosing an Object to Retrieve

The following fields are available in the Repository: Retrieve/Search dialog box:

Look in. Shows the folder hierarchy for the current folder. To navigate to a different folder, select one from this list to navigate there directly, or navigate using the object list below this field.

Up Folder button. Navigates to one level above the current folder in the hierarchy.

New Folder button. Creates a new folder at the current level in the hierarchy.

File name. The repository file name of the selected object. To retrieve that object, click Retrieve.

Files of type. The type of object that you have chosen to retrieve. Only objects of this type, together with folders, are shown in the object list. To display objects of a different type for retrieval, select the object type from the list.

Open as locked. By default, when an object is retrieved, it is locked in the repository so that others cannot update it. If you do not want the object to be locked on retrieval, uncheck this box.

Description, Keywords. If additional details about the object were defined when the object was stored, those details are displayed here. See the topic [Adding Information About Stored Objects](#) for more information.

Version. To retrieve a version of the object other than the latest, click this button. Detailed information for all versions is displayed, allowing you to choose the version you want.

Selecting an Object Version

To select a specific version of a repository object, in the Repository: Select Version dialog box:

1. (Optional) Sort the list by version, label, size, creation date or creating user, by double-clicking on the header of the appropriate column.
 2. Select the object version you want to work with.
 3. Click Continue.
-

Searching for objects in the repository

You can search for objects by name, folder, type, label, date, or other criteria.

Searching for objects by name

-
1. On the IBM® SPSS® Modeler main menu click:
Tools > Repository > Explore...
 - a. Specify connection settings to the repository if necessary. See the topic [Connecting to the Repository](#) for more information. For specific port, password, and other connection details, contact your local system administrator.
 2. Click the Search tab.
 3. In the Search for objects named field, specify the name of the object you want to find.

When searching for objects by name, an asterisk (*) can be used as a wildcard character to match any string of characters, and a question mark (?) matches any single character. For example, *cluster* matches all objects that include the string cluster anywhere in the name. The search string m0?_* matches M01_cluster.str and M02_cluster.str but not M01a_cluster.str. Searches are not case sensitive (cluster matches Cluster matches CLUSTER).

Note: If the number of objects is large, searches may take a few moments.

Searching by other criteria

You can perform a search based on title, label, dates, author, keywords, indexed content, or description. Only objects that match *all* specified search criteria will be found. For example, you could locate all streams containing one or more clustering models that also have a specific label applied, and which were modified after a specific date.

Object Types. You can restrict the search to models, streams, outputs, nodes, SuperNodes, projects, model palettes, or other types of objects.

- **Models.** You can search for models by category (classification, approximation, clustering, etc.) or by a specific modeling algorithm, such as Kohonen.
You can also search by fields used—for example, all models that use a field named *income* as an input or output (target) field.
- **Streams.** For streams, you can restrict the search by fields used, or model type (either category or algorithm) contained in the stream.

Topics. You can search on models associated with specific topics from a list set by repository users with the appropriate privileges (for more information, see the *Deployment Manager User's Guide*). To obtain the list, check this box, then click the Add Topics button that is displayed, select one or more topics from the list and click OK.

Label. Restricts the search to specific object version labels.

Dates. You can specify a creation or modification date and search on objects before, after, or between the specified date range.

Author. Restricts the search to objects created by a specific user.

Keywords. Search on specific keywords. In IBM SPSS Modeler, keywords are specified on the Annotation tab for a stream, model, or output object.

Description. Search on specific terms in the description field. In IBM SPSS Modeler, the description is specified on the Annotation tab for a stream, model, or output object. Multiple search phrases can be separated by semicolons—for example, *income*; *crop type*; *claim value*. (Note that within a search phrase, spaces matter. For example, *crop type* with one space and *crop type* with two spaces are not the same.)

Modifying Repository Objects

You can modify existing objects in the repository directly from SPSS® Modeler. You can:

- Create, rename, or delete folders
 - Lock or unlock objects
 - Delete objects
- [Creating, Renaming, and Deleting Folders](#)

- [Locking and Unlocking Repository Objects](#)
 - [Deleting Repository Objects](#)
-

Creating, Renaming, and Deleting Folders

1. To perform operations on folders in the repository, on the SPSS® Modeler main menu click:
Tools > Repository > Explore...
 - a. Specify connection settings to the repository if necessary. See the topic [Connecting to the Repository](#) for more information. For specific port, password, and other connection details, contact your local system administrator.
2. Ensure that the Folders tab is active.
3. To create a new folder, right-click the parent folder and click New Folder.
4. To rename a folder, right-click it and click Rename Folder.
5. To delete a folder, right-click it and click Delete Folder.

-

Locking and Unlocking Repository Objects

You can lock an object to prevent other users from updating any of its existing versions or creating new versions. A locked object is indicated by a padlock symbol over the object icon.

Figure 1. Locked object

To lock an object

1. In the repository explorer window, right-click the required object.
2. Click Lock.

To unlock an object

1. In the repository explorer window, right-click the required object.
2. Click Unlock.

Deleting Repository Objects

Before deleting an object from the repository, you must decide if you want to delete all versions of the object, or just a particular version.

To Delete All Versions of an Object

1. In the repository explorer window, right-click the required object.
2. Click Delete Objects.

To Delete the Most Recent Version of an Object

1. In the repository explorer window, right-click the required object.
2. Click Delete.

To Delete a Previous Version of an Object

1. In the repository explorer window, right-click the required object.
2. Click Delete Versions.

3. Select the version(s) to delete and click OK.

Managing Properties of Repository Objects

You can control various object properties from SPSS® Modeler. You can:

- View the properties of a folder
- View and edit the properties of an object
- Create, apply and delete version labels for an object
- [Viewing Folder Properties](#)
- [Viewing and Editing Object Properties](#)
- [Managing Object Version Labels](#)

Viewing Folder Properties

To view properties for any folder in the repository window, right-click the required folder. Click Folder Properties.

General tab

This tab displays the folder name, creation, and modification dates.

Permissions tab

In this tab you specify read and write permissions for the folder. All users and groups with access to the parent folder are listed. Permissions follow a hierarchy. For example, if you do not have read permission, you cannot have write permission. If you do not have write permission, you cannot have delete permission.

Users And Groups. Lists the repository users and groups that have at least Read access to this folder. Select the Write and Delete check boxes to add those access rights for this folder to a particular user or group. Click the Add Users/Groups icon on the right side of the Permissions tab to assign access to additional users and groups. The list of available users and groups is controlled by the administrator.

Cascade Permissions. Choose an option to control how changes made to the current folder are applied to its child folders, if any.

- **Cascade all permissions.** Cascades permission settings from the current folder to all child and descendant folders. This is a quick way to set permissions for several folders at once. Set permissions as required for the parent folder, and then cascade as required.
- **Cascade changes only.** Cascades only changes made since the last time changes were applied. For example, if a new group has been added and you want to give it access to all folders under the Sales branch, you can give the group access to the root Sales folder and cascade the change to all subfolders. All other permissions to existing subfolders remain as before.
- **Do not cascade.** Any changes made apply to the current folder only and do not cascade to child folders.

Related information

- [About the IBM SPSS Collaboration and Deployment Services Repository](#)
- [Connecting to the Repository](#)
- [Entering Credentials for the Repository](#)
- [Browsing the Repository Contents](#)
- [Storing Objects in the Repository](#)
- [Retrieving Objects from the Repository](#)
- [Searching for objects in the repository](#)
- [Creating, Renaming, and Deleting Folders](#)
- [Viewing and Editing Object Properties](#)

Viewing and Editing Object Properties

In the Object Properties dialog box you can view and edit properties. Although some properties cannot be changed, you can always update an object by adding a new version.

1. In the repository window, right-click the required object.
2. Click Object Properties.

General Tab

Name. The name of the object as viewed in the repository.

Created on. Date the object (not the version) was created.

Last modified. Date the most recent version was modified.

Author. The user's login name.

Description. By default, this contains the description specified on the object's Annotation tab in SPSS® Modeler.

Linked topics. The repository allows models and related objects to be organized by topics if required. The list of available topics is set by repository users with the appropriate privileges (for more information, see the *Deployment Manager User's Guide*).

Keywords. You specify keywords on the Annotation tab for a stream, model, or output object. Multiple keywords should be separated by spaces, up to a maximum of 255 characters. (If keywords contain spaces, use quotation marks to separate them.)

Versions Tab

Objects stored in the repository may have multiple versions. The Versions tab displays information about each version.

The following properties can be specified or modified for specific versions of a stored object:

Version. Unique identifier for the version generated based on the time when the version was stored.

Label. Current label for the version, if any. Unlike the version identifier, labels can be moved from one version of an object to another.

The file size, creation date, and author are also displayed for each version.

Edit Labels. Click the Edit Labels icon at the top right of the Versions tab to define, apply or remove labels for stored objects. See the topic [Managing Object Version Labels](#) for more information.

Permissions Tab

On the Permissions tab you can set read and write permissions for the object. All users and groups with access to the current object are listed. Permissions follow a hierarchy. For example, if you do not have read permission, you cannot have write permission. If you do not have write permission, you cannot have delete permission.

Users And Groups. Lists the repository users and groups that have at least Read access to this object. Select the Write and Delete check boxes to add those access rights for this object to a particular user or group. Click the Add Users/Groups icon on the right side of the Permissions tab to assign access to additional users and groups. The list of available users and groups is controlled by the administrator.

Managing Object Version Labels

The Edit Version Labels dialog box enables you to:

- Apply labels to the selected object
- Remove labels from the selected object
- Define a new label and apply it to the object

To apply labels to the object

1. Select one or more labels in the Available Labels list.
2. Click the right-arrow button to move the selected labels to the Applied Labels list.
3. Click OK.

To remove labels from the object

1. Select one or more labels in the Applied Labels list.

2. Click the left-arrow button to move the selected labels to the Available Labels list.
3. Click OK.

To define a new label and apply it to the object

1. Type the label name in the New Label field.
2. Click the right-arrow button to move the new label to the Applied Labels list.
3. Click OK.

Deploying streams

To enable a stream to be used with the thin-client application IBM® SPSS® Modeler Advantage, it must be deployed as a stream (.str file) in the repository.

Note: You cannot deploy a stream that has more than one source node in the scoring branch.

The stream can take full advantage of the enterprise-level features of IBM SPSS Collaboration and Deployment Services. See the topic [Storing and deploying repository objects](#) for more information.

To deploy the current stream (File menu method)

1. On the main menu, click:
File > Store > Deploy
2. Choose the deployment type and complete the rest of the dialog box as necessary.
3. Click Deploy as stream to deploy the stream for use with IBM SPSS Modeler Advantage or IBM SPSS Collaboration and Deployment Services.
4. Click Store. For more information, click Help.
5. Continue from "Completing the deployment process."

To deploy the current stream (Tools menu method)

1. On the main menu, click:
Tools > Stream Properties > Deployment
2. Choose the deployment type, complete the rest of the Deployment tab as necessary, and click Store. See the topic [Stream Deployment Options](#) for more information.

Completing the deployment process

1. Specify connection settings to the repository if necessary. See the topic [Connecting to the Repository](#) for more information. For specific port, password, and other connection details, contact your local system administrator.
2. In the Repository: Store dialog box, choose the folder where you want to store the object, specify any other information you want to record, and click Store. See the topic [Setting Object Properties](#) for more information.
 - [Stream Deployment dialog](#)
 - [Stream Deployment Options](#)
 - [The Scoring Branch](#)

Stream Deployment dialog

On this dialog you specify whether you want to deploy the stream for scoring purposes only, or for model refresh as well. If you choose scoring only, you just need to designate a terminal node as the scoring node. For model refresh, you need to designate additional nodes to enable the model to be refreshed.

You also specify on this screen whether you want to deploy as a stream (for use with IBM® SPSS® Modeler Advantage or IBM SPSS Collaboration and Deployment Services).

Deployment type. Choose how you want to deploy the stream. All streams require a designated scoring node before they can be deployed; additional requirements and options depend on the deployment type.

Note: The Association Rules, STP, and TCM modeling nodes do not support the Model Evaluation or Champion Challenger steps in IBM SPSS Collaboration and Deployment Services.

- <none>. The stream will not be deployed to the repository. All options are disabled except stream description preview.

- Scoring Only. The stream is deployed to the repository when you click the Store button. Data can be scored using the node that you designate in the Scoring node field.
- Model Refresh. Same as for Scoring Only but in addition, the model can be updated in the repository using the objects that you designate in the Modeling node and Model nugget fields. Note that automatic model refresh is not supported by default in IBM SPSS Collaboration and Deployment Services, so you must choose this deployment type if you want to use this feature when running a stream from the repository. See [Model Refresh](#) for more information.

Scoring node. Select a graph, output or export node to identify the stream branch to be used for scoring the data. While the stream can actually contain any number of valid branches, models, and terminal nodes, one and only one scoring branch must be designated for purposes of deployment. This is the most basic requirement to deploy any stream.

Scoring Parameters. Allows you to specify parameters that can be modified when the scoring branch is run. See [Scoring and modeling parameters](#) for more information.

Modeling node. For model refresh, specifies the modeling node used to regenerate or update the model in the repository. Must be a modeling node of the same type as that specified for Model nugget.

Model Build Parameters. Allows you to specify parameters that can be modified when the modeling node is run. See [Scoring and modeling parameters](#) for more information.

Model nugget. For model refresh, specifies the model nugget that will be updated or regenerated each time the stream is updated in the repository (typically as part of a scheduled job). The model must be located on the scoring branch. While multiple models may exist on the scoring branch, only one can be designated. Note that when the stream is initially created this may effectively be a placeholder model that is updated or regenerated as new data is available.

Deploy as stream. Click this option if you want to use the stream with IBM SPSS Modeler Advantage or IBM SPSS Collaboration and Deployment Services.

Check. Click this button to check whether this is a valid stream for deployment. All streams must have a designated scoring node before they can be deployed. Error messages are displayed if these conditions are not satisfied.

Store. Deploys the stream if it is valid. If not, an error message is displayed. Click the Fix button, correct the error, and try again.

Preview Stream Description. Enables you to view the contents of the stream description that IBM SPSS Modeler creates for the stream. See [Stream descriptions](#) for more information.

Note: The Association Rules, STP, and TCM modeling nodes do not support the Model Evaluation or Champion Challenger steps in IBM SPSS Collaboration and Deployment Services.

Stream Deployment Options

The Deployment tab in the Stream Options dialog box allows you to specify options for deploying the stream.

When you deploy a stream, it's stored in the repository as a file with the extension .str.

Deploying a stream allows you to take advantage of the additional functionality available with IBM® SPSS® Collaboration and Deployment Services, such as multi-user access, automated scoring, model refresh, and Champion Challenger analysis.

Note: The Association Rules, STP, and TCM modeling nodes do not support the Model Evaluation or Champion Challenger steps in IBM SPSS Collaboration and Deployment Services.

From the Deployment tab, you can also preview the stream description that IBM SPSS Modeler creates for the stream. See the topic [Stream descriptions](#) for more information.

Deployment type. Choose how you want to deploy the stream. All streams require a designated scoring node before they can be deployed; additional requirements and options depend on the deployment type.

Note: The Association Rules, STP, and TCM modeling nodes do not support the Model Evaluation or Champion Challenger steps in IBM SPSS Collaboration and Deployment Services.

- <none>. The stream will not be deployed to the repository. All options are disabled except stream description preview.
- Scoring Only. The stream is deployed to the repository when you click the Store button. Data can be scored using the node that you designate in the Scoring node field.
- Model Refresh. Same as for Scoring Only but in addition, the model can be updated in the repository using the objects that you designate in the Modeling node and Model nugget fields. Note that automatic model refresh is not supported by default in IBM SPSS Collaboration and Deployment Services, so you must choose this deployment type if you want to use this feature when running a stream from the repository. See [Model Refresh](#) for more information.

Scoring node. Select a graph, output or export node to identify the stream branch to be used for scoring the data. While the stream can actually contain any number of valid branches, models, and terminal nodes, one and only one scoring branch must be designated for purposes of deployment. This is the most basic requirement to deploy any stream.

Scoring Parameters. Allows you to specify parameters that can be modified when the scoring branch is run. See [Scoring and modeling parameters](#) for more information.

Modeling node. For model refresh, specifies the modeling node used to regenerate or update the model in the repository. Must be a modeling node of the same type as that specified for Model nugget.

Model Build Parameters. Allows you to specify parameters that can be modified when the modeling node is run. See [Scoring and modeling parameters](#) for more information.

Model nugget. For model refresh, specifies the model nugget that will be updated or regenerated each time the stream is updated in the repository (typically as part of a scheduled job). The model must be located on the scoring branch. While multiple models may exist on the scoring branch, only one can be designated. Note that when the stream is initially created this may effectively be a placeholder model that is updated or regenerated as new data is available.

Check. Click this button to check whether this is a valid stream for deployment. All streams must have a designated scoring node before they can be deployed. Error messages are displayed if these conditions are not satisfied.

Store. Deploys the stream if it is valid. If not, an error message is displayed. Click the Fix button, correct the error, and try again.

Preview Stream Description. Enables you to view the contents of the stream description that IBM SPSS Modeler creates for the stream. See [Stream descriptions](#) for more information.

Note: The Association Rules, STP, and TCM modeling nodes do not support the Model Evaluation or Champion Challenger steps in IBM SPSS Collaboration and Deployment Services.

- [Scoring and modeling parameters](#)

Scoring and modeling parameters

When deploying a stream to IBM® SPSS® Collaboration and Deployment Services, you can choose which parameters can be viewed or edited each time the model is updated or scored. For example, you might specify maximum and minimum values, or some other value that may be subject to change each time a job is run.

1. To make a parameter visible so it can be viewed or edited after the stream is deployed, select it from the list in the Scoring Parameters dialog box.

The list of available parameters is defined on the Parameters tab in the stream properties dialog box. See the topic [Setting Stream and Session Parameters](#) for more information.

The Scoring Branch

If you are deploying a stream, one branch of the stream must be designated as the **scoring branch** (that is, the one containing the scoring node). When you designate a branch as the scoring branch, that branch is highlighted on the stream canvas, as is the model link to the nugget on the scoring branch. This visual representation is particularly useful in complex streams with multiple branches, where the scoring branch might not be immediately obvious.

Note: Only one stream branch can be designated as the scoring branch.

If the stream already had a scoring branch defined, the newly-designated branch replaces it as the scoring branch. You can set the color of the scoring branch indication by means of a Custom Color option. See the topic [Setting display options](#) for more information.

You can show or hide the scoring branch indication by means of the Show/hide stream markup toolbar button.

Figure 1. Show/hide stream markup toolbar button

- [Identifying the Scoring Branch for Deployment](#)
- [Model Refresh](#)
- [How the Refresh Model is Selected](#)
- [Checking a scoring branch for errors](#)

Identifying the Scoring Branch for Deployment

You can designate the scoring branch either from the pop-up menu of a terminal node, or from the Tools menu. If you use the pop-up menu, the scoring node is set automatically in the Deployment tab of the stream properties.

To designate a branch as the scoring branch (pop-up menu)

1. Connect the model nugget to a terminal node (a processing or output node downstream from the nugget).
2. Right-click the terminal node.
3. On the menu, click Use as Scoring Branch.

To designate a branch as the scoring branch (Tools menu)

1. Connect the model nugget to a terminal node (a processing or output node downstream from the nugget).
2. On the main menu, click:
Tools > Stream Properties > Deployment
3. On the Deployment type list, click Scoring Only or Model Refresh as required. See the topic [Stream Deployment Options](#) for more information.
4. Click the Scoring node field and select a terminal node from the list.
5. Click OK.

Model Refresh

Model refresh is the process of rebuilding an existing model in a stream using newer data. The stream itself does not change in the repository. For example, the algorithm type and stream-specific settings remain the same, but the model is retrained on new data, and updated if the new version of the model works better than the old one.

Only one model nugget in a stream can be set to refresh--this is known as the **refresh model**. If you click the Model Refresh option on the Deployment tab of the stream properties (see [Stream Deployment Options](#)), the model nugget that you designate at that time becomes the refresh model. You can also designate a model as the refresh model from the pop-up menu of a model nugget. The nugget must already be on the scoring branch for this to be possible.

If you turn off the "refresh model" status of a nugget, this is equivalent to setting the deployment type of the stream to Scoring Only, and the Deployment tab of the stream properties dialog box is updated accordingly. You can turn this status on and off by means of the Use as Refresh Model option on the pop-up menu of the nugget on the current scoring branch.

Removing the model link of a nugget on the scoring branch also removes the "refresh model" status of the nugget. You can undo removal of the model link by means of the Edit menu or the toolbar; doing so also reinstates the "refresh model" status of the nugget.

How the Refresh Model is Selected

As well as the scoring branch, the link to the refresh model is also highlighted in the stream. The model nugget chosen as the refresh model, and therefore the link that is highlighted, depends on how many nuggets are in the stream.

Single Model in Stream

If a single linked model nugget is on the scoring branch when it is identified as such, that nugget becomes the refresh model for the stream.

Multiple Models in Stream

If there is more than one linked nugget in the stream, the refresh model is chosen as follows.

If a model nugget has been defined in the Deployment tab of the stream properties dialog box and is also in the stream, then that nugget becomes the refresh model.

If no nugget has been defined in the Deployment tab, or if one has been defined but is not on the scoring branch, then the nugget closest to the terminal node becomes the refresh model.

If you subsequently deselect all model links as refresh links, only the scoring branch is highlighted, not the links. The deployment type is set to Scoring Only.

Note: You can choose to set one of the links to Replace status, but not the other one. In this case, the model nugget chosen as the refresh model is the one that has a refresh link and which is closest to the terminal node when the scoring branch is designated.

No Models in Stream

If there are no models in the stream, or only models with no model links, the deployment type is set to Scoring Only.

Checking a scoring branch for errors

When you designate the scoring branch, it is checked for errors.

If an error is found, the scoring branch is highlighted in the scoring branch error color, and an error message is displayed. You can set the error color by means of a Custom Color option. See the topic [Setting display options](#) for more information.

If an error is found, proceed as follows:

1. Correct the error according to the contents of the error message.
2. On the main menu, click:
Tools > Stream Properties > Deployment
and click Check.
3. If necessary, repeat this process until no errors are found.

Saving streams to IBM Cloud Pak for Data

You can save streams to an IBM Cloud Pak for Data server where you can open them as flows and take advantage of the many features available in Cloud Pak for Data.

Cloud Pak for Data simplifies how you collect, organize, and analyze data and infuse AI across your business. Seamlessly integrate a broad range of data and AI software, leading governance and security, and a unified experience for collaboration. For more information, see <https://www.ibm.com/products/cloud-pak-for-data>. Contact your IBM representative if you're interested in Cloud Pak for Data.

To configure the server connection

These instructions are based on Firefox. Steps may vary based on which web browser you're using.

1. Open Firefox, paste your Cloud Pak for Data URL in the address bar, and press Enter.

You can obtain the URL by opening the Cloud Pak for Data web client and looking at the URL in your browser address bar (it's everything up to and not including /zen). By default, the URL takes the form `https://<namespace>-cpd-<namespace>.apps.<cluster-subdomain>`

where:

- `<namespace>` is your namespace (such as `ab123`).
- `<cluster-subdomain>` is the subdomain name of your cluster (such as `ocp454x86-aqt-mycompany.com`)

In this example, the URL is `https://ab123-cpd-ab123.apps.ocp454x86-aqt-mycompany.com`

For more information about the Cloud Pak for Data URL, see [the Cloud Pak for Data documentation](#).

2. Click the yellow padlock icon to the left of the address bar, then click the arrow beside Connection not secure.

3. Click More Information. The Page Info dialog opens.

4. In the Page Info dialog, go to Security and click View Certificate.

5. Scroll down to Miscellaneous and download the PEM certification file.

6. From the command line, import the certification file to your IBM® SPSS® Modeler client directory as follows:

On Windows:

```
"%JAVA_HOME%\bin\keytool.exe -importcert -trustcacerts -file <Certification file absolute path> -alias <alias> -keystore "<Modeler client installation path>"\jre\lib\security\cacerts
```

On macOS:

```
"%JAVA_HOME%/bin/keytool -importcert -trustcacerts -file <Certification file absolute path> -alias <alias> -keystore "<Modeler client installation path>"/jre/lib/security/cacerts
```

When prompted, enter `changeit` for the keystore password and enter `yes` to trust the certification.

7. On the main menu in IBM SPSS Modeler, click:

Tools > IBM Cloud Pak for Data Server > IBM Cloud Pak for Data Server Connections...

8. Specify connection settings to the server. Use the same URL you used in step 1. If you're not sure which username or password to use, contact your local system administrator. If you select the API Key login method, use the following method to obtain the URL:

- Log on to the Cloud Pak for Data cluster and run the command `oc get routes -n ibm-common-services`, then copy the `HOST/PORT` value for `cp-console`. In the following example, the URL is `https://cp-console.apps.wml46x04.cp.myserver.com`.

NAME	HOST/PORT	PATH	SERVICES	PORT
TERMINATION	WILDCARD			
cp-console	cp-console.apps.wml46x04.cp.myserver.com		icp-management-ingress	https
reencrypt/Redirect	None			
cp-proxy	cp-proxy.apps.wml46x04.cp.myserver.com		nginx-ingress-controller	https
passthrough/Redirect	None			

9. Click Connect to connect to the server.

To save streams to Cloud Pak for Data

1. On the main menu, click:

File...>Store as Flow.... Streams are referred to as *flows* after they're migrated to Cloud Pak for Data.

Alternatively, you can also right-click in the streams manager pane and select Store as Flow...

2. Choose the Cloud Pak for Data Server you configured previously. Then select the project to which you want to save the flow.

Tip: You can also select multiple streams to save at one time. On the main menu, click Tools...>IBM Cloud Pak for Data Server...>Bulk uploading streams to IBM Cloud Pak for Data Server. You'll then be prompted to select streams from your local file system, select a server, and select a project.

Exporting to external applications

- [About Exporting to External Applications](#)
- [Opening a Stream in IBM SPSS Modeler Advantage](#)

About Exporting to External Applications

IBM® SPSS® Modeler provides a number of mechanisms to export the entire data mining process to external applications, so that the work you do to prepare data and build models can be used to your advantage outside of IBM SPSS Modeler as well.

The previous section showed how you can deploy streams to an IBM SPSS Collaboration and Deployment Services repository to take advantage of its multi-user access, job scheduling and other features. In a similar way, IBM SPSS Modeler streams can also be used in conjunction with:

- IBM SPSS Modeler Advantage
- Applications that can import and export files in PMML format

For more information about using streams with IBM SPSS Modeler Advantage, see [Opening a Stream in IBM SPSS Modeler Advantage](#).

For information on exporting and importing models as PMML files, making it possible to share models with any other applications that support this format, see [Importing and exporting models as PMML](#).

Opening a Stream in IBM SPSS Modeler Advantage

IBM® SPSS® Modeler streams can be used in conjunction with the thin-client application IBM SPSS Modeler Advantage. While it is possible to create customized applications entirely within IBM SPSS Modeler Advantage, you can also use a stream already created in IBM SPSS Modeler as the basis of an application workflow.

To open a stream in IBM SPSS Modeler Advantage:

1. Deploy the stream in the IBM SPSS Collaboration and Deployment Services repository, being sure to click the Deploy as stream option. See the topic [Deploying streams](#) for more information.
2. Click the Open in IBM SPSS Modeler Advantage toolbar button, or from the main menu click:

File...>Open in IBM SPSS Modeler Advantage

1. Specify connection settings to the repository if necessary. See the topic [Connecting to the Repository](#) for more information. For specific port, password, and other connection details, contact your local system administrator.

Note: The repository server must also have the IBM SPSS Modeler Advantage software installed.

1. In the Repository: Store dialog, choose the folder where you want to store the object, specify any other information you want to record, and click the Store button. See the topic [Setting Object Properties](#) for more information.

Doing so launches IBM SPSS Modeler Advantage with the stream already open. The stream is closed in IBM SPSS Modeler.

Projects and reports

- [Introduction to Projects](#)
 - [Building a Project](#)
 - [Generating a Report](#)
-

Introduction to Projects

A **project** is a group of files related to a data mining task. Projects include data streams, graphs, generated models, reports, and anything else that you have created in IBM® SPSS® Modeler. At first glance, it may seem that IBM SPSS Modeler projects are simply a way to organize output, but they are actually capable of much more. Using projects, you can:

- Annotate each object in the project file.
- Use the CRISP-DM methodology to guide your data mining efforts. Projects also contain a CRISP-DM Help system that provides details and real-world examples on data mining with CRISP-DM.
- Add non-IBM SPSS Modeler objects to the project, such as a PowerPoint slide show used to present your data mining goals or white papers on the algorithms that you plan to use.
- Produce both comprehensive and simple update reports based on your annotations. These reports can be generated in HTML for easy publishing on your organization's intranet.

Note: If the project pane is not visible in the IBM SPSS Modeler window, click Project on the View menu.

Objects that you add to a project can be viewed in two ways: **Classes view** and **CRISP-DM view**. Anything that you add to a project is added to both views, and you can toggle between views to create the organization that works best.

- [CRISP-DM View](#)
- [Classes View](#)

Related information

- [CRISP-DM View](#)
 - [Classes View](#)
 - [Building a Project](#)
-

CRISP-DM View

By supporting the Cross-Industry Standard Process for Data Mining (CRISP-DM), IBM® SPSS® Modeler projects provide an industry-proven and non-proprietary way of organizing the pieces of your data mining efforts. CRISP-DM uses six phases to describe the process from start (gathering business requirements) to finish (deploying your results). Even though some phases do not typically involve work in IBM SPSS Modeler, the project pane includes all six phases so that you have a central location for storing and tracking all materials associated with the project. For example, the Business Understanding phase typically involves gathering requirements and meeting with colleagues to determine goals rather than working with data in IBM SPSS Modeler. The project pane allows you to store your notes from such meetings in the *Business Understanding* folder for future reference and inclusion in reports.

The CRISP-DM view in the project pane is also equipped with its own Help system to guide you through the data mining life cycle. From IBM SPSS Modeler, this help can be accessed by clicking CRISP-DM Help on the Help menu.

Note: If the project pane is not visible in the window, click Project on the View menu.

- [Setting the Default Project Phase](#)

Related information

- [Introduction to Projects](#)
- [Classes View](#)
- [Building a Project](#)

- [Setting the Default Project Phase](#)
-

Setting the Default Project Phase

Objects added to a project are added to a default phase of CRISP-DM. This means that you need to organize objects manually according to the data mining phase in which you used them. It is wise to set the default folder to the phase in which you are currently working.

To select which phase to use as your default:

1. In CRISP-DM view, right-click the folder for the phase to set as the default.
2. On the menu, click Set as Default.

The default folder is displayed in bold type.

Related information

- [CRISP-DM View](#)
-

Classes View

The Classes view in the project pane organizes your work in IBM® SPSS® Modeler categorically by the types of objects created. Saved objects can be added to any of the following categories:

- Streams
- Nodes
- Models
- Tables, graphs, reports
- Other (non-IBM SPSS Modeler files, such as slide shows or white papers relevant to your data mining work)

Adding objects to the Classes view also adds them to the default phase folder in the CRISP-DM view.

Note: If the project pane is not visible in the window, click Project on the View menu.

Related information

- [Introduction to Projects](#)
 - [Building a Project](#)
 - [CRISP-DM View](#)
 - [Setting the Default Project Phase](#)
-

Building a Project

A project is essentially a file containing references to all of the files that you associate with the project. This means that project items are saved both individually and as a reference in the project file (.cpj). Because of this referential structure, note the following:

- Project items must first be saved individually before being added to a project. If an item is unsaved, you will be prompted to save it before adding it to the current project.
 - Objects that are updated individually, such as streams, are also updated in the project file.
 - Manually moving or deleting objects (such as streams, nodes, and output objects) from the file system will render links in the project file invalid.
- [Creating a New Project](#)
 - [Adding to a Project](#)
 - [Transferring Projects to the IBM SPSS Collaboration and Deployment Services Repository](#)
 - [Setting Project Properties](#)
 - [Annotating a Project](#)
 - [Object Properties](#)
 - [Closing a Project](#)

Related information

- [Introduction to Projects](#)
 - [Adding to a Project](#)
 - [Creating a New Project](#)
 - [Closing a Project](#)
-

Creating a New Project

New projects are easy to create in the IBM® SPSS® Modeler window. You can either start building one, if none is open, or you can close an existing project and start from scratch.

On the main menu, click:

File > Project > New Project...

Related information

- [Building a Project](#)
-

Adding to a Project

Once you have created or opened a project, you can add objects, such as data streams, nodes, and reports, using several methods.

Adding Objects from the Managers

Using the managers in the upper right corner of the IBM® SPSS® Modeler window, you can add streams or output.

1. Select an object, such as a table or a stream, from one of the manager tabs.
2. Right-click, and click Add to Project.
If the object has been previously saved, it will automatically be added to the appropriate objects folder (in Classes view) or to the default phase folder (in CRISP-DM view).
3. Alternatively, you can drag and drop objects from the managers to the project pane.

Note: You may be asked to save the object first. When saving, be sure that Add file to project is selected in the Save dialog box. This will automatically add the object to the project after you save it.

Adding Nodes from the Canvas

You can add individual nodes from the stream canvas by using the Save dialog box.

1. Select a node on the canvas.
2. Right-click, and click Save Node. Alternatively, on the main menu click:
Edit > Node > Save Node...
3. In the Save dialog box, select Add file to project.
4. Create a name for the node and click Save.

This saves the file and adds it to the project. Nodes are added to the *Nodes* folder in Classes view and to the default phase folder in CRISP-DM view.

Adding External Files

You can add a wide variety of non-IBM SPSS Modeler objects to a project. This is useful when you are managing the entire data mining process within IBM SPSS Modeler. For example, you can store links to data, notes, presentations, and graphics in a project. In CRISP-DM view, external files can be added to the folder of your choice. In Classes view, external files can be saved only to the *Other* folder.

To add external files to a project:

1. Drag files from the desktop to the project.
or
2. Right-click the target folder in CRISP-DM or Classes view.
3. On the menu, click Add to Folder.
4. Select a file in the dialog box and click Open.

This will add a reference to the selected object inside IBM SPSS Modeler projects.

Related information

- [Setting the Default Project Phase](#)
 - [Building a Project](#)
-

Transferring Projects to the IBM SPSS Collaboration and Deployment Services Repository

You can transfer an entire project, including all component files, to the IBM® SPSS® Collaboration and Deployment Services Repository in one step. Any objects that are already in the target location will not be moved. This feature also works in reverse: you can transfer entire projects from the IBM SPSS Collaboration and Deployment Services Repository to your local file system.

Transferring a Project

Make sure that the project you want to transfer is open in the project pane.

To transfer a project:

1. Right-click the root project folder and click Transfer Project.
 2. If prompted, log in to IBM SPSS Collaboration and Deployment Services Repository.
 3. Specify the new location for the project and click OK.
-

Setting Project Properties

You can customize a project's contents and documentation by using the project properties dialog box. To access project properties:

1. Right-click an object or folder in the project pane and click Project Properties.
2. Click the Project tab to specify basic project information.

Created. Shows the project's creation date (not editable).

Summary. You can enter a summary for your data mining project that will be displayed in the project report.

Contents. Lists the type and number of components referenced by the project file (not editable).

Save unsaved object as. Specifies whether unsaved objects should be saved to the local file system, or stored in the repository. See the topic [About the IBM SPSS Collaboration and Deployment Services Repository](#) for more information.

Update object references when loading project. Select this option to update the project's references to its components. *Note:* The files added to a project are not saved in the project file itself. Rather, a reference to the files is stored in the project. This means that moving or deleting a file will remove that object from the project.

Related information

- [Building a Project](#)
 - [Annotating a Project](#)
-

Annotating a Project

The project pane provides a number of ways to annotate your data mining efforts. Project-level annotations are often used to track "big-picture" goals and decisions, while folder or node annotations provide additional detail. The Annotations tab provides enough space for you to document project-level details, such as the exclusion of data with irretrievable missing data or promising hypotheses formed during data exploration.

To annotate a project:

1. Select the project folder in either CRISP-DM or Classes view.
 2. Right-click the folder and click Project Properties.
 3. Click the Annotations tab.
 4. Enter keywords and text to describe the project.
- [Folder Properties and Annotations](#)

Related information

- [Building a Project](#)
 - [Setting Project Properties](#)
 - [Folder Properties and Annotations](#)
-

Folder Properties and Annotations

Individual project folders (in both CRISP-DM and Classes view) can be annotated. In CRISP-DM view, this can be an extremely effective way to document your organization's goals for each phase of data mining. For example, using the annotation tool for the *Business Understanding* folder, you can include documentation such as "The business objective for this study is to reduce churn among high-value customers." This text could then be automatically included in the project report by selecting the **Include in report** option.

To annotate a folder:

1. Select a folder in the project pane.
2. Right-click the folder and click **Folder Properties**.

In CRISP-DM view, folders are annotated with a summary of the purpose of each phase as well as guidance on completing the relevant data mining tasks. You can remove or edit any of these annotations.

Name. This area displays the name of the selected field.

Tooltip text. Create custom ToolTips that will be displayed when you hover the mouse pointer over a project folder. This is useful in CRISP-DM view, for example, to provide a quick overview of each phase's goals or to mark the status of a phase, such as "In progress" or "Complete."

Annotation field. Use this field for more lengthy annotations that can be collated in the project report. The CRISP-DM view includes a description of each data mining phase in the annotation, but you should feel free to customize this for your own project.

Include in report. To include the annotation in reports, select **Include in report**.

Related information

- [Building a Project](#)
 - [Annotating a Project](#)
-

Object Properties

You can view object properties and choose whether to include individual objects in the project report. To access object properties:

1. Right-click an object in the project pane.
2. On the menu, click **Object Properties**.

Name. This area lists the name of the saved object.

Path. This area lists the location of the saved object.

Include in report. Select this option to include the object details in a generated report.

Related information

- [Building a Project](#)
 - [Introduction to Projects](#)
-

Closing a Project

When you exit IBM® SPSS® Modeler or open a new project, the existing project file (.cpj) is closed.

Some files associated with the project (such as streams, nodes or graphs) may still be open. If you want to leave these files open, reply **No** to the message ... Do you want to save and close these files?

If you modify and save any associated files after the close of a project, these updated versions will be included in the project the next time you open it. To prevent this behavior, remove the file from the project or save it under a different filename.

Related information

- [Building a Project](#)
-

Generating a Report

One of the most useful features of projects is the ability to generate reports based on the project items and annotations. This is a critical component of effective data mining, as discussed throughout the CRISP-DM methodology. You can generate a report directly into one of several file types or to an output window on the screen for immediate viewing. From there, you can print, save, or view the report in a web browser. You can distribute saved reports to others in your organization.

Reports are often generated from project files several times during the data mining process for distribution to those involved in the project. The report culls information about the objects referenced from the project file as well as any annotations created. You can create reports based on either the Classes view or CRISP-DM view.

To generate a report:

1. Select the project folder in either CRISP-DM or Classes view.
2. Right-click the folder and click Project Report.
3. Specify the report options and click Generate Report.

The options in the report dialog box provide several ways to generate the type of report you need:

Output name. Specify the name of the output window if you choose to send the output of the report to the screen. You can specify a custom name or let IBM® SPSS® Modeler automatically name the window for you.

Output to screen. Select this option to generate and display the report in an output window. Note that you have the option to export the report to various file types from the output window.

Output to file. Select this option to generate and save the report as a file of the type specified in the File type list.

Filename. Specify a filename for the generated report. Files are saved by default to the IBM SPSS Modeler *|bin* directory. Use the ellipsis button (...) to specify a different location.

File type. Available file types are:

- **HTML document.** The report is saved as a single HTML file. If your report contains graphs, they are saved as PNG files and are referenced by the HTML file. When publishing your report on the Internet, make sure to upload both the HTML file and any images it references.
- **Text document.** The report is saved as a single text file. If your report contains graphs, only the filename and path references are included in the report.
- **Microsoft Word document.** The report is saved as a single document, with any graphs embedded directly into the document.
- **Microsoft Excel document.** The report is saved as a single spreadsheet, with any graphs embedded directly into the spreadsheet.
- **Microsoft PowerPoint document.** Each phase is shown on a new slide. Any graphs are embedded directly into the PowerPoint slides.
- **Output object.** When opened in IBM SPSS Modeler, this file (.cou) is the same as the Output to screen option in the Report Format group.

Note: To export to a Microsoft Office file, you must have the corresponding application installed.

Title. Specify a title for the report.

Report structure. Select either CRISP-DM or Classes. CRISP-DM view provides a status report with "big-picture" synopses as well as details about each phase of data mining. Classes view is an object-based view that is more appropriate for internal tracking of data and streams.

Author. The default user name is displayed, but you can change it.

Report includes. Select a method for including objects in the report. Select all folders and objects to include all items added to the project file. You can also include items based on whether Include in Report is selected in the object properties. Alternatively, to check on unreported items, you can choose to include only items marked for exclusion (where Include in Report is not selected).

Select. This option allows you to provide project updates by selecting only recent items in the report. Alternatively, you can track older and perhaps unresolved issues by setting parameters for old items. Select all items to dismiss time as a parameter for the report.

Order by. You can select a combination of the following object characteristics to order them within a folder:

- **Type.** Group objects by type.
- **Name.** Organize objects alphabetically.
- **Added date.** Sort objects using the date they were added to the project.

Related information

- [Saving and Exporting Generated Reports](#)

Saving and Exporting Generated Reports

A report generated to the screen is displayed in a new output window. Any graphs included in the report are displayed as in-line images.

Report Terminology

The total number of nodes in each stream is listed within the report. The numbers are shown under the following headings, which use IBM® SPSS® Modeler terminology, not CRISP-DM terminology:

- **Data readers.** Source nodes.
- **Data writers.** Export nodes.
- **Model builders.** Build, or Modeling, nodes.
- **Model appliers.** Generated models, also known as nuggets.
- **Output builders.** Graph or Output nodes.
- **Other.** Any other nodes related to the project. For example, those available on the Field Ops tab or Record Ops tab on the Nodes Palette.

To save a report:

1. On the File menu, click Save.
2. Specify a filename.
The report is saved as an output object.

To export a report:

3. On the File menu, click Export and the file type to which you want to export.
4. Specify a filename.

The report is saved in the format you chose.

You can export to the following file types:

- HTML
- Text
- Microsoft Word
- Microsoft Excel
- Microsoft PowerPoint

Note: To export to a Microsoft Office file, you must have the corresponding application installed.

Use the buttons at the top of the window to:

- Print the report.
- View the report as HTML in an external web browser.

- [Customizing the Nodes Palette](#)

Customizing IBM SPSS Modeler options

There are a number of operations you can perform to customize IBM® SPSS® Modeler to your needs. Primarily, this customization consists of setting specific user options such as memory allocation, default directories, and the use of sound and color. You can also customize the Nodes palette located at the bottom of the IBM SPSS Modeler window.

Related information

- [Setting IBM SPSS Modeler options](#)
 - [Customizing the Nodes Palette](#)
-

Setting IBM SPSS Modeler options

There are several ways to customize and set options for IBM® SPSS® Modeler:

- Set system options, such as memory usage and locale, by clicking System Options on the Tools > Options menu.
- Set user options, such as display fonts and colors, by clicking User Options on the Tools > Options menu.
- Specify the location of applications that work with IBM SPSS Modeler by clicking Helper Applications on the Tools > Options menu.
- Specify the default directories used in IBM SPSS Modeler by clicking Set Directory or Set Server Directory on the File menu.

You can also set options that apply to some or all of your streams. See the topic [Setting options for streams](#) for more information.

- [System Options](#)
 - [Setting Default Directories](#)
 - [Setting user options](#)
-

System Options

You can specify the preferred language or locale for IBM® SPSS® Modeler by clicking System Options on the Tools > Options menu. Here you can also set the maximum memory usage for SPSS Modeler, and specify how often to automatically save streams. Note that changes made in this dialog box will not take effect until you restart SPSS Modeler.

Maximum memory. Select to impose a limit in megabytes on IBM SPSS Modeler's memory usage. On some platforms, SPSS Modeler limits its process size to reduce the toll on computers with limited resources or heavy loads. If you are dealing with large amounts of data, this may cause an "out of memory" error. You can ease memory load by specifying a new threshold.

For example, attempting to display a very large decision tree may cause a memory error. In this case, we recommend that you increase the memory to the high value such as 4096Mb. In cases such as these, where you are likely to be processing very large amounts of data, after you increase the memory allowance shut down SPSS Modeler and start it from a command line to ensure the maximum amount of memory is used when processing your data.

To start from a command line (assuming SPSS Modeler is installed in the default location), in a Command Prompt window, enter the following:

```
C:\Program Files\IBM\SPSS\Modeler\18.4.0\bin\modelerclient.exe" -J-Xss4096M
```

Note: The maximum memory threshold you can specify is 58368Mb due a Java constraint.

Use system locale. This option is selected by default and set to English (United States). Deselect to specify another language from the list of available languages and locales.

Stream auto save interval (minutes). Specify how often you want SPSS Modeler to save streams automatically. The maximum is 60 minutes, minimum is 1 minute, and default is 5 minutes.

- [Managing Memory](#)
-

Managing Memory

In addition to the Maximum memory setting specified in the System Options dialog box, there are several ways you can optimize memory usage:

- Adjust the Maximum members for nominal fields option in the stream properties dialog box. This option specifies a maximum number of members for nominal fields after which the measurement level of the field becomes *Typeless*. See the topic [Setting general options for streams](#) for more information.
- Force IBM® SPSS® Modeler to free up memory by clicking in the lower right corner of the window where the memory that IBM SPSS Modeler is using and the amount allocated are displayed (xxMB / xxMB). Clicking this region turns it a darker shade, after which memory allocation figures will drop. Once the region returns to its regular color, IBM SPSS Modeler has freed up all the memory possible.

Setting Default Directories

You can specify the default directory used for file browsers and output by selecting Set Directory or Set Server Directory from the File menu.

- **Set Directory.** You can use this option to set the working directory. The default working directory is based on the installation path of your version of IBM® SPSS® Modeler or from the command line path used to launch IBM SPSS Modeler. In local mode, the working directory is the path used for all client-side operations and output files (if they are referenced with relative paths).
- **Set Server Directory.** The Set Server Directory option on the File menu is enabled whenever there is a remote server connection. Use this option to specify the default directory for all server files and data files specified for input or output. The default server directory is `$CLEO/data`, where `$CLEO` is the directory in which the Server version of IBM SPSS Modeler is installed. Using the command line, you can also override this default by using the `-server_directory` flag with the `modelerclient` command line argument.

Related information

- [Setting IBM SPSS Modeler options](#)

Setting user options

You can set general options for IBM® SPSS® Modeler by selecting User Options from the Tools > Options menu. These options apply to all streams used in IBM SPSS Modeler.

The following types of options can be set by clicking the corresponding tab:

- Notification options, such as model overwriting and error messages.
- Display options, such as graph and background colors.
- Syntax color display options.
- PMML export options used when exporting models to Predictive Model Markup Language (PMML).
- User or author information, such as your name, initials, and e-mail address. This information may be displayed on the Annotations tab for nodes and for other objects that you create.
- Switching between traditional mode and Analytic Server mode.

To set stream-specific options, such as decimal separators, time and data formats, optimization, stream layout, and stream scripts, use the Stream Properties dialog box, available from the File and Tools menus.

- [Setting Notification Options](#)
- [Setting display options](#)
- [Setting Syntax Display Options](#)
- [Setting PMML Export Options](#)
- [Setting User Information](#)
- [Setting the mode](#)

Setting Notification Options

Using the Notifications tab of the User Options dialog box, you can set various options regarding the occurrence and type of warnings and confirmation windows in IBM® SPSS® Modeler. You can also specify the behavior of the Outputs and Models tabs in the managers pane when new output and models are generated.

Show stream execution feedback dialog Select to display a dialog box, that includes a progress indicator, when a stream has been running for three seconds. The dialog box also includes details of the output objects created by the stream.

- Close dialog upon completion By default, the dialog box closes when the stream finishes running. Clear this check box if you want the dialog box to remain visible when the stream finishes.

Warn when a node overwrites a file Select to warn with an error message when node operations overwrite an existing file.

Warn when a node overwrites a database table Select to warn with an error message when node operations overwrite an existing database table.

Sound Notifications

Use the list to specify whether sounds notify you when an event or error occurs. There are a number of sounds available. Use the Play (loudspeaker) button to play a selected sound. Use the ellipsis button (...) to browse for and select a sound.

Note: The .wav files used to create sounds in IBM SPSS Modeler are stored in the /media/sounds directory of your installation.

- Mute all sounds Select to turn off sound notification for all events.

Visual Notifications

The options in this group are used to specify the behavior of the Outputs and Models tabs in the managers pane at the top right of the display when new items are generated. Select New Model or New Output from the list to specify the behavior of the corresponding tab.

The following option is available for New Model:

Replace previous model If selected (default), overwrites an existing model from this stream in the Models tab and on the stream canvas. If this box is unchecked, the model is added to the existing models on the tab and the canvas. Note that this setting is overridden by the model replacement setting on a model link.

The following option is available for New Output:

Warn when outputs exceed [n] Select whether to display a warning when the number of items on the Outputs tab exceeds a prespecified quantity. The default quantity is 20; however, you can change this if needed.

The following options are available in all cases:

Select tab Choose whether to switch to the Outputs or Models tab when the corresponding object is generated while the stream runs.

- Select Always to switch to the corresponding tab in the managers pane.
- Select If generated by current stream to switch to the corresponding tab only for objects generated by the stream currently visible in the canvas.
- Select Never to restrict the software from switching to the corresponding tab to notify you of generated outputs or models.

Flash tab Select whether to flash the Outputs or Models tab in the managers pane when new outputs or models have been generated.

- Select If not selected to flash the corresponding tab (if not already selected) whenever new objects are generated in the managers pane.
- Select Never to restrict the software from flashing the corresponding tab to notify you of generated objects.

Scroll palette to make visible (New Model only). Select whether to automatically scroll the Models tab in the managers pane to make the most recent model visible.

- Select Always to enable scrolling.
- Select If generated by current stream to scroll only for objects generated by the stream currently visible in the canvas.
- Select Never to restrict the software from automatically scrolling the Models tab.

Open window (New Output only). Select whether to automatically open an output window upon generation.

- Select Always to always open a new output window.
- Select If generated by current stream to open a new window for output generated by the stream currently visible in the canvas.
- Select Never to restrict the software from automatically opening new windows for generated output.

To revert to the system default settings for this tab, click Default Values.

Related information

- [Setting user options](#)

Setting display options

Using the Display tab of the User Options dialog box, you can set options for the display of fonts and colors in IBM® SPSS® Modeler.

Show welcome dialog on startup. Select to cause the welcome dialog box to be displayed on startup. The welcome dialog box has options to launch the application examples tutorial, open a demonstration stream or an existing stream or project, or to create a new stream.

Show stream and SuperNode markups. If selected, causes markup (if any) on streams and SuperNodes to be displayed by default. Markup includes stream comments, model links, and highlighting of scoring branches.

Standard Fonts & Colors (effective on restart). Options in this control box are used to specify the IBM SPSS Modeler screen design, color scheme, and the size of the fonts displayed. The options that you select here do not take effect until you close and restart IBM SPSS Modeler.

- Look and feel. Select a standard color scheme and screen design. You can choose from:
 - SPSS Standard, the default design.

- SPSS Classic, a design familiar to users of earlier versions of SPSS Modeler.
- Windows, a Windows design that can be useful for increased contrast in the stream canvas and palettes.
- Analytics Carbon, a modern design with sleek icons and colors.
- Default font size for nodes. Specify a font size to be used in the node palettes and for nodes that are displayed in the stream canvas.
- Specify fixed width font. To select a fixed width font, and associated font Size for use in scripting and CLEM expression controls, select this check box. The default font is **Monospace plain**; click Change... to display a list of other fonts that you can select.

Note: You can set the size of the node icons for a stream on the Layout pane of the Options tab of the stream properties dialog box. From the main menu, choose Tools > Stream Properties > Options > Layout.

Custom Colors. This table lists the currently selected colors that are used for various display items. For each of the items that are listed in the table, you can change the current color by double-clicking the corresponding row in the Color column and selecting a color from the list. To specify a custom color, scroll to the bottom of the list and click the Color... entry.

Chart Category Color Order. This table lists the currently selected colors that are used for display in newly created graphs. The order of the colors reflects the order in which they are used in the chart. For example, if a nominal field used as a color overlay contains four unique values, then only the first four colors that are listed here are used. For each of the items that are listed in the table, you can change the current color by double-clicking the corresponding row in the Color column and selecting a color from the list. To specify a custom color, scroll to the bottom of the list and click the Color... entry. Changes that you make here do not affect previously created graphs.

To revert to the system default settings for this tab, click Default Values.

Setting Syntax Display Options

Using the Syntax tab of the User Options dialog box, you can set options for the font attributes and display colors in scripts that you create in IBM® SPSS® Modeler.

Syntax highlighting. This table lists the currently selected colors used for various syntax items, including both the font and the window in which it is displayed. For each of the items listed in the table you can change the color by clicking the corresponding drop-down list in the row and selecting a color from the list. In addition, for font items, you can choose to add bold and italic emphasis.

Preview. This table shows an example syntax display that uses the colors and font attributes that you select in the Syntax highlighting table. This preview updates as soon as you change any selection.

Click Default Values to revert to the system default settings for this tab.

Setting PMML Export Options

On the PMML tab, you can control how IBM® SPSS® Modeler exports models to Predictive Model Markup Language (PMML). See the topic [Importing and exporting models as PMML](#) for more information.

Export PMML. Here you can configure variations of PMML that work best with your target application.

- Select With extensions to allow PMML extensions for special cases where there is no standard PMML equivalent. Note that in most cases this will produce the same result as standard PMML.
- Select As standard PMML... to export PMML that adheres as closely as possible to the PMML standard.

Standard PMML Options. When the As standard PMML... option is selected, you can choose one of two valid ways to export linear and logistic regression models:

- As PMML <GeneralRegression> models
- As PMML <Regression> models

For more information on PMML, see the Data Mining Group website at <http://www.dmg.org>.

Setting User Information

User/Author Information. Information you enter here can be displayed on the Annotations tab of nodes and other objects that you create.

Setting the mode

Modeler Mode Settings. On the Mode tab, you can choose from the following modes:

- Traditional SPSS Modeler mode shows all available nodes and expressions in the user interface.
- Analytic Server mode shows only the nodes and expressions supported by Analytic Server. But note that some nodes and some CLEM expressions will still be displayed even though they're not *fully* supported by Analytic Server. The following table provides general information about which nodes are supported, partially supported, and unsupported by Analytic Server.

See [Supported nodes](#) for further details.

See the [Analytic Server documentation](#) for more information about Analytic Server.

Note that if you configure SPSS® Modeler to show database nodes on the Database Modeling palette, they will not be impacted when switching modes. The database nodes will always be displayed. If you use IBM Db2 for z/OS or IBM Netezza integration, in some cases those nodes may disappear from the Database Modeling palette after switching to Analytic Server mode. If this happens, go to Tools > Options > Helper Applications and reset the check boxes.

Table 1. Node support

Customizing the Nodes Palette

Streams are built using nodes. The Nodes Palette at the bottom of the IBM® SPSS® Modeler window contains all of the nodes it is possible to use in stream building. See the topic [Nodes palette](#) for more information.

You can reorganize the Nodes Palette in two ways:

- Customize the Palette Manager. See the topic [Customizing the Palette Manager](#) for more information.
- Change how palette tabs that contain subpalettes are displayed on the Nodes Palette. See the topic [Creating a Subpalette](#) for more information.
- [Customizing the Palette Manager](#)
- [Changing a Palette Tab View](#)

Related information

- [Displaying Subpalettes on a Palette Tab](#)
- [Creating a Subpalette](#)
- [Changing a Palette Tab View](#)
- [Customizing IBM SPSS Modeler options](#)
- [Setting IBM SPSS Modeler options](#)

Customizing the Palette Manager

The Palette Manager can be customized to accommodate your usage of IBM® SPSS® Modeler. For example, if you frequently analyze time-series data from a database, you might want to be sure that the Database source node, the Time intervals node, the Time Series node, and the Time Plot graph node are available together from a unique palette tab. The Palette Manager enables you to easily make these adjustments by creating your custom palette tabs in the Nodes Palette.

The Palette Manager enables you to carry out various tasks:

- Control which palette tabs are shown on the Nodes Palette below the stream canvas.
- Change the order in which palette tabs are shown on the Nodes Palette.
- Create and edit your own palette tabs and any associated subpalettes.
- Edit the default node selections on your tabs.

To access the Palette Manager, on the Tools menu, click Manage Palettes.

Palette Name. Each available palette tab, whether shown on the Nodes Palette or not, is listed. This includes any palette tabs that you have created. See the topic [Creating a Palette Tab](#) for more information.

No. of nodes. The number of nodes displayed on each palette tab. A high number here means you may find it more convenient to create subpalettes to divide up the nodes on the tab. See the topic [Creating a Subpalette](#) for more information.

Shown? Select this field to display the palette tab on the Nodes Palette. See the topic [Displaying Palette Tabs on the Nodes Palette](#) for more information.

Sub Palettes. To select subpalettes for display on a palette tab, highlight the required Palette Name and click this button to display the Sub Palettes dialog box. See the topic [Creating a Subpalette](#) for more information.

Restore Defaults. To completely remove all changes and additions you have made to the palettes and subpalettes and return to the default palette settings, click this button.

- [Creating a Palette Tab](#)
 - [Displaying Palette Tabs on the Nodes Palette](#)
 - [Displaying Subpalettes on a Palette Tab](#)
 - [Creating a Subpalette](#)
-

Creating a Palette Tab

To create a custom palette tab:

1. From the Tools menu, open the Palette Manager.
2. To the right of the *Shown?* column, click the Add Palette button; the Create/Edit Palette dialog box is displayed.
3. Type in a unique Palette name.
4. In the Nodes available area, select the node to be added to the palette tab.
5. Click the Add Node right-arrow button to move the highlighted node to the Selected nodes area. Repeat until you have added all the nodes you want.

After you have added all of the required nodes, you can change the order in which they are displayed on the palette tab:

6. Use the simple arrow buttons to move a node up or down one row.
7. Use the line-arrow buttons to move a node to the bottom or top of the list.
8. To remove a node from a palette, highlight the node and click the Delete button to the right of the Selected nodes area.

Related information

Displaying Palette Tabs on the Nodes Palette

There may be options available within IBM® SPSS® Modeler that you never use; in this case, you can use the Palette Manager to hide the tabs containing these nodes.

To select which tabs are to be shown on the Nodes Palette:

1. From the Tools menu, open the Palette Manager.
2. Using the check boxes in the *Shown?* column, select whether to include or hide each palette tab.

To permanently remove a palette tab from the Nodes Palette, highlight the node and click the Delete button to the right of the *Shown?* column. Once deleted, a palette tab cannot be recovered.

Note: You cannot delete the default palette tabs supplied with IBM SPSS Modeler, except for the Favorites tab.

Changing the display order on the Nodes Palette

After you have selected which palette tabs you want to display, you can change the order in which they are displayed on the Nodes Palette:

1. Use the simple arrow buttons to move a palette tab up or down one row. Moving them up moves them to the left of the Nodes Palette, and vice versa.
2. Use the line-arrow buttons to move a palette tab to the bottom or top of the list. Those at the top of the list will be shown on the left of the Nodes Palette.

-

Displaying Subpalettes on a Palette Tab

In the same way that you can control which palette tabs are displayed on the Nodes Palette, you can control which subpalettes are available from their parent palette tab.

To select subpalettes for display on a palette tab:

1. From the Tools menu, open the Palette Manager.
2. Select the palette that you require.
3. Click the Sub Palettes button; the Sub Palettes dialog box is displayed.
4. Using the check boxes in the *Shown?* column, select whether to include each subpalette on the palette tab. The All subpalette is always shown and cannot be deleted.
5. To permanently remove a subpalette from the palette tab, highlight the subpalette and click the Delete button to the right of the *Shown?* column.

Note: You cannot delete the default subpalettes supplied with the Modeling palette tab.

Changing the display order on the Palette Tab

After you have selected which subpalettes you want to display, you can change the order in which they are displayed on the parent palette tab:

1. Use the simple arrow buttons to move a subpalette up or down one row.
2. Use the line-arrow buttons to move a subpalette to the bottom or top of the list.

The subpalettes you create are displayed on the Nodes Palette when you select their parent palette tab. See the topic [Changing a Palette Tab View](#) for more information.

Related information

 - [Creating a Subpalette](#)
 - [Changing a Palette Tab View](#)
-

Creating a Subpalette

Because you can add any existing node to the custom palette tabs that you create, it is possible that you will select more nodes than can be easily displayed on screen without scrolling. To prevent having to scroll, you can create subpalettes into which you place the nodes you chose for the palette tab. For example, if you created a palette tab that contains the nodes you use most frequently for creating your streams, you could create four subpalettes that break the selections down by source node, field operations, modeling, and output.

Note: You can only select subpalette nodes from those added to the parent palette tab.

To create a subpalette:

1. From the Tools menu, open the Palette Manager.
2. Select the palette to which you want to add subpalettes.
3. Click the Sub Palettes button; the Sub Palettes dialog box is displayed.
4. To the right of the *Shown?* column, click the Add Sub Palette button; the Create/Edit Sub Palette dialog box is displayed.
5. Type in a unique Sub palette name.
6. In the Nodes available area, select the node to be added to the subpalette.
7. Click the Add Node right-arrow button to move a selected node to the Selected nodes area.
8. When you have added the required nodes, click OK to return to the Sub Palettes dialog box.

The subpalettes you create are displayed on the Nodes Palette when you select their parent palette tab. See the topic [Changing a Palette Tab View](#) for more information.

-

Changing a Palette Tab View

Due to the large number of nodes available in IBM® SPSS® Modeler, they may not all be visible on smaller screens without scrolling to the left or right of the Nodes Palette; this is especially noticeable on the Modeling palette tab. To reduce the need to scroll, you can choose to display only the nodes contained in a subpalette (where available). See the topic [Creating a Subpalette](#) for more information.

To change the nodes shown on a palette tab, select the palette tab and then, from the menu on the left, select to display either all nodes, or just those in a specific subpalette.

Performance considerations for streams and nodes

You can design your streams to maximize performance by arranging the nodes in the most efficient configuration, by enabling node caches when appropriate, and by paying attention to other considerations as detailed in this section.

Aside from the considerations discussed here, additional and more substantial performance improvements can typically be gained by making effective use of your database, particularly through SQL optimization.

- [Order of Nodes](#)
 - [Node Caches](#)
 - [Performance: Process Nodes](#)
 - [Performance: Modeling Nodes](#)
 - [Performance: CLEM Expressions](#)
-

Order of Nodes

Even when you are not using SQL optimization, the order of nodes in a stream can affect performance. The general goal is to minimize downstream processing; therefore, when you have nodes that reduce the amount of data, place them near the beginning of the stream. IBM® SPSS® Modeler Server can apply some reordering rules automatically during compilation to bring forward certain nodes when it can be proven safe to do so. (This feature is enabled by default. Check with your system administrator to make sure it is enabled in your installation.)

When using SQL optimization, you want to maximize its availability and efficiency. Since optimization halts when the stream contains an operation that cannot be performed in the database, it is best to group SQL-optimized operations together at the beginning of the stream. This strategy keeps more of the processing in the database, so less data is carried into IBM SPSS Modeler.

The following operations can be done in most databases. Try to group them at the *beginning* of the stream:

- Merge by key (join)
- Select
- Aggregate
- Sort
- Sample
- Append
- Distinct operations in *include* mode, in which all fields are selected
- Filler operations
- Basic derive operations using standard arithmetic or string manipulation (depending on which operations are supported by the database)
- Set-to-flag

The following operations cannot be performed in most databases. They should be placed in the stream *after* the operations in the preceding list:

- Operations on any nondatabase data, such as flat files
 - Merge by order
 - Balance
 - Distinct operations in *discard* mode or where only a subset of fields are selected as distinct
 - Any operation that requires accessing data from records other than the one being processed
 - State and count field derivations
 - History node operations
 - Operations involving "@" (time-series) functions
 - Type-checking modes *Warn* and *Abort*
 - Model construction, application, and analysis
- Note:* Decision trees, rulesets, linear regression, and factor-generated models can generate SQL and can therefore be pushed back to the database.
- Data output to anywhere other than the same database that is processing the data

-

Node Caches

To optimize stream running, you can set up a *cache* on any nonterminal node. When you set up a cache on a node, the cache is filled with the data that passes through the node the next time you run the data stream. From then on, the data is read from the cache (which is stored on disk in a temporary directory) rather than from the data source.

Caching is most useful following a time-consuming operation such as a sort, merge, or aggregation. For example, suppose that you have a source node set to read sales data from a database and an Aggregate node that summarizes sales by location. You can set up a cache on the Aggregate node rather than on the source node because you want the cache to store the aggregated data rather than the entire data set.

Note: Caching at source nodes, which simply stores a copy of the original data as it is read into IBM® SPSS® Modeler, will not improve performance in most circumstances.

Nodes with caching enabled are displayed with a small document icon at the top right corner. When the data is cached at the node, the document icon is green.

To Enable a Cache

1. On the stream canvas, right-click the node and click Cache on the menu.
2. On the caching submenu, click Enable.
3. You can turn the cache off by right-clicking the node and clicking Disable on the caching submenu.

Caching Nodes in a Database

For streams run in a database, data can be cached midstream to a temporary table in the database rather than the file system. When combined with SQL optimization, this may result in significant gains in performance. For example, the output from a stream that merges multiple tables to create a data mining view may be cached and reused as needed. By automatically generating SQL for all downstream nodes, performance can be further improved.

To take advantage of database caching, both SQL optimization and database caching must be enabled. Note that Server optimization settings override those on the Client. See the topic [Setting optimization options for streams](#) for more information.

With database caching enabled, simply right-click any nonterminal node to cache data at that point, and the cache will be created automatically directly in the database the next time the stream is run. If database caching or SQL optimization is not enabled, the cache will be written to the file system instead.

Note: The following databases support temporary tables for the purpose of caching: Db2, Oracle, SQL Server, and Teradata. Other databases, such as Netezza, will use a normal table for database caching. The SQL code can be customized for specific databases - contact Services for assistance.

Performance: Process Nodes

Sort. The Sort node must read the entire input data set before it can be sorted. The data is stored in memory up to some limit, and the excess is spilled to disk. The sorting algorithm is a combination algorithm: data is read into memory up to the limit and sorted using a fast hybrid quick-sort algorithm. If all the data fits in memory, then the sort is complete. Otherwise, a merge-sort algorithm is applied. The sorted data is written to file and the next chunk of data is read into memory, sorted, and written to disk. This is repeated until all the data has been read; then the sorted chunks are merged. Merging may require repeated passes over the data stored on disk. At peak usage, the Sort node will have two complete copies of the data set on disk: sorted and unsorted.

The overall running time of the algorithm is on the order of $N \log(N)$, where N is the number of records. Sorting in memory is faster than merging from disk, so the actual running time can be reduced by allocating more memory to the sort. The algorithm allocates to itself a fraction of physical RAM controlled by the IBM® SPSS® Modeler Server configuration option *Memory usage multiplier*. To increase the memory used for sorting, provide more physical RAM or increase this value. Note that when the proportion of memory used exceeds the working set of the process so that part of the memory is paged to disk, performance degrades because the memory-access pattern of the in-memory sort algorithm is random and can cause excessive paging. The sort algorithm is used by several nodes other than the Sort node, but the same performance rules apply.

Binning. The Binning node reads the entire input data set to compute the bin boundaries, before it allocates records to bins. The data set is cached while the boundaries are computed; then it is rescanned for allocation. When the binning method is *fixed-width* or *mean+standard deviation*, the data set is cached directly to disk. These methods have a linear running time and require enough disk space to store the entire data set. When the binning method is *ranks* or *tiles*, the data set is sorted using the sort algorithm described earlier, and the sorted data set is used as the cache. Sorting gives these methods a running time of $M \log(N)$, where M is the number of binned fields and N is the number of records; it requires disk space equal to twice the data set size.

Generating a Derive node based on generated bins will improve performance in subsequent passes. Derive operations are much faster than binning.

Merge by Key (Join). The Merge node, when the merge method is *keys* (equivalent to a database join), sorts each of its input data sets by the key fields. This part of the procedure has a running time of $M \log(N)$, where M is the number of inputs and N is the number of records in the largest input; it requires sufficient disk space to store all of its input data sets plus a second copy of the largest data set. The running time of the merge itself is proportional to the size of the output data set, which depends on the frequency of matching keys. In the worst case, where the output is the Cartesian product of the inputs, the running time may approach MN . This is rare—most joins have many fewer matching keys. If one data set is relatively larger than the other(s), or if the incoming data is already sorted by a key field, then you can improve the performance of this node using the Optimization tab.

Aggregate. When the *Keys are contiguous* option is not set, this node reads (but does not store) its entire input data set before it produces any aggregated output. In the more extreme situations, where the size of the aggregated data reaches a limit (determined by the IBM SPSS Modeler Server configuration option *Memory usage multiplier*), the remainder of the data set is sorted and processed as if the *Keys are contiguous* option were set. When this option is set, no data is stored because the aggregated output records are produced as the input data is read.

Distinct. The Distinct node stores all of the unique key fields in the input data set; in cases where all fields are key fields and all records are unique it stores the entire data set. By default the Distinct node sorts the data on the key fields and then selects (or discards) the first distinct record from each group. For smaller data sets with a low number of distinct keys, or those that have been pre-sorted, you can choose options to improve the speed and efficiency of processing.

Type. In some instances, the Type node caches the input data when reading values; the cache is used for downstream processing. The cache requires sufficient disk space to store the entire data set but speeds up processing.

Evaluation. The Evaluation node must sort the input data to compute tiles. The sort is repeated for each model evaluated because the scores and consequent record order are different in each case. The running time is $M \log(N)$, where M is the number of models and N is the number of records.

Related information

- [Performance: Modeling Nodes](#)
- [Performance: CLEM Expressions](#)

Performance: Modeling Nodes

Neural Net and Kohonen. Neural network training algorithms (including the Kohonen algorithm) make many passes over the training data. The data is stored in memory up to a limit, and the excess is spilled to disk. Accessing the training data from disk is expensive because the access method is random, which can lead to excessive disk activity. You can disable the use of disk storage for these algorithms, forcing all data to be stored in memory, by selecting the Optimize for speed option on the Model tab of the node's dialog box. Note that if the amount of memory required to store the data is greater than the working set of the server process, part of it will be paged to disk and performance will suffer accordingly.

When Optimize for memory is enabled, a percentage of physical RAM is allocated to the algorithm according to the value of the IBM® SPSS® Modeler Server configuration option *Modeling memory limit percentage*. To use more memory for training neural networks, either provide more RAM or increase the value of this option, but note that setting the value too high will cause paging.

The running time of the neural network algorithms depends on the required level of accuracy. You can control the running time by setting a stopping condition in the node's dialog box.

K-Means. The K-Means clustering algorithm has the same options for controlling memory usage as the neural network algorithms. Performance on data stored on disk is better, however, because access to the data is sequential.

-

Performance: CLEM Expressions

CLEM sequence functions (“@ functions”) that look back into the data stream must store enough of the data to satisfy the longest look-back. For operations whose degree of look-back is unbounded, all values of the field must be stored. An unbounded operation is one where the offset value is not a literal integer; for example, @OFFSET(Sales, Month). The offset value is the field name *Month*, whose value is unknown until executed. The server must save all values of the *Sales* field to ensure accurate results. Where an upper bound is known, you should provide it as an additional argument; for example, @OFFSET(Sales, Month, 12). This operation instructs the server to store no more than the 12 most recent values of *Sales*. Sequence functions, bounded or otherwise, almost always inhibit SQL generation.

Overview of Accessibility in IBM SPSS Modeler

IBM® SPSS® Modeler provides accessibility support for all users, as well as specific support for users with visual and other functional impairments. This section describes the features and methods of working using accessibility enhancements, such as screen readers and keyboard shortcuts.

Related information

- [Types of Accessibility Support](#)
 - [Tips for use](#)
-

Types of Accessibility Support

Whether you have a visual impairment or are dependent on the keyboard for manipulation, there is a wide variety of alternative methods for using this data mining toolkit. For example, you can build streams, specify options, and read output, all without using the mouse. Available keyboard shortcuts are listed in the topics that follow. Additionally, IBM® SPSS® Modeler provides extensive support for screen readers, such as JAWS for Windows. You can also optimize the color scheme to provide additional contrast. These types of support are discussed in the following topics.

- [Accessibility for the Visually Impaired](#)
- [Accessibility for Blind Users](#)

- [Keyboard Accessibility](#)
- [Using a Screen Reader](#)

- [Using a Screen Reader with HTML Output](#)
- [Accessibility in the Interactive Tree Window](#)

Accessibility for the Visually Impaired

There are a number of properties you can specify in IBM® SPSS® Modeler that will enhance your ability to use the software.

Display Options

You can select colors for the display of graphs. You can also choose to use your specific Windows settings for the software itself. This may help to increase visual contrast.

1. To set display options, on the Tools menu, click User Options.
2. Click the Display tab. The options on this tab include the software color scheme, chart colors, and font sizes for nodes.

Note: The screen reader is not able to read graphs, so these are not accessible to visually-impaired users.

Use of Sounds for Notification

By turning sounds on or off, you can control the way you are alerted to particular operations in the software. For example, you can activate sounds for events such as node creation and deletion or the generation of new output or models.

1. To set notification options, on the Tools menu, click User Options.
2. Click the Notifications tab.

Controlling the Automatic Launching of New Windows

The Notifications tab on the User Options dialog box is also used to control whether newly generated output, such as tables and charts, are launched in a separate window. It may be easier for you to disable this option and open an output window only when required.

1. To set these options, on the Tools menu, click User Options.
2. Click the Notifications tab.
3. In the dialog box, select New Output from the list in the Visual Notifications group.
4. Under Open Window, select Never.

Node Size

Nodes can be displayed using either a standard or small size. You may want to adjust these sizes to fit your needs.

1. To set node size options, on the File menu, click Stream Properties.
2. Click the Layout tab.
3. From the Icon Size list, select Standard.

Accessibility for Blind Users

Support for blind users is predominately dependent on the use of a screen reader, such as JAWS for Windows. To optimize the use of a screen reader with IBM® SPSS® Modeler, you can specify a number of settings.

Display Options

Screen readers tend to perform better when the visual contrast is greater on the screen. If you already have a high-contrast Windows setting, you can choose to use these Windows settings for the software itself.

1. To set display options, on the Tools menu, click User Options.
2. Click the Display tab.

Note: The screen reader is not able to read graphs, so these are not accessible to blind users.

Use of Sounds for Notification

By turning on or off sounds, you can control the way you are alerted to particular operations in the software. For example, you can activate sounds for events such as node creation and deletion or the generation of new output or models.

1. To set notification options, on the Tools menu, click User Options.
2. Click the Notifications tab.

Controlling the Automatic Launching of New Windows

The Notifications tab on the User Options dialog box is also used to control whether newly generated output is launched in a separate window. It may be easier for you to disable this option and open an output window as needed.

1. To set these options, on the Tools menu, click User Options.
2. Click the Notifications tab.
3. In the dialog box, select New Output from the list in the Visual Notifications group.
4. Under Open Window, select Never.

Keyboard Accessibility

The product's functionality is accessible from the keyboard. At the most basic level, you can press Alt plus the appropriate key to activate window menus (such as Alt+F to access the File menu) or press the Tab key to scroll through dialog box controls. However, there are special issues related to each of the product's main windows and helpful hints for navigating dialog boxes.

This section will cover the highlights of keyboard accessibility, from opening a stream to using node dialog boxes to working with output. Additionally, lists of keyboard shortcuts are provided for even more efficient navigation.

Shortcuts for navigating the main window

You do most of your data mining work in the main window of IBM® SPSS® Modeler. The main area is called the **stream canvas** and is used to build and run data streams. The bottom part of the window contains the **node palettes**, which contain all available nodes. The palettes are organized on tabs corresponding to the type of data mining operation for each group of nodes. For example, nodes used to bring data into IBM SPSS Modeler are grouped on the Sources tab, and nodes used to derive, filter, or type fields are grouped on the Field Ops tab (short for Field Operations).

The right side of the window contains several tools for managing streams, output, and projects. The top half on the right contains the **managers** and has three tabs that are used to manage streams, output, and generated models. You can access these objects by selecting the tab and an object from the list. The bottom half on the right contains the **project pane**, which allows you to organize your work into projects. There are two tabs in this area reflecting two different views of a project. The **Classes view** sorts project objects by type, while the **CRISP-DM view** sorts objects by the relevant data mining phase, such as Data Preparation or Modeling. These various aspects of the IBM SPSS Modeler window are discussed throughout the Help system and User's Guide.

Following is a table of shortcuts used to move within the main IBM SPSS Modeler window and build streams. Shortcuts for dialog boxes and output are listed in the topics that follow. Note that these shortcut keys are available only from the main window.

Table 1. Main Window Shortcuts

Shortcut Key	Function
Ctrl+F5	Moves focus to the node palettes.
Ctrl+F6	Moves focus to the stream canvas.
Ctrl+F7	Moves focus to the managers pane.
Ctrl+F8	Moves focus to the project pane.

Table 2. Node and Stream Shortcuts

Shortcut Key	Function
Ctrl+N	Creates a new blank stream canvas.
Ctrl+O	Displays the Open dialog box, from where you can select and open an existing stream.
Ctrl+number keys	Moves focus to the corresponding tab on a window or pane. For example, within a tabbed pane or window, Ctrl+1 moves to the first tab starting from the left, Ctrl+2 to the second, etc.
Ctrl+Down Arrow	Used in the node palette to move focus from a palette tab to the first node under that tab.
Ctrl+Up Arrow	Used in the node palette to move focus from a node to its palette tab.
Enter	When a node is selected in the node palette (including refined models in the generated models palette), this keystroke adds the node to the stream canvas. Pressing Enter when a node is already selected on the canvas opens the dialog box for that node.
Ctrl+Enter	When a node is selected in the palette, adds that node to the stream canvas without selecting it, and moves focus to the first node in the palette.
Alt+Enter	When a node is selected in the palette, adds that node to the stream canvas and selects it, while moving focus to the first node in the palette.
Shift+Spacebar	When a node or comment has focus in the palette, toggles between selecting and deselecting that node or comment. If any other nodes or comments are also selected, this causes them to be deselected.
Ctrl+Shift+Spacebar	When a node or comment has focus in the stream, or a node or comment has focus on the palette, toggles between selecting and deselecting the node or comment. This does not affect any other selected nodes or comments.
Left/Right Arrow	If the stream canvas has focus, moves the entire stream horizontally on the screen. If a palette tab has focus, cycles between tabs. If a palette node has focus, moves between nodes in the palette.
Up/Down Arrow	If the stream canvas has focus, moves the entire stream vertically on the screen. If a palette node has focus, moves between nodes in the palette. If a subpalette has focus, moves between other subpalettes for this palette tab.

Shortcut Key	Function
Alt+Left/Right Arrow	Moves selected nodes and comments on the stream canvas horizontally in the direction of the arrow key.
Alt+Up/Down Arrow	Moves selected nodes and comments on the stream canvas vertically in the direction of the arrow key.
Ctrl+A	Selects all nodes in a stream.
Ctrl+Q	When a node has focus, selects it and all nodes downstream, and deselects all nodes upstream.
Ctrl+W	When a selected node has focus, deselects it and all selected nodes downstream.
Ctrl+Alt+D	Duplicates a selected node.
Ctrl+Alt+L	When a model nugget is selected in the stream, opens an Insert dialog box to enable you to load a saved model from a .nod file into the stream.
Ctrl+Alt+R	Displays the Annotations tab for a selected node, enabling you to rename the node.
Ctrl+Alt+U	Creates a User Input source node.
Ctrl+Alt+C	Toggles the cache for a node on or off.
Ctrl+Alt+F	Flushes the cache for a node.
Tab	On the stream canvas, cycles through all the source nodes and comments in the current stream. On a node palette, moves between nodes in the palette. On a selected subpalette, moves to the first node in the subpalette.
Shift+Tab	Performs the same operation as Tab but in reverse order.
Ctrl+Tab	With focus on the managers pane or project pane, moves focus to the stream canvas. With focus on a node palette, moves focus between a node and its palette tab.
Any alphabetic key	With focus on a node in the current stream, gives focus and cycles to the next node whose name starts with the key pressed.
F1	Opens the Help system at a topic relevant to the focus.
F2	Starts the connection process for a node selected in the canvas. Use the Tab key to move to the required node on the canvas, and press Shift+Spacebar to finish the connection.
F3	Deletes all connections for the selected node on the canvas.
F6	Moves focus between the managers pane, project pane and node palettes.
F10	Opens the File menu.
Shift+F10	Opens the pop-up menu for the node or stream.
Delete	Deletes a selected node from the canvas.
Esc	Closes a pop-up menu or dialog box.
Ctrl+Alt+X	Expands a SuperNode.
Ctrl+Alt+Z	Zooms in on a SuperNode.
Ctrl+Alt+Shift+Z	Zooms out of a SuperNode.
Ctrl+E	With focus in the stream canvas, this runs the current stream.

A number of standard shortcut keys are also used in IBM SPSS Modeler, such as Ctrl+C to copy. See the topic [Using shortcut keys](#) for more information.

Shortcuts for Dialog Boxes and Tables

Several shortcut and screen reader keys are helpful when you are working with dialog boxes, tables, and tables in dialog boxes. A complete list of special keyboard and screen reader shortcuts follows.

Table 1. Dialog Box and Expression Builder Shortcuts

Shortcut Key	Function
Alt+4	Used to dismiss all open dialog boxes or output windows. Output can be retrieved from the Outputs tab in the managers pane.
Ctrl+End	With focus on any control in the Expression Builder, this will move the insertion point to the end of the expression.

Shortcut Key	Function
Ctrl+1	In the Expression Builder, moves focus to the expression edit control.
Ctrl+2	In the Expression Builder, moves focus to the function list.
Ctrl+3	In the Expression Builder, moves focus to the field list.

Table Shortcuts

Table shortcuts are used for output tables as well as table controls in dialog boxes for nodes such as Type, Filter, and Merge. Typically, you will use the Tab key to move between table cells and Ctrl+Tab to leave the table control. *Note:* Occasionally, a screen reader may not immediately begin reading the contents of a cell. Pressing the arrow keys once or twice will reset the software and start the speech.

Table 2. Table Shortcuts

Shortcut Key	Function
Ctrl+W	For tables, reads the short description of the selected roW. For example, "Selected row 2 values are sex, flag, m/f, etc."
Ctrl+Alt+W	For tables, reads the long description of the selected roW. For example, "Selected row 2 values are field = sex, type = flag, sex = m/f, etc."
Ctrl+D	For tables, reads the short Description of the selected area. For example, "Selection is one row by six columns."
Ctrl+Alt+D	For tables, provides the long Description of the selected area. For example, "Selection is one row by six columns. Selected columns are Field, Type, Missing. Selected row is 1."
Ctrl+T	For tables, provides a short description of the selected columns. For example, "Fields, Type, Missing."
Ctrl+Alt+T	For tables, provides a long description of the selected columns. For example, "Selected columns are Fields, Type, Missing."
Ctrl+R	For tables, provides the number of Records in the table.
Ctrl+Alt+R	For tables, provides the number of Records in the table as well as column names.
Ctrl+I	For tables, reads the cell Information, or contents, for the cell that has focus.
Ctrl+Alt+I	For tables, reads the long description of cell Information (column name and contents of the cell) for the cell that has focus.
Ctrl+G	For tables, provides short General selection information.
Ctrl+Alt+G	For tables, provides long General selection information.
Ctrl+Q	For tables, provides a Quick toggle of the table cells. Ctrl+Q reads long descriptions, such as "Sex=Female," as you move through the table using the arrow keys. Selecting Ctrl+Q again will toggle to short descriptions (cell contents).
F8	For tables, when the focus is the table, sets the focus to the column header.
Spacebar	For tables, when the focus is the column header, enables column sorting.

Shortcuts for Comments

When working with on-screen comments, you can use the following shortcuts.

Table 1. Comment Shortcuts

Shortcut Key	Function
Alt+C	Toggles the show/hide comment feature.
Alt+M	Inserts a new comment if comments are currently displayed; shows comments if they are currently hidden.
Tab	On the stream canvas, cycles through all the source nodes and comments in the current stream.
Enter	When a comment has focus, indicates the start of editing.
Alt+Enter or Ctrl+Tab	Ends editing and saves editing changes.
Esc	Cancels editing. Changes made during editing are lost.
Alt+Shift+Up Arrow	Reduces the height of the text area by one grid cell (or one pixel) if snap-to-grid is on (or off).
Alt+Shift+Down Arrow	Increases the height of the text area by one grid cell (or one pixel) if snap-to-grid is on (or off).
Alt+Shift+Left Arrow	Reduces the width of the text area by one grid cell (or one pixel) if snap-to-grid is on (or off).
Alt+Shift+Right Arrow	Increases the width of the text area by one grid cell (or one pixel) if snap-to-grid is on (or off).

Shortcuts for Cluster Viewer and Model Viewer

Shortcut keys are available for navigating around the Cluster Viewer and Model Viewer windows.

Table 1. General Shortcuts - Cluster Viewer and Model Viewer

Shortcut Key	Function
Tab	Moves focus to the next screen control.
Shift+Tab	Moves focus to the previous screen control.
Down Arrow	If a drop-down list has focus, opens the list or moves to the next item on the list. If a menu has focus, moves to the next item on the menu. If a thumbnail graph has focus, moves to the next one in the set (or to the first one if the last thumbnail has focus).
Up Arrow	If a drop-down list is open, moves to the previous item on the list. If a menu has focus, moves to the previous item on the menu. If a thumbnail graph has focus, moves to the previous one in the set (or to the last one if the first thumbnail has focus).
Enter	Closes an open drop-down list, or makes a selection on an open menu.
F6	Toggles focus between the left- and right-hand panes of the window.
Left and Right Arrows	If a tab has focus, moves to the previous or next tab. If a menu has focus, moves to the previous or next menu.
Alt+letter	Selects the button or menu having this letter underlined in its name.
Esc	Closes an open menu or drop-down list.

Cluster Viewer only

The Cluster Viewer has a Clusters view that contains a cluster-by-features grid.

To choose the Clusters view instead of the Model Summary view:

1. Press Tab repeatedly until the View button is selected.
2. Press Down Arrow twice to select Clusters.
From here you can select an individual cell within the grid:
3. Press Tab repeatedly until you arrive at the last icon in the visualization toolbar.

Figure 1. Show Visualization Tree icon

4. Press Tab once more, then Spacebar, then an arrow key.

The following keyboard shortcuts are now available:

Table 2. Cluster Viewer Shortcuts

Shortcut Key	Function
Arrow key	Moves focus between individual cells in the grid. The cell distribution display in the right-hand pane changes as the focus moves.
Ctrl+, (comma)	Selects or deselects the entire column in the grid in which a cell has focus. To add a column to the selection, use the arrow keys to navigate to a cell in that column and press Ctrl+, again.
Tab	Moves focus out of the grid and onto the next screen control.
Shift+Tab	Moves focus out of the grid and back to the previous screen control.
F2	Enters edit mode (label and description cells only).
Enter	Saves editing changes and exits edit mode (label and description cells only).
Esc	Exits edit mode without saving changes (label and description cells only).

Shortcut Keys Example: Building Streams

To make the stream-building process more clear for users dependent on the keyboard or on a screen reader, following is an example of building a stream without the use of the mouse. In this example, you will build a stream containing a Variable File node, a Derive node, and a Histogram node using the following steps:

1. **Start IBM® SPSS® Modeler.** When IBM SPSS Modeler first starts, focus is on the Favorites tab of the node palette.
2. **Ctrl+Down Arrow.** Moves focus from the tab itself to the body of the tab.
3. **Right Arrow.** Moves focus to the Variable File node.
4. **Spacebar.** Selects the Variable File node.
5. **Ctrl+Enter.** Adds the Variable File node to the stream canvas. This key combination also keeps selection on the Variable File node so that the next node added will be connected to it.
6. **Tab.** Moves focus back to the node palette.
7. **Right Arrow 4 times.** Moves to the Derive node.
8. **Spacebar.** Selects the Derive node.
9. **Alt+Enter.** Adds the Derive node to the canvas and moves selection to the Derive node. This node is now ready to be connected to the next added node.
10. **Tab.** Moves focus back to the node palette.
11. **Right Arrow 5 times.** Moves focus to the Histogram node in the palette.
12. **Spacebar.** Selects the Histogram node.
13. **Enter.** Adds the node to the stream and moves focus to the stream canvas.

Continue with the next example, or save the stream if you want to try the next example at a later time.

-

Shortcut Keys Example: Editing Nodes

In this example, you will use the stream built in the earlier example. The stream consists of a Variable File node, a Derive node, and a Histogram node. The instructions begin with focus on the third node in the stream, the Histogram node.

1. **Ctrl+Left Arrow 2 times.** Moves focus back to the Variable File node.
2. **Enter.** Opens the Variable File dialog box. Tab through to the File field and type a text file path and name to select that file. Press Ctrl+Tab to navigate to the lower part of the dialog box, tab through to the OK button and press Enter to close the dialog box.
3. **Ctrl+Right Arrow.** Gives focus to the second node, a Derive node.
4. **Enter.** Opens the Derive node dialog box. Tab through to select fields and specify derive conditions. Press Ctrl+Tab to navigate to the OK button and press Enter to close the dialog box.
5. **Ctrl+Right Arrow.** Gives focus to the third node, a Histogram node.
6. **Enter.** Opens the Histogram node dialog box. Tab through to select fields and specify graph options. For drop-down lists, press Down Arrow to open the list and to highlight a list item, then press Enter to select the list item. Tab through to the OK button and press Enter to close the dialog box.

At this point, you can add additional nodes or run the current stream. Keep in mind the following tips when you are building streams:

- When manually connecting nodes, use F2 to create the start point of a connection, tab to move to the end point, then use Shift+Spacebar to finalize the connection.

- Use F3 to destroy all connections for a selected node in the canvas.
- Once you have created a stream, use Ctrl+E to run the current stream.

A complete list of shortcut keys is available. See the topic [Shortcuts for navigating the main window](#) for more information.

Using a Screen Reader

A number of screen readers are available on the market. IBM® SPSS® Modeler is configured to support JAWS for Windows using the Java Access Bridge, which is installed along with IBM SPSS Modeler. If you have JAWS installed, simply launch JAWS before launching IBM SPSS Modeler to use this product.

Note: We recommend that you have at least 6GB space to run JAWS with SPSS Modeler.

Due to the nature of IBM SPSS Modeler's unique graphical representation of the data mining process, charts and graphs are optimally used visually. It is possible, however, for you to understand and make decisions based on output and models viewed textually using a screen reader.

Note: With 64-bit client machines, some assistive technology features do not work. This is because the Java Access Bridge is not designed for 64-bit operation.

Using the IBM SPSS Modeler Dictionary File

An IBM SPSS Modeler dictionary file (*Awt.JDF*) is available for inclusion with JAWS. To use this file:

1. Navigate to the */accessibility* subdirectory of your IBM SPSS Modeler installation and copy the dictionary file (*Awt.JDF*).
2. Copy it to the directory with your JAWS scripts.

You may already have a file named *Awt.JDF* on your machine if you have other JAVA applications running. In this case, you may not be able to use this dictionary file without manually editing the dictionary file.

Using a Screen Reader with HTML Output

When viewing output displayed as HTML within IBM® SPSS® Modeler using a screen reader, you may encounter some difficulties. A number of types of output are affected, including:

- Output viewed on the Advanced tab for Regression, Logistic Regression, and Factor/PCA nodes
- Report node output

In each of these windows or dialog boxes, there is a tool on the toolbar that can be used to launch the output into your default browser, which provides standard screen reader support. You can then use the screen reader to convey the output information.

Accessibility in the Interactive Tree Window

The standard display of a decision tree model in the Interactive Tree window may cause problems for screen readers. To access an accessible version, on the Interactive Tree menus click:

View > Accessible Window

This displays a view similar to the standard tree map, but one which JAWS can read correctly. You can move up, down, right, or left using the standard arrow keys. As you navigate the accessible window, the focus in the Interactive Tree window moves accordingly. Use the Spacebar to change the selection, or use Ctrl+Spacebar to extend the current selection.

Tips for use

There are several tips for making the IBM® SPSS® Modeler environment more accessible to you. The following are general hints when working in IBM SPSS Modeler.

- Exiting extended text boxes. Use Ctrl+Tab to exit extended text boxes. Note that Ctrl+Tab is also used to exit table controls.
- Using the Tab key rather than arrow keys. When selecting options for a dialog box, use the Tab key to move between option buttons. The arrow keys will not work in this context.
- Drop-down lists. In a drop-down list for dialog boxes, you can use either the Escape key or the space bar to select an item and then close the list. You can also use the Escape key to close drop-down lists that do not close when you have tabbed to another control.
- Execution status. When you are running a stream on a large database, JAWS can lag behind in reading the stream status to you. Press the Ctrl key periodically to update the status reporting.
- Using the node palettes. When you first enter a tab of the node palettes, JAWS will sometimes read "groupbox" instead of the name of the node. In this case, you can use Ctrl+Right Arrow and then Ctrl+Left Arrow to reset the screen reader and hear the node name.
- Reading menus. Occasionally, when you are first opening a menu, JAWS may not read the first menu item. If you suspect that this may have happened, use the Down Arrow and then the Up Arrow to hear the first item in the menu.
- Cascaded menus. JAWS does not read the first level of a cascaded menu. If you hear a break in speaking while moving through a menu, press the Right Arrow key to hear the child menu items.

Additionally, if you have IBM SPSS Modeler Text Analytics installed, the following tips can make the interactive workbench interface more accessible to you.

- Entering dialog boxes. You may need to press the Tab key to put the focus on the first control upon entering a dialog box.
- Exiting extended text boxes. Use Ctrl+Tab to exit extended text boxes and move to the next control. Note that Ctrl+Tab is also used to exit table controls.
- Typing the first letter to find element in tree list. When looking for an element in the categories pane, extracted results pane, or library tree, you can type the first letter of the element when the pane has the focus. This will select the next occurrence of an element beginning with the letter you entered.
- Drop-down lists. In a drop-down list for dialog boxes, you can use the space bar to select an item and then close the list.

Additional tips for use are discussed at length in the following topics.

-

Interference with Other Software

When testing IBM® SPSS® Modeler with screen readers, such as JAWS, our development team discovered that the use of a Systems Management Server (SMS) within your organization may interfere with JAWS' ability to read Java-based applications, such as IBM SPSS Modeler. Disabling SMS will correct this situation. Visit the Microsoft website for more information on SMS.

Unicode support

- [Unicode Support in IBM SPSS Modeler](#)
-

Unicode Support in IBM SPSS Modeler

IBM® SPSS® Modeler is fully Unicode-enabled for both IBM SPSS Modeler and IBM SPSS Modeler Server. This makes it possible to exchange data with other applications that support Unicode, including multi-language databases, without any loss of information that might be caused by conversion to or from a locale-specific encoding scheme.

- IBM SPSS Modeler stores Unicode data internally and can read and write multi-language data stored as Unicode in databases without loss.
- IBM SPSS Modeler can read and write UTF-8 encoded text files. Text file import and export will default to the locale-encoding but support UTF-8 as an alternative. This setting can be specified in the file import and export nodes, or the default encoding can be changed in the stream properties dialog box. See the topic [Setting general options for streams](#) for more information.

- Statistics, SAS, and Text data files stored in the locale-encoding will be converted to UTF-8 on import and back again on export. When writing to any file, if there are Unicode characters that do not exist in the locale character set, they will be substituted and a warning will be displayed. This should occur only where the data has been imported from a data source that supports Unicode (a database or UTF-8 text file) and that contains characters from a different locale or from multiple locales or character sets.
- IBM SPSS Modeler Solution Publisher images are UTF-8 encoded and are truly portable between platforms and locales.

About Unicode

The goal of the Unicode standard is to provide a consistent way to encode multilingual text so that it can be easily shared across borders, locales, and applications. The Unicode Standard, now at version 4.0.1, defines a character set that is a superset of all of the character sets in common use in the world today and assigns to each character a unique name and code point. The characters and their code points are identical to those of the Universal Character Set (UCS) defined by ISO-10646. For more information, see the [Unicode Home Page](#).

Batch Mode Execution

- [Introduction to Batch Mode](#)
- [Working in Batch Mode](#)

Introduction to Batch Mode

Data mining is usually an interactive process—you interact with data and models to improve your understanding of the data and the domain it represents. However, IBM® SPSS® Modeler streams can also be used to process data and perform data mining tasks in **batch mode**, with no visible user interface. Batch mode allows long-running or repetitive tasks to be performed without your intervention and without the presence of the user interface on the screen.

Note: Database modeling and SQL optimization require that IBM SPSS Modeler Server connectivity be enabled on the IBM SPSS Modeler computer. With this setting enabled, you can access database algorithms, push back SQL directly from IBM SPSS Modeler, and access IBM SPSS Modeler Server. To verify the current license status, choose the following from the IBM SPSS Modeler menu.

Help > About > Additional Details

If connectivity is enabled, you see the option Server Enablement in the License Status tab.

See [Connecting to IBM SPSS Modeler Server](#) for more information.

Examples of tasks appropriate for batch mode include:

- Running a time-consuming modeling exercise in the background.
- Running a stream at a scheduled time (for example, overnight, when the resultant load on the computer will not be inconvenient).
- Running a data preprocessing stream on a large volume of data (for example, in the background and/or overnight).
- Running regularly scheduled tasks, such as monthly reports.
- Running a stream as an embedded part of another process, such as a scoring engine facility.

Note: IBM SPSS Modeler operations can be scheduled in batch mode using the appropriate operating system commands or utilities (for example, the `at` command under Windows NT).

- [Batch mode log files](#)
- [Scripting in Batch Mode](#)
- [Using Parameters in Batch Mode](#)
- [Working with Output in Batch Mode](#)

Working in Batch Mode

Working in batch mode typically involves:

1. Invoking IBM® SPSS® Modeler in batch mode using the `clemb` command.
2. Connecting to a server.
3. Loading an existing stream or script file.
4. Executing the stream or script.

Note: SPSS Modeler Batch requires 4GB of available memory.

Once execution is complete, you can then consult the log file produced by default in batch mode and view the results of graphs, output nodes, and models. For more information about these steps, see the following topics.

If only SPSS Modeler Batch is installed (not SPSS Modeler client), to run a stream containing a Statistics node, you also need to complete the following steps:

1. Install SPSS Modeler Server and IBM SPSS Statistics Server on the same machine.
2. Run a utility on the SPSS Modeler Server host machine to create the statistics.ini file, which tells IBM SPSS Statistics the installation path for SPSS Modeler Server. To run the utility, open a command prompt, change to the SPSS Modeler Server bin directory, and run the following command.

On Windows:

```
statisticsutility -location=<statistics_installation_path>/bin
```

On Linux:

```
./statisticsutility -location=<statistics_installation_path>/bin
```

3. Run the batch command. For example:

```
clemb -server -hostname 9.30.51.42 -port 28181 -username xxxxxxxxx -password xxxxxxxxx -stream "c:\test\StatisticsOutputNode.str" -execute -log "c:\log\report.log"
```

- [Invoking the Software](#)
- [Using Command Line Arguments](#)
- [Batch mode log files](#)
- [Scripting in Batch Mode](#)
- [Using Parameters in Batch Mode](#)
- [Working with Output in Batch Mode](#)

Invoking the Software

You can use the command line of your operating system to launch IBM® SPSS® Modeler as follows:

1. On a computer where IBM SPSS Modeler is installed, open a DOS, or command-prompt, window.
2. To launch the IBM SPSS Modeler interface in interactive mode, type the **modelerclient** command followed by the required arguments; for example:

```
modelerclient -stream report.str -execute
```

The available arguments (flags) allow you to connect to a server, load streams, run scripts, or specify other parameters as needed.

Related information

- [Introduction to Batch Mode](#)
- [Batch mode log files](#)
- [Scripting in Batch Mode](#)
- [Using Parameters in Batch Mode](#)
- [Working with Output in Batch Mode](#)

Using Command Line Arguments

In order for IBM® SPSS® Modeler to open and execute files (such as streams and scripts) in batch mode, you need to alter the initial command (**clemb**) that launches the software. There are a number of command line arguments, also referred to as **flags**, that you can use to:

- Connect to a server.
- Load streams, scripts, models, states, projects, and output files. (If you have licensed IBM SPSS Collaboration and Deployment Services Repository, you can connect to a repository and load objects from it.)
- Specify log file options.
- Set default directories for use in IBM SPSS Modeler.

All of the above operations require the use of flags appended to the **clemb** command. Flags follow the form **-flag**, where the hyphen precedes the argument itself. For example, using the flag **-server** in conjunction with the initial argument **clemb** will connect to the server specified using other flag options.

You can combine the `clem` command with a number of other startup flags, such as `-server`, `-stream`, and `-execute`, in order to load and execute streams in batch mode. The following command loads and executes the stream `report.str` without invoking the user interface:

```
clem -server -hostname myserver -port 80  
-username dminer -password 1234 -stream report.str -execute
```

For a complete list of command line arguments, see [Command Line Arguments](#).

- IBM SPSS Modeler states and scripts are also executed in this manner, using the `-state` and `-script` flags, respectively. Multiple states and streams can be loaded by specifying the relevant flag for each item.
- Multiple arguments can be combined into a single command file and specified at startup using the @ symbol. See the topic [Combining Multiple Arguments](#) for more information.

Related information

- [Invoking the software](#)
- [Using command line arguments](#)
- [System arguments](#)
- [Server connection arguments](#)
- [IBM SPSS Collaboration and Deployment Services Repository Connection Arguments](#)
- [Introduction to Batch Mode](#)

Batch mode log files

Running in batch mode produces a log file. By default, the name of this log file is `clem_batch.log`, but you can specify an alternative name using the `-log` flag. For example, the following command runs `report.str` in batch mode and sends the logging information to `report.log`:

```
clem -server -hostname myserver -port 80  
-username dminer -password 1234 -stream report.str  
-execute -log report.log
```

Normally, the log file overwrites any existing file of the same name, but you can make IBM® SPSS® Modeler append to the log file instead by using the `-appendlog` flag. Logging can also be suppressed altogether by using the `-nolog` flag.

Note: Logging arguments are available only when running in batch mode.

On **Windows** and **Linux**, by default, `clem_batch.log` is generated to the same location as the `clem` command (for example, <installation_path>/bin on Windows and <installation_path>/ on Linux).

On **Mac OS**, by default, `clem_batch.log` is generated to <installation_path>/IBM SPSS Modeler.app/Contents/log.

Scripting in Batch Mode

In its simplest form, batch mode execution of IBM® SPSS® Modeler streams is performed one at a time using the command line arguments discussed in this guide. A given stream is executed without significantly altering its node parameters. While this may work well for automated production of monthly churn reports or predictions, it cannot handle the sophisticated processes that many advanced data miners would like to automate.

For example, a financial institution may want to construct a number of models using different data or modeling parameters, test the models on another set of data, and produce a report on the results. Because this process requires repetitive modifications to a stream and the creation and deletion of nodes, automating it requires the use of scripting. Scripting allows complex processes that would otherwise require user intervention to be automated and executed in batch mode.

To Execute a Script in Batch Mode

1. Append the `clem` command with the `-script` flag, specifying the name of the script that you want to execute.
2. Also use the `-execute` flag with the above arguments to execute the specified script. This will run the stand-alone script in its entirety.

For example, to load and execute a script that runs a model producing churn scores that are stored as output for the data warehouse, you would use the following command:

```
clem -server -hostname myserver -port 80  
-username dminer -password 1234  
-script clemscript.txt -execute
```

Related information

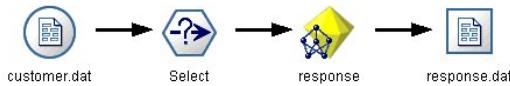

- [Introduction to Batch Mode](#)
- [Invoking the Software](#)
- [Batch mode log files](#)
- [Using Parameters in Batch Mode](#)
- [Working with Output in Batch Mode](#)

Using Parameters in Batch Mode

You can modify the effect of executing a stream in batch mode by supplying parameters to the command line launch of IBM® SPSS® Modeler. These might be **simple parameters** used directly in CLEM expressions, or they might be node properties, also called **slot parameters**, which are used to modify the settings of nodes in the stream.

For example, the following stream selects a subset of data from a file, passes it through a neural net, and sends the results to a file:

Figure 1. Stream operations in the user interface

The value of the field *Month* determines the selected data; the expression in the Select node is:

```
Month == '$P-mth'
```

When running the same stream in batch mode, select the appropriate month by setting the value of the parameter *mth* in the command line:

```
clemb -server -hostname myserver -port 80
-username dminer -password 1234
-stream predict.str -Pmth=Jan -execute
```

Note: In command line arguments, the **-P** flag is used to denote a parameter.

Sometimes the required command line control of the stream involves modifying the settings of the nodes in the stream using slot parameters. Consider the following stream, which reads a file, processes its contents, and sends a report to another file:

Figure 2. Stream operations in the user interface

Suppose that you want to generate the report once a month, reading the appropriate month's data and sending the report to a file whose name indicates the relevant month. You might want to set the filenames for the source data and for the report. The following command sets the appropriate slot parameters and executes the stream:

```
clemb -stream report.str -Porder.full_filename=APR_orders.dat
-Preport.filename=APR_report.txt -execute
```

Note: This command does not contain the operating-system-specific code that schedules it to run monthly.

Working with Output in Batch Mode

Working with visual output, such as tables, graphs, and charts, typically requires a user interface. Since batch mode does not launch the IBM® SPSS® Modeler user interface, output objects are diverted to a file so that you can view them later, either in the user interface or in another software package. Using the properties available for nodes (slot parameters), you can control the formats and filenames of output objects created during batch mode.

Overview

Source nodes enable you to import data stored in a number of formats, such as flat files, IBM® SPSS® Statistics (.sav), SAS, Microsoft Excel, and ODBC-compliant relational databases. You can also generate synthetic data using the User Input node.

The Sources palette contains the following nodes:

	The Analytic Server source enables you to run a stream on Hadoop Distributed File System (HDFS). The information in an Analytic Server data source can come from a variety of places, such as text files and databases. See the topic Analytic Server Source node for more information.
	The Database node can be used to import data from a variety of other packages using ODBC (Open Database Connectivity), including Microsoft SQL Server, Db2, Oracle, and others. See the topic Database source node for more information.
	The Variable File node reads data from free-field text files—that is, files whose records contain a constant number of fields but a varied number of characters. This node is also useful for files with fixed-length header text and certain types of annotations. See the topic Variable File Node for more information.
	The Fixed File node imports data from fixed-field text files—that is, files whose fields are not delimited but start at the same position and are of a fixed length. Machine-generated or legacy data are frequently stored in fixed-field format. See the topic Fixed File Node for more information.
	The Statistics File node reads data from the .sav or .zsav file format used by IBM SPSS Statistics, as well as cache files saved in IBM SPSS Modeler, which also use the same format.
	The Data Collection node imports survey data from various formats used by market research software conforming to the Data Collection Data Model. A Data Collection Developer Library must be installed to use this node. See the topic Data Collection Node for more information.
	The IBM Cognos source node imports data from Cognos Analytics databases.
	The IBM Cognos TM1 source node imports data from Cognos TM1 databases.

	The SAS File node imports SAS data into IBM SPSS Modeler. See the topic SAS Source Node for more information.
	The Excel node imports data from Microsoft Excel in the .xlsx file format. An ODBC data source is not required. See the topic Excel Source node for more information.
	The XML source node imports data in XML format into the stream. You can import a single file, or all files in a directory. You can optionally specify a schema file from which to read the XML structure.
	The User Input node provides an easy way to create synthetic data—either from scratch or by altering existing data. This is useful, for example, when you want to create a test dataset for modeling. See the topic User Input Node for more information.
	The Simulation Generate node provides an easy way to generate simulated data—either from scratch using user specified statistical distributions or automatically using the distributions obtained from running a Simulation Fitting node on existing historical data. This is useful when you want to evaluate the outcome of a predictive model in the presence of uncertainty in the model inputs.
	Use the Geospatial source node to bring map or spatial data into your data mining session. See the topic Geospatial Source Node for more information.
	The JSON source node imports data from a JSON file. See JSON Source node for more information.

To begin a stream, add a source node to the stream canvas. Next, double-click the node to open its dialog box. The various tabs in the dialog box allow you to read in data; view the fields and values; and set a variety of options, including filters, data types, field role, and missing-value checking.

Setting Field Storage and Formatting

Options on the Data tab for Fixed File, Variable File, XML Source, and User Input nodes allow you to specify the storage type for fields as they are imported or created in IBM® SPSS® Modeler. For Fixed File, Variable File and User Input nodes you can also specify the field formatting, and other metadata.

For data read from other sources, storage is determined automatically but can be changed using a conversion function, such as `to_integer`, in a Filler node or Derive node.

Field Use the Field column to view and select fields in the current dataset.

Override Select the check box in the Override column to activate options in the Storage and Input Format columns.

Data Storage

Storage describes the way data are stored in a field. For example, a field with values of 1 and 0 stores integer data. This is distinct from the measurement level, which describes the usage of the data, and does not affect storage. For example, you may want to set the measurement level for an integer field with values of 1 and 0 to *Flag*. This usually indicates that 1 = *True* and 0 = *False*. While storage must be determined at the source, measurement level can be changed using a Type node at any point in the stream. See the topic [Measurement levels](#) for more information.

Available storage types are:

- String Used for fields that contain non-numeric data, also called alphanumeric data. A string can include any sequence of characters, such as *fred*, *Class 2*, or *1234*. Note that numbers in strings cannot be used in calculations.
- Integer A field whose values are integers.
- Real Values are numbers that may include decimals (not limited to integers). The display format is specified in the Stream Properties dialog box and can be overridden for individual fields in a Type node (Format tab).
- Date Date values specified in a standard format such as year, month, and day (for example, 2007–09–26). The specific format is specified in the Stream Properties dialog box.
- Time Time measured as a duration. For example, a service call lasting 1 hour, 26 minutes, and 38 seconds might be represented as 01:26:38, depending on the current time format as specified in the Stream Properties dialog box.
- Timestamp Values that include both a date and time component, for example 2007–09–26 09:04:00, again depending on the current date and time formats in the Stream Properties dialog box. Note that timestamp values may need to be wrapped in double-quotes to ensure they are interpreted as a single value rather than separate date and time values. (This applies for example when entering values in a User Input node.)
- List Introduced in SPSS Modeler version 17, along with new measurement levels of Geospatial and Collection, a List storage field contains multiple values for a single record. There are list versions of all of the other storage types.

Table 1. List storage type icons

Icon	Storage type
	List of string

Icon	Storage type
[#]	List of integer
[#]	List of real
[#]	List of time
[#]	List of date
[#]	List of timestamp
[#]	List with a depth greater than zero

In addition, for use with the Collection measurement level, there are list versions of the following measurement levels.

Table 2. List measurement level icons

Icon	Measurement level
[#]	List of continuous
[#]	List of categorical
[#]	List of flags
[#]	List of nominal
[#]	List of ordinal

Lists can be imported into SPSS Modeler in one of three source nodes (Analytic Server, Geospatial, or Variable File), or created within your streams through use of the Derive or Filler field operation nodes.

For more information on Lists and their interaction with the Collection and Geospatial measurement levels, see [List storage and associated measurement levels](#)

Storage conversions. You can convert storage for a field using a variety of conversion functions, such as `to_string` and `to_integer`, in a Filler node. See the topic [Storage Conversion Using the Filler Node](#) for more information. Note that conversion functions (and any other functions that require a specific type of input such as a date or time value) depend on the current formats specified in the Stream Properties dialog box. For example, if you want to convert a string field with values *Jan 2018, Feb 2018*, (and so forth) to date storage, select MON YYYY as the default date format for the stream. Conversion functions are also available from the Derive node, for temporary conversion during a derive calculation. You can also use the Derive node to perform other manipulations, such as recoding string fields with categorical values. See the topic [Recoding Values with the Derive Node](#) for more information.

Reading in mixed data. Note that when reading in fields with numeric storage (either integer, real, time, timestamp, or date), any non-numeric values are set to null or system missing. This is because unlike some applications, IBM SPSS Modeler does not allow mixed storage types within a field. To avoid this, any fields with mixed data should be read in as strings, either by changing the storage type in the source node or in the external application as necessary.

Field Input Format (Fixed File, Variable File, and User Input nodes only)

For all storage types except String and Integer, you can specify formatting options for the selected field using the drop-down list. For example, when merging data from various locales, you may need to specify a period (.) as the decimal separator for one field, while another will require a comma separator.

Input options specified in the source node override the formatting options specified in the stream properties dialog box; however, they do not persist later in the stream. They are intended to parse input correctly based on your knowledge of the data. The specified formats are used as a guide for parsing the data as they are read into IBM SPSS Modeler, not to determine how they should be formatted after being read into IBM SPSS Modeler. To specify formatting on a per-field basis elsewhere in the stream, use the Format tab of a Type node. See the topic [Field Format Settings Tab](#) for more information.

Options vary depending on the storage type. For example, for the Real storage type, you can select Period (.) or Comma (,) as the decimal separator. For timestamp fields, a separate dialog box opens when you select Specify from the drop-down list. See the topic [Setting Field Format options](#) for more information.

For all storage types, you can also select Stream default to use the stream default settings for import. Stream settings are specified in the stream properties dialog box.

Additional Options

Several other options can be specified using the Data tab:

- To view storage settings for data that are no longer connected through the current node (train data, for example), select View unused field settings. You can clear the legacy fields by clicking Clear.
- At any point while working in this dialog box, click Refresh to reload fields from the data source. This is useful when you are altering data connections to the source node or when you are working between tabs on the dialog box.
- [List storage and associated measurement levels](#)

Related information

- [Common Source Node Tabs](#)

List storage and associated measurement levels

Introduced in SPSS® Modeler version 17, to work with the new measurement levels of Geospatial and Collection, a List storage field contains multiple values for a single record. Lists are enclosed in square brackets ([]). Examples of lists are: [1,2,4,16] and ["abc", "def"].

Lists can be imported into SPSS Modeler in one of three source nodes (Analytic Server, Geospatial, or Variable File), created within your streams through use of the Derive or Filler field operation nodes, or generated by the Merge node when using the Ranked Condition merge method.

Lists are considered to have a depth; for example, a simple list with items that are contained within single square brackets, in the format [1,3], is recorded in IBM® SPSS Modeler with a depth of zero. In addition to simple lists that have a depth of zero, you can use nested lists, where each value within a list is a list itself.

The depth of a nested list depends on the associated measurement level. For Typeless there is no set depth limit, for Collection the depth is zero, and for Geospatial, the depth must be between zero and two inclusive depending on the number of nested items.

For zero depth lists you can set the measurement level as either Geospatial or Collection. Both of these levels are parent measurement levels and you set the measurement sublevel information in the Values dialog box. The measurement sublevel of a Collection determines the measurement level of the elements within that list. All measurement levels (except typeless and geospatial) are available as sublevels for Collections. The Geospatial measurement level has six sublevels of Point, LineString, Polygon, MultiPoint, MultiLineString, and MultiPolygon; for more information, see [Geospatial measurement sublevels](#).

Note: The Collection measurement level can only be used with lists of depth 0, the Geospatial measurement level can only be used with lists of a maximum depth of 2, and the Typeless measurement level can be used with any list depth.

The following example shows the difference between a zero depth list and a nested list by using the structure of the Geospatial measurement sublevels Point and LineString:

- The Geospatial measurement sublevel of Point has a field depth of zero:

[1,3] two coordinates

[1,3,-1] three coordinates

- The Geospatial measurement sublevel of LineString has a field depth of one:

[[1,3], [5,0]] two coordinates

[[1,3,-1], [5,0,8]] three coordinates

The Point field (with a depth of zero) is a normal list where each value is made up of two or three coordinates. The LineString field (with a depth of one) is a list of points, where each point is made up of a further series of list values.

For more information about list creation, see [Deriving a list or geospatial field](#).

Unsupported control characters

Some of the processes in SPSS® Modeler cannot handle data that includes various control characters. If your data uses these characters you may see an error message such as the following example:

Unsupported control characters found in values of field {0}

The unsupported characters are: from 0x0 to 0x3F inclusive, and 0x7F; however, the tab (0x9(\t)), new line (0xA(\n)), and carriage return (0xD(\r)) characters do not cause a problem.

If you see an error message that relates to unsupported characters, in your stream, after your Source node, use a Filler node and the CLEM expression **stripctrlchars** to replace the characters.

Related information

- [Common Source Node Tabs](#)
-

Analytic Server Source node

The Analytic Server source enables you to run a stream on Hadoop Distributed File System (HDFS). The information in an Analytic Server data source can come from a variety of places, including:

- Text files on HDFS
- Databases
- HCatalog

Typically, a stream with an Analytic Server Source will be executed on HDFS; however, if a stream contains a node that is not supported for execution on HDFS, then as much of the stream as possible will be "pushed back" to Analytic Server, and then SPSS® Modeler Server will attempt to process the remainder of the stream. You will need to subsample very large datasets; for example, by placing a Sample node within the stream.

If you want to use your own Analytic Server connection instead of the default connection defined by your administrator, deselect Use default Analytic Server and select your connection.

Data source. Assuming you or your SPSS Modeler Server administrator has established a connection, you select a data source containing the data you wish to use. A data source contains the files and metadata associated with that source. Click Select to display a list of available data sources. See the topic [Selecting a data source](#) for more information.

If you need to create a new data source or edit an existing one, click Launch Data Source Editor....

Note that using multiple Analytic Server connections can be useful in controlling the flow of data. For example, when using the Analytic Server Source and Export nodes, you may want to use different Analytic Server connections in different branches of a stream so that when each branch runs it uses its own Analytic Server and no data will be pulled to the IBM® SPSS Modeler Server. Note that if a branch contains more than one Analytic Server connection, the data will be pulled from the Analytic Servers to the IBM SPSS Modeler Server.

- [Selecting a data source](#)
 - [Amending credentials](#)
 - [Supported nodes](#)
-

Selecting a data source

The Data Sources table displays a list of the available data sources. Select the source you want to use and click OK.

Click Show Owner to display the data source owner.

Filter by enables you to filter the data source listing on Keyword, which checks the filter criteria against the data source name and data source description, or Owner. You can enter a combination of string, numeric, or wild card characters described below as filter criteria. The search string is case sensitive. Click Refresh to update the Data Sources table.

- An underscore can be used to represent any single character in the search string.
 - % A percent sign can be used to represent any sequence of zero or more characters in the search string.
-

Amending credentials

If your credentials for accessing Analytic Server are different from the credentials for accessing SPSS® Modeler Server, you will need to enter the Analytic Server credentials when running a stream on Analytic Server. If you do not know your credentials, contact your server administrator.

Supported nodes

Many SPSS® Modeler nodes are supported for execution on HDFS, but there may be some differences in the execution of certain nodes, and some are not currently supported. This topic details the current level of support.

General

- Some characters that are normally acceptable within a quoted Modeler field name will not be accepted by Analytic Server.
- For a Modeler stream to be run in Analytic Server, it must begin with one or more Analytic Server Source nodes and end in a single modeling node or Analytic Server Export node.
- It is recommended that you set the storage of continuous targets as real rather than integer. Scoring models always write real values to the output data files for continuous targets, while the output data model for the scores follows the storage of the target. Thus, if a continuous target has integer storage, there will be a mismatch in the written values and the data model for the scores, and this mismatch will cause errors when you attempt to read the scored data.
- If a field measurement is Geospatial, the function for @OFFSET is not supported.

Source

- A stream that begins with anything other than an Analytic Server source node will be run locally.

Record operations

All Record operations are supported, with the exception of the Streaming TS and Space-Time-Boxes nodes. Further notes on supported node functionality follow.

Select

- Supports the same set of functions supported by the [Derive node](#).

Sample

- Block-level sampling is not supported.
- Complex Sampling methods are not supported.
- First n sampling with "Discard sample" is not supported.
- First n sampling with $N > 20000$ is not supported.
- 1-in- n sampling is not supported when "Maximum sample size" not set.
- 1-in- n sampling is not supported when $N * "Maximum sample size" > 20000$.
- Random % block level sampling is not supported.
- Random % currently supports supplying a seed.

Aggregate

- Contiguous keys are not supported. If you are reusing an existing stream that is set up to sort the data and then use this setting in the Aggregate node, change the stream to remove the Sort node.
- Order statistics (Median, 1st Quartile, 3rd Quartile) are computed approximately, and supported through the Optimization tab.

Sort

- The Optimization tab is not supported.

In a distributed environment, there are a limited number of operations that preserve the record order established by the Sort node.

- A Sort followed by an Export node produces a sorted data source.
- A Sort followed by a Sample node with First record sampling returns the first N records.

In general, you should place a Sort node as close as possible to the operations that need the sorted records.

Merge

- Merge by Order is not supported.
- The Optimization tab is not supported.
- Merge operations are relatively slow. If you have available space in HDFS, it can be much faster to merge your data sources once and use the merged source in following streams than to merge the data sources in each stream.

R Transform

The R syntax in the node should consist of record-at-a-time operations.

Field operations

All Field operations are supported, with the exception of the Anonymize, Transpose, Time Intervals, and History nodes. Further notes on supported node functionality follow.

Auto Data Prep

- Training the node is not supported. Applying the transformations in a trained Auto Data Prep node to new data is supported.

Derive

- All Derive functions are supported, with the exception of sequence functions.
- Deriving a new field as a Count is essentially a sequence operation, and thus not supported.
- Split fields cannot be derived in the same stream that uses them as splits; you will need to create two streams; one that derives the split field and one that uses the field as splits.

Filler

- Supports the same set of functions supported by the [Derive node](#).

Binning

The following functionality is not supported.

- Optimal binning
- Ranks
- Tiles -> Tiling: Sum of values
- Tiles -> Ties: Keep in current and Assign randomly
- Tiles ->Custom N: Values over 100, and any N value where 100 % N is not equal to zero.

RFM Analysis

- The Keep in current option for handling ties is not supported. RFM recency, frequency, and monetary scores will not always match those computed by Modeler from the same data. The score ranges will be the same but score assignments (bin numbers) may differ by one.

Graphs

All Graph nodes are supported.

Modeling

The following Modeling nodes are supported: Time Series, TCM, Isotonic-AS, Extension Model, Tree-AS, C&R Tree, Quest, CHAID, Linear, Linear-AS, Neural Net, GLE, LSVM, TwoStep-AS, Random Trees, STP, Association Rules, XGBoost-AS, Random Forest, and K-Means-AS. Further notes on those nodes' functionality follow.

Linear

When building models on big data, you will typically want to change the objective to Very large datasets, or specify splits.

- Continued training of existing PSM models is not supported.
- The Standard model building objective is only recommended if split fields are defined so that the number of records in each split is not too large, where the definition of "too large" is dependent upon the power of individual nodes in your Hadoop cluster. By contrast, you also need to be careful to ensure that splits are not defined so finely that there are too few records to build a model.
- The Boosting objective is not supported.
- The Bagging objective is not supported.
- The Very large datasets objective is not recommended when there are few records; it will often either not build a model or will build a degraded model.
- Automatic Data Preparation is not supported. This can cause problems when trying to build a model on data with many missing values; normally these would be imputed as part of automatic data preparation. A workaround would be to use a tree model or a neural network with the Advanced setting to impute missing values selected.
- The accuracy statistic is not computed for split models.

Neural Net

When building models on big data, you will typically want to change the objective to Very large datasets, or specify splits.

- Continued training of existing standard or PSM models is not supported.
- The Standard model building objective is only recommended if split fields are defined so that the number of records in each split is not too large, where the definition of "too large" is dependent upon the power of individual nodes in your Hadoop cluster. By contrast, you also need to be careful to ensure that splits are not defined so finely that there are too few records to build a model.
- The Boosting objective is not supported.
- The Bagging objective is not supported.
- The Very large datasets objective is not recommended when there are few records; it will often either not build a model or will build a degraded model.
- When there are many missing values in the data, use the Advanced setting to impute missing values.
- The accuracy statistic is not computed for split models.

C&R Tree, CHAID, and Quest

When building models on big data, you will typically want to change the objective to Very large datasets, or specify splits.

- Continued training of existing PSM models is not supported.
- The Standard model building objective is only recommended if split fields are defined so that the number of records in each split is not too large, where the definition of "too large" is dependent upon the power of individual nodes in your Hadoop cluster. By contrast, you also need to be careful to ensure that splits are not defined so finely that there are too few records to build a model.
- The Boosting objective is not supported.

- The Bagging objective is not supported.
- The Very large datasets objective is not recommended when there are few records; it will often either not build a model or will build a degraded model.
- Interactive sessions is not supported.
- The accuracy statistic is not computed for split models.
- When a split field is present, tree models built locally in Modeler are slightly different from tree models built by Analytic Server, and thus produce different scores. The algorithms in both cases are valid; the algorithms used by Analytic Server are simply newer. Given the fact that tree algorithms tend to have many heuristic rules, the difference between the two components is normal.

Model scoring

All models supported for modeling are also supported for scoring. In addition, locally-built model nuggets for the following nodes are supported for scoring: C&RT, Quest, CHAID, Linear, and Neural Net (regardless of whether the model is standard, boosted bagged, or for very large datasets), Regression, C5.0, Logistic, Genlin, GLMM, Cox, SVM, Bayes Net, TwoStep, KNN, Decision List, Discriminant, Self Learning, Anomaly Detection, Apriori, Carma, K-Means, Kohonen, R, and Text Mining.

- No raw or adjusted propensities will be scored. As a workaround you can get the same effect by manually computing the raw propensity using a Derive node with the following expression: if 'predicted-value' == 'value-of-interest' then 'prob-of-that-value' else 1-'prob-of-that-value' endif

R

The R syntax in the nugget should consist of record-at-a-time operations.

Output

The Matrix, Analysis, Data Audit, Transform, Set Globals, Statistics, Means, and Table nodes are supported. Further notes on supported node functionality follow.

Data Audit

The Data Audit node cannot produce the mode for continuous fields.

Means

The Means node cannot produce a standard error or 95% confidence interval.

Table

The Table node is supported by writing a temporary Analytic Server data source containing the results of upstream operations. The Table node then pages through the contents of that data source.

Export

A stream can begin with an Analytic Server source node and end with an export node other than the Analytic Server export node, but data will move from HDFS to SPSS Modeler Server, and finally to the export location.

Database source node

The Database source node can be used to import data from a variety of other packages using ODBC (Open Database Connectivity), including Microsoft SQL Server, Db2, Oracle, and others.

To read or write to a database, you must have an ODBC data source installed and configured for the relevant database, with read or write permissions as needed. The IBM SPSS Data Access Pack includes a set of ODBC drivers that can be used for this purpose, and these drivers are available from the download site. If you have questions about creating or setting permissions for ODBC data sources, contact your database administrator.

Supported ODBC drivers

For the latest information on which databases and ODBC drivers are supported and tested for use with IBM® SPSS® Modeler, see the product compatibility matrices on the corporate Support site (<http://www.ibm.com/support>).

Where to install drivers

Note: ODBC drivers must be installed and configured on each computer where processing may occur.

- If you are running IBM SPSS Modeler in local (standalone) mode, the drivers must be installed on the local computer.
- If you are running IBM SPSS Modeler in distributed mode against a remote IBM SPSS Modeler Server, the ODBC drivers need to be installed on the computer where IBM SPSS Modeler Server is installed. For IBM SPSS Modeler Server on UNIX systems, see also "Configuring ODBC drivers on UNIX systems" later in this section.
- If you need to access the same data sources from both IBM SPSS Modeler and IBM SPSS Modeler Server, the ODBC drivers must be installed on both computers.
- If you are running IBM SPSS Modeler over Terminal Services, the ODBC drivers need to be installed on the Terminal Services server on which you have IBM SPSS Modeler installed.

Access data from a database

To access data from a database, complete the following steps.

- Install an ODBC driver and configure a data source to the database you want to use.
- In the Database node dialog box, connect to a database using Table mode or SQL Query mode.
- Select a table from the database.
- Using the tabs in the Database node dialog box, you can alter usage types and filter data fields.

More details on the preceding steps are given in the related documentation topics.

Note: If you call database Stored Procedures (SPs) from SPSS Modeler you might see a single output field returned named `RowsAffected` rather than the expected output of the SP. This occurs when ODBC does not return sufficient information to be able to determine the output datamodel of the SP. SPSS Modeler has only limited support for SPs that return output and it is suggested that instead of using SPs you should extract the SELECT from the SP and use either of the following actions.

- Create a view based on the SELECT and choose the view in the Database source node
 - Use the SELECT directly in the Database source node.
- [Setting Database Node Options](#)
 - [Adding a database connection](#)
 - [Potential database issues](#)
 - [Specifying preset values for a database connection](#)
 - [Selecting a Database Table](#)
 - [Querying the database](#)
 - [Using a custom database configuration file](#)

Setting Database Node Options

You can use the options on the Data tab of the Database source node dialog box to gain access to a database and read data from the selected table.

Mode. Select Table to connect to a table using the dialog box controls.

Select SQL Query to query the database selected below using SQL. See the topic [Querying the database](#) for more information.

Data source. For both Table and SQL Query modes, you can enter a name in the Data Source field or select Add new database connection from the drop-down list.

The following options are used to connect to a database and select a table using the dialog box:

Table name. If you know the name of the table you would like to access, enter it in the Table Name field. Otherwise, click the Select button to open a dialog box listing the available tables.

Quote table and column names. Specify whether you want table and column names to be enclosed in quotation marks when queries are sent to the database (if, for example, they contain spaces or punctuation).

- The As needed option will quote table and field names *only* if they include nonstandard characters. Nonstandard characters include non-ASCII characters, space characters, and any non-alphanumeric character other than a full stop (.)
- Select Always if you want *all* table and field names quoted.
- Select Never if you *never* want table and field names quoted.

Strip lead and trail spaces. Select options for discarding leading and trailing spaces in strings.

Note: Comparisons between strings that do and do not use SQL pushback may generate different results where trailing spaces exist.

Reading empty strings from Oracle. When reading from or writing to an Oracle database, be aware that, unlike IBM® SPSS® Modeler and unlike most other databases, Oracle treats and stores empty string values as equivalent to null values. This means that the same data extracted from an Oracle database may behave differently than when extracted from a file or another database, and the data may return different results.

Related information

- [Database source node](#)
- [Adding a database connection](#)
- [Selecting a Database Table](#)
- [Querying the database](#)
- [Using Stream Parameters in an SQL Query](#)

Adding a database connection

To open a database, first select the data source to which you want to connect. On the Data tab, select Add new database connection from the Data Source drop-down list.

This opens the Database Connections dialog box.

Note: For an alternative way to open this dialog, from the main menu, choose: Tools > Databases...

Data sources. Lists the available data sources. Scroll down if you do not see the desired database. Once you have selected a data source and entered any passwords, click Connect. Click Refresh to update the list.

Mode. Select one of the following modes:

- Username and password. If the data source is password protected, enter your user name and the associated password.
- Stored credential. If a credential has been configured in IBM® SPSS® Collaboration and Deployment Services, you can select this option to browse for it in the repository. The credential's user name and password must match the user name and password required to access the database.

Connections. Shows currently connected databases.

- Default. You can optionally choose one connection as the default. Doing so causes Database source or export nodes to have this connection predefined as their data source, though this can be edited if desired.
- Save. Optionally select one or more connections that you want to redisplay in subsequent sessions.
- Data source. The connection strings for the currently connected databases.
- Preset. Indicates (with a * character) whether preset values have been specified for the database connection. To specify preset values, click this column in the row corresponding to the database connection, and choose Specify from the list. See the topic [Specifying preset values for a database connection](#) for more information.

To remove connections, select one from the list and click Remove.

Driver. If you select Driver for the mode instead of Data Source, choose the desired driver from the list.

- In the Attributes field, enter the database connection string. See your database documentation for the proper string to use.
- Enter any display name.
- Enter the database user name and password and click Connect.

To read or write to a database, you must have an ODBC data source installed and configured for the relevant database, with read or write permissions as needed. The IBM SPSS Data Access Pack includes a set of ODBC drivers that can be used for this purpose, and these drivers are available from the download site. If you have questions about creating or setting permissions for ODBC data sources, contact your database administrator.

Supported ODBC drivers

For the latest information on which databases and ODBC drivers are supported and tested for use with IBM SPSS Modeler, see the product compatibility matrices on the corporate Support site (<http://www.ibm.com/support>).

Where to install drivers

Note: ODBC drivers must be installed and configured on each computer where processing may occur.

- If you are running IBM SPSS Modeler in local (standalone) mode, the drivers must be installed on the local computer.
- If you are running IBM SPSS Modeler in distributed mode against a remote IBM SPSS Modeler Server, the ODBC drivers need to be installed on the computer where IBM SPSS Modeler Server is installed. For IBM SPSS Modeler Server on UNIX systems, see also "Configuring ODBC drivers on UNIX systems" later in this section.
- If you need to access the same data sources from both IBM SPSS Modeler and IBM SPSS Modeler Server, the ODBC drivers must be installed on both computers.
- If you are running IBM SPSS Modeler over Terminal Services, the ODBC drivers need to be installed on the Terminal Services server on which you have IBM SPSS Modeler installed.

Configuring ODBC drivers on UNIX systems

By default, the DataDirect Driver Manager is not configured for IBM SPSS Modeler Server on UNIX systems. To configure UNIX to load the DataDirect Driver Manager, enter the following commands:

```
cd <modeler_server_install_directory>/bin  
rm -f libspssodbc.so
```

Then run this command if you want to use the UTF8 driver wrapper:

```
ln -s libspssodbc_datadirect.so libspssodbc.so
```

Or run this command instead if you want to use the UTF16 driver wrapper:

```
ln -s libspssodbc_datadirect_utf16.so libspssodbc.so
```

Doing so removes the default link and creates a link to the DataDirect Driver Manager.

Note: The UTF16 driver wrapper is required to use SAP HANA or IBM Db2 CLI drivers for some databases. DashDB requires the IBM Db2 CLI driver.

To configure SPSS Modeler Server:

1. Configure the SPSS Modeler Server start up script modelersrv.sh to source the IBM SPSS Data Access Pack odbc.sh environment file by adding the following line to modelersrv.sh:

```
. /<pathtoSDAPinstall>/odbc.sh
```

Where <pathtoSDAPinstall> is the full path to your IBM SPSS Data Access Pack installation.

2. Restart SPSS Modeler Server.

In addition, for SAP HANA and IBM Db2 only, add the following parameter definition to the DSN in your odbc.ini file to avoid buffer overflows during connection:

```
DriverUnicodeType=1
```

Note: The libspssodbc_datadirect_utf16.so wrapper is also compatible with the other SPSS Modeler Server supported ODBC drivers.

Potential database issues

Depending on which database you use; there some potential issues that you should be aware of.

IBM Db2

When attempting to cache a node in a stream which reads data from a Db2 database, you may see the following error message:

```
A default table space could not be found with a pagesize of at least 4096 that authorization
ID TEST is authorized to use
```

To configure Db2 to enable in-database caching to work properly in SPSS® Modeler, the database administrator should create a "user temporary" tablespace and grant access to this tablespace to the relevant Db2 accounts.

We recommend using a pagesize of 32768 in the new tablespace, as this will increase the limit on the number of fields that can be successfully cached.

IBM Db2 for z/OS

- Scoring a subset of algorithms, with confidences enabled, using generated SQL can return an error on execution. The issue is specific to Db2 for z/OS; to fix this, use the SPSS Modeler Server Scoring Adapter for Db2 on z/OS.
- When running streams against Db2 for z/OS, you may experience database errors if the timeout for idle database connections is enabled and set too low. In Db2 for z/OS version 8, the default changed from no timeout to 2 minutes. The solution is to increase the value of the Db2 system parameter **IDLE THREAD TIMEOUT (IDTHTOIN)**, or reset the value to 0.

Oracle

When you run a stream that contains an Aggregate node, the values returned for the 1st and 3rd Quartiles, when pushing back SQL to an Oracle database, may differ from those that are returned in native mode.

Specifying preset values for a database connection

For some databases, you can specify a number of default settings for the database connection. The settings all apply to database export.

The database types that support this feature are as follows.

- SQL Server Enterprise and Developer editions. See the topic [Settings for SQL Server](#) for more information.
- Oracle Enterprise or Personal editions. See the topic [Settings for Oracle](#) for more information.

- IBM Db2 for z/OS and Teradata both connect to a database or schema in a similar way. See the topic [Settings for IBM Db2 for z/OS, IBM Db2 LUW, and Teradata](#) for more information.

If you are connected to a database or schema that does not support this feature, you see the message No presets can be configured for this database connection.

- [Settings for SQL Server](#)
- [Settings for Oracle](#)
- [Settings for IBM Db2 for z/OS, IBM Db2 LUW, and Teradata](#)

Settings for SQL Server

These settings are displayed for SQL Server Enterprise and Developer editions.

Use compression. If selected, creates tables for export with compression.

Compression for. Choose the level of compression.

- Row. Enables row-level compression (for example, the equivalent of `CREATE TABLE MYTABLE (...) WITH (DATA_COMPRESSION = ROW)`; in SQL).
- Page. Enables page-level compression (for example, `CREATE TABLE MYTABLE (...) WITH (DATA_COMPRESSION = PAGE)`; in SQL).

Settings for Oracle

Oracle settings - Basic option

These settings are displayed for Oracle Enterprise or Personal editions using the Basic option.

Use compression. If selected, creates tables for export with compression.

Compression for. Choose the level of compression.

- Default. Enables default compression (for example, `CREATE TABLE MYTABLE (...) COMPRESS`; in SQL). In this case, it has the same effect as the Basic option.
- Basic. Enables basic compression (for example, `CREATE TABLE MYTABLE (...) COMPRESS BASIC`; in SQL).

Oracle settings - Advanced option

These settings are displayed for Oracle Enterprise or Personal editions using the Advanced option.

Use compression. If selected, creates tables for export with compression.

Compression for. Choose the level of compression.

- Default. Enables default compression (for example, `CREATE TABLE MYTABLE (...) COMPRESS`; in SQL). In this case, it has the same effect as the Basic option.
- Basic. Enables basic compression (for example, `CREATE TABLE MYTABLE (...) COMPRESS BASIC`; in SQL).
- OLTP. Enables OLTP compression (for example, `CREATE TABLE MYTABLE (...) COMPRESS FOR OLTP`; in SQL).
- Query Low/High. (Exadata servers only) Enables hybrid columnar compression for query (for example, `CREATE TABLE MYTABLE (...) COMPRESS FOR QUERY LOW`; or `CREATE TABLE MYTABLE (...) COMPRESS FOR QUERY HIGH`; in SQL). Compression for query is useful in data warehousing environments; `HIGH` provides a higher compression ratio than `LOW`.
- Archive Low/High. (Exadata servers only) Enables hybrid columnar compression for archive (for example, `CREATE TABLE MYTABLE (...) COMPRESS FOR ARCHIVE LOW`; or `CREATE TABLE MYTABLE (...) COMPRESS FOR ARCHIVE HIGH`; in SQL). Compression for archive is useful for compressing data that will be stored for long periods of time; `HIGH` provides a higher compression ratio than `LOW`.

Settings for IBM Db2 for z/OS, IBM Db2 LUW, and Teradata

When you specify presets for IBM Db2 for z/OS, IBM Db2 LUW, or Teradata, you are prompted to select the following items:

Use server scoring adapter database or Use server scoring adapter schema. If selected, enables the Server scoring adapter database or Server scoring adapter schema option.

Server scoring adapter database or Server scoring adapter schema From the drop-down list, select the connection you require.

In addition, for Teradata, you can also set query banding details to provide additional metadata to assist with items such as workload management; collating, identifying, and resolving queries; and tracking database usage.

Spelling query banding. Choose if the query banding will be set once for the entire time you are working with a Teradata database connection (For Session), or if it will be set every time you run a stream (For Transaction).

Note: If you set query banding on a stream, the banding is lost if you copy that stream to another machine. To prevent this, you can use scripting to run your stream and use the key word *querybanding* in the script to apply the settings you require.

Required database permissions

For SPSS® Modeler database capabilities to function correctly, grant access to the following items to any user IDs used:

Db2 LUW

SYSIBM.SYSDUMMY1
SYSIBM.SYSFOREIGNKEYS
SYSIBM.SYSINDEXES
SYSIBM.SYSKEYCOLUSE
SYSIBM.SYSKEYS
SYSIBM.SYSPARMS
SYSIBM.SYSRELS

Selecting a Database Table

After you have connected to a data source, you can choose to import fields from a specific table or view. From the Data tab of the Database dialog box, you can either enter the name of a table in the Table Name field or click Select to open the Select Table/View dialog box which lists the available tables and views.

Show table owner. Select if a data source requires that the owner of a table must be specified before you can access the table. Deselect this option for data sources that do not have this requirement.

Note: SAS and Oracle databases usually require you to show the table owner.

Tables/Views. Select the table or view to import.

Show. Lists the columns in the data source to which you are currently connected. Click one of the following options to customize your view of the available tables:

- Click User Tables to view ordinary database tables created by database users.
- Click System Tables to view database tables owned by the system (for example, tables that provide information about the database, such as details of indexes). This option can be used to view the tabs used in Excel databases. (Note that a separate Excel source node is also available. See the topic [Excel Source node](#) for more information.)
- Click Views to view virtual tables based on a query involving one or more ordinary tables.
- Click Synonyms to view synonyms created in the database for any existing tables.

Name/Owner filters. These fields allow you to filter the list of displayed tables by name or owner. For example, type `SYS` to list only tables with that owner. For wildcard searches, an underscore (`_`) can be used to represent any single character and a percent sign (`%`) can represent any sequence of zero or more characters.

Set As Default. Saves the current settings as the default for the current user. These settings will be restored in the future when a user opens a new table selector dialog box *for the same data source name and user login only*.

Related information

- [Database source node](#)
- [Setting Database Node Options](#)
- [Adding a database connection](#)
- [Querying the database](#)
- [Using Stream Parameters in an SQL Query](#)

Querying the database

Once you've connected to a data source, you can choose to import fields using SQL queries. From the main dialog box, select SQL Query as the connection mode. This adds a query editor window in the dialog box. Using the query editor, you can create or load one or more SQL queries whose result set will be read into the data stream.

If you specify multiple SQL queries, separate them with semicolons (`;`) and ensure that there's no multiple SELECT statement.

To cancel and close the query editor window, select Table as the connection mode.

You can include SPSS® Modeler stream parameters (a type of user-defined variable) in the SQL query. See [Using Stream Parameters in an SQL Query](#) for more information.

Load Query. Click to open the file browser and load a previously saved query.

Save Query. Click to open the Save Query dialog box to save the current query.

Import Default. Click to import an example SQL

`SELECT` statement constructed automatically using the table and columns selected in the dialog box.

Clear. Clear the contents of the work area. Use this option when you want to start over.

Split text. The default option Never means that the query will be sent to the database as a whole. Alternatively, you can choose As needed, which means that SPSS Modeler attempts to parse the query and identify if there are SQL statements that should be send to the database one after another.

Important: Depending on the database you're using, SPSS Modeler may attempt to run the custom SQL you entered to obtain the data model the SQL results in. For example, when using MySQL or Google BigQuery, by default `SQLExecute()` is called when getting the table schema; so SPSS Modeler will run the SQL and obtain the data model. This isn't the case for most database drivers.

If you want to avoid this, see [Using a custom database configuration file](#) for details about customizing how SPSS Modeler processes SQL in such cases.

- [Using Stream Parameters in an SQL Query](#)

Using Stream Parameters in an SQL Query

When writing an SQL query to import fields, you can include SPSS® Modeler stream parameters that have been previously defined. All types of stream parameter are supported.

The following table shows how some examples of stream parameters will be interpreted in the SQL query.

Table 1. Examples of stream parameters

Stream Parameter Name (example)	Storage	Stream Parameter Value	Interpreted as
PString	String	ss	'ss'
PInt	Integer	5	5
PReal	Real	5.5	5.5
PTime	Time	23:05:01	t{'23:05:01'}
PDate	Date	2011-03-02	d{'2011-03-02'}
PTimestamp	TimeStamp	2011-03-02 23:05:01	ts{'2011-03-02 23:05:01'}
PColumn	Unknown	IntValue	IntValue

In the SQL query, you specify a stream parameter in the same way as in a CLEM expression, namely by '\$P-<parameter_name>', where <parameter_name> is the name that has been defined for the stream parameter.

When referencing a field, the storage type must be defined as Unknown, and the parameter value must be enclosed in quotation marks if needed. Thus, using the examples shown in the table, if you entered the SQL query:

```
select "IntValue" from Table1 where "IntValue" < '$P-PInt';
```

it would be evaluated as:

```
select "IntValue" from Table1 where "IntValue" < 5;
```

If you were to reference the **IntValue** field by means of the **PColumn** parameter, you would need to specify the query as follows to get the same result:

```
select "IntValue" from Table1 where "'$P-PColumn'" < '$P-PInt';
```

Using a custom database configuration file

If you need to customize the way SPSS® Modeler processes SQL, you can use a custom database configuration file. This allows for a range of customizations you might need depending on your specific circumstances. Full documentation for this capability isn't available. Contact your database administrator or IBM Support for assistance with your specific needs regarding this capability, but note that IBM doesn't support customizations done via these configuration files that aren't provided by IBM.

To implement a custom database configuration file

1. Create a .cfg file for your specific database.
2. Add options as desired. Extensive customization is possible. Note that the file must be properly named and properly formatted according to your specific database.
3. Place the file in the config folder of your SPSS Modeler Server and/or SPSS Modeler Client installation directory.

The .cfg file name must follow the format odbc-<db>-custom-properties.cfg, where <db> is one of the following database names:

- bigquery
- db2
- greenplum
- hana
- hive
- impala
- informix
- mssql
- mysql
- neoview
- netezza

- oracle
- postgresql
- redshift
- soliddb
- sybase
- teradata
- vertica

Example: execute_while_getting_schema

When using MySQL database with custom SQL in a Database source node, by default the MySQL database driver calls `SQLExecute()` when getting the table schema. As a result, SPSS Modeler needs to run your SQL and obtain the data model. If you don't want SPSS Modeler to obtain the data model, follow these steps:

1. Create a file called odbc-mysql-custom-properties.cfg.
2. Add the following line and set it to `N` to override the default behavior for MySQL:

```
execute_while_getting_schema, N
```

3. Copy the file into the config directory of your SPSS Modeler Server and SPSS Modeler Client installations.

Example: sqlmx_sort_by

By default, `order_by` isn't permitted within nested SQL during SQL pushback. By enabling `order_by`, you can force SQL pushback to work for the Sample node when there's a Sort node ahead of it. For example, to enable `order_by` on Google BigQuery database, follow these steps:

1. Create a file called odbc-bigquery-custom-properties.cfg.
2. Add the following line and set it to `y` to override the default behavior for Google BigQuery:

```
sqlmx_sort_by, Y
```

3. Copy the file into the config directory of your SPSS Modeler Server and SPSS Modeler Client installations.

Example: uda_list_sql_basic and uda_list_sql_parameter

You may want to use custom SQL to retrieve database functions and aggregate functions. For example, on Oracle database, follow these steps:

1. Create a file called odbc-oracle-custom-properties.cfg.
2. Add the following lines to the file:

```
#Define the UDA (database window aggregates) sqls

uda_list_sql_basic, "SELECT '<src_database_name>',OBJECT_NAME,OWNER,'', '' , CASE WHEN OWNER='SYS' THEN
1 ELSE 0 END BUILTIN FROM ALL_ARGUMENTS WHERE OBJECT_ID IN (SELECT OBJECT_ID FROM ALL PROCEDURES WHERE
AGGREGATE = 'YES') AND OBJECT_ID NOT IN (SELECT DISTINCT OBJECT_ID FROM ALL_ARGUMENTS WHERE PLS_TYPE IS
NULL) AND ARGUMENT_NAME IS NULL ORDER BY OBJECT_ID"

uda_list_sql_parameter, "SELECT POSITION, DATA_PRECISION,DATA_SCALE,DATA_TYPE,'',DATA_TYPE,'',0 FROM
ALL_ARGUMENTS WHERE OBJECT_ID IN (SELECT OBJECT_ID FROM ALL PROCEDURES WHERE AGGREGATE = 'YES') AND
OBJECT_ID NOT IN (SELECT DISTINCT OBJECT_ID FROM ALL_ARGUMENTS WHERE PLS_TYPE IS NULL) ORDER BY
OBJECT_ID,POSITION"
```

3. Copy the file into the config directory of your SPSS Modeler Server and SPSS Modeler Client installations.

`uda_list_sql_basic` and `uda_list_sql_parameter` may use other custom SQL provided they conform to the following table schemas below (step 2 is an example).

```
#table schema for uda_list_sql_basic
databaseName,function,schema,catalog,description,isBuiltIn

#table schema for uda_list_sql_parameter
position,precision,scale,returnType,returnTypeName,parameterTypes,parameterTypeNames,isVarArg
```

Variable File Node

You can use Variable File nodes to read data from free-field text files (files whose records contain a constant number of fields but a varied number of characters), also known as delimited text files. This type of node is also useful for files with fixed-length header text and certain types of annotations. Records are read one at a time and passed through the stream until the entire file is read.

Note regarding reading in geospatial data

If the node contains geospatial data, and the node was created as an export from a flat file, you must follow some extra steps to set up the geospatial metadata. For more information, see [Importing geospatial data into the Variable File Node](#).

Notes for reading in delimited text data

- Records must be delimited by a newline character at the end of each line. The newline character must not be used for any other purpose (such as within any field name or value). Leading and trailing spaces should ideally be stripped off to save space, although this is not critical. Optionally these spaces can be stripped out by the node.
- Fields must be delimited by a comma or other character that ideally is used only as a delimiter, meaning it does not appear within field names or values. If this is not possible, then all text fields can be wrapped in double quotation marks, if none of the field names or text values contains a double quotation mark. If field names or values do contain double quotation marks, then text fields can be wrapped in single quotation marks as an alternative, again if single quotation marks are not used elsewhere within values. If neither single or double quotation marks can be used, then text values need to be amended to remove or replace either the delimiter character, or single or double quotation marks.
- Each row, including the header row, should contain the same number of fields.
- The first line should contain the field names. If not, clear Read field names from file to give each field a generic name such as Field1, Field2, and so on.
- The second line must contain the first record of data. There must no blank lines or comments.
- Numeric values must not include the thousands separator or grouping symbol—without the comma in 3,000.00, for example. The decimal indicator (period or full-stop in the US or the UK) must be used only where appropriate.
- Date and time values should be in one of the formats that are recognized in the Stream Options dialog box, such as **DD/MM/YYYY** or **HH:MM:SS**. All dates and time fields in the file should ideally follow the same format, and any field that contains a date must use the same format for all values within that field.
- [Setting options for the Variable File Node](#)
- [Importing geospatial data into the Variable File Node](#)

Setting options for the Variable File Node

You set the options on the File tab of the Variable File node dialog box.

File Specify the name of the file. You can enter a filename or click the ellipsis button (...) to select a file. The file path is shown once you select a file, and its contents are displayed with delimiters in the panel below it.

The sample text that is displayed from your data source can be copied and pasted into the following controls: EOL comment characters and user-specified delimiters. Use Ctrl-C and Ctrl-V to copy and paste.

Read field names from file Selected by default, this option treats the first row in the data file as labels for the column. If your first row is not a header, deselect to automatically give each field a generic name, such as *Field1*, *Field2*, for the number of fields in the dataset.

Specify number of fields Specify the number of fields in each record. The number of fields can be detected automatically as long as the records are new-line terminated. You can also set a number manually.

Skip header characters Specify how many characters you want to ignore at the beginning of the first record.

EOL comment characters Specify characters, such as # or !, to indicate annotations in the data. Wherever one of these characters appears in the data file, everything up to but not including the next new-line character will be ignored.

Strip lead and trail spaces Select options for discarding leading and trailing spaces in strings on import.

Note: Comparisons between strings that do and do not use SQL pushback may generate different results where trailing spaces exist.

Invalid characters Select Discard to remove invalid characters from the data source. Select Replace with to replace invalid characters with the specified symbol (one character only). Invalid characters are null characters or any character that does not exist in the encoding method specified.

Encoding Specifies the text-encoding method used. You can choose between the system default, stream default, or UTF-8.

- The system default is specified in the Windows Control Panel or, if running in distributed mode, on the server computer.
- The stream default is specified in the Stream Properties dialog box.

Decimal symbol Select the type of decimal separator that is used in your data source. The Stream default is the character that is selected from the Options tab of the stream properties dialog box. Otherwise, select either Period (.) or Comma (,) to read all data in this dialog box using the chosen character as the decimal separator.

Line delimiter is newline character To use the newline character as the line delimiter, instead of a field delimiter, select this option. For example, this may be useful if there is an odd number of delimiters in a row that cause the line to wrap. Note that selecting this option means you cannot

select Newline in the Delimiters list.

Note: If you select this option, any blank values at the end of data rows will be stripped out.

Delimiters. Using the check boxes listed for this control, you can specify which characters, such as the comma (,), define field boundaries in the file. You can also specify more than one delimiter, such as ", |" for records that use multiple delimiters. The default delimiter is the comma.

Note: If the comma is also defined as the Decimal symbol, the default settings here will not work. In cases where the comma is both the Field delimiter and the Decimal symbol, select Other in the Field delimiters list. Then manually specify a comma in the entry field.

Select Allow multiple blank delimiters to treat multiple adjacent blank delimiter characters as a single delimiter. For example, if one data value is followed by four spaces and then another data value, this group would be treated as two fields rather than five.

Lines to scan for column and type Specify how many lines and columns to scan for specified data types.

Automatically recognize dates and times To enable IBM® SPSS® Modeler to automatically attempt to recognize data entries as dates or times, select this check box. For example, this means that an entry such as 07-11-1965 will be identified as a date and 02:35:58 will be identified as a time; however, ambiguous entries such as 07111965 or 023558 will show up as integers since there are no delimiters between the numbers.

Note: To avoid potential data problems when you use data files from previous versions of IBM SPSS Modeler, this box is turned off by default for information that is saved in versions prior to 13.

Treat square brackets as lists If you select this check box, the data included between opening and closing square brackets is treated as a single value, even if the content includes delimiter characters such as commas and double quotes. For example, this might include two or three dimensional geospatial data, where the coordinates contained within square brackets are processed as a single list item. For more information, see [Importing geospatial data into the Variable File Node](#)

Quotes. Using the drop-down lists, you can specify how single and double quotation marks are treated on import. You can choose to Discard all quotation marks, Include as text by including them in the field value, or Pair and discard to match pairs of quotation marks and remove them. If a quotation mark is unmatched, you will receive an error message. Both Discard and Pair and discard store the field value (without quotation marks) as a string.

Note: When using Pair and discard, spaces are kept. When using Discard, trailing spaces inside and outside quotes are removed (for example, ' " ab c" , "d ef " , " gh i " ' will result in 'ab c, d ef, gh i'). When using Include as text, quotes are treated as normal characters, so leading and trailing spaces will be stripped naturally.

At any point while you are working in this dialog box, click Refresh to reload fields from the data source. This is useful when you are altering data connections to the source node or when you are working between tabs in the dialog box.

Importing geospatial data into the Variable File Node

If the node contains geospatial data, was created as an export from a flat file, and is used in the same stream in which it was created, the node retains the geospatial metadata and no further configuration steps are needed.

However, if the node is exported and used in a different stream, the geospatial list data is automatically converted to a string format; you must follow some extra steps to restore the list storage type and the associated geospatial metadata.

For more information about lists, see [List storage and associated measurement levels](#).

For more information about the details you can set as geospatial metadata, see [Geospatial measurement sublevels](#).

To set up the geospatial metadata, use the following steps.

1. On the File tab of the Variable File node, select the Treat square brackets as lists check box. Selecting this check box means that the data included between opening and closing square brackets is treated as a single value, even if the content includes delimiter characters such as commas and double quotation marks. Failure to select this check box means that your data is read as a string storage type, any commas in the field are processed as delimiters, and your data structure is interpreted incorrectly.
2. If your data includes single or double quotation marks, select the Pair and discard option in the Single quotes and Double quotes fields, as appropriate.
3. On the Data tab of the Variable File node, for the geospatial data fields, select the Override check box, and change the Storage type from a string to a list.
4. By default, the list Storage type is set as a *List of real* and the underlying value storage type of the list field is set to *Real*. To change the underlying value storage type or the depth, click *Specify...* to display the Storage subdialog box.
5. In the Storage subdialog box you can modify the following settings:
 - Storage Specify the overall storage type of the data field. By default the storage type is set to List; however, the drop-down list contains all other storage types (String, Integer, Real, Date, Time, and Timestamp). If you select any storage type other than List, Value storage and Depth options are unavailable.
 - Value storage Specify the storage types of the elements in the list, as opposed to the field as a whole. When you import geospatial fields, the only relevant storage types are Real and Integer; the default setting is Real.
 - Depth Specify the depth of the list field. The required depth depends on the type of geospatial field and follows these criteria:
 - Point – 0
 - LineString – 1
 - Polygon – 1

- MultiPoint – 1
- MultiLineString – 2
- MultiPolygon – 2

Warning: You must know the type of geospatial field you are converting back into a list and the required depth for that kind of field. If this information is set incorrectly, it is not possible to use the field.

6. On the Types tab of the Variable File node, for the geospatial data field, ensure the Measurement cell contains the correct measurement level. To change the measurement level, in the Measurement cell, click Specify... to display the Values dialog box.
7. In the Values dialog box, the Measurement, Storage, and Depth for the list are displayed. Select the Specify values and labels option and, from the Type drop-down list, select the correct type for the Measurement. Depending on the Type, you might be prompted for more details such as if the data represents 2 or 3 dimensions and which coordinate system is used.

For more information about coordinate systems, see [Setting geospatial options for streams](#).

Fixed File Node

You can use Fixed File nodes to import data from fixed-field text files (files whose fields are not delimited but start at the same position and are of a fixed length). Machine-generated or legacy data are frequently stored in fixed-field format. Using the File tab of the Fixed File node, you can easily specify the position and length of columns in your data.

- [Setting options for the Fixed File node](#)

Setting options for the Fixed File node

The File tab of the Fixed File node enables you to bring data into IBM® SPSS® Modeler and to specify the position of columns and length of records. Using the data preview pane in the center of the dialog box, you can click to add arrows specifying the break points between fields.

File. Specify the name of the file. You can enter a filename or click the ellipsis button (...) to select a file. Once you have selected a file, the file path is shown and its contents are displayed with delimiters in the panel below.

The data preview pane can be used to specify column position and length. The ruler at the top of the preview window helps to measure the length of variables and to specify the break point between them. You can specify break point lines by clicking in the ruler area above the fields. Break points can be moved by dragging and can be discarded by dragging them outside of the data preview region. The ruler is designed to handle ASCII characters.

- Each break-point line automatically adds a new field to the fields table below.
- Start positions indicated by the arrows are automatically added to the Start column in the table below.

Line oriented. Select if you want to skip the new-line character at the end of each record.

Skip header lines. Specify how many lines you want to ignore at the beginning of the first record. This is useful for ignoring column headers.

Record length. Specify the number of characters in each record.

Field. All fields that you have defined for this data file are listed here. There are two ways to define fields:

- Specify fields interactively using the data preview pane above.
- Specify fields manually by adding empty field rows to the table below. Click the button to the right of the fields pane to add new fields. Then, in the empty field, enter a field name, a start position, and a length. These options will automatically add arrows to the data preview pane, which can be easily adjusted.

To remove a previously defined field, select the field in the list and click the red delete button.

Start. Specify the position of the first character in the field. For example, if the second field of a record begins on the sixteenth character, you would enter 16 as the starting point.

Length. Specify how many characters are in the longest value for each field. This determines the cutoff point for the next field.

Strip lead and trail spaces. Select to discard leading and trailing spaces in strings on import.

Note: Comparisons between strings that do and do not use SQL pushback may generate different results where trailing spaces exist.

Invalid characters. Select Discard to remove invalid characters from the data input. Select Replace with to replace invalid characters with the specified symbol (one character only). Invalid characters are null (0) characters or any character that does not exist in the current encoding.

Encoding. Specifies the text-encoding method used. You can choose between the system default, stream default, or UTF-8.

- The system default is specified in the Windows Control Panel or, if running in distributed mode, on the server computer.
- The stream default is specified in the Stream Properties dialog box.

Decimal symbol. Select the type of decimal separator used in your data source. Stream default is the character selected from the Options tab of the stream properties dialog box. Otherwise, select either Period (.) or Comma (,) to read all data in this dialog box using the chosen character as the decimal separator.

Automatically recognize dates and times. To enable IBM SPSS Modeler to automatically attempt to recognize data entries as dates or times, select this check box. For example, this means that an entry such as 07-11-1965 will be identified as a date and 02:35:58 will be identified as a time; however, ambiguous entries such as 07111965 or 023558 will show up as integers since there are no delimiters between the numbers.

Note: To avoid potential data problems when using data files from previous versions of IBM SPSS Modeler, this box is turned off by default for information saved in versions prior to 13.

Lines to scan for type. Specify how many lines to scan for specified data types.

At any point while working in this dialog box, click Refresh to reload fields from the data source. This is useful when altering data connections to the source node or when working between tabs on the dialog box.

Statistics File Node

You can use the Statistics File node to read data directly from a saved IBM® SPSS® Statistics file (.sav or .zsav). This format is now used to replace the cache file from earlier versions of IBM SPSS Modeler. If you would like to import a saved cache file, you should use the IBM SPSS Statistics File node.

Import file. Specify the name of the file. You can enter a filename or click the ellipsis button (...) to select a file. The file path is shown once you have selected a file.

File is password encrypted. Select this box if you know the file is password protected; you are prompted to enter the Password. If the file is password protected, and you do not enter the password, a warning message is displayed if you attempt to change to another tab, refresh the data, preview the node contents, or try to execute a stream containing the node.

Note: Password protected files can only be opened by IBM SPSS Modeler version 16 or greater.

Variable names. Select a method of handling variable names and labels upon import from an IBM SPSS Statistics .sav or .zsav file. Metadata that you choose to include here persists throughout your work in IBM SPSS Modeler and may be exported again for use in IBM SPSS Statistics.

- **Read names and labels.** Select to read both variable names and labels into IBM SPSS Modeler. By default, this option is selected and variable names are displayed in the Type node. Labels may be displayed in charts, model browsers, and other types of output, depending on the options specified in the stream properties dialog box. By default, the display of labels in output is disabled.
- **Read labels as names.** Select to read the descriptive variable labels from the IBM SPSS Statistics .sav or .zsav file rather than the short field names, and use these labels as variable names in IBM SPSS Modeler.

Values. Select a method of handling values and labels upon import from an IBM SPSS Statistics .sav or .zsav file. Metadata that you choose to include here persists throughout your work in IBM SPSS Modeler and may be exported again for use in IBM SPSS Statistics.

- **Read data and labels.** Select to read both actual values and value labels into IBM SPSS Modeler. By default, this option is selected and values themselves are displayed in the Type node. Value labels may be displayed in the Expression Builder, charts, model browsers, and other types of output, depending on the options specified in the stream properties dialog box.
- **Read labels as data.** Select if you want to use the value labels from the .sav or .zsav file rather than the numerical or symbolic codes used to represent the values. For example, selecting this option for data with a gender field whose values of 1 and 2 actually represent *male* and *female*, respectively, will convert the field to a string and import *male* and *female* as the actual values.

It is important to consider missing values in your IBM SPSS Statistics data before selecting this option. For example, if a numeric field uses labels only for missing values (0 = *No Answer*, -99 = *Unknown*), then selecting the option above will import only the value labels *No Answer* and *Unknown* and will convert the field to a string. In such cases, you should import the values themselves and set missing values in a Type node.

Use field format information to determine storage. If this box is cleared, field values that are formatted in the .sav file as integers (i.e., fields specified as Fn.0 in the Variable View in IBM SPSS Statistics) are imported using integer storage. All other field values except strings are imported as real numbers.

If this box is selected (default), all field values except strings are imported as real numbers, whether formatted in the .sav file as integers or not.

Multiple response sets. Any multiple response sets defined in the IBM SPSS Statistics file will automatically be preserved when the file is imported. You can view and edit multiple response sets from any node with a Filter tab. See the topic [Editing Multiple Response Sets](#) for more information.

Data Collection Node

Data Collection source nodes import survey data based on the Survey Reporter Developer Kit that is provided with your Data Collection product. This format distinguishes *case data*—the actual responses to questions gathered during a survey—from the *metadata* that describes how the

case data is collected and organized. Metadata consists of information such as question texts, variable names and descriptions, multiple response variable definitions, translations of the text strings, and the definition of the structure of the case data.

Note: This node requires the Survey Reporter Developer Kit, which is distributed along with your Data Collection product. Aside from installing the Developer Kit, no additional configuration is required.

Comments

- Survey data is read from the flat, tabular VDATA format, or from sources in the hierarchical HDATA format if they include a metadata source.
 - Types are instantiated automatically by using information from the metadata.
 - When survey data is imported into SPSS® Modeler, questions are rendered as fields, with a record for each respondent.
- [Data Collection Import File Options](#)

Data Collection Import File Options

The File tab in the Data Collection node enables you to specify options for the metadata and case data you want to import.

Metadata Settings

Note: To see the full list of available provider file types, you need to install the Survey Reporter Developer Kit, available with your Data Collection software product.

Metadata Provider. Survey data can be imported from a number of formats as supported by your Data Collection Survey Reporter Developer Kit. Available provider types include the following:

- DataCollectionMDD. Reads metadata from a questionnaire definition file (.mdd). This is the standard Data Collection Data Model format.
- ADO Database. Reads case data and metadata from ADO files. Specify the name and location of the .adoinfo file that contains the metadata. The internal name of this DSC is *mrADODsc*.
- In2data Database. Reads In2data case data and metadata. The internal name of this DSC is *mrI2dDsc*.
- Data Collection Log File. Reads metadata from a standard Data Collection log file. Typically, log files have a .tmp filename extension. However, some log files may have another filename extension. If necessary, you can rename the file so that it has a .tmp filename extension. The internal name of this DSC is *mrLogDsc*.
- Quancept Definitions File. Converts metadata to Quancept script. Specify the name of the Quancept .qdi file. The internal name of this DSC is *mrQdiDrsDsc*.
- Quanvert Database. Reads Quanvert case data and metadata. Specify the name and location of the .qvinfo or .pkd file. The internal name of this DSC is *mrQvDsc*.
- Data Collection Participation Database. Reads a project's Sample and History Table tables and creates derived categorical variables corresponding to the columns in those tables. The internal name of this DSC is *mrSampleReportingMDSC*.
- Statistics File. Reads case data and metadata from an IBM® SPSS® Statistics .sav file. Writes case data to an IBM SPSS Statistics .sav file for analysis in IBM SPSS Statistics. Writes metadata from an IBM SPSS Statistics .sav file to an .mdd file. The internal name of this DSC is *mrSavDsc*.
- Surveycraft File. Reads SurveyCraft case data and metadata. Specify the name of the SurveyCraft .vq file. The internal name of this DSC is *mrSCDsc*.
- Data Collection Scripting File. Reads from metadata in an mrScriptMetadata file. Typically, these files have an .mdd or .dms filename extension. The internal name of this DSC is *mrScriptMDSC*.
- Triple-S XML File. Reads metadata from a Triple-S file in XML format. The internal name of this DSC is *mrTripleSDsc*.

Metadata properties. Optionally, select Properties to specify the survey version to import as well as the language, context, and label type to use. See the topic [Data Collection Import Metadata Properties](#) for more information.

Case Data Settings

Note: To see the full list of available provider file types, you need to install the Survey Reporter Developer Kit, available with your Data Collection software product.

Get Case Data Settings. When reading metadata from .mdd files only, click Get Case Data Settings to determine what case data sources are associated with the selected metadata, along with the specific settings needed to access a given source. This option is available only for .mdd files.

Case Data Provider. The following provider types are supported:

- ADO Database. Reads case data using the Microsoft ADO interface. Select **OLE-DB UDL** for the case data type, and specify a connection string in the Case Data UDL field. See the topic [Database Connection String](#) for more information. The internal name of this component is *mrADODsc*.
- Delimited Text File (Excel). Reads case data from a comma-delimited (.CSV) file, such as can be output by Excel. The internal name is *mrCsvDsc*.
- Data Collection Data File. Reads case data from a native Data Collection Data Format file. The internal name is *mrDataFileDsc*.
- In2data Database. Reads case data and metadata from an In2data database (.i2d) file. The internal name is *mrI2dDsc*.
- Data Collection Log File. Reads case data from a standard Data Collection log file. Typically, log files have a .tmp filename extension. However, some log files may have another filename extension. If necessary, you can rename the file so that it has a .tmp filename extension. The internal name is *mrLogDsc*.
- Quantum Data File. Reads case data from any Quantum-format ASCII file (.dat). The internal name is *mrPunchDsc*.
- Quancept Data File. Reads case data from a Quancept .drs, .drz, or .dru file. The internal name is *mrQdiDrsDsc*.
- Quanvert Database. Reads case data from a Quanvert qvinfo or .pkd file. The internal name is *mrQvDsc*.
- Data Collection Database (MS SQL Server). Reads case data to a relational Microsoft SQL Server database. See the topic [Database Connection String](#) for more information. The internal name is *mrRdbDsc*.
- Statistics File. Reads case data from an IBM SPSS Statistics .sav file. The internal name is *mrSavDsc*.
- Surveycraft File. Reads case data from a SurveyCraft .qdt file. Both the .vq and .qdt files must be in the same directory, with read and write access for both files. This is not how they are created by default when using SurveyCraft, so one of the files needs to be moved to import SurveyCraft data. The internal name is *mrScDsc*.
- Triple-S Data File. Reads case data from a Triple-S data file, in either fixed-length or comma-delimited format. The internal name is *mrTripleDsc*.
- Data Collection XML. Reads case data from a Data Collection XML data file. Typically, this format may be used to transfer case data from one location to another. The internal name is *mrXmlDsc*.

Case Data Type. Specifies whether case data is read from a file, folder, OLE-DB UDL, or ODBC DSN, and updates the dialog box options accordingly. Valid options depend on the type of provider. For database providers, you can specify options for the OLE-DB or ODBC connection. See the topic [Database Connection String](#) for more information.

Case Data Project. When reading case data from an Data Collection database, you can enter the name of the project. For all other case data types, this setting should be left blank.

Variable Import

Import System Variables. Specifies whether system variables are imported, including variables that indicate interview status (in progress, completed, finish date, and so on). You can choose None, All, or Common.

Import "Codes" Variables. Controls import of variables that represent codes used for open-ended "Other" responses for categorical variables.

Import "SourceFile" Variables. Controls import of variables that contain filenames of images of scanned responses.

Import multi-response variables as. Multiple response variables can be imported as multiple flag fields (a multiple dichotomy set), which is the default method for new streams. Streams created in releases of IBM SPSS Modeler prior to 12.0 imported multiple responses into a single field, with values separate by commas. The older method is still supported to allow existing streams to run as they did previously, but updating older streams to use the new method is recommended. See the topic [Importing Multiple Response Sets](#) for more information.

Data Collection Import Metadata Properties

When importing Data Collection survey data, in the Metadata Properties dialog box, you can specify the survey version to import as well as the language, context, and label type to use. Note that only one language, context, and label type can be imported at a time.

Version. Each survey version can be regarded as a snapshot of the metadata used to collect a particular set of case data. As a questionnaire undergoes changes, multiple versions may be created. You can import the latest version, all versions, or a specific version.

- **All versions.** Select this option if you want to use a combination (superset) of all of the available versions. (This is sometimes called a superversion). When there is a conflict between the versions, the most recent versions generally take precedence over the older versions. For example, if a category label differs in any of the versions, the text in the latest version will be used.
- **Latest version.** Select this option if you want to use the most recent version.

- **Specify version.** Select this option if you want to use a particular survey version.

Choosing all versions is useful when, for example, you want to export case data for more than one version and there have been changes to the variable and category definitions that mean that case data collected with one version is not valid in another version. Selecting all of the versions for which you want to export the case data means that generally you can export the case data collected with the different versions at the same time without encountering validity errors due to the differences between the versions. However, depending on the version changes, some validity errors may still be encountered.

Language. Questions and associated text can be stored in multiple languages in the metadata. You can use the default language for the survey or specify a particular language. If an item is unavailable in the specified language, the default is used.

Context. Select the user context you want to use. The user context controls which texts are displayed. For example, select Question to display question texts or Analysis to display shorter texts suitable for displaying when analyzing the data.

Label type. Lists the types of labels that have been defined. The default is label, which is used for question texts in the Question user context and variable descriptions in the Analysis user context. Other label types can be defined for instructions, descriptions, and so forth.

Importing Multiple Response Sets

Multiple response variables can be imported from Data Collection as multiple dichotomy sets, with a separate flag field for each possible value of the variable. For example, if respondents are asked to select which museums they have visited from a list, the set would include a separate flag field for each museum listed.

After importing the data, you can add or edit multiple response sets from any node that includes a Filter tab. See the topic [Editing Multiple Response Sets](#) for more information.

Importing multiple responses into a single field (for streams created in previous releases)

In older releases of SPSS® Modeler, rather than import multiple responses as described above, they were imported into a single field, with values separate by commas. This method is still supported in order to support for existing streams, but it is recommended that any such streams be updated to use the new method.

Data Collection Column Import Notes

Columns from the Data Collection data are read into SPSS® Modeler as summarized in the following table.

Table 1. Data Collection column import summary

Data Collection Column Type	SPSS Modeler Storage	Measurement Level
Boolean flag (yes/no)	String	Flag (values 0 and 1)
Categorical	String	Nominal
Date or time stamp	Timestamp	Continuous
Double (floating point value within a specified range)	Real	Continuous
Long (integer value within a specified range)	Integer	Continuous
Text (free text description)	String	Typeless
Level (indicates grids or loops within a question)	Doesn't occur in VDATA and is not imported into SPSS Modeler	
Object (binary data such as a facsimile showing scribbled text or a voice recording)	Not imported into SPSS Modeler	
None (unknown type)	Not imported into SPSS Modeler	
Respondent.Serial column (associates a unique ID with each respondent)	Integer	Typeless

To avoid possible inconsistencies between value labels read from metadata and actual values, all metadata values are converted to lower case. For example, the value label *E1720_years* would be converted to *e1720_years*.

IBM Cognos source node

The IBM Cognos source node enables you to bring Cognos database data or single list reports into your data mining session. In this way, you can combine the business intelligence features of Cognos with the predictive analytics capabilities of IBM® SPSS® Modeler. You can import relational, dimensionally-modeled relational (DMR), and OLAP data.

From a Cognos server connection, you first select a location from which to import the data or reports. A location contains a Cognos model and all of the folders, queries, reports, views, shortcuts, URLs, and job definitions associated with that model. A Cognos model defines business rules, data descriptions, data relationships, business dimensions and hierarchies, and other administrative tasks.

If you are importing data, you then select the objects that you want to import from the selected package. Objects that you can import include query subjects (which represent database tables) or individual query items (which represent table columns). See [Cognos object icons](#) for more information.

If the package has filters defined, you can import one or more of these. If a filter that you import is associated with imported data, that filter is applied before the data is imported. The data to be imported must be in UTF-8 format.

If you are importing a report, you select a package, or a folder within a package, containing one or more reports. You then select the individual report you want to import. Only single list reports can be imported; multiple lists are not supported.

If parameters have been defined, either for a data object or a report, you can specify values for these parameters before importing the object or report.

Note: The Cognos source node only supports Cognos CQM packages. DQM packages are not supported.

- [Importing Cognos data](#)
- [Importing Cognos reports](#)
- [Cognos connections](#)
- [Cognos location selection](#)
- [Specifying parameters for data or reports](#)

Cognos object icons

The various types of objects you can import from a Cognos Analytics database are represented by different icons, as the following table illustrates.

Table 1. Cognos object icons

Icon	Object
	Package
	Namespace
	Query subject
	Query item
	Measure dimension
	Measure
	Dimension
	Level hierarchy
	Level
	Filter
	Report
	Standalone calculation

Importing Cognos data

To import data from an IBM Cognos Analytics database, on the Data tab of the IBM Cognos dialog box ensure that Mode is set to Data.

Connection. Click Edit to display a dialog box where you can define the details of a new Cognos connection from which to import data or reports. If you are already logged in to a Cognos server through IBM® SPSS® Modeler, you can also edit the details of the current connection. See [Cognos connections](#) for more information.

Location. When you have established the Cognos server connection, click Edit next to this field to display a list of available packages from which to import content. See [Cognos location selection](#) for more information.

Content. Displays the name of the selected package, together with the namespaces associated with the package. Double-click a namespace to display the objects that you can import. The various object types are denoted by different icons. See [Cognos object icons](#) for more information.

To choose an object to import, select the object and click the upper of the two right arrows to move the object into the Fields to import pane. Selecting a query subject imports all of its query items. Double-clicking a query subject expands it so that you can choose one or more of its

individual query items. You can perform multiple selections with Ctrl-click (select individual items), Shift-click (select a block of items) and Ctrl-A (select all items).

To choose a filter to apply (if the package has filters defined), navigate to the filter in the Content pane, select the filter and click the lower of the two right arrows to move the filter into the Filters to apply pane. You can perform multiple selections with Ctrl-click (select individual filters) and Shift-click (select a block of filters).

Fields to import. Lists the database objects that you have chosen to import into IBM SPSS Modeler for processing. If you no longer require a particular object, select it and click the left arrow to return it to the Content pane. You can perform multiple selections in the same way as for Content.

Filters to apply. Lists the filters that you have chosen to apply to the data before it is imported. If you no longer require a particular filter, select it and click the left arrow to return it to the Content pane. You can perform multiple selections in the same way as for Content.

Parameters. If this button is enabled, the selected object has parameters defined. You can use parameters to make adjustments (for example, perform a parameterized calculation) before importing the data. If parameters are defined but no default is provided, the button displays a warning triangle. Click the button to display the parameters and optionally edit them. If the button is disabled, the report has no parameters defined.

Aggregate data before importing. Check this box if you want to import aggregated data rather than raw data.

Importing Cognos reports

To import a predefined report from an IBM Cognos database, on the Data tab of the IBM Cognos dialog box ensure that Mode is set to Report. Only single list reports can be imported; multiple lists are not supported.

Connection. Click Edit to display a dialog box where you can define the details of a new Cognos connection from which to import data or reports. If you are already logged in to a Cognos server through IBM® SPSS® Modeler, you can also edit the details of the current connection. See [Cognos connections](#) for more information.

Location. When you have established the Cognos server connection, click Edit next to this field to display a list of available packages from which to import content. See [Cognos location selection](#) for more information.

Content. Displays the name of the selected package or folder that contains reports. Navigate to a specific report, select it, and click the right arrow to bring the report into the Report to import field.

Report to import. Indicates the report that you have chosen to import into IBM SPSS Modeler. If you no longer require the report, select it and click the left arrow to return it to the Content pane, or bring a different report into this field.

Parameters. If this button is enabled, the selected report has parameters defined. You can use parameters to make adjustments before importing the report (for example, specifying a start and end date for report data). If parameters are defined but no default is provided, the button displays a warning triangle. Click the button to display the parameters and optionally edit them. If the button is disabled, the report has no parameters defined.

Cognos connections

In the Cognos Connections dialog box, you can select the Cognos Analytics server from which to import or export database objects.

Cognos server URL Type the URL of the Cognos Analytics server from which to import or export. This is the value of the "External dispatcher URI" environment property of IBM Cognos Configuration on the Cognos server. Contact your Cognos system administrator if you are not sure which URL to use.

Mode Select Set Credentials if you want to log in with a specific Cognos namespace, username, and password (for example, as an administrator). Select Use Anonymous connection to log in with no user credentials, in which case you do not complete the other fields.

Alternatively, if you have an IBM Cognos credential that is stored in the IBM® SPSS® Collaboration and Deployment Services Repository, you can use this credential instead of entering user name and password information, or creating an anonymous connection. To use an existing credential, select Stored Credentials and either enter the Credential Name or browse for it.

The Cognos Namespace is modeled by a domain in IBM SPSS Collaboration and Deployment Services.

Namespace ID Specify the Cognos security authentication provider that is used to log on to the server. The authentication provider is used to define and maintain users, groups, and roles, and to control the authentication process. Note this is the Namespace ID, not the Namespace Name (the ID is not always the same as the Name).

User name Enter the Cognos user name with which to log on to the server.

Password Enter the password that is associated with the specified user name.

Save as Default Click this button to store these settings as your default, to avoid having to reenter them every time you open the node.

Cognos location selection

The Specify Location dialog box enables you to select a Cognos package from which to import data, or a package or folder from which to import reports.

Public Folders. If you are importing data, this lists the packages and folders available from the chosen server. Select the package you want to use and click OK. You can select only one package per Cognos source node.

If you are importing reports, this lists the folders and packages containing reports that are available from the chosen server. Select a package or report folder and click OK. You can select only one package or report folder per Cognos source node, though report folders can contain other report folders as well as individual reports.

Specifying parameters for data or reports

If parameters have been defined in Cognos Analytics, either for a data object or a report, you can specify values for these parameters before importing the object or report. An example of parameters for a report would be start and end dates for the report contents.

Name. The parameter name as it is specified in the Cognos database.

Type. A description of the parameter.

Value. The value to assign to the parameter. To enter or edit a value, double-click its cell in the table. Values are not validated here, so any invalid values are detected at run time.

Automatically remove invalid parameters from table. This option is selected by default and will remove any invalid parameters found within the data object or report.

IBM Cognos TM1 Source Node

The IBM Cognos TM1 source node enables you to bring Cognos TM1 data into your data mining session. In this way, you can combine the enterprise planning features of Cognos with the predictive analytics capabilities of IBM® SPSS® Modeler. You can import a flattened version of the multidimensional OLAP cube data.

Note: The TM1 user needs the following permissions: Write privilege of cubes, Read privilege of dimensions, and Write privilege of dimension elements. In addition, IBM Cognos TM1 10.2 Fix Pack 3, or later, is required before SPSS Modeler can import and export Cognos TM1 data. Existing streams that were based on previous versions will still function.

Administrator credentials are not required for this node. But if you are still using the old legacy pre-17.1 TM1 node, administrator credentials are still required.

SPSS Modeler only supports working with Cognos TM1 via IntegratedSecurityMode 1, 4, and 5.

You need to modify the data in TM1 before the data is imported. The data to be imported must be in UTF-8 format.

From an IBM Cognos TM1 administration host connection, you first select a TM1 server from which to import the data; a server contains one or more TM1 cubes. You then select the required cube and within the cube you select the columns and rows you want to import.

Note: Before you can use the TM1 Source or Export nodes in SPSS Modeler, you must verify some settings in the tm1s.cfg file; this is the TM1 server configuration file in the root directory of the TM1 server.

- HTTPPortNumber - set a valid port number; typically 1-65535. Note that this is not the port number you subsequently specify in the connection in the node; it is an internal port used by TM1 that is disabled by default. If necessary, contact your TM1 administrator to confirm the valid setting for this port.
- UseSSL - if you set this to *True*, HTTPS is used as the transport protocol. In this case you must import the TM1 certification to the SPSS Modeler Server JRE.
- [Importing IBM Cognos TM1 data](#)

Importing IBM Cognos TM1 data

To import data from an IBM Cognos TM1 database, on the Data tab of the IBM Cognos TM1 dialog box, specify the server connection details and select the cube and data details.

Note: Before importing data you must carry out some preprocessing within TM1 to ensure the data is in a format that's recognizable to IBM® SPSS® Modeler. This involves filtering your data using the Subset Editor to get the view into the correct size and shape for import.

Note that zero (0) values imported from TM1 will be treated as "null" values (TM1 does not distinguish between blank and zero values). Also, note that non-numeric data (or metadata) from *regular dimensions* can be imported into IBM SPSS Modeler. But importing non-numeric *measures* is not currently supported.

Connection Type. Select Admin Server or TM1 Server. Note that the Admin Server has been removed from [Planning Analytics on Cloud](#), so if you have old streams that connect to an old Admin Server, you can modify them to point to Planning Analytics on Cloud instead. If you select Admin Server here, then you must enter the URL for the server (the host name of the REST API) and the name of the server. If you select TM1 Server, proceed to the following sections.

TM1 Server URL. Type the URL of the administration host where the TM1 server you want to connect to is installed. The administration host is defined as a single URL for all TM1 servers. From this URL, all IBM Cognos TM1 servers installed and running on your environment can be discovered and accessed. Click Login. If you have not previously connected to this server you are prompted to enter your User name and Password; alternatively, you can search for previously entered login details that you have saved as a Stored Credential.

Select a TM1 cube view to import. Displays the name of the cubes within the TM1 server from which you can import data. Double-click a cube to display the view data you can import.

Note:

Only cubes with a dimension can be imported into IBM SPSS Modeler.

If an alias has been defined for an element in your TM1 cube (for example, if a value of 23277 has an alias of **Sales**), the value will be imported – not the alias.

To choose data to import, select the view and click the right arrow to move it into the View to import field. If the view you require isn't visible, double-click a cube to expand its list of views. You can select a public or a private view.

Row dimension(s). Lists the name of the row dimension in the data that you have chosen to import. Scroll through the list of levels and select the one you require.

Column dimension. Lists the name of the column dimension in the data that you have chosen to import. Scroll through the list of levels and select the one you require.

Context dimension(s). Display only. Shows the context dimensions that relate to the selected columns and rows.

TWC source node

The TWC source node imports weather data from The Weather Company, an IBM Business. You can use it to obtain historical or forecast weather data for a location. This can help you develop weather-driven business solutions for better decision-making using the most accurate and precise weather data available.

With this node, you can input weather-related data such as `latitude`, `longitude`, `time`, `day_ind` (indicates night or day), `temp`, `dewpt` (dew point), `rh` (relative humidity), `feels_like` temperature, `heat_index`, `wc` (wind chill), `wx_phrase` (mostly cloudy, partly cloudy, etc), `pressure`, `clds` (clouds), `vis` (visibility), `wspd` (wind speed), `gust`, `wdir` (wind direction), `wdir_cardinal` (NW, NNW, N, etc), `uv_index` (ultraviolet index), and `uv_desc` (low, high, etc).

The TWC source node uses the following APIs:

- TWC Historical Observations Airport (<http://goo.gl/DplOKj>) for historical weather data
- TWC Hourly Forecast (<http://goo.gl/IJjhvZ>) for forecast weather data

Location

Latitude. Enter the latitude value of the location you wish to obtain weather data for, in the format [-90.0~90.0].

Longitude. Enter the longitude value of the location you wish to obtain weather data for, in the format [-180.0~180.0].

Misc

License Key. A license key is required. Enter the license key you obtained from The Weather Company. If you don't have a key, contact your administrator or your IBM representative.

Instead of issuing the key to all users, your administrator may have instead specified the key in a new config.cfg file on the IBM® SPSS® Modeler Server, in which case you can leave this field blank. If specified in both locations, the key in this dialog takes precedence. Note to administrators:

To add the license key on the server, create a new file called config.cfg with the contents `LicenseKey=<LICENSEKEY>` (where `<LICENSEKEY>` is the license key) at the location `<ModelerServerInstallation>\ext\bin\pasw.twcdata`.

Units. Select the measurement unit to use: English, Metric, or Hybrid. The default is Metric.

Time Format

UTC. Select UTC time format if you're importing historical weather data and you don't want SPSS Modeler to access the TWC Hourly Forecast API. Your license key only needs privileges to access the TWC Historical Observations Airport API if you select this option.

Local. Select local time format if you need SPSS Modeler to access the TWC Hourly Forecast API to convert the time from UTC time to local time. Your license key needs privileges to access both TWC APIs if you select this option.

Data Type

Historical. If you want to import historical weather data, select Historical and then specify a start and end date in the format `YYYYMMDD` (for example, `20120101` for January 1, 2012).

Forecast. If you want to import forecast weather data, select Forecast and then specify the hours to forecast.

SAS Source Node

This feature is available in SPSS® Modeler Professional and SPSS Modeler Premium.

The SAS source node enables you to bring SAS data into your data mining session. You can import four types of files:

- SAS for Windows/OS2 (.sd2)
- SAS for UNIX (.ssd)
- SAS Transport File (.tpt)
- SAS version 7/8/9 (.sas7bdat)

When the data is imported, all variables are kept and no variable types are changed. All cases are selected.

- [Setting Options for the SAS Source Node](#)
-

Setting Options for the SAS Source Node

This feature is available in SPSS® Modeler Professional and SPSS Modeler Premium.

Import. Select which type of SAS file to transport. You can choose SAS for Windows/OS2 (.sd2), SAS for UNIX (.SSD), SAS Transport File (.tpt), or SAS Version 7/8/9 (.sas7bdat).

Import file. Specify the name of the file. You can enter a filename or click the ellipsis button (...) to browse to the file's location.

Member. Select a member to import from the SAS transport file selected above. You can enter a member name or click Select to browse through all members in the file.

Read user formats from a SAS data file. Select to read user formats. SAS files store data and data formats (such as variable labels) in different files. Most often, you will want to import the formats as well. If you have a large dataset, however, you may want to deselect this option to save memory.

Format file. If a format file is required, this text box is activated. You can enter a filename or click the ellipsis button (...) to browse to the file's location.

Variable names. Select a method of handling variable names and labels upon import from a SAS file. Metadata that you choose to include here persists throughout your work in IBM® SPSS Modeler and may be exported again for use in SAS.

- **Read names and labels.** Select to read both variable names and labels into IBM SPSS Modeler. By default, this option is selected and variable names are displayed in the Type node. Labels may be displayed in the Expression Builder, charts, model browsers, and other types of output, depending on the options specified in the stream properties dialog box.
- **Read labels as names.** Select to read the descriptive variable labels from the SAS file rather than the short field names and use these labels as variable names in IBM SPSS Modeler.
- [Selecting a Member](#)

Related information

- [SAS Source Node](#)
-

Selecting a Member

This feature is available in SPSS® Modeler Professional and SPSS Modeler Premium.

Once you have specified a SAS transport file, you need to select which member to read into IBM® SPSS Modeler. This dialog box enables you to browse through all members available from the transport file.

Excel Source node

The Excel source node enables you to import data from Microsoft Excel in the .xlsx file format.

File type. Select the Excel file type that you are importing.

Import file. Specifies the name and location of the spreadsheet file to import.

Use Named Range. Enables you to specify a named range of cells as defined in the Excel worksheet. Click the ellipses button (...) to choose from the list of available ranges. If a named range is used, other worksheet and data range settings are no longer applicable and are disabled as a result.

Choose worksheet. Specifies the worksheet to import, either by index or by name.

- By index. Specify the index value for the worksheet you want to import, beginning with 0 for the first worksheet, 1 for the second worksheet, and so on.
- By name. Specify the name of the worksheet you want to import. Click the ellipses button (...) to choose from the list of available worksheets.

Range on worksheet. You can import data beginning with the first non-blank row or with an explicit range of cells.

- Range starts on first non-blank row. Locates the first non-blank cell and uses this as the upper left corner of the data range.
- Explicit range of cells. Enables you to specify an explicit range by row and column. For example, to specify the Excel range A1:D5, you can enter A1 in the first field and D5 in the second (or alternatively, R1C1 and R5C4). All rows in the specified range are returned, including blank rows.

On blank rows. If more than one blank row is encountered, you can choose whether to Stop reading, or choose Return blank rows to continue reading all data to the end of the worksheet, including blank rows.

First row has column names. Indicates that the first row in the specified range should be used as field (column) names. If not selected, field names are generated automatically.

Lines to scan for column and type. You can increase this value if you want IBM® SPSS® Modeler to scan more rows of your Excel data to determine the column type and storage type. The default is 200 rows. Note that this setting can impact performance.

Field Storage and Measurement Level

When reading values from Excel, fields with numeric storage are read in with a measurement level of *Continuous* by default, and string fields are read in as *Nominal*. You can manually change the measurement level (continuous versus nominal) on the Type tab, but the storage is determined automatically (although it can be changed using a conversion function, such as `to_integer`, in a Filler node or Derive node if necessary). See the topic [Setting Field Storage and Formatting](#) for more information.

By default, fields with a mix of numeric and string values read in as numbers, which means that any string values will be set to null (system missing) values in IBM SPSS Modeler. This happens because, unlike Excel, IBM SPSS Modeler does not allow mixed storage types within a field. To avoid this, you can manually set the cell format to Text in the Excel spreadsheet, which causes all values (including numbers) to read in as strings.

XML Source Node

This feature is available in SPSS® Modeler Professional and SPSS Modeler Premium.

Use the XML source node to import data from a file in XML format into an IBM® SPSS Modeler stream. XML is a standard language for data exchange, and for many organizations it is the format of choice for this purpose. For example, a government tax agency might want to analyze data from tax returns that have been submitted online and which have their data in XML format (see <http://www.w3.org/standards/xml/>).

Importing XML data into an IBM SPSS Modeler stream enables you to perform a wide range of predictive analytics functions on the source. The XML data is parsed into a tabular format in which the columns correspond to the different levels of nesting of the XML elements and attributes. The XML items are displayed in XPath format (see <http://www.w3.org/TR/xpath20/>).

Important: The XML source node does not consider namespace declaration. So, for example, your XML files cannot contain a colon (:) character in the **name** tag. If they do, you'll receive errors during execution about invalid characters.

Read a single file. By default, SPSS Modeler reads a single file, which you specify in the XML data source field.

Read all XML files in a directory. Choose this option if you want to read all the XML files in a particular directory. Specify the location in the Directory field that appears. Select the Include subdirectories check box to additionally read XML files from all the subdirectories of the specified directory.

XML data source. Type the full path and file name of the XML source file you want to import, or use the Browse button to find the file.

XML schema. (Optional) Specify the full path and file name of an XSD or DTD file from which to read the XML structure, or use the Browse button to find this file. If you leave this field blank, the structure is read from the XML source file. An XSD or DTD file can have more than one root element. In this case, when you change the focus to a different field, a dialog is displayed where you choose the root element you want to use. See the topic [Selecting from Multiple Root Elements](#) for more information.

Note: XSD Indicators are ignored by SPSS Modeler

XML structure. A hierarchical tree showing the structure of the XML source file (or the schema, if you specified one in the XML schema field). To define a record boundary, select an element and click the right-arrow button to copy the item to the Records field.

Display attributes. Displays or hides the attributes of the XML elements in the XML structure field.

Records (XPath expression). Shows the XPath syntax for an element copied from the XML structure field. This element is then highlighted in the XML structure, and defines the record boundary. Each time this element is encountered in the source file, a new record is created. If this field is empty, the first child element under the root is used as the record boundary.

Read all data. By default, all data in the source file is read into the stream.

Specify data to read. Choose this option if you want to import individual elements, attributes or both. Choosing this option enables the Fields table where you can specify the data you want to import.

Fields. This table lists the elements and attributes selected for import, if you have selected the Specify data to read option. You can either type the XPath syntax of an element or attribute directly into the XPath column, or select an element or attribute in the XML structure and click the right-arrow button to copy the item into the table. To copy all the child elements and attributes of an element, select the element in the XML structure and click the double-arrow button.

- XPath. The XPath syntax of the items to be imported.
- Location. The location in the XML structure of the items to be imported. Fixed path shows the path of the item relative to the element highlighted in the XML structure (or the first child element under the root, if no element is highlighted). Any location denotes an item of the given name at any location in the XML structure. Custom is displayed if you type a location directly into the XPath column.
- [Selecting from Multiple Root Elements](#)
- [Removing Unwanted Spaces from XML Source Data](#)

Selecting from Multiple Root Elements

This feature is available in SPSS® Modeler Professional and SPSS Modeler Premium.

While a properly formed XML file can only have a single root element, an XSD or DTD file can contain multiple roots. If one of the roots matches that in the XML source file, that root element is used, otherwise you need to select one to use.

Choose the root to display. Select the root element you want to use. The default is the first root element in the XSD or DTD structure.

Removing Unwanted Spaces from XML Source Data

This feature is available in SPSS® Modeler Professional and SPSS Modeler Premium.

Line breaks in the XML source data may be implemented by a [CR] [LF] character combination. In some cases these line breaks can occur in the middle of a text string, for example:

```
<description>An in-depth look at creating applications[CR][LF]
with XML.</description>
```

These line breaks may not be visible when the file is opened in some applications, for example a Web browser. However, when the data are read into the stream through the XML source node, the line breaks are converted to a series of space characters.

You can correct this by using a Filler node to remove these unwanted spaces:

Here is an example of how you can achieve this:

1. Attach a Filler node to the XML source node.
2. Open the Filler node and use the field chooser to select the field with the unwanted spaces.
3. Set Replace to Based on condition and set Condition to true.
4. In the Replace with field, enter `replace(" ", "", @FIELD)` and click OK.
5. Attach a Table node to the Filler node and run the stream.

In the Table node output, the text now appears without the additional spaces.

User Input Node

The User Input node provides an easy way for you to create synthetic data--either from scratch or by altering existing data. This is useful, for example, when you want to create a test dataset for modeling.

Creating Data from Scratch

The User Input node is available from the Sources palette and can be added directly to the stream canvas.

1. Click the Sources tab of the nodes palette.
2. Drag and drop or double-click to add the User Input node to the stream canvas.
3. Double-click to open its dialog box and specify fields and values.

Note: User Input nodes that are selected from the Sources palette will be completely blank, with no fields and no data information. This enables you to create synthetic data entirely from scratch.

Generating Data from an Existing Data Source

You can also generate a User Input node from any nonterminal node in the stream:

1. Decide at which point in the stream you want to replace a node.
2. Right-click on the node that will feed its data into the User Input node and choose Generate User Input Node from the menu.
3. The User Input node appears with all downstream processes attached to it, replacing the existing node at that point in your data stream. When generated, the node inherits all of the data structure and field type information (if available) from the metadata.

Note: If data have not been run through all nodes in the stream, then the nodes are not fully instantiated, meaning that storage and data values may not be available when replacing with a User Input node.

- [Setting Options for the User Input Node](#)
-

Setting Options for the User Input Node

The dialog box for a User Input node contains several tools you can use to enter values and define the data structure for synthetic data. For a generated node, the table on the Data tab contains field names from the original data source. For a node added from the Sources palette, the table is blank. Using the table options, you can perform the following tasks:

- Add new fields using the Add a New Field button at the right in the table.
- Rename existing fields.
- Specify data storage for each field.
- Specify values.
- Change the order of fields on the display.

Entering Data

For each field, you can specify values or insert values from the original dataset using the value picker button to the right of the table. See the rules described below for more information on specifying values. You can also choose to leave the field blank--fields left blank are filled with the system null (`$null$`).

To specify string values, simply type them in the Values column, separated by spaces:

Fred Ethel Martin

Strings that include spaces can be wrapped in double-quotes:

```
"Bill Smith" "Fred Martin" "Jack Jones"
```

For numeric fields, you can either enter multiple values in the same manner (listed with spaces between):

```
10 12 14 16 18 20
```

Or you can specify the same series of numbers by setting its limits (10, 20) and the steps in between (2). Using this method, you would type:

```
10,20,2
```

These two methods can be combined by embedding one within the other, such as:

```
1 5 7 10,20,2 21 23
```

This entry will produce the following values:

```
1 5 7 10 12 14 16 18 20 21 23
```

Date and time values can be entered using the current default format selected in the Stream Properties dialog box, for example:

```
11:04:00 11:05:00 11:06:00
```

```
2007-03-14 2007-03-15 2007-03-16
```

For timestamp values, which have both a date and time component, double-quotes must be used:

```
"2007-03-14 11:04:00" "2007-03-14 11:05:00" "2007-03-14 11:06:00"
```

For additional details see comments on data storage below.

Generate data. Enables you to specify how the records are generated when you run the stream.

- **All combinations.** Generates records containing every possible combination of the field values, so each field value will appear in several records. This can sometimes generate more data than is wanted, so often you might follow this node with a sample node.
- **In order.** Generates records in the order in which the data field values are specified. Each field value only appears in one record. The total number of records is equal to the largest number of values for a single field. Where fields have fewer than the largest number, undefined (\$null\$) values are inserted.

Show example

For example, the following entries will generate the records listed in the two following table examples.

- **Age.** 30, 60, 10
- **BP.** LOW
- **Cholesterol.** NORMAL HIGH
- **Drug.** (left blank)

Table 1. Generate data field set to All combinations

Age	BP	Cholesterol	Drug
30	LOW	NORMAL	\$null\$
30	LOW	HIGH	\$null\$
40	LOW	NORMAL	\$null\$
40	LOW	HIGH	\$null\$
50	LOW	NORMAL	\$null\$
50	LOW	HIGH	\$null\$
60	LOW	NORMAL	\$null\$
60	LOW	HIGH	\$null\$

Table 2. Generate data field set to In order

Age	BP	Cholesterol	Drug
30	LOW	NORMAL	\$null\$
40	\$null\$	HIGH	\$null\$
50	\$null\$	\$null\$	\$null\$
60	\$null\$	\$null\$	\$null\$

Data Storage

Storage describes the way data are stored in a field. For example, a field with values of 1 and 0 stores integer data. This is distinct from the measurement level, which describes the usage of the data, and does not affect storage. For example, you may want to set the measurement level for an integer field with values of 1 and 0 to *Flag*. This usually indicates that 1 = *True* and 0 = *False*. While storage must be determined at the source, measurement level can be changed using a Type node at any point in the stream. See the topic [Measurement levels](#) for more information.

Available storage types are:

- String Used for fields that contain non-numeric data, also called alphanumeric data. A string can include any sequence of characters, such as *fred*, *Class 2*, or *1234*. Note that numbers in strings cannot be used in calculations.
- Integer A field whose values are integers.
- Real Values are numbers that may include decimals (not limited to integers). The display format is specified in the Stream Properties dialog box and can be overridden for individual fields in a Type node (Format tab).
- Date Date values specified in a standard format such as year, month, and day (for example, 2007–09–26). The specific format is specified in the Stream Properties dialog box.
- Time Time measured as a duration. For example, a service call lasting 1 hour, 26 minutes, and 38 seconds might be represented as 01:26:38, depending on the current time format as specified in the Stream Properties dialog box.
- Timestamp Values that include both a date and time component, for example 2007–09–26 09:04:00, again depending on the current date and time formats in the Stream Properties dialog box. Note that timestamp values may need to be wrapped in double-quotes to ensure they are interpreted as a single value rather than separate date and time values. (This applies for example when entering values in a User Input node.)
- List Introduced in SPSS® Modeler version 17, along with new measurement levels of Geospatial and Collection, a List storage field contains multiple values for a single record. There are list versions of all of the other storage types.

Table 3. List storage type icons

Icon	Storage type
[A]	List of string
[I]	List of integer
[#]	List of real
[C]	List of time
[D]	List of date
[T]	List of timestamp
[L]	List with a depth greater than zero

In addition, for use with the Collection measurement level, there are list versions of the following measurement levels.

Table 4. List measurement level icons

Icon	Measurement level
[P]	List of continuous
[C]	List of categorical
[F]	List of flags
[N]	List of nominal
[O]	List of ordinal

Lists can be imported into SPSS Modeler in one of three source nodes (Analytic Server, Geospatial, or Variable File), or created within your streams through use of the Derive or Filler field operation nodes.

For more information on Lists and their interaction with the Collection and Geospatial measurement levels, see [List storage and associated measurement levels](#)

Storage conversions. You can convert storage for a field using a variety of conversion functions, such as `to_string` and `to_integer`, in a Filler node. See the topic [Storage Conversion Using the Filler Node](#) for more information. Note that conversion functions (and any other functions that require a specific type of input such as a date or time value) depend on the current formats specified in the Stream Properties dialog box. For example, if you want to convert a string field with values *Jan 2018*, *Feb 2018*, (and so forth) to date storage, select MON YYYY as the default date format for the stream. Conversion functions are also available from the Derive node, for temporary conversion during a derive calculation. You can also use the Derive node to perform other manipulations, such as recoding string fields with categorical values. See the topic [Recoding Values with the Derive Node](#) for more information.

Reading in mixed data. Note that when reading in fields with numeric storage (either integer, real, time, timestamp, or date), any non-numeric values are set to null or system missing. This is because unlike some applications, IBM® SPSS Modeler does not allow mixed storage types within a field. To avoid this, any fields with mixed data should be read in as strings, either by changing the storage type in the source node or in the external application as necessary.

Note: Generated User Input nodes may already contain storage information garnered from the source node if instantiated. An uninstantiated node does not contain storage or usage type information.

Rules for Specifying Values

For symbolic fields, you should leave spaces between multiple values, such as:

HIGH MEDIUM LOW

For numeric fields, you can either enter multiple values in the same manner (listed with spaces between):

10 12 14 16 18 20

Or you can specify the same series of numbers by setting its limits (10, 20) and the steps in between (2). Using this method, you would type:

10,20,2

These two methods can be combined by embedding one within the other, such as:

1 5 7 10,20,2 21 23

This entry will produce the following values:

1 5 7 10 12 14 16 18 20 21 23

Related information

- [User Input Node](#)

Simulation Generate Node

The Simulation Generate node provides an easy way to generate simulated data, either without historical data using user specified statistical distributions, or automatically using the distributions obtained from running a Simulation Fitting node on existing historical data. Generating simulated data is useful when you want to evaluate the outcome of a predictive model in the presence of uncertainty in the model inputs.

Creating data without historical data

The Simulation Generate node is available from the Sources palette and can be added directly to the stream canvas.

1. Click the Sources tab of the nodes palette.
2. Drag and drop or double-click to add the Simulation Generate node to the stream canvas.
3. Double-click to open its dialog box and specify fields, storage types, statistical distributions and distribution parameters.

Note: Simulation Generate nodes that are selected from the Sources palette will be completely blank, with no fields and no distribution information. This enables you to entirely create simulated data without historical data.

Generating simulated data using existing historical data

A Simulation Generate node can also be created by executing a Simulation Fitting terminal node:

1. Right-click on the Simulation Fitting node and choose Run from the menu.
2. The Simulation Generate node appears on the stream canvas with an update link to the Simulation Fitting node.
3. When generated, the Simulation Generate node inherits all of the fields, storage types, and statistical distribution information from the Simulation Fitting node.

Defining an update link to a simulation fitting node

You can create a link between a Simulation Generate node and a Simulation Fitting node. This is useful if you want to update one or more fields with the information of the best fitting distribution, determined by fitting to historical data.

1. Right click on the Simulation Generate node.
2. From the menu, select Define Update Link. The cursor changes to the Link cursor.
3. Click on another node. If this node is a Simulation Fitting node, a link is made. If this node is not a Simulation Fitting node, no link is made, and the cursor changes back to a normal cursor.

If the fields in the Simulation Fitting node are different to those in the Simulation Generate node, a message is displayed informing you that there is a difference.

When the Simulation Fitting node is used to update the linked Simulation Generate node, the result depends on whether the same fields are present in both nodes, and if the fields are unlocked in the Simulation Generate node. The results of updating a Simulation Fitting node are shown in the following table.

Table 1. Results of updating a Simulation Fitting node

	Field in Simulation	Fitting node
Field in Simulation Generate node	Present	Missing
Present and unlocked.	Field is overwritten.	Field is deleted.
Missing.	Field is added.	No change.
Present and locked.	The distribution of the field is not overwritten. The information in the Fit Details dialog box and the correlations are updated.	The field is not overwritten. The correlations are set to zero.
Do not clear Min/Max when refitting check box is selected.	The field is overwritten, apart from the values in the Min, Max column.	

	Field in Simulation	Fitting node
Do not recalculate correlations when refitting check box is selected.	If the field is unlocked, it is overwritten.	The correlations are not overwritten.

Removing an update link to a simulation fitting node

You can remove a link between a Simulation Generate node and a Simulation Fitting node by taking the following steps:

1. Right click on the Simulation Generate node.
2. From the menu, select Remove Update Link. The link is removed.

- [Setting Options for the Simulation Generate Node](#)
- [Clone Field](#)
- [Fit Details](#)
- [Specify Parameters](#)
- [Distributions](#)

Setting Options for the Simulation Generate Node

You can use the options on the Data tab of the Simulation Generate node dialog box to do the following:

- View, specify, and edit the statistical distribution information for the fields.
- View, specify, and edit the correlations between the fields.
- Specify the number of iterations and cases to simulate.

Select an item. Enables you to switch between the three views of the Simulation Generate node: Simulated Fields, Correlations, and Advanced Options.

Simulated Fields view

If the Simulation Generate node has been generated or updated from a Simulation Fitting node using historical data, in the Simulated Fields view you can view and edit the statistical distribution information for each field. The following information about each field is copied to the Types tab of the Simulation Generate node from the Simulation Fitting node:

- Measurement level
- Values
- Missing
- Check
- Role

If you do not have historical data, you can define fields and specify their distributions by selecting a storage type, and selecting a distribution type and entering the required parameters. Generating data in this way means that information about the measurement level of each field will not be available until the data are instantiated, for example, on the Types tab or in a Type node.

The Simulated Fields view contains several tools, which you can use to perform the following tasks:

- Add and remove fields.
- Change the order of fields on the display.
- Specify a storage type for each field.
- Specify a statistical distribution for each field.
- Specify parameter values for the statistical distribution of each field.

Simulated Fields. This table contains one empty row if the Simulation Generate node has been added to the stream canvas from the Sources palette. When this row is edited, a new empty row is added to the bottom of the table. If the Simulation Generate node has been created from a Simulation Fitting node, this table will contain one row for each field of the historical data. Extra rows can be added to the table by clicking the Add new field icon.

The Simulated Fields table is made up of the following columns:

- Field. Contains the names of the fields. The field names can be edited by typing in the cells.
- Storage. The cells in this column contain a drop-down list of storage types. Available storage types are String, Integer, Real, Time, Date, and Timestamp. The choice of storage type determines which distributions are available in the Distribution column. If the Simulation Generate node has been created from a Simulation Fitting node, the storage type is copied over from the Simulation Fitting node.
- Note: For fields with datetime storage types, you must specify the distribution parameters as integers. For example, to specify a mean date of 1 January 1970, use the integer 0. The signed integer represents the number of seconds since (or before) midnight on 1 January 1970.
- Status. Icons in the Status column indicate the fit status for each field.

No distribution has been specified for the field or one or more distribution parameter is missing. In order to run the simulation, you must specify a distribution for this field and enter valid values for the parameters.

	The field is set to the closest fitting distribution. Note: This icon can only ever be displayed if the Simulation Generate node is created from a Simulation Fitting node.
	The closest fitting distribution has been replaced with an alternative distribution from the Fit Details sub-dialog box. See the topic Fit Details for more information.
	The distribution has been manually specified or edited, and might include a parameter specified at more than one level.

- Locked. Locking a simulated field, by selecting the check box in the column with the lock icon, excludes the field from automatic updating by a linked Simulation Fitting node. This is most useful when you manually specify a distribution and want to ensure that it will not be affected by automatic distribution fitting when a linked Simulation Fitting node is executed.
- Distribution. The cells in this column contain a drop-down list of statistical distributions. The choice of storage type determines which distributions are available in this column for a given field. See the topic [Distributions](#) for more information.
Note: You cannot specify the Fixed distribution for every field. If you want every field in your generated data to be fixed, you can use a User Input node followed by a Balance node.
- Parameters. The distribution parameters associated with each fitted distribution are displayed in this column. Multiple values of a parameter are comma separated. Specifying multiple values for a parameter generates multiple iterations for the simulation. See the topic [Iterations](#) for more information. If parameters are missing, this is reflected in the icon displayed in the Status column. To specify values for the parameters, click this column in the row corresponding to the field of interest and choose Specify from the list. This opens the Specify Parameters sub-dialog box. See the topic [Specify Parameters](#) for more information. This column is disabled if Empirical is chosen in the Distribution column.
- Min, Max. In this column, for some distributions, you can specify a minimum value, a maximum value, or both for the simulated data. Simulated data that are smaller than the minimum value and larger than the maximum value will be rejected, even though they would be valid for the specified distribution. To specify minimum and maximum values, click this column in the row corresponding to the field of interest and choose Specify from the list. This opens the Specify Parameters sub-dialog box. See the topic [Specify Parameters](#) for more information. This column is disabled if Empirical is chosen in the Distribution column.

Use Closest Fit. Only enabled if the Simulation Generate node has been created automatically from a Simulation Fitting node using historical data, and a single row in the Simulated Fields table is selected. Replaces the information for the field in the selected row with the information of the best fitting distribution for the field. If the information in the selected row has been edited, pressing this button will reset the information back to the best fitting distribution determined from the Simulation Fitting node.

Fit Details. Only enabled if the Simulation Generate node has been created automatically from a Simulation Fitting node. Opens the Fit Details sub-dialog box. See the topic [Fit Details](#) for more information.

Several useful tasks can be carried out using the icons on the right of the Simulated Fields view. These icons are described in the following table.

Table 1. Icons on the Simulated Fields view

Icon	Tooltip	Description
	Edit distribution parameters	Only enabled when a single row in the Simulated Fields table is selected. Opens the Specify Parameters sub-dialog box for the selected row. See the topic Specify Parameters for more information.
	Add new field	Only enabled when a single row in the Simulated Fields table is selected. Adds a new empty row to the bottom of the Simulated Fields table.
	Create multiple copies	Only enabled when a single row in the Simulated Fields table is selected. Opens the Clone Field sub-dialog box. See the topic Clone Field for more information.
	Delete selected field	Deletes the selected row from the Simulated Fields table.
	Move to top	Only enabled if the selected row is not already the top row of the Simulated Fields table. Moves the selected row to the top of the Simulated Fields table. This action affects the order of the fields in the simulated data.
	Move up	Only enabled if the selected row is not the top row of the Simulated Fields table. Moves the selected row up one position in the Simulated Fields table. This action affects the order of the fields in the simulated data.
	Move down	Only enabled if the selected row is not the bottom row of the Simulated Fields table. Moves the selected row down one position in the Simulated Fields table. This action affects the order of the fields in the simulated data.
	Move to bottom	Only enabled if the selected row is not already the bottom row of the Simulated Fields table. Moves the selected row to the bottom of the Simulated Fields table. This action affects the order of the fields in the simulated data.

Do not clear Min and Max when refitting. When selected, the minimum and maximum values are not overwritten when the distributions are updated by executing a connected Simulation Fitting node.

Correlations view

Input fields to predictive models are often known to be correlated--for example, height and weight. Correlations between fields that will be simulated must be accounted for in order to ensure that the simulated values preserve those correlations.

If the Simulation Generate node has been generated or updated from a Simulation Fitting node using historical data, in the Correlations view you can view and edit the calculated correlations between pairs of fields. If you do not have historical data, you can specify the correlations manually based on your knowledge of how the fields are correlated.

Note: Before any data are generated, the correlation matrix is automatically checked to see if it is positive semi-definite, and can therefore be inverted. A matrix can be inverted if its columns are linearly independent. If the correlation matrix cannot be inverted, it will be automatically adjusted to make it invertible.

You can choose to display the correlations in a matrix or list format.

Correlations matrix. Displays the correlations between pairs of fields in a matrix. The field names are listed, in alphabetical order, down the left and along the top of the matrix. Only the cells below the diagonal can be edited; a value between -1.000 and 1.000, inclusive, must be entered. The cell above the diagonal is updated when focus is changed away from its mirrored cell below the diagonal; both cells then display the same value. The diagonal cells are always disabled and always have a correlation of 1.000. The default value for all other cells is 0.000. A value of 0.000 specifies that there is no correlation between the associated pair of fields. Only continuous and ordinal fields are included in the matrix. Nominal, categorical and flag fields, and fields that are assigned the Fixed distribution are not shown in the table.

Correlations list. Displays the correlations between pairs of fields in a table. Each row of the table shows the correlation between a pair of fields. Rows cannot be added or deleted. The columns with the headings Field 1 and Field 2 contain the field names, which cannot be edited. The Correlation column contains the correlations, which can be edited; a value between -1.000 and 1.000, inclusive, must be entered. The default value for all cells is 0.000. Only continuous and ordinal fields are included in the list. Nominal, categorical and flag fields, and fields that are assigned the Fixed distribution are not shown in the list.

Reset correlations. Opens the Reset Correlations dialog box. If historical data is available, you can choose one of three options:

- Fitted. Replaces the current correlations with those calculated using the historical data.
- Zeroes. Replaces the current correlations with zeroes.
- Cancel. Closes the dialog box. The correlations are unchanged.

If historical data is not available, but you have made changes to the correlations, you can choose to replace the current correlations with zeroes, or cancel.

Show As. Select Table to display the correlations as a matrix. Select List to display the correlations as a list.

Do not recalculate correlations when refitting. Select this option if you want to manually specify correlations and prevent them from being overwritten when automatically fitting distributions using a Simulation Fitting node and historical data.

Use fitted multiway contingency table for inputs with a categorical distribution. By default, all fields with a categorical distribution are included in a contingency table (or multiway contingency table, depending on the number of fields with a categorical distribution). The contingency table is constructed, like the correlations, when a Simulation Fitting node is executed. The contingency table cannot be viewed. When this option is selected, fields with a categorical distribution are simulated using the actual percentages from the contingency table. That is, any associations between nominal fields are recreated in the new, simulated data. When this option is cleared, fields with categorical distributions are simulated using the expected percentages from the contingency table. If you modify a field, the field is removed from the contingency table.

Advanced Options view

Number of cases to simulate. Displays the options for specifying the number of cases to be simulated, and how any iterations will be named.

- Maximum number of cases. This specifies the maximum number of cases of simulated data, and associated target values, to generate. The default value is 100,00, minimum value is 1000, and maximum value is 2,147,483,647.
- Iterations. This number is calculated automatically and cannot be edited. An iteration is created automatically each time a distribution parameter has multiple values specified.
- Total rows. Only enabled when the number of iterations is greater than 1. The number is calculated automatically, using the equation shown, and cannot be edited.
- Create iteration field. Only enabled when the number of iterations is greater than 1. When selected, the Name field is enabled. See the topic [Iterations](#) for more information.
- Name. Only enabled when the Create iteration field check box is selected, and the number of iterations is greater than 1. Edit the name of the iteration field by typing in this text field. See the topic [Iterations](#) for more information.

Random seed. Setting a random seed allows you to replicate your simulation.

- Replicate results. When selected, the Generate button and Random seed field are enabled.
- Random seed. Only enabled when the Replicate results check box is selected. In this field you can specify an integer to be used as the random seed. The default value is 629111597.
- Generate. Only enabled when the Replicate results check box is selected. Creates a pseudo-random integer between 1 and 999999999, inclusive, in the Random seed field.

Clone Field

In the Clone Field dialog box you can specify how many copies of the selected field to create, and how each copy is named. It is useful to have multiple copies of fields when investigating compounded effects, for example interest or growth rates over a number of successive time periods.

The title bar of the dialog box contains the name of the selected field.

Number of copies to make. Contains the number of copies of the field to create. Click the arrows to select the number of copies to create. The minimum number of copies is 1 and the maximum is 512. The number of copies is initially set to 10.

Copy suffix character(s). Contains the characters that are added to the end of the field name for each copy. These characters separate the field name from the copy number. The suffix characters can be edited by typing in this field. This field can be left empty; in this case there will be no characters between the field name and copy number. The default character is an underscore.

Initial copy number. Contains the suffix number for the first copy. Click the arrows to select the initial copy number. The minimum initial copy number is 1 and the maximum is 1000. The default initial copy number is 1.

Copy number step. Contains the increment for the suffix numbers. Click the arrows to select the increment. The minimum increment is 1 and the maximum is 255. The increment is initially set to 1.

Fields. Contains a preview of the field names for the copies, which is updated if any of the fields of the Clone Field dialog box are edited. This text is generated automatically and cannot be edited.

OK. Generates all the copies as specified in the dialog box. The copies are added to the Simulated Fields table in the Simulation Generate node dialog box, directly below the row that contains the field that was copied.

Cancel. Closes the dialog box. Any changes that have been made are discarded.

Fit Details

The Fit Details dialog box is only available if the Simulation Generate node was created or updated by executing a Simulation Fitting node. It displays the results of automatic distribution fitting for the selected field. Distributions are ordered by goodness of fit, with the closest fitting distribution listed first. In this dialog box you can perform the following tasks:

- Examine the distributions fitted to the historical data.
- Select one of the fitted distributions.

Field. Contains the name of the selected field. This text cannot be edited.

Treat as (Measure). Displays the measurement type of the selected field. This is taken from the Simulated Fields table in the Simulation Generate node dialog box. The measurement type can be changed by clicking the arrow and selecting a measurement type from the drop-down list. There are three options: Continuous, Nominal, and Ordinal.

Distributions. The Distributions table shows all the distributions that are appropriate for the measurement type. The distributions that have been fitted to the historical data are ordered by goodness of fit, from best fitting to worst fitting. Goodness of fit is determined by the fit statistic chosen in the Simulation Fitting node. The distributions that were not fitted to the historical data are listed in the table in alphabetical order below the distributions that were fitted.

The Distribution table contains the following columns:

- **Use.** The selected radio button indicates which distribution is currently chosen for the field. You can override the closest fitting distribution by selecting the radio button for the desired distribution in the Use column. Selecting a radio button in the Use column also displays a plot of the distribution superimposed on a histogram (or bar chart) of the historical data for the selected field. Only one distribution can be selected at a time.
- **Distribution.** Contains the name of the distribution. This column cannot be edited.
- **Fit Statistics.** Contains the calculated fit statistics for the distribution. This column cannot be edited. The contents of the cell depends on the measurement type of the field:
 - **Continuous.** Contains the results of the Anderson-Darling and Kolmogorov-Smirnov tests. The p-values associated with the tests are also shown. The fit statistic chosen as the Goodness of fit criteria in the Simulation Fitting node is shown first and is used to order the distributions. The Anderson-Darling statistics are displayed as A=aval P=pval. The Kolmogorov-Smirnov statistics are displayed as K=kval P=pval. If a statistic cannot be calculated, a dot is displayed instead of a number.
 - **Nominal and Ordinal.** Contains the results of the chi-squared test. The p-value associated with the test is also shown. The statistics are displayed as Chi-Sq=val P=pval. If the distribution was not fitted, Not fitted is displayed. If the distribution cannot be mathematically fit, Cannot be fit is displayed.

Note: The cell is always empty for the Empirical distribution.

- **Parameters.** Contains the distribution parameters associated with each fitted distribution. The parameters are displayed as `parameter_name = parameter_value`, with the parameters separated by a single space. For the categorical distribution, the parameter names are the categories and the parameter values are the associated probabilities. If the distribution was not fitted to the historical data, the cell is empty. This column cannot be edited.

Histogram thumbnail. Shows a plot of the selected distribution superimposed on a histogram of the historical data of the selected field.

Distribution thumbnail. Shows an explanation and illustration of the selected distribution.

OK. Closes the dialog box and updates the values of the Measurement, Distribution, Parameters and Min, Max columns of the Simulated Fields table for the selected field with the information from the selected distribution. The icon in the Status column is also updated to reflect whether the selected distribution is the distribution with the closest fit to the data.

Cancel. Closes the dialog box. Any changes that have been made are discarded.

Specify Parameters

In the Specify Parameters dialog box you can manually specify the parameter values for the distribution of the selected field. You can also choose a different distribution for the selected field.

The Specify Parameters dialog box can be opened in three ways:

- Double click on a field name in the Simulated Fields table in the Simulation Generate node dialog box.
- Click the Parameters or Min, Max column of the Simulated Fields table, and choose Specify from the list.
- In the Simulated Fields table, select a row, and then click the Edit distribution parameters icon.

Field. Contains the name of the selected field. This text cannot be edited.

Distribution. Contains the distribution of the selected field. This is taken from the Simulated Fields table. The distribution can be changed by clicking the arrow and selecting a distribution from the drop-down list. The available distributions depend on the storage type of the selected field.

Sides. This option is only available for the when the dice distribution is selected in the Distribution field. Click the arrows to select the number of sides, or categories, to split the field in to. The minimum number of sides is two, and the maximum is 20. The number of sides is initially set to 6.

Distribution parameters. The Distribution parameters table contains one row for each parameter of the chosen distribution.

Note: Distribution uses a rate parameter, with a shape parameter $\alpha = k$ and an inverse scale parameter $\beta = 1/\theta$.

The table contains two columns:

- **Parameter.** Contains the names of the parameters. This column cannot be edited.
 - **Value(s).** Contains the values of the parameters. If the Simulation Generate node has been created or updated from a Simulation Fitting node, the cells in this column contain the parameter values that have been determined by fitting the distribution to the historical data. If the Simulation Generate node has been added to the stream canvas from the Source nodes palette, the cells in this column are empty. The values can be edited by typing in the cells. See the topic [Distributions](#) for more information about the parameters needed by each distribution, and acceptable parameter values.
- Multiple values for a parameter must be separated by commas. Specifying multiple values for a parameter will define multiple iterations of the simulation. You can only specify multiple values for one parameter.

Note: For fields with datetime storage types, you must specify the distribution parameters as integers. For example, to specify a mean date of 1 January 1970, use the integer 0.

Note: When the dice distribution is selected, the Distribution parameters table is slightly different. The table contains one row for each side (or category). The table contains a Value column and a Probability column. The Value column contains a label for each category. The default values for the labels are the integers 1-N, where N is the number of sides. The labels can be edited by typing in the cells. Any value can be entered into the cells. If you want to use a value that is not a number, the storage type of the data field must be changed to string if the storage type is not already set to string. The Probability column contains the probability of each category. The probabilities cannot be edited, and are calculated as 1/N.

Preview. Shows a sample plot of the distribution, based on the specified parameters. If two or more values have been specified for one parameter, sample plots for each value of the parameter are shown. If historical data is available for the selected field, the plot of the distribution is superimposed on a histogram of the historical data.

Optional Settings. Use these options to specify a minimum value, a maximum value, or both for the simulated data. Simulated data that are smaller than the minimum value and larger than the maximum value will be rejected, even though they would be valid for the specified distribution.

- **Specify minimum.** Select to enable the Reject values below field. The check box is disabled if the Empirical distribution is selected.
- **Reject values below.** Only enabled if Specify minimum is selected. Enter a minimum value for the simulated data. Any simulated values smaller than this value will be rejected.
- **Specify maximum.** Select to enable the Reject values above field. The check box is disabled if the Empirical distribution is selected.

- **Reject values above.** Only enabled if Specify maximum is selected. Enter a maximum value for the simulated data. Any simulated values larger than this value will be rejected.

OK. Closes the dialog box and updates the values of the Distribution, Parameters and Min, Max columns of the Simulated Fields table for the selected field. The icon in the Status column is also updated to reflect the selected distribution.

Cancel. Closes the dialog box. Any changes that have been made are discarded.

- [Iterations](#)

Iterations

If you have specified more than one value for a fixed field or a distribution parameter, an independent set of simulated cases - effectively, a separate simulation - is generated for each specified value. This allows you to investigate the effect of varying the field or parameter. Each set of simulated cases is referred to as an *iteration*. In the simulated data, the iterations are stacked up.

If the Create iteration field check box on the Advanced Options view of the Simulation Generate node dialog is selected, an iteration field is added to the simulated data as a nominal field with numeric storage. The name of this field can be edited by typing in the Name field on the Advanced Options view. This field contains a label which indicates to which iteration each simulated case belongs. The form of the labels depends on the type of iteration:

- **Iterating a fixed field.** The label is the name of the field, followed by an equals sign, followed by the value of the field for that iteration, that is
field_name = field_value
- **Iterating a distribution parameter.** The label is the name of the field, followed by a colon, followed by the name of the iterated parameter, followed by an equals sign, followed by the value of the parameter for that iteration, that is
field_name:parameter_name = parameter_value
- **Iterating a distribution parameter for a categorical or range distribution.** The label is the name of the field, followed by a colon, followed by "Iteration", followed by the iteration number, that is
field_name: Iteration iteration_number

Distributions

You can manually specify the probability distribution for any field by opening the Specify Parameters dialog box for that field, selecting the desired distribution from the Distribution list, and entering the distribution parameters in the Distribution parameters table. Following are some notes on particular distributions:

- **Categorical.** The categorical distribution describes an input field that has a fixed number of numeric values, referred to as categories. Each category has an associated probability such that the sum of the probabilities over all categories equals one.
Note: If you specify probabilities for the categories that do not sum to 1, you will receive a warning.
- **Negative Binomial - Failures.** Describes the distribution of the number of failures in a sequence of trials before a specified number of successes are observed. The parameter *Threshold* is the specified number of successes and the parameter *Probability* is the probability of success in any given trial.
- **Negative Binomial - Trials.** Describes the distribution of the number of trials that are required before a specified number of successes are observed. The parameter *Threshold* is the specified number of successes and the parameter *Probability* is the probability of success in any given trial.
- **Range.** This distribution consists of a set of intervals with a probability assigned to each interval such that the sum of the probabilities over all intervals equals 1. Values within a given interval are drawn from a uniform distribution defined on that interval. Intervals are specified by entering a minimum value, a maximum value and an associated probability.
For example, you believe that the cost of a raw material has a 40% chance of falling in the range of \$10 - \$15 per unit, and a 60% chance of falling in the range of \$15 - \$20 per unit. You would model the cost with a Range distribution consisting of the two intervals [10 - 15] and [15 - 20], setting the probability associated with the first interval to 0.4 and the probability associated with the second interval to 0.6. The intervals do not have to be contiguous and they can even be overlapping. For example, you might have specified the intervals \$10 - \$15 and \$20 - \$25 or \$10 - \$15 and \$13 - \$16.
- **Weibull.** The parameter *Location* is an optional location parameter, which specifies where the origin of the distribution is located.

The following table shows the distributions that are available for custom distribution fitting, and the acceptable values for the parameters. Some of these distributions are available for custom fitting to particular storage types, even though they are not fitted automatically to these storage types by the Simulation Fitting node.

Table 1. Distributions available for custom fitting

Distribution	Storage type supported for custom fitting	Parameters	Parameter limits	Notes
Bernoulli	Integer, real, datetime	Probability	$0 \leq \text{Probability} \leq 1$	
Beta	Integer, real, datetime	Shape 1 Shape 2 Minimum Maximum	≥ 0 ≥ 0 $< \text{Maximum}$ $> \text{Minimum}$	Minimum and maximum are optional.
Binomial	Integer, real, datetime	Number of trials (n) Probability Minimum Maximum	> 0 , integer $0 \leq \text{Probability} \leq 1$ $< \text{Maximum}$ $> \text{Minimum}$	Number of trials must be an integer. Minimum and maximum are optional.
Categorical	Integer, real, datetime, string	Category name (or label)	$0 \leq \text{Value} \leq 1$	Value is the probability of the category. The values must sum to 1, otherwise a warning is generated.
Dice	Integer, string	Sides	$2 \leq \text{Sides} \leq 20$	The probability of each category (side) is calculated as $1/N$, where N is the number of sides. The probabilities cannot be edited.
Empirical	Integer, real, datetime			You cannot edit the empirical distribution, or select it as a type. The Empirical distribution is only available when there is historical data.
Exponential	Integer, real, datetime	Scale Minimum Maximum	> 0 $< \text{Maximum}$ $> \text{Minimum}$	Minimum and maximum are optional.
Fixed	Integer, real, datetime, string	Value		You cannot specify the Fixed distribution for every field. If you want every field in your generated data to be fixed, you can use a User Input node followed by a Balance node.
Gamma	Integer, real, datetime	Shape Scale Minimum Maximum	≥ 0 ≥ 0 $< \text{Maximum}$ $> \text{Minimum}$	Minimum and maximum are optional. Distribution uses a rate parameter, with a shape parameter $\alpha = k$ and an inverse scale parameter $\beta = 1/\theta$.
Lognormal	Integer, real, datetime	Shape 1 Shape 2 Minimum Maximum	≥ 0 ≥ 0 $< \text{Maximum}$ $> \text{Minimum}$	Minimum and maximum are optional.
Negative Binomial - Failures	Integer, real, datetime	Threshold Probability Minimum Maximum	≥ 0 $0 \leq \text{Probability} \leq 1$ $< \text{Maximum}$ $> \text{Minimum}$	Minimum and maximum are optional.
Negative Binomial - Trials	Integer, real, datetime	Threshold Probability Minimum Maximum	≥ 0 $0 \leq \text{Probability} \leq 1$ $< \text{Maximum}$ $> \text{Minimum}$	Minimum and maximum are optional.
Normal	Integer, real, datetime	Mean Standard deviation Minimum Maximum	≥ 0 > 0 $< \text{Maximum}$ $> \text{Minimum}$	Minimum and maximum are optional.
Poisson	Integer, real, datetime	Mean Minimum Maximum	≥ 0 $< \text{Maximum}$ $> \text{Minimum}$	Minimum and maximum are optional.
Range	Integer, real, datetime	Begin(X) End(X) Probability(X)		X is the index of each bin. The probability values must sum to 1.
Triangular	Integer, real, datetime	Mode Minimum Maximum	$\text{Minimum} \leq \text{Value} \leq \text{Maximum}$ $< \text{Maximum}$ $> \text{Minimum}$	
Uniform	Integer, real, datetime	Minimum Maximum	$< \text{Maximum}$ $> \text{Minimum}$	

Distribution	Storage type supported for custom fitting	Parameters	Parameter limits	Notes
Weibull	Integer, real, datetime	Rate Scale Location Minimum Maximum	> 0 > 0 ≥ 0 < Maximum > Minimum	Location, maximum and minimum are optional.

Extension Import node

With the Extension Import node, you can run R or Python for Spark scripts to import data.

- [Extension Import node - Syntax tab](#)
- [Extension Import node - Console Output tab](#)
- [Filtering or renaming fields](#)
- [Viewing and setting information about types](#)

Extension Import node - Syntax tab

Select your type of syntax – R or Python for Spark. Then enter or paste your custom script for importing data. When your syntax is ready, you can click Run to execute the Extension Import node.

R example

```
# import R demo data cars to modeler
modelerData <- cars

# write the data model that matches the data
var1<-c(fieldName="speed",fieldLabel="",fieldStorage="integer",fieldMeasure="",fieldFormat="", fieldRole="")
var2<-c(fieldName="dist",fieldLabel="",fieldStorage="integer",fieldMeasure="",fieldFormat="", fieldRole="")
modelerDataModel<-data.frame(var1, var2)
```

Python for Spark example

```
import spss.pyspark.runtime
from pyspark.sql import SQLContext
from pyspark.sql.types import *

cxt = spss.pyspark.runtime.getContext()
if cxt.isComputeDataModelOnly():
    _schema = StructType([StructField("Age", LongType(), nullable=True), \
                          StructField("Sex", StringType(), nullable=True), \
                          StructField("BP", StringType(), nullable=True), \
                          StructField("Cholesterol", StringType(), nullable=True), \
                          StructField("Na", DoubleType(), nullable=True), \
                          StructField("K", DoubleType(), nullable=True), \
                          StructField("Drug", StringType(), nullable=True)])
    cxt.setSparkOutputSchema(_schema)
else:
    sqlContext = cxt.getSparkSQLContext()
    # the demo data is in modeler installation path
    df = sqlContext.read.option("inferSchema", "true").option("header",
    "true").csv("/opt/IBM/SPSS/ModelerServer/Cloud/demos/DRUG1n")
    cxt.setSparkOutputData(df)
    df.show()
    # print (df.dtypes[:])
```

Extension Import node - Console Output tab

The Console Output tab contains any output that is received when the R script or Python for Spark script on the Syntax tab runs (for example, if using an R script, it shows output received from the R console when the R script in the R Syntax field on the Syntax tab is executed). This output might include R or Python error messages or warnings that are produced when the R or Python script is executed. The output can be used, primarily, to debug the script. The Console Output tab also contains the script from the R Syntax or Python Syntax field.

Every time the Extension Import script is executed, the content of the Console Output tab is overwritten with the output received from the R console or Python for Spark. The output cannot be edited.

Filtering or renaming fields

You can rename or exclude fields at any point in a stream. For example, as a medical researcher, you may not be concerned about the potassium level (field-level data) of patients (record-level data); therefore, you can filter out the **K** (potassium) field. This can be done using a separate Filter node or using the Filter tab on a source or output node. The functionality is the same regardless of which node it is accessed from.

- From source nodes, such as Variable File, Fixed File, Statistics File, XML, or Extension Import, you can rename or filter fields as the data are read into IBM® SPSS® Modeler.
- Using a Filter node, you can rename or filter fields at any point in the stream.
- From Statistics Export, Statistics Transform, Statistics Model, and Statistics Output nodes, you can filter or rename fields to conform to IBM SPSS Statistics naming standards. See the topic [Renaming or Filtering Fields for IBM SPSS Statistics](#) for more information.
- You can use the Filter tab in any of the above nodes to define or edit multiple response sets. See the topic [Editing Multiple Response Sets](#) for more information.
- Finally, you can use a Filter node to map fields from one source node to another.

Viewing and setting information about types

From various source nodes as well as the Type node, you can specify field metadata and properties that are invaluable to modeling and other work in IBM® SPSS® Modeler. These properties include:

- Specifying a usage type, such as range, set, ordered set, or flag, for each field in your dataset.
- Setting options for handling missing values and system nulls.
- Setting the role of a field for modeling purposes.
- Specifying values for a field as well as options used to automatically read values from the dataset.
- Specifying field and value labels.

Select help specific to your situation from the list below.

Geospatial Source Node

You use the Geospatial source node to bring map or spatial data into your data mining session. You can import data in one of two ways:

- In a shape file (.shp)
- By connecting to an ESRI server that contains a hierarchical file system which includes map files.

Note: You can only connect to public map services.

Spatio-Temporal Prediction (STP) models can include map or spatial elements in their predictions. For more information, see [Spatio-Temporal Prediction modeling node](#)

- [Setting Options for the Geospatial Source Node](#)

Setting Options for the Geospatial Source Node

Datasource type You can import data from either a Shape file (.shp), or connect to a Map service.

If you are using a Shape file, either enter the file name and the filepath to it, or browse to select the file. The file must either be on the local directory or accessed from a mapped drive; you cannot access the file by using a uniform naming convention (UNC) path.

Note: Shape data requires both a .shp and a .dbf file. The two files must have the same name and be in the same folder. The .dbf file is automatically imported when you select the .shp file. In addition, there might be a .prj file that specifies the coordinate system for the shape data.

If you are using a Map service, enter the URL to the service and click Connect. After you connect to the service, the layers within that service are displayed in the bottom of the dialog box in a tree structure in the Available maps pane; expand the tree and select the layer that you require.

Note: You can only connect to public map services.

Automatic definition of geospatial data

By default, SPSS® Modeler automatically defines, when possible, any geospatial data fields in the source node with the correct metadata. Metadata might include the measurement level of the geospatial field (such as Point or Polygon) and the coordinate system that is used by the fields, including details such as the origin point (for example, latitude 0, longitude 0) and the units of measure. For more information about measurement levels, see [Geospatial measurement sublevels](#).

The .shp and .dbf files that make up the shape file contain a common identifier field that is used as a key. For example, the .shp file might contain countries, with the country name field used as an identifier, and the .dbf file might contain information about those countries with the name of the country that is also used as the identifier.

Note: If the coordinate system is not the same as the default SPSS Modeler coordinate system you may have to reproject the data to use the required coordinate system. For more information, see [Reprojection Node](#).

Related information

- [Geospatial Source Node](#)
 - [Reprojection Node](#)
-

JSON Source node

Use the JSON source node to import data from a JSON file into an SPSS® Modeler stream, using UTF-8 encoding. Data in a JSON file can be in form of *object*, *array*, or *value*. This JSON source node only supports reading in an *array* of objects, and the object can't be nested.

Example JSON data:

```
[  
  {  
    "After": 122762,  
    "Promotion": 1467,  
    "Cost": 23.99,  
    "Class": "Confection",  
    "Before": 11495  
  },  
  {  
    "After": 137097,  
    "Promotion": 1745,  
    "Cost": 79.29,  
    "Class": "Drink",  
    "Before": 123378  
  }  
]
```

When SPSS Modeler reads data from a JSON file, it performs the following translations.

Table 1. JSON data storage translation

JSON Value	SPSS Modeler Data Storage
string	String
number(int)	Integer
number(real)	Real
true	1(Integer)
false	0(Integer)
null	Missing values

The following options are available in the JSON source node dialog.

JSON data source. Select the JSON file to import.

JSON string format. Specify the format of the JSON string. Select Records if your JSON file is a collection of name and value pairs. The JSON source node imports names as field names in SPSS Modeler. Or select Values if your JSON data only uses values (no names).

Common Source Node Tabs

The following options can be specified for all source nodes by clicking the corresponding tab:

- **Data tab.** Used to change the default storage type.

- **Filter tab.** Used to eliminate or rename data fields. This tab offers the same functionality as the Filter node. See the topic [Setting filtering options](#) for more information.
 - **Types tab.** Used to set measurement levels. This tab offers the same functionality as the Type node.
 - **Annotations tab.** Used for all nodes, this tab offers options to rename nodes, supply a custom ToolTip, and store a lengthy annotation.
- [Setting Measurement Levels in the Source Node](#)**
- [Filtering Fields from the Source Node](#)**

Related information

- [Setting Field Storage and Formatting](#)
- [Setting Measurement Levels in the Source Node](#)

Setting Measurement Levels in the Source Node

Field properties can be specified in a source node or in a separate Type node. The functionality is similar in both nodes. The following properties are available:

- Field Double-click any field name to specify value and field labels for data in IBM® SPSS® Modeler. For example, field metadata imported from IBM SPSS Statistics can be viewed or modified here. Similarly, you can create new labels for fields and their values. The labels that you specify here are displayed throughout IBM SPSS Modeler depending on the selections you make in the stream properties dialog box.
- Measurement This is the measurement level, used to describe characteristics of the data in a given field. If all of the details of a field are known, it is called **fully instantiated**. For more information, see [Measurement levels](#).
Note: The measurement level of a field is different from its storage type, which indicates whether the data are stored as strings, integers, real numbers, dates, times, timestamps, or lists.
- Values This column enables you to specify options for reading data values from the data set, or use the Specify option to specify measurement levels and values in a separate dialog box. You can also choose to pass fields without reading their values. For more information, see [Data Values](#).
Note: You cannot amend the cell in this column if the corresponding Field entry contains a list.
- Missing Used to specify how missing values for the field will be handled. For more information, see [Defining Missing Values](#).
Note: You cannot amend the cell in this column if the corresponding Field entry contains a list.
- Check In this column, you can set options to ensure that field values conform to the specified values or ranges. For more information, see [Checking Type Values](#).
Note: You cannot amend the cell in this column if the corresponding Field entry contains a list.
- Role Used to tell modeling nodes whether fields will be Input (predictor fields) or Target (predicted fields) for a machine-learning process. Both and None are also available roles, along with Partition, which indicates a field used to partition records into separate samples for training, testing, and validation. The value Split specifies that separate models will be built for each possible value of the field. For more information, see [Setting the field role](#).

See the topic [Type Node](#) for more information.

- [When to instantiate at the source node](#)

Related information

- [Common Source Node Tabs](#)
- [Data Values](#)
- [Checking Type Values](#)
- [Setting the field role](#)

When to instantiate at the source node

There are two ways you can learn about the data storage and values of your fields. This *instantiation* can occur at either the source node, when you first bring data into IBM® SPSS® Modeler, or by inserting a Type node into the data stream.

Instantiating at the source node is useful when:

- The dataset is small.
- You plan to derive new fields using the Expression Builder (instantiating makes field values available from the Expression Builder).

Generally, if your dataset is not very large and you don't plan to add fields later in the stream, instantiating at the source node is the most convenient method.

Note: If you export data in a database export node, the data must be fully instantiated.

Filtering Fields from the Source Node

The Filter tab on a source node dialog box enables you to exclude fields from downstream operations based on your initial examination of the data. This is useful, for example, if there are duplicate fields in the data or if you are already familiar enough with the data to exclude irrelevant fields. Alternatively, you can add a separate Filter node later in the stream. The functionality is similar in both cases. See the topic [Setting filtering options](#) for more information.

Overview of Record Operations

Record operations nodes are used to make changes to data at the record level. These operations are important during the **Data Understanding** and **Data Preparation** phases of data mining because they allow you to tailor the data to your particular business need.

For example, based on the results of the data audit conducted using the Data Audit node (Output palette), you might decide that you would like customer purchase records for the past three months to be merged. Using a Merge node, you can merge records based on the values of a key field, such as *Customer ID*. Or you might discover that a database containing information about Web site hits is unmanageable with over one million records. Using a Sample node, you can select a subset of data for use in modeling.

The Record Operations palette contains the following nodes:

	The Select node selects or discards a subset of records from the data stream based on a specific condition. For example, you might select the records that pertain to a particular sales region.
	The Sample node selects a subset of records. A variety of sample types are supported, including stratified, clustered, and nonrandom (structured) samples. Sampling can be useful to improve performance, and to select groups of related records or transactions for analysis.
	The Balance node corrects imbalances in a dataset, so it conforms to a specified condition. The balancing directive adjusts the proportion of records where a condition is true by the factor specified.
	The Aggregate node replaces a sequence of input records with summarized, aggregated output records.
	The Recency, Frequency, Monetary (RFM) Aggregate node enables you to take customers' historical transactional data, strip away any unused data, and combine all of their remaining transaction data into a single row that lists when they last dealt with you, how many transactions they have made, and the total monetary value of those transactions.
	The Sort node sorts records into ascending or descending order based on the values of one or more fields.
	The Merge node takes multiple input records and creates a single output record containing some or all of the input fields. It is

	useful for merging data from different sources, such as internal customer data and purchased demographic data.
	The Append node concatenates sets of records. It is useful for combining datasets with similar structures but different data.
	The Distinct node removes duplicate records, either by passing the first distinct record to the data stream or by discarding the first record and passing any duplicates to the data stream instead.
	The Streaming Time Series node builds and scores time series models in one step. You can use the node with data in either a local or distributed environment; in a distributed environment you can harness the power of IBM® SPSS® Analytic Server
	The Spectral Clustering© algorithm uses several eigenvectors to project data into a space with fewer dimensions. Then a k-means clustering algorithm is applied in the new space to separate the data into clusters. It's reasonably fast for small records with many fields, and computationally expensive for large data sets. The Spectral Clustering node in SPSS Modeler exposes the core features and commonly used parameters of the Spectral Clustering library. The node is implemented in Python.
	Space-Time-Boxes (STB) are an extension of Geohashed spatial locations. More specifically, an STB is an alphanumeric string that represents a regularly shaped region of space and time.
	The Streaming TCM node builds and scores temporal causal models in one step.
	The CPLEX Optimization node provides the ability to use complex mathematical (CPLEX) based optimization via an Optimization Programming Language (OPL) model file. This functionality was available in the IBM Analytical Decision Management product, which is no longer supported. But you can also use the CPLEX node in SPSS Modeler without requiring IBM Analytical Decision Management.

Many of the nodes in the Record Operations palette require you to use a CLEM expression. If you are familiar with CLEM, you can type an expression in the field. However, all expression fields provide a button that opens the CLEM Expression Builder, which helps you create such expressions automatically.

Figure 1. Expression Builder button

Select Node

You can use Select nodes to select or discard a subset of records from the data stream based on a specific condition, such as `BP = "HIGH"`.

Mode. Specifies whether records that meet the condition will be included or excluded from the data stream.

- **Include.** Select to include records that meet the selection condition.
- **Discard.** Select to exclude records that meet the selection condition.

Condition. Displays the selection condition that will be used to test each record, which you specify using a CLEM expression. Either enter an expression in the window or use the Expression Builder by clicking the calculator (Expression Builder) button to the right of the window.

If you choose to discard records based on a condition, such as the following:

```
(var1='value1' and var2='value2')
```

the Select node by default also discards records having null values for all selection fields. To avoid this, append the following condition to the original one:

```
and not(@NULL(var1) and @NULL(var2))
```

Select nodes are also used to choose a proportion of records. Typically, you would use a different node, the Sample node, for this operation. However, if the condition you want to specify is more complex than the parameters provided, you can create your own condition using the Select node. For example, you can create a condition such as:

```
BP = "HIGH" and random(10) <= 4
```

This will select approximately 40% of the records showing high blood pressure and pass those records downstream for further analysis.

-

Sample Node

You can use Sample nodes to select a subset of records for analysis, or to specify a proportion of records to discard. A variety of sample types are supported, including stratified, clustered, and nonrandom (structured) samples. Sampling can be used for several reasons:

- To improve performance by estimating models on a subset of the data. Models estimated from a sample are often as accurate as those derived from the full dataset, and may be more so if the improved performance allows you to experiment with different methods you might not otherwise have attempted.
- To select groups of related records or transactions for analysis, such as selecting all the items in an online shopping cart (or market basket), or all the properties in a specific neighborhood.
- To identify units or cases for random inspection in the interest of quality assurance, fraud prevention, or security.

Note: If you simply want to partition your data into training and test samples for purposes of validation, a Partition node can be used instead. See the topic [Partition Node](#) for more information.

Types of Samples

Clustered samples. Sample groups or clusters rather than individual units. For example, suppose you have a data file with one record per student. If you cluster by school and the sample size is 50%, then 50% of schools will be chosen and all students from each selected school will be picked. Students in unselected schools will be rejected. On average, you would expect about 50% of students to be picked, but because schools vary in size, the percentage may not be exact. Similarly, you could cluster shopping cart items by transaction ID to make sure that all items from selected transactions are maintained. For an example that clusters properties by town, see the *complexsample_property.str* sample stream.

Stratified samples. Select samples independently within non-overlapping subgroups of the population, or strata. For example, you can ensure that men and women are sampled in equal proportions, or that every region or socioeconomic group within an urban population is represented. You can also specify a different sample size for each stratum (for example, if you think that one group has been under-represented in the original data). For an example that stratifies properties by county, see the *complexsample_property.str* sample stream.

Systematic or 1-in-n sampling. When selection at random is difficult to obtain, units can be sampled systematically (at a fixed interval) or sequentially.

Sampling weights. Sampling weights are automatically computed while drawing a complex sample and roughly correspond to the "frequency" that each sampled unit represents in the original data. Therefore, the sum of the weights over the sample should estimate the size of the original data.

Sampling Frame

A sampling frame defines the potential source of cases to be included in a sample or study. In some cases, it may be feasible to identify every single member of a population and include any one of them in a sample--for example, when sampling items that come off a production line. More often, you will not be able to access every possible case. For example, you cannot be sure who will vote in an election until after the election has happened. In this case, you might use the electoral register as your sampling frame, even though some registered people won't vote, and some people may vote despite not having been listed at the time you checked the register. Anybody not in the sampling frame has no prospect of being sampled. Whether your sampling frame is close enough in nature to the population you are trying to evaluate is a question that must be addressed for each real-life case.

Sample node options

You can choose the Simple or Complex method as appropriate for your requirements.

Simple sampling options

The Simple method allows you to select a random percentage of records, select contiguous records, or select every *n*th record.

Mode. Select whether to pass (include) or discard (exclude) records for the following modes:

- Include sample. Includes selected records in the data stream and discards all others. For example, if you set the mode to Include sample and set the 1-in-n option to 5, then every fifth record will be included, yielding a dataset that is roughly one-fifth the original size. This is the default mode when sampling data, and the only mode when using the complex method.
- Discard sample. Excludes selected records and includes all others. For example, if you set the mode to Discard sample and set the 1-in-n option to 5, then every fifth record will be discarded. This mode is only available with the simple method.

Sample. Select the method of sampling from the following options:

- First. Select to use contiguous data sampling. For example, if the maximum sample size is set to 10000, then the first 10,000 records will be selected.
- 1-in-n. Select to sample data by passing or discarding every *n*th record. For example, if *n* is set to 5, then every fifth record will be selected.
- Random %. Select to sample a random percentage of the data. For example, if you set the percentage to 20, then 20% of the data will either be passed to the data stream or discarded, depending on the mode selected. Use the field to specify a sampling percentage. You can also specify a seed value using the Set random seed control.

Use block level sampling (in-database only). This option is enabled only if you choose random percentage sampling when performing in-database mining on an Oracle or IBM Db2 database. In these circumstances, block-level sampling can be more efficient.

Note: You do not get an exact number of rows returned each time you run the same random sample settings. This is because each input record has a probability of $\frac{N}{100}$ of being included in the sample (where *N* is the Random % you specify in the node) and the probabilities are independent; therefore the results are not exactly *N*%.

Maximum sample size. Specifies the maximum number of records to include in the sample. This option is redundant and therefore disabled when First and Include are selected. Also note that when used in combination with the Random % option, this setting may prevent certain records from being selected. For example, if you have 10 million records in your dataset, and you select 50% of records with a maximum sample size of three million records, then 50% of the first six million records will be selected, and the remaining four million records have no chance of being selected. To avoid this limitation, select the Complex sampling method, and request a random sample of three million records without specifying a cluster or stratify variable.

Complex sampling options

Complex sample options allow for finer control of the sample, including clustered, stratified, and weighted samples along with other options.

Cluster and stratify. Allows you to specify cluster, stratify, and input weight fields if needed. See the topic [Cluster and Stratify Settings](#) for more information.

Sample type.

- Random. Selects clusters or records randomly within each strata.
- Systematic. Selects records at a fixed interval. This option works like the *1 in n* method, except the position of the first record changes depending on a random seed. The value of *n* is determined automatically based on the sample size or proportion.

Sample units. You can select proportions or counts as the basic sample units.

Sample size. You can specify the sample size in several ways:

- Fixed. Allows you to specify the overall size of the sample as a count or proportion.
- Custom. Allows you to specify the sample size for each subgroup or strata. This option is only available if a stratification field has been specified in the Cluster and Stratify sub dialog box.
- Variable. Allows the user to pick a field that defines the sample size for each subgroup or strata. This field should have the same value for each record within a particular stratum; for example, if the sample is stratified by county, then all records with county = Surrey must have the same value. The field must be numeric and its values must match the selected sample units. For proportions, values should be greater than 0 and less than 1; for counts, the minimum value is 1.

Minimum sample per stratum. Specifies a minimum number of records (or minimum number of clusters if a cluster field is specified).

Maximum sample per stratum. Specifies a maximum number of records or clusters. If you select this option without specifying a cluster or stratify field, a random or systematic sample of the specified size will be selected.

Set random seed. When sampling or partitioning records based on a random percentage, this option allows you to duplicate the same results in another session. By specifying the starting value used by the random number generator, you can ensure the same records are assigned each time the node is executed. Enter the desired seed value, or click the Generate button to automatically generate a random value. If this option is not selected, a different sample will be generated each time the node is executed.

Note: When using the Set random seed option with records read from a database, a Sort node may be required prior to sampling in order to ensure the same result each time the node is executed. This is because the random seed depends on the order of records, which is not guaranteed to stay the same in a relational database. See the topic [Sort Node](#) for more information.

Cluster and Stratify Settings

The Cluster and Stratify dialog box enables you to select cluster, stratification, and weight fields when drawing a complex sample.

Clusters. Specifies a categorical field used to cluster records. Records are sampled based on cluster membership, with some clusters included and others not. But if any record from a given cluster is included, all are included. For example, when analyzing product associations in shopping carts, you could cluster items by transaction ID to make sure that all items from selected transactions are maintained. Instead of sampling records—which would destroy information about what items are sold together—you can sample transactions to make sure that all records for selected transactions are preserved.

Stratify by. Specifies a categorical field used to stratify records so that samples are selected independently within non-overlapping subgroups of the population, or strata. If you select a 50% sample stratified by gender, for example, then two 50% samples will be taken, one for the men and one for the women. For example, strata may be socioeconomic groups, job categories, age groups, or ethnic groups, allowing you to ensure adequate sample sizes for subgroups of interest. If there are three times more women than men in the original dataset, this ratio will be preserved by sampling separately from each group. Multiple stratification fields can also be specified (for example, sampling product lines within regions or vice-versa).

Note: If you stratify by a field that has missing values (null or system missing values, empty strings, white space, and blank or user-defined missing values), then you cannot specify custom sample sizes for strata. If you want to use custom sample sizes when stratifying by a field with missing or blank values, then you need to fill them upstream.

Use input weight. Specifies a field used to weight records prior to sampling. For example, if the weight field has values ranging from 1 to 5, records weighted 5 are five times as likely to be selected. The values of this field will be overwritten by the final output weights generated by the node (see following paragraph).

New output weight. Specifies the name of the field where final weights are written if no input weight field is specified. (If an input weight field is specified, its values are replaced by the final weights as noted above, and no separate output weight field is created.) The output weight values indicate the number of records represented by each sampled record in the original data. The sum of the weight values gives an estimate of the sample size. For example, if a random 10% sample is taken, the output weight will be 10 for all records, indicating that each sampled record represents roughly ten records in the original data. In a stratified or weighted sample, the output weight values may vary based on the sample proportion for each stratum.

Comments

- Clustered sampling is useful if you cannot get a complete list of the population you want to sample, but can get complete lists for certain groups or clusters. It is also used when a random sample would produce a list of test subjects that it would be impractical to contact. For example, it would be easier to visit all farmers in one county than a selection of farmers scattered across every county in the nation.
- You can specify both cluster and stratify fields in order to sample clusters independently within each strata. For example, you could sample property values stratified by county, and cluster by town within each county. This will ensure that an independent sample of towns is drawn from within each county. Some towns will be included and others will not, but for each town that is included, all properties within the town are included.
- To select a random sample of units from within each cluster, you can string two Sample nodes together. For example, you could first sample townships stratified by county as described above. Then attach a second Sample node and select *town* as a stratify field, allowing you to sample a proportion of records from within each township.
- In cases where a combination of fields is required to uniquely identify clusters, a new field can be generated using a Derive node. For example, if multiple shops use the same numbering system for transactions, you could derive a new field that concatenates the shop and transaction IDs.

Related information

- [Sample Node](#)
- [Sample node options](#)
- [Sample Sizes for Strata](#)

Sample Sizes for Strata

When drawing a stratified sample, the default option is to sample the same proportion of records or clusters from each stratum. If one group outnumbers another by a factor of 3, for example, you typically want to preserve the same ratio in the sample. If this is not the case, however, you can specify the sample size separately for each stratum.

The Sample Sizes for Strata dialog box lists each value of the stratification field, allowing you to override the default for that stratum. If multiple stratification fields are selected, every possible combination of values is listed, allowing you to specify the size for each ethnic group within each city, for example, or each town within each county. Sizes are specified as proportions or counts, as determined by the current setting in the Sample node.

To Specify Sample Sizes for Strata

1. In the Sample node, select Complex, and select one or more stratification fields. See the topic [Cluster and Stratify Settings](#) for more information.
2. Select Custom, and select Specify Sizes.
3. In the Sample Sizes for Strata dialog box, click the Read Values button at lower left to populate the display. If necessary, you may need to instantiate values in an upstream source or Type node. See the topic [What is instantiation?](#) for more information.
4. Click in any row to override the default size for that stratum.

Notes on Sample Size

Custom sample sizes may be useful if different strata have different variances, for example, in order to make sample sizes proportional to the standard deviation. (If the cases within the stratum are more varied, you need to sample more of them to get a representative sample.) Or if a stratum is small, you may wish to use a higher sample proportion to ensure that a minimum number of observations is included.

Note: If you stratify by a field that has missing values (null or system missing values, empty strings, white space, and blank or user-defined missing values), then you cannot specify custom sample sizes for strata. If you want to use custom sample sizes when stratifying by a field with missing or blank values, then you need to fill them upstream.

Balance Node

You can use Balance nodes to correct imbalances in datasets so they conform to specified test criteria. For example, suppose that a dataset has only two values--*low* or *high*--and that 90% of the cases are *low* while only 10% of the cases are *high*. Many modeling techniques have trouble with such biased data because they will tend to learn only the *low* outcome and ignore the *high* one, since it is more rare. If the data are well balanced with approximately equal numbers of *low* and *high* outcomes, models will have a better chance of finding patterns that distinguish the two groups. In this case, a Balance node is useful for creating a balancing directive that reduces cases with a *low* outcome.

Balancing is carried out by duplicating and then discarding records based on the conditions you specify. Records for which no condition holds are always passed through. Because this process works by duplicating and/or discarding records, the original sequence of your data is lost in downstream operations. Be sure to derive any sequence-related values before adding a Balance node to the data stream.

Note: Balance nodes can be generated automatically from distribution charts and histograms. For example, you can balance your data to show equal proportions across all categories of a categorical field, as shown in a distribution plot.

Example. When building an RFM stream to identify recent customers who have positively responded to previous marketing campaigns, the marketing department of a sales company uses a Balance node to balance the differences between true and false responses in the data.

- [Setting Options for the Balance Node](#)

Related information

- [Overview of Record Operations](#)
 - [Setting Options for the Balance Node](#)
-

Setting Options for the Balance Node

Record balancing directives. Lists the current balancing directives. Each directive includes both a factor and a condition that tells the software to "increase the proportion of records by a factor specified where the condition is true." A factor lower than 1.0 means that the proportion of indicated records will be decreased. For example, if you want to decrease the number of records where drug Y is the treatment drug, you might create a balancing directive with a factor of 0.7 and a condition `Drug = "drugY"`. This directive means that the number of records where drug Y is the treatment drug will be reduced to 70% for all downstream operations.

Note: Balance factors for reduction may be specified to four decimal places. Factors set below 0.0001 will result in an error, since the results do not compute correctly.

- **Create conditions** by clicking the button to the right of the text field. This inserts an empty row for entering new conditions. To create a CLEM expression for the condition, click the Expression Builder button.
- **Delete directives** using the red delete button.
- **Sort directives** using the up and down arrow buttons.

Only balance training data. If a partition field is present in the stream, this option balances data in the training partition only. In particular, this may be useful if generating adjusted propensity scores, which require an unbalanced testing or validation partition. If no partition field is present in the stream (or if multiple partition fields are specified), then this option is ignored and all data are balanced.

- [Balance Node](#)
-

Aggregate Node

Aggregation is a data preparation task frequently used to reduce the size of a dataset. Before proceeding with aggregation, you should take time to clean the data, concentrating especially on missing values. Once you have aggregated, potentially useful information regarding missing values may be lost.

You can use an Aggregate node to replace a sequence of input records with summary, aggregated output records. For example, you might have a set of input sales records such as those shown in the following table.

Table 1. Sales record input example

Age	Sex	Region	Branch	Sales
23	M	S	8	4
45	M	S	16	4
37	M	S	8	5
30	M	S	5	7
44	M	N	4	9
25	M	N	2	11
29	F	S	16	6
41	F	N	4	8
23	F	N	6	2
45	F	N	4	5
33	F	N	6	10

You can aggregate these records with *Sex* and *Region* as key fields. Then choose to aggregate *Age* with the mode Mean and *Sales* with the mode Sum. Select Include record count in field in the Aggregate node dialog box and your aggregated output would be as shown in the following table.

Table 2. Aggregated record example

Age (mean)	Sex	Region	Sales (sum)	Record Count
35.5	F	N	25	4
29	F	S	6	1
34.5	M	N	20	2
33.75	M	S	20	4

From this you learn, for example, that the average age of the four female sales staff in the North region is 35.5, and the sum total of their sales was 25 units.

Note: Fields such as *Branch* are automatically discarded when no aggregate mode is specified.

- [Setting options for the Aggregate node](#)
- [Aggregate optimization settings](#)

Related information

- [Overview of Record Operations](#)
- [Setting options for the Aggregate node](#)

Setting options for the Aggregate node

On the Aggregate node you specify the following.

- One or more key fields to use as categories for the aggregation
- One or more aggregate fields for which to calculate the aggregate values
- One or more aggregation modes (types of aggregation) to output for each aggregate field

You can also specify the default aggregation modes to use for newly added fields, and use expressions (similar to formulae) to categorize aggregation.

Note that for added performance, aggregations operations may benefit from enabling parallel processing.

Key fields. Lists fields that can be used as categories for aggregation. Both continuous (numeric) and categorical fields can be used as keys. If you choose more than one key field, the values will be combined to produce a key value for aggregating records. One aggregated record will be generated for each unique key field. For example, if `Sex` and `Region` are your key fields, each unique combination of `M` and `F` with regions `N` and `S` (four unique combinations) will have an aggregated record. To add a key field, use the Field Chooser button to the right of the window.

The rest of the dialog box is split into two main areas - Basic Aggregates and Aggregate Expressions.

Basic Aggregates

Aggregate fields. Lists the fields for which values will be aggregated as well as the selected modes of aggregation. To add fields to this list, use the Field Chooser button on the right. The following aggregation modes are available.

Note: Some modes are not applicable to non-numeric fields (for example, Sum for a date/time field). Modes that cannot be used with a selected aggregate field are disabled.

- Sum. Select to return summed values for each key field combination. The sum is the total of the values, across all cases with nonmissing values.
- Mean. Select to return the mean values for each key field combination. The mean is a measure of central tendency, and is the arithmetic average (the sum divided by the number of cases).
- Min. Select to return minimum values for each key field combination.
- Max. Select to return maximum values for each key field combination.
- SDev. Select to return the standard deviation for each key field combination. The standard deviation is a measure of dispersion around the mean, and is equal to the square root of the variance measurement.
- Median. Select to return the median values for each key field combination. The median is a measure of central tendency that is not sensitive to outlying values (unlike the mean, which can be affected by a few extremely high or low values). Also known as the 50th percentile or 2nd quartile.
- Count. Select to return the count of non-null values for each key field combination.
- Variance. Select to return the variance values for each key field combination. The variance is a measure of dispersion around the mean, equal to the sum of squared deviations from the mean divided by one less than the number of cases.
- 1st Quartile. Select to return the 1st quartile (25th percentile) values for each key field combination.
- 3rd Quartile. Select to return the 3rd quartile (75th percentile) values for each key field combination.

Note: When running a stream containing an Aggregate node, the values returned for 1st and 3rd Quartiles when pushing back SQL to an Oracle database may differ from those returned in native mode.

Default mode. Specify the default aggregation mode to be used for newly added fields. If you frequently use the same aggregation, select one or more modes here and use the Apply to All button on the right to apply the selected modes to all fields listed above.

New field name extension. Select to add a suffix or prefix, such as `1` or `new`, to duplicate aggregated fields. For example, the result of a minimum values aggregation on the field `Age` will produce a field name called `Age_Min_1` if you have selected the suffix option and specified `1` as the extension. Note that aggregation extensions such as `_Min` or `Max_` are automatically added to the new field, indicating the type of aggregation performed. Select Suffix or Prefix to indicate your preferred extension style.

Include record count in field. Select to include an extra field in each output record called `Record_Count`, by default. This field indicates how many input records were aggregated to form each aggregate record. Create a custom name for this field by typing in the edit field.

Note: System null values are excluded when aggregates are computed, but they are included in the record count. Blank values, on the other hand, are included in both aggregation and record count. To exclude blank values, you can use a Filler node to replace blanks with null values. You can also remove blanks using a Select node.

Aggregate Expressions

Expressions are similar to formulas that are created from values, field names, operators, and functions. Unlike functions that work on a single record at a time, aggregate expressions operate on a group, set, or collection of records.

Note: You can only create aggregate expressions if the stream includes a database connection (by means of a Database source node).

New expressions are created as derived fields; to create an expression you use the *Database Aggregates* functions which are available from the Expression Builder.

For more information, see [The Expression Builder](#).

Note that there is a connection between the Key Fields and any aggregate expressions you create because the aggregate expressions are grouped by the key field.

Valid aggregate expressions are ones that evaluate to aggregate outcomes; a couple of examples of valid aggregate expressions, and the rules that govern them, are as follows:

- You can use scalar functions to combine multiple aggregation functions together to produce a single aggregation result. For example:

```
max(C01) - min(C01)
```

- An aggregation function can operate on the result of multiple scalar functions. For example:

```
sum (C01*C01)
```

Aggregate optimization settings

On the Optimization tab you specify the following.

Keys are contiguous. Select this option if you know that all records with the same key values are grouped together in the input (for example, if the input is sorted on the key fields). Doing so can improve performance.

Allow approximation for Median and Quartiles. The Order statistics (Median, 1st Quartile, and 3rd Quartile) are currently not supported when processing data in Analytic Server. If you are using Analytic Server you can select this check box to use an approximated value for these statistics instead which is calculated by binning the data and then computing an estimate for the statistic based on the distribution across the bins. By default, this option is unchecked.

Number of bins. Only available if you select the Allow approximation for Median and Quartiles check box. Select the number of bins to be used when estimating the statistic; the number of bins affects the Maximum error %. By default, the number of bins is 1000, which corresponds to a maximum error of 0.1 percent of the range.

Related information

- [Aggregate Node](#)
- [Setting options for the Aggregate node](#)

RFM Aggregate Node

The Recency, Frequency, Monetary (RFM) Aggregate node enables you to take customers' historical transactional data, strip away any unused data, and combine all of their remaining transaction data into a single row, using their unique customer ID as a key, that lists when they last dealt with you (recency), how many transactions they have made (frequency), and the total value of those transactions (monetary).

Before proceeding with any aggregation, you should take time to clean the data, concentrating especially on any missing values.

Once you have identified and transformed the data using the RFM Aggregate node, you may use an RFM Analysis node to carry out further analysis. See the topic [RFM Analysis Node](#) for more information.

Note that once the data file has been run through the RFM Aggregate node, it will not have any target values; therefore, before being able to use it as inputs for further predictive analysis with any modeling nodes such as C5.0 or CHAID, you will need to merge it with other customer data (for example, by matching the customer IDs). See the topic [Merge Node](#) for more information.

The RFM Aggregate and RFM Analysis nodes in IBM® SPSS® Modeler are set up to use independent binning; that is, they rank and bin data on each measure of recency, frequency, and monetary value, without regard to their values or the other two measures.

- [Setting Options for the RFM Aggregate Node](#)

Related information

- [Overview of Record Operations](#)
- [Setting Options for the RFM Aggregate Node](#)

Setting Options for the RFM Aggregate Node

The Settings tab of the RFM Aggregate node contains the following fields.

Calculate Recency relative to Specify the date from which the recency of transactions will be calculated. This may be either a Fixed date that you enter, or Today's date, as set by your system. Today's date is entered by default and is automatically updated when the node is executed.

Note: The display of the Fixed date may be different for different locales. For example, if the value **2007-8-10** is stored in your stream as **Fri Aug 10 00:00:00 CST 2007** it is a time and date in the time zone 'UTC+8'. However, it displays as **Thu Aug 9 12:00:00 EDT 2007** in the time zone 'UTC-8'.

IDs are contiguous If your data are presorted so that all records with the same ID appear together in the data stream, select this option to speed up processing. If your data are not presorted (or you are not sure), leave this option unselected, and the node will sort the data automatically.

ID Select the field to be used to identify the customer and their transactions. To display the fields from which you can select, use the Field Chooser button on the right.

Date Select the date field to be used to calculate recency against. To display the fields from which you can select, use the Field Chooser button on the right.

Note that this requires a field with a storage of date, or timestamp, in the appropriate format to use as input. For example, if you have a string field with values like **Jan 2007**, **Feb 2007**, and so on, you can convert this to a date field using a Filler node and the `to_date()` function. See the topic [Storage Conversion Using the Filler Node](#) for more information.

Value Select the field to be used to calculate the total monetary value of the customer's transactions. To display the fields from which you can select, use the Field Chooser button on the right. Note: This must be a numeric value.

New field name extension Select to append either a suffix or prefix, such as "12_month", to the newly generated recency, frequency, and monetary fields. Select Suffix or Prefix to indicate your preferred extension style. For example, this may be useful when examining several time periods.

Discard records with value below If required, you can specify a minimum value below which any transaction details are not used when calculating the RFM totals. The units of value relate to the Value field selected.

Include only recent transactions If you are analyzing a large database, you can specify that only the latest records are used. You can chose to use the data recorded either after a certain date or within a recent period:

- Transaction date after Specify the transaction date after which records will be included in your analysis.
- Transaction within the last Specify the number and type of periods (days, weeks, months, or years) back from the Calculate recency relative to date after which records will be included in your analysis.

Save date of second most recent transaction If you want to know the date of the second most recent transaction for each customer, select this box. In addition, you can then select the Save date of third most recent transaction box as well. For example, this can help you identify customers who may have carried out many transactions some considerable time ago, but only one recent transaction.

Sort Node

You can use Sort nodes to sort records into ascending or descending order based on the values of one or more fields. For example, Sort nodes are frequently used to view and select records with the most common data values. Typically, you would first aggregate the data using the Aggregate node and then use the Sort node to sort the aggregated data into descending order of record counts. Displaying these results in a table will allow you to explore the data and to make decisions, such as selecting the records of the top 10 best customers.

The Settings tab of the Sort node contains the following fields.

Sort by. All fields selected to use as sort keys are displayed in a table. A key field works best for sorting when it is numeric.

- Add fields to this list using the Field Chooser button on the right.
- Select an order by clicking the Ascending or Descending arrow in the table's *Order* column.
- Delete fields using the red delete button.
- Sort directives using the up and down arrow buttons.

Default sort order. Select either Ascending or Descending to use as the default sort order when new fields are added above.

Note: The Sort node is not applied if there is a Distinct node down the model stream. For information about the Distinct node, see [Distinct node](#).

Sort Optimization Settings

If you are working with data you know are already sorted by some key fields, you can specify which fields are already sorted, allowing the system to sort the rest of the data more efficiently. For example, you want to sort by *Age* (descending) and *Drug* (ascending) but know your data are already sorted by *Age* (descending).

Data is presorted. Specifies whether the data are already sorted by one or more fields.

Specify existing sort order. Specify the fields that are already sorted. Using the Select Fields dialog box, add fields to the list. In the *Order* column, specify whether each field is sorted in ascending or descending order. If you are specifying multiple fields, make sure that you list them in the correct sorting order. Use the arrows to the right of the list to arrange the fields in the correct order. If you make a mistake in specifying the correct existing sort order, an error will appear when you run the stream, displaying the record number where the sorting is inconsistent with what you specified.

Note: Sorting speed may benefit from enabling parallel processing.

Merge Node

The function of a Merge node is to take multiple input records and create a single output record containing all or some of the input fields. This is a useful operation when you want to merge data from different sources, such as internal customer data and purchased demographic data. You can merge data in the following ways.

- Merge by Order concatenates corresponding records from all sources in the order of input until the smallest data source is exhausted. It is important if using this option that you have sorted your data using a Sort node.
- Merge using a Key field, such as *Customer ID*, to specify how to match records from one data source with records from the other(s). Several types of joins are possible, including inner join, full outer join, partial outer join, and anti-join. See the topic [Types of Joins](#) for more information.
- Merge by Condition means that you can specify a condition to be satisfied for the merge to take place. You can specify the condition directly in the node, or build the condition using the Expression Builder.
- Merge by Ranked Condition is a left sided outer join in which you specify a condition to be satisfied for the merge to take place and a ranking expression which sorts into order from low to high. Most often used to merge geospatial data, you can specify the condition directly in the node, or build the condition using the Expression Builder.

Types of Joins

When using a key field for data merging, it is useful to spend some time thinking about which records will be excluded and which will be included. There are a variety of joins, which are discussed in detail below.

The two basic types of joins are referred to as inner and outer joins. These methods are frequently used to merge tables from related datasets based on common values of a key field, such as *Customer ID*. Inner joins allow for clean merging and an output dataset that includes only complete records. Outer joins also include complete records from the merged data, but they also allow you to include unique data from one or more input tables.

The types of joins allowed are described in greater detail below.

	An inner join includes only records in which a value for the key field is common to all input tables. That is, unmatched records will not be included in the output dataset.
	A full outer join includes all records, both matching and nonmatching, from the input tables. Left and right outer joins are referred to as partial outer joins and are described below.
	A partial outer join includes all records matched using the key field as well as unmatched records from specified tables. (Or, to put it another way, all records from some tables and only matching records from others.) Tables (such as A and B shown here) can be selected for inclusion in the outer join using the Select button on the Merge tab. Partial joins are also called left or right outer joins when only two tables are being merged. Since IBM® SPSS® Modeler allows the merging of more than two tables, we refer to this as a partial outer join.
	An anti-join includes only unmatched records for the first input table (Table A shown here). This type of join is the opposite of an inner join and does not include complete records in the output dataset.

For example, if you have information about farms in one dataset and farm-related insurance claims in another, you can match the records from the first source to the second source using the Merge options.

To determine if a customer in your farm sample has filed an insurance claim, use the inner join option to return a list showing where all IDs match from the two samples.

Figure 1. Sample output for an inner join merge

	id	name	region	farmsize	rainfall	landquality	farmincome	maincrop	claimtype	claimvalue
1	id604	name604	southwest	1860.000	103.0...	3.000	625251.000	potatoes	decomm...	281082.0...
2	id605	name605	north	1700.000	46.000	8.000	621148.000	wheat	decomm...	122006.0...
3	id620	name620	north	880.000	74.000	6.000	426988.000	rapeseed	arable_de	118885.0...

Using the full outer join option returns both matching and nonmatching records from the input tables. The system-missing value (\$null\$) will be used for any incomplete values.

Figure 2. Sample output for a full outer join merge

	id	name	region	farmsize	rainfall	landquality	farmincome	maincrop	claimtype	claimvalue
1	\$null\$	\$null\$	\$null\$	\$null\$	\$null\$	\$null\$	\$null\$	\$null\$	decomm...	74703.1C
2	id602	name602	north	1780.000	42.000	9.000	734118.000	maize	\$null\$	\$null\$
3	id604	name604	southwest	1860.000	103.0...	3.000	625251.000	potatoes	decomm...	281082.0
4	id605	name605	north	1700.000	46.000	8.000	621148.000	wheat	decomm...	122006.0
5	\$null\$	\$null\$	\$null\$	\$null\$	\$null\$	\$null\$	\$null\$	\$null\$	arable_de	122135.0

A partial outer join includes all records matched using the key field as well as unmatched records from specified tables. The table displays all of the records matched from the ID field as well as the records matched from the first dataset.

Figure 3. Sample output for a partial outer join merge

	id	claimtype	claimvalue	name	region	farmsize	rainfall	landquality	farmincome	maincrop
1	id602	\$null\$	\$null\$	name602	north	1780.000	42.000	9.000	734118.000	maize
2	id604	decomm...	281082.0...	name604	southwest	1860.000	103.0...	3.000	625251.000	potatoes
3	id605	decomm...	122006.0...	name605	north	1700.000	46.000	8.000	621148.000	wheat
4	id607	\$null\$	\$null\$	name607	southeast	1820.000	29.000	6.000	211605.000	maize
5	id608	\$null\$	\$null\$	name608	southeast	1640.000	108.0...	7.000	1167040.0...	maize
6	id609	\$null\$	\$null\$	name609	southwest	1600.000	101.0...	5.000	758755.000	wheat
7	id615	\$null\$	\$null\$	name615	midlands	920.000	86.000	6.000	442554.000	potatoes
8	id618	\$null\$	\$null\$	name618	southeast	1180.000	98.000	3.000	368646.000	maize

If you are using the anti-join option, the table returns only unmatched records for the first input table.

Figure 4. Sample output for an anti-join merge

	id	name	region	farmsize	rainfall	landquality	farmincome	maincrop
1	id602	name602	north	1780.000	42.000	9.000	734118.000	maize
2	id607	name607	southeast	1820.000	29.000	6.000	211605.000	maize
3	id608	name608	southeast	1640.000	108.0...	7.000	1167040.0...	maize
4	id609	name609	southwest	1600.000	101.0...	5.000	756755.000	wheat
5	id615	name615	midlands	920.000	66.000	6.000	442554.000	potatoes
6	id618	name618	southeast	1180.000	98.000	3.000	368646.000	maize
7	id619	name619	north	840.000	64.000	8.000	457552.000	potatoes

Specifying a Merge Method and Keys

The Merge tab of the Merge node contains the following fields.

Merge Method Select the method to be used for merging records. Selecting either Keys or Condition activates the bottom half of the dialog box.

- Order Merges records by order such that the *n*th record from each input is merged to produce the *n*th output record. When any record runs out of a matching input record, no more output records are produced. This means that the number of records that are created is the number of records in the smallest dataset. It is important if using this option that you have sorted your data using a Sort node.
- Keys Uses a key field, such as *Transaction ID*, to merge records with the same value in the key field. This is equivalent to a database "equi-join." If a key value occurs more than once, all possible combinations are returned. For example, if records with the same key field value A contain differing values B, C, and D in other fields, the merged fields produce a separate record for each combination of A with value B, A with value C, and A with value D.

Note: Null values are not considered identical in the merge-by-key method and will not join.

- Condition Use this option to specify a condition for the merge. For more information, see [Specifying Conditions for a Merge](#).
- Ranked condition Use this option to specify whether each row pairing in the primary and all secondary data sets are to be merged; use the ranking expression to sort any multiple matches into order from low to high. For more information, see [Specifying Ranked Conditions for a Merge](#).

Possible keys Lists only those fields with exactly matching field names in all input data sources. Select a field from this list and use the arrow button to add it as a key field used for merging records. More than one key field can be used. You can rename non-matching input fields by using a Filter node, or the Filter tab of a source node.

Keys for merge Lists all fields that are used to merge records from all input data sources based on values of the key fields. To remove a key from the list, select one and use the arrow button to return it to the Possible Keys list. When more than one key field is selected, the option below is enabled.

Combine duplicate key fields When more than one key field is selected above, this option ensures that there is only one output field of that name. This option is enabled by default except in the case when streams have been imported from earlier versions of IBM® SPSS® Modeler. When this option is disabled, duplicate key fields must be renamed or excluded by using the Filter tab in the Merge node dialog box.

Include only matching records (inner join) Select to merge only complete records.

Include matching and non-matching records (full outer join) Select to perform a "full outer join." This means that if values for the key field are not present in all input tables, the incomplete records are still retained. The undefined value (\$null\$) is added to the key field and included in the output record.

Include matching and selected non-matching records (partial outer join) Select to perform a "partial outer join" of the tables you select in a subdialog box. Click Select to specify tables for which incomplete records will be retained in the merge.

Include records in the first dataset not matching any others (anti-join) Select to perform a type of "anti-join," where only nonmatching records from the first dataset are passed downstream. You can specify the order of input datasets using arrows on the Inputs tab. This type of join does not include complete records in the output dataset. For more information, see [Types of Joins](#).

- [Filtering Fields from the Merge Node](#)

Selecting Data for Partial Joins

For a partial outer join, you must select the table(s) for which incomplete records will be retained. For example, you may want to retain all records from a Customer table while retaining only matched records from the Mortgage Loan table.

To select datasets for partial joins:

1. Click the Merge tab of the Merge node.

2. Select Include matching and selected non-matching records (partial outer join).
3. Click the Select button to open a dialog box where you can specify datasets for the partial join.

Outer Join column. In the *Outer Join* column, select datasets to include in their entirety. For a partial join, overlapping records will be retained as well as incomplete records for datasets selected here. See the topic [Types of Joins](#) for more information.

Related information

- [Merge Node](#)

Specifying Conditions for a Merge

By setting the merge method to Condition, you can specify one or more conditions to be satisfied for the merge to take place.

You can either enter the conditions directly into the Condition field, or build them with the aid of the Expression Builder by clicking the calculator symbol to the right of the field.

Add tags to duplicate field names to avoid merge conflicts If two or more of the datasets to be merged contain the same field names, select this check box to add a different prefix tag to the start of the field column headers. For example, if there are two fields called *Name* the result of the merge would contain *1_Name* and *2_Name*. If the tag has been renamed in the data source, the new name is used instead of the numbered prefix tag. If you do not select this check box, and there are duplicate names in the data, a warning is displayed to the right of the check box.

Related information

- [Merge Node](#)

Specifying Ranked Conditions for a Merge

A Ranked Condition merge can be considered as a left sided outer join merge by condition; the left side of the merge is the primary data set where each record is an event. For example, in a model that is used to find patterns in crime data, each record in the primary data set would be a crime and its associated information (location, type, and so on). In this example, the right side might contain the relevant geospatial data sets.

The merge uses both a merge condition and a ranking expression. The merge condition can use a geospatial function such as *within* or *close_to*. During the merge, all of the fields in the right side data sets are added to the left side data set but multiple matches result in a list field. For example:

- Left side: Crime data
- Right side: Counties data set and roads data set
- Merge conditions: Crime data *within* counties and *close_to* roads, along with a definition of what counts as *close_to*.

In this example, if a crime occurred within the required *close_to* distance of three roads (and the number of matches to be returned is set to at least three), then all three roads are returned as a list item.

By setting the merge method to Ranked condition, you can specify one or more conditions to be satisfied for the merge to take place.

Primary dataset Select the primary data set for the merge; the fields from all other data sets are added to the data set you select. This can be considered as the left side of an outer join merge.

When you select a primary data set, all the other input data sets that are connected to the Merge node are automatically listed in the Merges table.

Add tags to duplicate field names to avoid merge conflicts If two or more of the data sets to be merged contain the same field names, select this check box to add a different prefix tag to the start of the field column headers. For example, if there are two fields that are called *Name* the result of the merge would contain *1_Name* and *2_Name*. If the tag has been renamed in the data source, the new name is used instead of the numbered prefix tag. If you do not select this check box, and there are duplicate names in the data, a warning is displayed to the right of the check box.

Merges

Dataset

Shows the name of the secondary data sets that are connected as inputs to the Merge node. By default, where there is more than one secondary data set, they are listed in the order in which they were connected to the Merge node.

Merge Condition

Enter the unique conditions for merging each of the data sets in the table with the primary data set. You can either type the conditions directly into the cell, or build them with the aid of the Expression Builder by clicking the calculator symbol to the right of the cell. For example, you might use geospatial predicates to create a merge condition that places crime data from one data set within the county data of another data set. The default merge condition depends on the geospatial measurement level, as shown in the list below.

- Point, LineString, MultiPoint, MultiLineString - default condition of *close_to*.
- Polygon, MultiPolygon - default condition of *within*.

For more information about these levels, see [Geospatial measurement sublevels](#).

If a data set contains multiple geospatial fields of different types, the default condition that is used depends on the first measurement level that is found in the data, in the following descending order.

- Point
- LineString
- Polygon

Note: Defaults are only available when there is a geospatial data field in the secondary database.

Ranking Expression

Specify an expression to rank the merging of the data sets; this expression is used to sort multiple matches into an order that is based on the ranking criteria. You can either type the conditions directly into the cell, or build them with the aid of the Expression Builder by clicking the calculator symbol to the right of the cell.

Default ranking expressions of distance and area are provided in the Expression Builder and both rank low to high, meaning that, for example, the top match for distance is the smallest value. An example of ranking by distance is when the primary data set contains crimes and their associated location and each other data set contains objects with locations; in this case the distance between the crimes and the objects can be used as a ranking criteria. The default ranking expression depends on the geospatial measurement level, as shown in the list below.

- Point, LineString, MultiPoint, MultiLineString - the default expression is *distance*.
- Polygon, MultiPolygon - the default expression is *area*.

Note: Defaults are only available when there is a geospatial data field in the secondary database.

Number of Matches

Specify the number of matches that are returned, based on the condition and ranking expressions. The default number of matches depend on the geospatial measurement level in the secondary data set, as shown in the list below; however, you can double-click in the cell to enter your own value, up to a maximum of 100.

- Point, LineString, MultiPoint, MultiLineString - default value of 3.
- Polygon, MultiPolygon - default value of 1.
- Data set that contains no geospatial fields - default value of 1.

As an example, if you set up a merge that is based on a Merge Condition of *close_to* and a Ranking Expression of *distance*, the top three (closest) matches from the secondary data sets to each record in the primary data set are returned as the values in the resultant list field.

Filtering Fields from the Merge Node

Merge nodes include a convenient way of filtering or renaming duplicate fields as a result of merging multiple data sources. Click the Filter tab in the dialog box to select filtering options.

The options presented here are nearly identical to those for the Filter node. There are, however, additional options not discussed here that are available on the Filter menu. See the topic [Filtering or renaming fields](#) for more information.

Field. Displays the input fields from currently connected data sources.

Tag. Lists the tag name (or number) associated with the data source link. Click the Inputs tab to alter active links to this Merge node.

Source node. Displays the source node whose data is being merged.

Connected node. Displays the node name for the node that is connected to the Merge node. Frequently, complex data mining requires several merge or append operations that may include the same source node. The connected node name provides a way of differentiating these.

Filter. Displays the current connections between input and output field. Active connections show an unbroken arrow. Connections with a red X indicate filtered fields.

Field. Lists the output fields after merging or appending. Duplicate fields are displayed in red. Click in the Filter field above to disable duplicate fields.

View current fields. Select to view information on fields selected to be used as key fields.

View unused field settings. Select to view information on fields that are not currently in use.

Related information

- [Merge Node](#)
-

Setting Input Order and Tagging

Using the Inputs tab in the Merge and Append node dialog boxes, you can specify the order of input data sources and make any changes to the tag name for each source.

Tags and order of input datasets. Select to merge or append only complete records.

- **Tag.** Lists current tag names for each input data source. Tag names, or **tags**, are a way of uniquely identifying the data links for the merge or append operation. For example, imagine water from various pipes that is combined at one point and flows through a single pipe. Data in IBM® SPSS® Modeler flows similarly, and the merging point is often a complex interaction between the various data sources. Tags provide a way of managing the inputs ("pipes") to a Merge or Append node so that if the node is saved or disconnected, the links remain and are easily identifiable.

When you connect additional data sources to a Merge or Append node, default tags are automatically created using numbers to represent the order in which you connected the nodes. This order is unrelated to the order of fields in the input or output datasets. You can change the default tag by entering a new name in the *Tag* column.

- **Source Node.** Displays the source node whose data is being combined.
- **Connected Node.** Displays the node name for the node that is connected to the Merge or Append node. Frequently, complex data mining requires several merge operations that may include the same source node. The connected node name provides a way of differentiating these.
- **Fields.** Lists the number of fields in each data source.

View current tags. Select to view tags that are actively being used by the Merge or Append node. In other words, current tags identify links to the node that have data flowing through. Using the pipe metaphor, current tags are analogous to pipes with existing water flow.

View unused tag settings. Select to view tags, or links, that were previously used to connect to the Merge or Append node but are not currently connected with a data source. This is analogous to empty pipes still intact within a plumbing system. You can choose to connect these "pipes" to a new source or remove them. To remove unused tags from the node, click Clear. This clears all unused tags at once.

-

Merge Optimization Settings

The system provides two options that can help you merge data more efficiently in certain situations. These options allow you to optimize merging when one input dataset is significantly larger than the other datasets or when your data are already sorted by all or some of the key fields that you are using for the merge.

Note: Optimizations from this tab only apply to IBM® SPSS® Modeler native node execution only; that is, when the Merge node does not pushback to SQL. Optimization settings have no effect on SQL generation.

One input dataset is relatively large. Select to indicate that one of the input datasets is much larger than the others. The system will cache the smaller datasets in memory and then perform the merge by processing the large dataset without caching or sorting it. You will commonly use this type of join with data designed using a star-schema or similar design, where there is a large central table of shared data (for example, in transactional data). If you select this option, click *Select* to specify the large dataset. Note that you can select only *one* large dataset. The following table summarizes which joins can be optimized using this method.

Table 1. Summary of join optimizations

Type of Join	Can be optimized for a large input dataset?
Inner	Yes

Type of Join	Can be optimized for a large input dataset?
Partial	Yes, if there are no incomplete records in the large dataset.
Full	No
Anti-join	Yes, if the large dataset is the first input.

All inputs are already sorted by key field(s). Select to indicate that the input data are already sorted by one or more of the key fields that you are using for the merge. Make sure *all* your input datasets are sorted.

Specify existing sort order. Specify the fields that are already sorted. Using the Select Fields dialog box, add fields to the list. You can select from only the key fields that are being used for the merge (specified in the Merge tab). In the Order column, specify whether each field is sorted in ascending or descending order. If you are specifying multiple fields, make sure that you list them in the correct sorting order. Use the arrows to the right of the list to arrange the fields in the correct order. If you make a mistake in specifying the correct existing sort order, an error will appear when you run the stream, displaying the record number where the sorting is inconsistent with what you specified.

Depending on the case sensitivity of the collation method used by the database, optimization may not function correctly where one or more inputs are sorted by the database. For example, if you have two inputs where one is case sensitive and the other is case insensitive, the results of sorting could be different. Merge optimization causes records to be processed using their sorted order. As a result, if inputs are sorted using different collation methods, the Merge node reports an error and displays the record number where sorting is inconsistent. When all inputs are from one source, or are sorted using mutually inclusive collations, records can be merged successfully.

Note: Merging speed may benefit from enabling parallel processing.

Related information

- [Merge Node](#)
-

Append Node

You can use Append nodes to concatenate sets of records. Unlike Merge nodes, which join records from different sources together, Append nodes read and pass downstream all of the records from one source until there are no more. Then the records from the next source are read using the same data structure (number of records, number of fields, and so on) as the first, or primary, input. When the primary source has more fields than another input source, the system null string (\$null\$) will be used for any incomplete values.

Append nodes are useful for combining datasets with similar structures but different data. For example, you might have transaction data stored in different files for different time periods, such as a sales data file for March and a separate one for April. Assuming that they have the same structure (the same fields in the same order), the Append node will join them together into one large file, which you can then analyze.

Note: In order to append files, the field measurement levels must be similar. For example, a *Nominal* field cannot be appended with a field whose measurement level is *Continuous*.

-

Setting Append Options

Match fields by. Select a method to use when matching fields to append.

- **Position.** Select to append datasets based on the position of fields in the main data source. When using this method, your data should be sorted to ensure proper appending.
- **Name.** Select to append datasets based on the name of fields in the input datasets. Also select Match case to enable case sensitivity when matching field names.

Output Field. Lists the source nodes that are connected to the Append node. The first node on the list is the primary input source. You can sort the fields in the display by clicking on the column heading. This sorting does not actually reorder the fields in the dataset.

Include fields from. Select Main dataset only to produce output fields based on the fields in the main dataset. The main dataset is the first input, specified on the Inputs tab. Select All datasets to produce output fields for all fields in all datasets regardless of whether there is a matching field across all input datasets.

Tag records by including source dataset in field. Select to add an additional field to the output file whose values indicate the source dataset for each record. Specify a name in the text field. The default field name is *Input*.

Distinct node

Duplicate records in a data set must be removed before data mining can begin. For example, in a marketing database, individuals may appear multiple times with different address or company information. You can use the Distinct node to find or remove duplicate records in your data, or to create a single, composite record from a group of duplicate records.

To use the Distinct node, you must first define a set of key fields that determine when two records are considered to be duplicates.

If you do not pick all your fields as key fields, then two "duplicate" records may not be truly identical because they can still differ in the values of the remaining fields. In this case, you can also define a sort order that is applied within each group of duplicate records. This sort order gives you fine control over which record is treated as the first within a group. Otherwise, all duplicates are considered to be interchangeable and any record might be selected. The incoming order of the records is not taken into account, so it does not help to use an upstream Sort node (see "Sorting records within the distinct node" below).

Mode. Specify whether to create a composite record, or to either include or exclude (discard) the first record.

- **Create a composite record for each group.** Provides a way for you to aggregate non-numeric fields. Selecting this option makes the Composite tab available where you specify how to create the composite records. See [Distinct Composite Settings](#) for more information.
- **Include only the first record in each group.** Selects the first record from each group of duplicate records and discards the rest. The *first* record is determined by the sort order defined below, and not by the incoming order of the records.
- **Discard only the first record in each group.** Discards the first record from each group of duplicate records and selects the remainder instead. The *first* record is determined by the sort order defined below, and not by the incoming order of the records. This option is useful for *finding* duplicates in your data so that you can examine them later in the stream.

Key fields for grouping. Lists the field or fields used to determine whether records are identical. You can:

- Add fields to this list using the field picker button on the right.
- Delete fields from the list by using the red X (remove) button.

Within groups, sort records by. Lists the fields used to determine how records are sorted within each group of duplicates, and whether they are sorted in ascending or descending order. You can:

- Add fields to this list using the field picker button on the right.
- Delete fields from the list by using the red X (remove) button.
- Move fields using the up or down buttons, if you are sorting by more than one field.

You must specify a sort order if you have chosen to include or exclude the first record in each group, and it matters to you which record is treated as the first.

Default sort order. Specify whether, by default, records are sorted in Ascending or Descending order of the sort key values.

Sorting records within the Distinct node

If the order of records within a group of duplicates is important to you, then you must specify the order using the Within groups, sort records by option in the Distinct node. Do not rely on an upstream Sort node. Remember that the incoming order of the records is not taken into account -- only the order specified within the node.

If you do not specify any sort fields (or you specify insufficient sort fields), then the records within each group of duplicates will be unordered (or incompletely ordered) and the results may be unpredictable.

For example, assume we have a very large set of log records pertaining to a number of machines. The log contains data such as the following:

Table 1. Machine log data

Timestamp	Machine	Temperature
17:00:22	Machine A	31
13:11:30	Machine B	26
16:49:59	Machine A	30
18:06:30	Machine X	32
16:17:33	Machine A	29

Timestamp	Machine	Temperature
19:59:04	Machine C	35
19:20:55	Machine Y	34
15:36:14	Machine X	28
12:30:41	Machine Y	25
14:45:49	Machine C	27
19:42:00	Machine B	34
20:51:09	Machine Y	36
19:07:23	Machine X	33

To reduce the number of records down to the latest record for each machine, use **Machine** as the key field and use **Timestamp** as the sort field (in descending order). The input order does not affect the result because the sort selection specifies which of the many rows for a given Machine is to be returned, and the final data output would be as follows.

Table 2. Sorted machine log data

Timestamp	Machine	Temperature
17:00:22	Machine A	31
19:42:00	Machine B	34
19:59:04	Machine C	35
19:07:23	Machine X	33
20:51:09	Machine Y	36

Distinct Optimization Settings

If the data on which you are working has only a small number of records, or has already been sorted, you can optimize the way in which it is handled to enable IBM® SPSS® Modeler to process the data more efficiently.

Note: If you either select Input dataset has a low number of distinct keys, or use SQL generation for the node, any row within the distinct key value can be returned; to control which row is returned within a distinct key you need to specify the sort order by using the Within groups, sort records by fields on the Settings tab. The optimization options do not affect the results output by the Distinct node as long as you have specified a sort order on the Settings tab.

Input dataset has a low number of distinct keys. Select this option if you have a small number of records, or a small number of unique values of the key field(s), or both. Doing so can improve performance.

Input dataset is already ordered by grouping fields and sorting fields on the Settings tab. Only select this option if your data is already sorted by all of the fields listed under Within groups, sort records by on the Settings tab, and if the ascending or descending sort order of the data is the same. Doing so can improve performance.

Disable SQL generation. Select this option to disable SQL generation for the node.

-

Distinct Composite Settings

If the data on which you are working has multiple records, for example for the same person, you can optimize the way in which the data is handled by creating a single composite, or aggregate, record to process.

Note: This tab is only available when you select Create a composite record for each group on the Settings tab.

Setting options for the Composite tab

Field. This column shows all fields, except key fields in the data model, in their natural sort order. If the node is not connected, no fields are shown. To sort the rows alphabetically by field name, click the column header. You can select more than one row using either Shift-click or Ctrl-click. In addition, if you right-click a field, a menu is displayed from which you can choose to select all rows, sort the rows by ascending or descending field name or value, select fields by either measure or storage type, or select a value to automatically add the same Fill with values based on entry to every selected row.

Fill with values based on. Select the value type to be used for the composite record for the Field. The available options depend on the field type.

- For numeric range fields you can choose from:
 - First record in group
 - Last record in group
 - Total
 - Mean
 - Minimum
 - Maximum
 - Custom
- For time or date fields you can choose from:
 - First record in group
 - Last record in group
 - Earliest
 - Most Recent
 - Custom
- For string or typeless fields you can choose from:
 - First record in group
 - Last record in group
 - First alphanumeric
 - Last alphanumeric
 - Custom

In each case, you can use the Custom option to exercise more control over which value is used to fill the composite record. See [Distinct Composite - Custom Tab](#) for more information.

Include record count in field. Select this option to include an extra field in each output record, called **Record_Count** by default. This field indicates how many input records were aggregated to form each aggregate record. To create a custom name for this field, type your entry in the edit field.

- [Distinct Composite - Custom Tab](#)

Distinct Composite - Custom Tab

The Custom Fill dialog box gives you more control over which value is used to complete the new composite record. Note that must instantiate your data first before using this option if only customizing a single Field row on the Composite tab.

Note: This dialog box is only available when you select the Custom value in the Fill with values based on column on the Composite tab. Depending on the field type, you can choose from one of the following options.

- **Select by frequency.** Choose a value based on the frequency with which it occurs in the data record.
Note: Not available for Fields with a with a type of Continuous, Typeless, or Date/Time.
 - **Use.** Select from either Most or Least Frequent.
 - **Ties.** If there are two or more records with the same frequency of occurrence, specify how to select the required record. You can choose from one of four options: Use First, Use Last, Use Lowest, or Use Highest.
- **Includes value (T/F).** Select this to convert a field to a flag which identifies if any of the records in a group has a specified value. You can then select the Value from the list of those for the selected field.
Note: Not available if you select more than one Field row on the Composite tab
- **First match in list.** Select this to prioritize which value to give to the composite record. You can then select one of the Items from the list of those for the selected field.
Note: Not available if you select more than one Field row on the Composite tab
- **Concatenate values.** Select this to retain all the values in a group by concatenating them into a string. You must specify a delimiter to be used between each value.
Note: This is the only option available if you select one or more Field rows with a type of Continuous, Typeless, or Date/Time.
- **Use delimiter.** You can choose to use a Space or Comma as a delimiter value in the concatenated string. Alternatively, in the Other field, you can enter your own delimiter value character.
Note: Only available if you select the Concatenate values option.

Streaming Time Series node

You use the Streaming Time Series node to build and score time series models in one step. A separate time series model is built for each target field, however model nuggets are not added to the generated models palette and the model information cannot be browsed.

Methods for modeling time series data require a uniform interval between each measurement, with any missing values indicated by empty rows. If your data does not already meet this requirement, you will have to transform values as needed.

Other points to note in connection with Time Series nodes are:

- Fields must be numeric.
- Date fields cannot be used as inputs.
- Partitions are ignored.

The Streaming Time Series node estimates exponential smoothing, univariate Autoregressive Integrated Moving Average (ARIMA), and multivariate ARIMA (or transfer function) models for time series and produces forecasts based on the time series data. Also available is an Expert Modeler, which attempts to automatically identify and estimate the best-fitting ARIMA or exponential smoothing model for one or more target fields.

For more information about time series modeling, see [Time series data](#).

The Streaming Time Series node is supported for use in a streaming deployment environment, through IBM® SPSS® Modeler Solution Publisher, using the IBM SPSS Collaboration and Deployment Services Scoring Service.

- [Streaming Time Series node - field options](#)
 - [Streaming Time Series node - data specification options](#)
 - [Streaming Time Series node - build options](#)
 - [Streaming Time Series node - model options](#)
-

Streaming Time Series node - field options

Use predefined roles This option uses the role settings (targets, predictors and so on) from an upstream Type node (or the Types tab of an upstream source node).

Use custom field assignments. To manually assign targets, predictors and other roles, select this option.

Note: If you have partitioned your data, the partitions are taken into account if you select Use predefined roles, but not if you select Use custom field assignments.

Fields. Use the arrow buttons to assign items manually from this list to the various role fields on the right of the screen. The icons indicate the valid measurement levels for each role field.

To select all the fields in the list, click the All button, or click an individual measurement level button to select all fields with that measurement level.

Targets Select one or more of the fields as your target for the prediction.

Candidate inputs Select one or more fields as inputs for the prediction.

Events and Interventions Use this area to designate certain input fields as event or intervention fields. This designation identifies a field as containing time series data that can be affected by events (predictable recurring situations; for example, sales promotions) or interventions (one-time incidents; for example, power outage or employee strike).

Streaming Time Series node - data specification options

The Data Specifications tab is where you set all the options for the data to be included in your model. As long as you specify both a Date/time field and Time interval, you can click the Run button to build a model with all the default options, but normally you will want to customize the build for your own purposes.

The tab contains several different panes on which you set the customizations that are specific to your model.

- [Streaming Time Series node - observations](#)
- [Streaming Time Series node - time interval for analysis](#)

- [Streaming Time Series node - aggregation and distribution options](#)
 - [Streaming Time Series node - missing value options](#)
 - [Streaming Time Series node - estimation period](#)
-

Streaming Time Series node - observations

Use the settings in this pane to specify the fields that define the observations.

Observations that are specified by a date/time field

You can specify that the observations are defined by a date, time, or timestamp field. In addition to the field that defines the observations, select the appropriate time interval that describes the observations. Depending on the specified time interval, you can also specify other settings, such as the interval between observations (increment) or the number of days per week. The following considerations apply to the time interval:

- Use the value Irregular when the observations are irregularly spaced in time, such as the time at which a sales order is processed. When Irregular is selected, you must specify the time interval that is used for the analysis, from the Time Interval settings on the Data Specifications tab.
- When the observations represent a date and time and the time interval is hours, minutes, or seconds, then use Hours per day, Minutes per day, or Seconds per day. When the observations represent a time (duration) without reference to a date and the time interval is hours, minutes, or seconds, then use Hours (non-periodic), Minutes (non-periodic), or Seconds (non-periodic).
- Based on the selected time interval, the procedure can detect missing observations. Detecting missing observations is necessary since the procedure assumes that all observations are equally spaced in time and that no observations are missing. For example, if the time interval is Days and the date 2015-10-27 is followed by 2015-10-29, then an observation is missing for 2015-10-28. Values are imputed for any missing observations; use the Missing Value Handling area of the Data Specifications tab to specify settings for handling missing values.
- The specified time interval allows the procedure to detect multiple observations in the same time interval that need to be aggregated together and to align observations on an interval boundary, such as the first of the month, to ensure that the observations are equally spaced. For example, if the time interval is Months, then multiple dates in the same month are aggregated together. This type of aggregation is referred to as *grouping*. By default, observations are summed when grouped. You can specify a different method for grouping, such as the mean of the observations, from the Aggregation and Distribution settings on the Data Specifications tab.
- For some time intervals, the additional settings can define breaks in the normal equally spaced intervals. For example, if the time interval is Days, but only weekdays are valid, you can specify that there are five days in a week, and the week begins on Monday.

Observations that are defined as periods or cyclic periods

Observations can be defined by one or more integer fields that represent periods or repeating cycles of periods, up to an arbitrary number of cycle levels. With this structure, you can describe series of observations that don't fit one of the standard time intervals. For example, a fiscal year with only 10 months can be described with a cycle field that represents years and a period field that represents months, where the length of one cycle is 10.

Fields that specify cyclic periods define a hierarchy of periodic levels, where the lowest level is defined by the Period field. The next highest level is specified by a cycle field whose level is 1, followed by a cycle field whose level is 2, and so on. Field values for each level, except the highest, must be periodic with respect to the next highest level. Values for the highest level cannot be periodic. For example, in the case of the 10-month fiscal year, months are periodic within years and years are not periodic.

- The length of a cycle at a particular level is the periodicity of the next lowest level. For the fiscal year example, there is only one cycle level and the cycle length is 10 since the next lowest level represents months and there are 10 months in the specified fiscal year.
- Specify the starting value for any periodic field that does not start from 1. This setting is necessary for detecting missing values. For example, if a periodic field starts from 2 but the starting value is specified as 1, then the procedure assumes that there is a missing value for the first period in each cycle of that field.

Streaming Time Series node - time interval for analysis

The time interval that you use for analysis can differ from the time interval of the observations. For example, if the time interval of the observations is Days, you might choose Months for the time interval for analysis. The data is then aggregated from daily to monthly data before the model is built. You can also choose to distribute the data from a longer to a shorter time interval. For example, if the observations are quarterly then you can distribute the data from quarterly to monthly data.

Use the settings in this pane to specify the time interval for the analysis. The method by which the data is aggregated or distributed is specified from the Aggregation and Distribution settings on the Data Specifications tab.

The available choices for the time interval at which the analysis is done depend on how the observations are defined and the time interval of those observations. In particular, when the observations are defined by cyclic periods, only aggregation is supported. In that case, the time interval of the analysis must be greater than or equal to the time interval of the observations.

Streaming Time Series node - aggregation and distribution options

Use the settings in this pane to specify settings for aggregating or distributing the input data with respect to the time intervals of the observations.

Aggregation functions

When the time interval that is used for the analysis is longer than the time interval of the observations, the input data are aggregated. For example, aggregation is done when the time interval of the observations is Days and the time interval for analysis is Months. The following aggregation functions are available: mean, sum, mode, min, or max.

Distribution functions

When the time interval that is used for the analysis is shorter than the time interval of the observations, the input data are distributed. For example, distribution is done when the time interval of the observations is Quarters and the time interval for analysis is Months. The following distribution functions are available: mean or sum.

Grouping functions

Grouping is applied when observations are defined by date/times and multiple observations occur in the same time interval. For example, if the time interval of the observations is Months, then multiple dates in the same month are grouped and associated with the month in which they occur. The following grouping functions are available: mean, sum, mode, min, or max. Grouping is always done when the observations are defined by date/times and the time interval of the observations is specified as Irregular.

Note: Although grouping is a form of aggregation, it is done before any handling of missing values whereas formal aggregation is done after any missing values are handled. When the time interval of the observations is specified as Irregular, aggregation is done only with the grouping function.

Aggregate cross-day observations to previous day

Specifies whether observations with times that cross a day boundary are aggregated to the values for the previous day. For example, for hourly observations with an eight-hour day that starts at 20:00, this setting specifies whether observations between 00:00 and 04:00 are included in the aggregated results for the previous day. This setting applies only if the time interval of the observations is Hours per day, Minutes per day or Seconds per day and the time interval for analysis is Days.

Custom settings for specified fields

You can specify aggregation, distribution, and grouping functions on a field by field basis. These settings override the default settings for the aggregation, distribution, and grouping functions.

Streaming Time Series node - missing value options

Use the settings in this pane to specify how any missing values in the input data are to be replaced with an imputed value. The following replacement methods are available:

Linear interpolation

Replaces missing values by using a linear interpolation. The last valid value before the missing value and the first valid value after the missing value are used for the interpolation. If the first or last observation in the series has a missing value, then the two nearest non-missing values at the beginning or end of the series are used.

Replaces missing values by using a linear interpolation.

- For non-seasonal data, the last valid value before the missing value and the first valid value after the missing value are used for the interpolation. If missing values are at the beginning or the end of a time series, then a linear extrapolation method is used based on the two nearest valid values.
- For seasonal data, a missing value is linearly interpolated using the last valid value of the same period before the missing value and the first valid value of the same period after the missing value. If one of the two values of the same period can't be found for the missing value, then the data will be regarded as non-seasonal data and linear interpolation of non-seasonal data is used to impute the missing value.

Series mean

Replaces missing values with the mean for the entire series.

Mean of nearby points

Replaces missing values with the mean of valid surrounding values. The span of nearby points is the number of valid values before and after the missing value that are used to compute the mean.

Median of nearby points

Replaces missing values with the median of valid surrounding values. The span of nearby points is the number of valid values before and after the missing value that are used to compute the median.

Linear trend

This option uses all non-missing observations in the series to fit a simple linear regression model, which is then used to impute the missing values.

Other settings:

Lowest data quality score (%)

Computes data quality measures for the time variable and for input data corresponding to each time series. If the data quality score is lower than this threshold, the corresponding time series will be discarded.

Streaming Time Series node - estimation period

In the Estimation Period pane, you can specify the range of records to be used in model estimation. By default, the estimation period starts at the time of the earliest observation and ends at the time of the latest observation across all series.

By start and end times

You can specify both the start and end of the estimation period or you can specify just the start or just the end. If you omit the start or the end of the estimation period, the default value is used.

- If the observations are defined by a date/time field, enter values for start and end in the same format that is used for the date/time field.
- For observations that are defined by cyclic periods, specify a value for each of the cyclic periods fields. Each field is displayed in a separate column.

By latest or earliest time intervals

Defines the estimation period as a specified number of time intervals that start at the earliest time interval or end at the latest time interval in the data, with an optional offset. In this context, the time interval refers to the time interval of the analysis. For example, assume that the observations are monthly but the time interval of the analysis is quarters. Specifying Latest and a value of 24 for the Number of time intervals means the latest 24 quarters.

Optionally, you can exclude a specified number of time intervals. For example, specifying the latest 24 time intervals and 1 for the number to exclude means that the estimation period consists of the 24 intervals that precede the last one.

Streaming Time Series node - build options

The Build Options tab is where you set all the options for building your model. You can, of course, just click the Run button to build a model with all the default options, but normally you will want to customize the build for your own purposes.

The tab contains two different panes on which you set the customizations that are specific to your model.

- [Streaming Time Series node - general build options](#)
-

Streaming Time Series node - general build options

The options available on this pane depend on which of the following three settings you choose from the Method list:

- Expert Modeler. Choose this option to use the Expert Modeler, which automatically finds the best-fitting model for each dependent series.
- Exponential Smoothing. Use this option to specify a custom exponential smoothing model.
- ARIMA. Use this option to specify a custom ARIMA model.

Expert Modeler

Under Model Type, select the type of models you want to build:

- All models. The Expert Modeler considers both ARIMA and exponential smoothing models.
- Exponential smoothing models only. The Expert Modeler considers only exponential smoothing models.
- ARIMA models only. The Expert Modeler considers only ARIMA models.

Expert Modeler considers seasonal models. This option is only enabled if a periodicity is defined for the active dataset. When this option is selected, the Expert Modeler considers both seasonal and nonseasonal models. If this option is not selected, the Expert Modeler considers only nonseasonal models.

Expert Modeler considers sophisticated exponential smoothing models. When this option is selected, the Expert Modeler searches a total of 13 exponential smoothing models (7 of them existed in the original Time Series node, and 6 of them were added in version 18.1). If this option is not selected, the Expert Modeler only searches the original 7 exponential smoothing models.

Under Outliers, select from the following options

Detect outliers automatically. By default, automatic detection of outliers is not performed. Select this option to perform automatic detection of outliers, then select the desired outlier types.

For more information, see [Outliers](#).

Input fields must have a measurement level of *Flag*, *Nominal*, or *Ordinal* and must be numeric (for example, 1/0, not True/False, for a flag field), before they are included in this list.

For more information, see [Pulses and steps](#).

The Expert Modeler considers only simple regression and not arbitrary transfer functions for inputs that are identified as event or intervention fields on the Fields tab.

Exponential Smoothing

Model Type. Exponential smoothing models are classified as either seasonal or nonseasonal.¹ Seasonal models are only available if the periodicity defined by using the Time Intervals pane on the Data Specifications tab is seasonal. The seasonal periodicities are: cyclic periods, years, quarters, months, days per week, hours per day, minutes per day, and seconds per day. The following model types are available:

- Simple. This model is appropriate for a series in which there is no trend or seasonality. Its only relevant smoothing parameter is level. Simple exponential smoothing is most similar to an ARIMA with zero orders of autoregression, one order of differencing, one order of moving average, and no constant.
- Holt's linear trend. This model is appropriate for a series in which there is a linear trend and no seasonality. Its relevant smoothing parameters are level and trend, and, in this model, they are not constrained by each other's values. Holt's model is more general than Brown's model but may take longer to compute estimates for large series. Holt's exponential smoothing is most similar to an ARIMA with zero orders of autoregression, two orders of differencing, and two orders of moving average.
- Damped trend. This model is appropriate for a series in which there is a linear trend that is dying out and no seasonality. Its relevant smoothing parameters are level, trend, and damping trend. Damped exponential smoothing is most similar to an ARIMA with one order of autoregression, one order of differencing, and two orders of moving average.
- Multiplicative trend. This model is appropriate for a series in which there is a trend that changes with the magnitude of the series and no seasonality. Its relevant smoothing parameters are level and trend. Multiplicative trend exponential smoothing is not similar to any ARIMA model.
- Brown's linear trend. This model is appropriate for a series in which there is a linear trend and no seasonality. Its relevant smoothing parameters are level and trend, but, in this model, they are assumed to be equal. Brown's model is therefore a special case of Holt's model. Brown's exponential smoothing is most similar to an ARIMA with zero orders of autoregression, two orders of differencing, and two orders of moving average, with the coefficient for the second order of moving average equal to one half of the coefficient for the first order squared.
- Simple seasonal. This model is appropriate for a series in which there is no trend and a seasonal effect that is constant over time. Its relevant smoothing parameters are level and season. Seasonal exponential smoothing is most similar to an ARIMA with zero orders of autoregression; one order of differencing; one order of seasonal differencing; and orders 1, p , and $p+1$ of moving average, where p is the number of periods in a seasonal interval. For monthly data, $p = 12$.
- Winters' additive. This model is appropriate for a series in which there is a linear trend and a seasonal effect that is constant over time. Its relevant smoothing parameters are level, trend, and season. Winters' additive exponential smoothing is most similar to an ARIMA with zero orders of autoregression; one order of differencing; one order of seasonal differencing; and $p+1$ orders of moving average, where p is the number of periods in a seasonal interval. For monthly data, $p=12$.
- Damped trend with additive seasonal. This model is appropriate for a series in which there is a linear trend that is dying out and a seasonal effect that is constant over time. Its relevant smoothing parameters are level, trend, damping trend, and season. Damped trend and additive seasonal exponential smoothing is not similar to any ARIMA model.
- Multiplicative trend with additive seasonal. This model is appropriate for a series in which there is a trend that changes with the magnitude of the series and a seasonal effect that is constant over time. Its relevant smoothing parameters are level, trend, and season. Multiplicative trend and additive seasonal exponential smoothing is not similar to any ARIMA model.
- Multiplicative seasonal. This model is appropriate for a series in which there is no trend and a seasonal effect that changes with the magnitude of the series. Its relevant smoothing parameters are level and season. Multiplicative seasonal exponential smoothing is not similar to any ARIMA model.
- Winters' multiplicative. This model is appropriate for a series in which there is a linear trend and a seasonal effect that changes with the magnitude of the series. Its relevant smoothing parameters are level, trend, and season. Winters' multiplicative exponential smoothing is not similar to any ARIMA model.
- Damped trend with multiplicative seasonal. This model is appropriate for a series in which there is a linear trend that is dying out and a seasonal effect that changes with the magnitude of the series. Its relevant smoothing parameters are level, trend, damping trend, and season. Damped trend and multiplicative seasonal exponential smoothing is not similar to any ARIMA model.
- Multiplicative trend with multiplicative seasonal. This model is appropriate for a series in which there are a trend and a seasonal effect that both change with the magnitude of the series. Its relevant smoothing parameters are level, trend, and season. Multiplicative trend and multiplicative seasonal exponential smoothing is not similar to any ARIMA model.

Target Transformation. You can specify a transformation to be performed on each dependent variable before it is modeled.

For more information, see [Series transformations](#).

- None. No transformation is performed.
- Square root. Square root transformation is performed.
- Natural log. Natural log transformation is performed.

ARIMA

Specify the structure of a custom ARIMA model.

ARIMA Orders. Enter values for the various ARIMA components of your model into the corresponding cells of the grid. All values must be non-negative integers. For autoregressive and moving average components, the value represents the maximum order. All positive lower orders are included in the model. For example, if you specify 2, the model includes orders 2 and 1. Cells in the Seasonal column are only enabled if a periodicity is defined for the active dataset.

- Autoregressive (p). The number of autoregressive orders in the model. Autoregressive orders specify which previous values from the series are used to predict current values. For example, an autoregressive order of 2 specifies that the value of the series two time periods in the past is used to predict the current value.
- Difference (d). Specifies the order of differencing applied to the series before estimating models. Differencing is necessary when trends are present (series with trends are typically nonstationary and ARIMA modeling assumes stationarity) and is used to remove their effect. The order of differencing corresponds to the degree of series trend; first-order differencing accounts for linear trends, second-order differencing accounts for quadratic trends, and so on.
- Moving Average (q). The number of moving average orders in the model. Moving average orders specify how deviations from the series mean for previous values are used to predict current values. For example, moving-average orders of 1 and 2 specify that deviations from the mean value of the series from each of the last two time periods be considered when predicting current values of the series.

Seasonal. Seasonal autoregressive, moving average, and differencing components play the same roles as their nonseasonal counterparts. For seasonal orders, however, current series values are affected by previous series values that are separated by one or more seasonal periods. For example, for monthly data (seasonal period of 12), a seasonal order of 1 means that the current series value is affected by the series value 12 periods before the current one. A seasonal order of 1, for monthly data, is then the same as specifying a nonseasonal order of 12.

Detect outliers automatically. Select this option to perform automatic detection of outliers, and select one or more of the outlier types available.

Type of Outliers to Detect. Select the outlier type(s) you want to detect. The supported types are:

- Additive (default)
- Level shift (default)
- Innovational
- Transient
- Seasonal additive
- Local trend
- Additive patch

Transfer Function Orders and Transformations. To specify transformations and to define transfer functions for any or all of the input fields in your ARIMA model, click Set; a separate dialog box is displayed in which you enter the transfer and transformation details.

Include constant in model. Inclusion of a constant is standard unless you are sure that the overall mean series value is 0. Excluding the constant is recommended when differencing is applied.

Further details

- For more information on types of outliers, see [Outliers](#).
- For more information on transfer and transformation functions, see [Transfer and transformation functions](#).
- [Transfer and transformation functions](#)

¹ Gardner, E. S. 1985. Exponential smoothing: The state of the art. *Journal of Forecasting*, 4, 1-28.

Transfer and transformation functions

Use the Transfer Function Orders and Transformations dialog box to specify transformations and to define transfer functions for any or all of the input fields in your ARIMA model.

Target Transformations. In this pane you can specify a transformation to be performed on each target variable before it is modeled.

- None. No transformation is performed.
- Square root. Square root transformation is performed.
- Natural log. Natural log transformation is performed.

For more information, see [Series transformations](#).

Candidate Inputs Transfer functions and Transformation. You use transfer functions to specify the manner in which past values of the input fields are used to forecast future values of the target series. The list on the left hand side of the pane shows all input fields. The remaining information in this pane is specific to the input field you select.

Transfer Function Orders. Enter values for the various components of the transfer function into the corresponding cells of the Structure grid. All values must be non-negative integers. For numerator and denominator components, the value represents the maximum order. All positive lower orders are included in the model. In addition, order 0 is always included for numerator components. For example, if you specify 2 for numerator, the model includes orders 2, 1, and 0. If you specify 3 for denominator, the model includes orders 3, 2, and 1. Cells in the Seasonal column are only enabled if a periodicity is defined for the active dataset.

Numerator. The numerator order of the transfer function specifies which previous values from the selected independent (predictor) series are used to predict current values of the dependent series. For example, a numerator order of 1 specifies that the value of an independent series one time period in the past, in addition to the current value of the independent series, is used to predict the current value of each dependent series.

Denominator. The denominator order of the transfer function specifies how deviations from the series mean, for previous values of the selected independent (predictor) series, are used to predict current values of the dependent series. For example, a denominator order of 1 specifies that deviations from the mean value of an independent series one time period in the past is considered when predicting the current value of each dependent series.

Difference. Specifies the order of differencing applied to the selected independent (predictor) series before estimating models. Differencing is necessary when trends are present and is used to remove their effect.

Seasonal. Seasonal numerator, denominator, and differencing components play the same roles as their nonseasonal counterparts. For seasonal orders, however, current series values are affected by previous series values that are separated by one or more seasonal periods. For example, for monthly data (seasonal period of 12), a seasonal order of 1 means that the current series value is affected by the series value 12 periods prior to the current one. A seasonal order of 1, for monthly data, is then the same as specifying a nonseasonal order of 12.

Delay. Setting a delay causes the input field's influence to be delayed by the number of intervals specified. For example, if the delay is set to 5, the value of the input field at time t doesn't affect forecasts until five periods have elapsed ($t + 5$).

Transformation. Specification of a transfer function for a set of independent variables also includes an optional transformation to be performed on those variables.

- None. No transformation is performed.
- Square root. Square root transformation is performed.
- Natural log. Natural log transformation is performed.

Streaming Time Series node - model options

Confidence limit width (%). Confidence intervals are computed for the model predictions and residual autocorrelations. You can specify any positive value less than 100. By default, a 95% confidence interval is used.

The option to Extend records into the future sets the number of time intervals to forecast beyond the end of the estimation period. The time interval in this case is the time interval of the analysis, which you specify on the Data Specifications tab. When forecasts are requested, autoregressive models are automatically built for any input series that are not also targets. These models are then used to generate values for those input series in the forecast period. There is no maximum limit for this setting.

Future Values to Use in Forecasting

- Compute future values of inputs If you select this option, the forecast values for predictors, noise predictions, variance estimation, and future time values are calculated automatically. When forecasts are requested, autoregressive models are automatically built for any input series that are not also targets. These models are then used to generate values for those input series in the forecast period.
 - Select fields whose values you wish to add to the data. For each record that you want to forecast (excluding holdouts), if you are using predictor fields (with the role set to **Input**), you can specify estimated values for the forecast period for each predictor. You can either specify values manually, or choose from a list.
 - Field. Click the field selector button and choose any fields that may be used as predictors. Note that fields selected here may or may not be used in modeling; to actually use a field as a predictor, it must be selected in a downstream modeling node. This dialog box simply gives you a convenient place to specify future values so they can be shared by multiple downstream modeling nodes without specifying them separately in each node. Also note that the list of available fields may be constrained by selections on the Build Options tab.
- Note that if future values are specified for a field that is no longer available in the stream (because it has been dropped or because of updated selections made on the Build Options tab), the field is shown in red.
- Values. For each field, you can choose from a list of functions, or click Specify to either enter values manually or choose from a list of predefined values. If the predictor fields relate to items that are under your control, or which are otherwise knowable in advance, you should enter values manually. For example, if you are forecasting next month's revenues for a hotel based on the number of room reservations, you could specify the number of reservations you actually have for that period. Conversely, if a predictor field relates to something outside your control, such as a stock price, you could use a function such as the most recent value or the mean of recent points.
- The available functions depend on the measurement level of the field.

Table 1. Functions available for measurement levels

Measurement level	Functions
Continuous or Nominal field	Blank Mean of recent points Most recent value Specify
Flag field	Blank Most recent value True False Specify

Mean of recent points calculates the future value from the mean of the last three data points.

Most recent value sets the future value to that of the most recent data point.

True/False sets the future value of a flag field to True or False as specified.

Specify opens a dialog box for specifying future values manually, or choosing them from a predefined list.

Make Available for Scoring

You can set the default values here for the scoring options that appear on the dialog box for the model nugget.

- Calculate upper and lower confidence limits. If selected, this option creates new fields (with the default prefixes \$TSLCI- and \$TSUCI-) for the lower and upper confidence intervals, for each target field.
- Calculate noise residuals. If selected, this option creates a new field (with the default prefix \$TSResidual-) for the model residuals for each target field, together with a total of these values.

Model Settings

Maximum number of models to be displayed in output. Specify the maximum number of models you want to include in the output. Note that if the number of models built exceeds this threshold, the models are not shown in the output but they're still available for scoring. Default value is 10. Displaying a large number of models may result in poor performance or instability.

SMOTE node

The Synthetic Minority Over-sampling Technique (SMOTE) node provides an over-sampling algorithm to deal with imbalanced data sets. It provides an advanced method for balancing data. The SMOTE process node is implemented in Python and requires the imbalanced-learn® Python library. For details about the imbalanced-learn library, see <https://imbalanced-learn.org/stable/>¹.

The Python tab on the Nodes Palette contains the SMOTE node and other Python nodes.

¹Lemaître, Nogueira, Aridas. "Imbalanced-learn: A Python Toolbox to Tackle the Curse of Imbalanced Datasets in Machine Learning." *Journal of Machine Learning Research*, vol. 18, no. 17, 2017, pp. 1-5. (<http://jmlr.org/papers/v18/16-365.html>)

- [SMOTE node Settings](#)
- [SMOTE node Settings](#)

SMOTE node Settings

Define the following settings on the SMOTE node's Settings tab.

Target Setting

Target Field. Select the target field. All flag, nominal, ordinal, and discrete measurement types are supported. If the Use partitioned data option is selected in the Partition section, only training data will be over-sampled.

Over Sample Ratio

Select Auto to automatically select an over-sample ratio, or select Set Ratio (minority over majority) to set a custom ratio value. The ratio is the number of samples in the minority class over the number of samples in the majority class. The value must be greater than 0 and less than or equal to 1.

Random Seed

Set random seed. Select this option and click Generate to generate the seed used by the random number generator.

Methods

Algorithm Kind. Select the type of SMOTE algorithm you wish to use.

Samples Rules

K Neighbours. Specify the number of the nearest neighbors to use for constructing synthetic samples

M Neighbours. Specify the number of nearest neighbors to use for determining if a minority sample is in danger. This will only be used if the Borderline1 or Borderline2 SMOTE algorithm type is selected.

Partition

Use partitioned data. Select this option if you only want training data to be over-sampled.

The SMOTE node requires the imbalanced-learn® Python library. The following table shows the relationship between the settings in the SPSS® Modeler SMOTE node dialog and the Python algorithm.

Table 1. Node properties mapped to Python library parameters

SPSS Modeler setting	Script name (property name)	Python API parameter name
Over sample ratio (number input control)	sample_ratio_value	ratio
Random seed	random_seed	random_state
K_Neighbours	k_neighbours	k
M_Neighbours	m_neighbours	m
Algorithm kind	algorithm_kind	kind

Extension Transform node

With the Extension Transform node, you can take data from an IBM® SPSS® Modeler stream and apply transformations to the data using R scripting or Python for Spark scripting. When the data has been modified, it is returned to the stream for further processing, model building and model scoring. The Extension Transform node makes it possible to transform data using algorithms that are written in R or Python for Spark, and enables the user to develop data transformation methods that are tailored to a particular problem.

To use this node with R, you must install IBM SPSS Modeler - Essentials for R. See the *IBM SPSS Modeler - Essentials for R: Installation Instructions* for installation instructions and compatibility information. You must also have a compatible version of R installed on your computer.

- [Extension Transform node - Syntax tab](#)
- [Extension Transform node - Console Output tab](#)

Extension Transform node - Syntax tab

Select your type of syntax – R or Python for Spark. See the following sections for more information. When your syntax is ready, you can click Run to execute the Extension Transform node.

R Syntax

R Syntax. You can enter, or paste, custom R scripting syntax for data analysis into this field.

Convert flag fields. Specifies how flag fields are treated. There are two options: Strings to factor, Integers and Reals to double, and Logical values (True, False). If you select Logical values (True, False) the original values of the flag fields are lost. For example, if a field has values Male and Female, these are changed to True and False.

Convert missing values to the R 'not available' value (NA). When selected, any missing values are converted to the R NA value. The value NA is used by R to identify missing values. Some R functions that you use might have an argument that can be used to control how the function behaves when the data contain NA. For example, the function might allow you to choose to automatically exclude records that contain NA. If this option is not selected, any missing values are passed to R unchanged, and might cause errors when your R script is executed.

Convert date/time fields to R classes with special control for time zones. When selected, variables with date or datetime formats are converted to R date/time objects. You must select one of the following options:

- **R POSIXct.** Variables with date or datetime formats are converted to R POSIXct objects.
- **R POSIXlt (list).** Variables with date or datetime formats are converted to R POSIXlt objects.

Note: The POSIX formats are advanced options. Use these options only if your R script specifies that datetime fields are treated in ways that require these formats. The POSIX formats do not apply to variables with time formats.

Python Syntax

Python Syntax. You can enter, or paste, custom Python scripting syntax for data analysis into this field. For more information about Python for Spark, see [Python for Spark](#) and [Scripting with Python for Spark](#).

Extension Transform node - Console Output tab

The Console Output tab contains any output that is received when the R script or Python for Spark script on the Syntax tab runs (for example, if using an R script, it shows output received from the R console when the R script in the R Syntax field on the Syntax tab is executed). This output might include R or Python error messages or warnings that are produced when the R or Python script is executed. The output can be used, primarily, to debug the script. The Console Output tab also contains the script from the R Syntax or Python Syntax field.

Every time the Extension Transform script is executed, the content of the Console Output tab is overwritten with the output received from the R console or Python for Spark. The output cannot be edited.

Space-Time-Boxes Node

Space-Time-Boxes (STB) are an extension of Geohashed spatial locations. More specifically, an STB is an alphanumeric string that represents a regularly shaped region of space and time.

For example, the STB dr5ru7|2013-01-01 00:00:00|2013-01-01 00:15:00 is made up of the following three parts:

- The geohash dr5ru7
- The start timestamp 2013-01-01 00:00:00
- The end timestamp 2013-01-01 00:15:00

As an example, you could use space and time information to improve confidence that two entities are the same because they are virtually in the same place at the same time. Alternatively, you could improve the accuracy of relationship identification by showing that two entities are related due to their proximity in space and time.

You can choose the Individual Records or Hangouts mode as appropriate for your requirements. Both modes require the same basic details, as follows:

Latitude field. Select the field that identifies the latitude (in WGS84 coordinate system).

Longitude field. Select the field that identifies the longitude (in WGS84 coordinate system).

Timestamp field. Select the field that identifies the time or date.

Individual Record Options

Use this mode to add an additional field to a record to identify its location at a given time.

Derive. Select one or more densities of space and time from which to derive the new field. See [Defining Space-Time-Box density](#) for more information.

Field name extension. Type the extension that you would like added to the new field name(s). You can choose to add this extension as either a Suffix or Prefix.

Hangout Options

A hangout can be thought of as a location and/or time in which an entity is continually or repeatedly found. For example, this could be used to identify a vehicle that makes regular transportation runs and identify any deviations from the norm.

The hangout detector monitors the movement of entities and flags conditions where an entity is observed to be "hanging out" in the area. The hangout detector automatically assigns each flagged hangout to one or more STBs, and uses in-memory entity and event tracking to detect hangouts with optimum efficiency.

STB Density. Select the density of space and time from which to derive the new field. For example, a value of STB_GH4_10MINS would correspond to a four-character geohash box of size approximately 20 km by 20 km and a 10-minute time window. See [Defining Space-Time-Box density](#) for more information.

Entity ID field. Select the entity to be used as the hangout identifier. This ID field identifies the event.

Minimum number of events. An event is a row in the data. Select the minimum number of occurrences of an event for the entity to be considered to be hanging out. A hangout must also qualify based on the following Dwell time is at least field.

Dwell time is at least. Specify the minimum duration over which the entity must dwell in the same location. This can help exclude, for example, a car waiting at a traffic light from being considered as hanging out. A hangout must also qualify based on the previous Minimum number of events field.

Following is more detail about what qualifies as a hangout:

Let e_1, \dots, e_n denote all time ordered events that are received from a given entity ID during a time duration (t_1, t_n). These events qualify as a hangout if:

- $n \geq \text{minimum number of events}$
- $t_n - t_1 \geq \text{minimum dwell time}$
- All events e_1, \dots, e_n occur in the same STB

Allow hangouts to span STB boundaries. If this option is selected the definition of a hangout is less strict and could include, for example, an entity that hangs out in more than one Space-Time-Box. For example, if your STBs are defined as whole hours, selecting this option would recognize an entity that hangs out for an hour as valid, even if the hour consisted of the 30 minutes before midnight and the 30 minutes after midnight. If this option is not selected, 100% of hangout time must be within a single Space-Time-Box.

Min proportion of events in qualifying timebox (%). Only available if Allow hangouts to span STB boundaries is selected. Use this to control the degree to which a hangout reported in one STB might in fact overlap another. Select the minimum proportion of events that must occur within a single STB to identify a hangout. If set to 25%, and the proportion of events is 26%, this qualifies as being a hangout.

For example, suppose you configure the hangout detector to require at least two events (minimum number of events = 2) and a contiguous hover time of at least 2 minutes in a 4-byte-geohash space box and a 10-minute time box (STB_NAME = STB_GH4_10MINS). When a hangout is detected, say the entity hovers in the same 4-byte-geohash space box while the three qualifying events occur within a 10-minute time span between 4:57pm and 5:07pm at 4:58pm, 5:01pm, and 5:03pm. The qualifying timebox percent value specifies the STBs that be credit for the hangout, as follows:

- 100%. Hangout is reported in the 5:00 - 5:10pm time-box and not in the 4:50 - 5:00pm time-box (events 5:01pm and 5:03pm meet all conditions that are required for a qualifying hangout and 100% of these events occurred in the 5:00 - 5:10 time box).
- 50%. Hangouts in both the time-boxes are reported (events 5:01pm and 5:03pm meet all conditions that are required for a qualifying hangout and at least 50% of these events occurred in the 4:50 - 5:00 time box and at least 50% of these events occurred in the 5:00 - 5:10 time box).
- 0%. Hangouts in both the time-boxes are reported.

When 0% is specified, hangout reports include the STBs representing every time box that is touched by the qualifying duration. The qualifying duration needs to be less than or equal to the corresponding duration of the time box in the STB. In other words, there should never be a configuration where a 10-minute STB is configured in tandem with a 20-minute qualifying duration.

A hangout is reported as soon as the qualifying conditions are met, and is not reported more than once per STB. Suppose that three events qualify for a hangout, and 10 total events occur within a qualifying duration all within the same STB. In that case, the hangout is reported when the third qualifying event occurs. None of the additional seven events trigger a hangout report.

Note:

- The hangout detector's in-memory event data is not shared across processes. Therefore, a particular entity has affinity with a particular hangout detector node. That is, incoming motion data for an entity must always be consistently passed to the hangout detector node tracking that entity, which is ordinarily the same node throughout the run.
- The hangout detector's in-memory event data is volatile. Whenever the hangout detector is exited and restarted, any work-in-progress hangouts are lost. This means stopping and restarting the process might cause the system to miss reporting real hangouts. A potential remedy involves replaying some of the historical motion data (for example, going back 48 hours and replaying the motion records that are applicable to any node that was restarted).
- The hangout detector must be fed data in time-sequential order.
- [Defining Space-Time-Box density](#)

Related information

- [Defining Space-Time-Box density](#)
-

Defining Space-Time-Box density

Choose the size (density) of your Space-Time-Boxes (STB) by specifying the physical area and elapsed time to be included in each.

Geo density. Select the size of the area to be included in each STB.

Time interval. Select the number of hours to be included in each STB.

Field name. Prefixed with STB, this is automatically completed based on your selections in the preceding two fields.

Streaming TCM Node

The Streaming TCM node can be used to build and score temporal causal models in one step.

For more information about temporal causal modeling, see [Temporal Causal Models](#).

 - [Streaming TCM Node - Estimation Period options](#)
 - [Streaming TCM Node - Model options](#)
-

Streaming TCM Node - Time Series options

On the Fields tab, use the Time Series settings to specify the series to include in the model system.

Select the option for the data structure that applies to your data. For multidimensional data, click Select Dimensions to specify the dimension fields. The specified order of the dimension fields defines the order in which they appear in all subsequent dialogs and output. Use the up and down arrow buttons on the Select Dimensions subdialog to reorder the dimension fields.

For column-based data, the term *series* has the same meaning as the term *field*. For multidimensional data, fields that contain time series are referred to as *metric* fields. A time series, for multidimensional data, is defined by a metric field and a value for each of the dimension fields. The following considerations apply to both column-based and multidimensional data.

- Series that are specified as candidate inputs or as both target and input are considered for inclusion in the model for each target. The model for each target always includes lagged values of the target itself.
- Series that are specified as forced inputs are always included in the model for each target.
- At least one series must be specified as either a target or as both target and input.
- When Use predefined roles is selected, fields that have a role of Input are set as candidate inputs. No predefined role maps to a forced input. For more information, see the topic [Roles](#).

Multidimensional data

For multidimensional data, you specify metric fields and associated roles in a grid, where each row in the grid specifies a single metric and role. By default, the model system includes series for all combinations of the dimension fields for each row in the grid. For example, if there are dimensions for *region* and *brand* then, by default, specifying the metric *sales* as a target means that there is a separate sales target series for each combination of *region* and *brand*.

For each row in the grid, you can customize the set of values for any of the dimension fields by clicking the ellipsis button for a dimension. This action opens the Select Dimension Values subdialog. You can also add, delete, or copy grid rows.

The Series Count column displays the number of sets of dimension values that are currently specified for the associated metric. The displayed value can be larger than the actual number of series (one series per set). This condition occurs when some of the specified combinations of dimension values do not correspond to series contained by the associated metric.

- [Streaming TCM Node - Select Dimension Values](#)
-

Streaming TCM Node - Select Dimension Values

For multidimensional data, you can customize the analysis by specifying which dimension values apply to a particular metric field with a particular role. For example, if *sales* is a metric field and *channel* is a dimension with values 'retail' and 'web,' you can specify that 'web' sales is an input and 'retail' sales is a target. You can also specify dimension subsets that apply to all metric fields used in the analysis. For example, if *region* is a dimension field that indicates geographical region, then you can limit the analysis to particular regions.

All values

Specifies that all values of the current dimension field are included. This option is the default.

Select values to include or exclude

Use this option to specify the set of values for the current dimension field. When **Include** is selected for the Mode, only values that are specified in the Selected values list are included. When **Exclude** is selected for the Mode, all values other than the values that are specified in the Selected values list are included.

You can filter the set of values from which to choose. Values that meet the filter condition appear in the Matched tab and values that do not meet the filter condition appear in the Unmatched tab of the Unselected values list. The All tab lists all unselected values, regardless of any filter condition.

- You can use asterisks (*) to indicate wildcard characters when you specify a filter.
 - To clear the current filter, specify an empty value for the search term on the Filter Displayed Values dialog.
-

Streaming TCM Node - Observations options

On the Fields tab, use the Observations settings to specify the fields that define the observations.

Observations that are defined by date/times

You can specify that the observations are defined by a date, time, or timestamp field. In addition to the field that defines the observations, select the appropriate time interval that describes the observations. Depending on the specified time interval, you can also specify other settings, such as the interval between observations (increment) or the number of days per week. The following considerations apply to the time interval:

- Use the value **Irregular** when the observations are irregularly spaced in time, such as the time at which a sales order is processed. When **Irregular** is selected, you must specify the time interval that is used for the analysis, from the Time Interval settings on the Data Specifications tab.
- When the observations represent a date and time and the time interval is hours, minutes, or seconds, then use Hours per day, Minutes per day, or Seconds per day. When the observations represent a time (duration) without reference to a date and the time interval is hours, minutes, or seconds, then use Hours (non-periodic), Minutes (non-periodic), or Seconds (non-periodic).
- Based on the selected time interval, the procedure can detect missing observations. Detecting missing observations is necessary since the procedure assumes that all observations are equally spaced in time and that there are no missing observations. For example, if the time interval is Days and the date 2014-10-27 is followed by 2014-10-29, then there is a missing observation for 2014-10-28. Values are imputed for any missing observations. Settings for handling missing values can be specified from the Data Specifications tab.
- The specified time interval allows the procedure to detect multiple observations in the same time interval that need to be aggregated together and to align observations on an interval boundary, such as the first of the month, to ensure that the observations are equally spaced. For example, if the time interval is Months, then multiple dates in the same month are aggregated together. This type of aggregation is referred to as *grouping*. By default, observations are summed when grouped. You can specify a different method for grouping, such as the mean of the observations, from the Aggregation and Distribution settings on the Data Specifications tab.
- For some time intervals, the additional settings can define breaks in the normal equally spaced intervals. For example, if the time interval is Days, but only weekdays are valid, you can specify that there are five days in a week, and the week begins on Monday.

Observations that are defined by periods or cyclic periods

Observations can be defined by one or more integer fields that represent periods or repeating cycles of periods, up to an arbitrary number of cycle levels. With this structure, you can describe series of observations that don't fit one of the standard time intervals. For example, a fiscal year with only 10 months can be described with a cycle field that represents years and a period field that represents months, where the length of one cycle is 10.

Fields that specify cyclic periods define a hierarchy of periodic levels, where the lowest level is defined by the Period field. The next highest level is specified by a cycle field whose level is 1, followed by a cycle field whose level is 2, and so on. Field values for each level, except the highest, must be periodic with respect to the next highest level. Values for the highest level cannot be periodic. For example, in the case of the 10-month fiscal year, months are periodic within years and years are not periodic.

- The length of a cycle at a particular level is the periodicity of the next lowest level. For the fiscal year example, there is only one cycle level and the cycle length is 10 since the next lowest level represents months and there are 10 months in the specified fiscal

- year.
- Specify the starting value for any periodic field that does not start from 1. This setting is necessary for detecting missing values. For example, if a periodic field starts from 2 but the starting value is specified as 1, then the procedure assumes that there is a missing value for the first period in each cycle of that field.
-

Streaming TCM Node - Time Interval options

The time interval that is used for the analysis can differ from the time interval of the observations. For example, if the time interval of the observations is Days, you might choose Months for the time interval for analysis. The data are then aggregated from daily to monthly data before the model is built. You can also choose to distribute the data from a longer to a shorter time interval. For example, if the observations are quarterly then you can distribute the data from quarterly to monthly data.

The available choices for the time interval at which the analysis is done depend on how the observations are defined and the time interval of those observations. In particular, when the observations are defined by cyclic periods, then only aggregation is supported. In that case, the time interval of the analysis must be greater than or equal to the time interval of the observations.

The time interval for the analysis is specified from the Time Interval settings on the Data Specifications tab. The method by which the data are aggregated or distributed is specified from the Aggregation and Distribution settings on the Data Specifications tab.

Streaming TCM Node - Aggregation and Distribution options

Aggregation functions

When the time interval that is used for the analysis is longer than the time interval of the observations, the input data are aggregated. For example, aggregation is done when the time interval of the observations is Days and the time interval for analysis is Months. The following aggregation functions are available: mean, sum, mode, min, or max.

Distribution functions

When the time interval that is used for the analysis is shorter than the time interval of the observations, the input data are distributed. For example, distribution is done when the time interval of the observations is Quarters and the time interval for analysis is Months. The following distribution functions are available: mean or sum.

Grouping functions

Grouping is applied when observations are defined by date/times and multiple observations occur in the same time interval. For example, if the time interval of the observations is Months, then multiple dates in the same month are grouped and associated with the month in which they occur. The following grouping functions are available: mean, sum, mode, min, or max. Grouping is always done when the observations are defined by date/times and the time interval of the observations is specified as Irregular.

Note: Although grouping is a form of aggregation, it is done before any handling of missing values whereas formal aggregation is done after any missing values are handled. When the time interval of the observations is specified as Irregular, aggregation is done only with the grouping function.

Aggregate cross-day observations to previous day

Specifies whether observations with times that cross a day boundary are aggregated to the values for the previous day. For example, for hourly observations with an eight-hour day that starts at 20:00, this setting specifies whether observations between 00:00 and 04:00 are included in the aggregated results for the previous day. This setting applies only if the time interval of the observations is Hours per day, Minutes per day or Seconds per day and the time interval for analysis is Days.

Custom settings for specified fields

You can specify aggregation, distribution, and grouping functions on a field by field basis. These settings override the default settings for the aggregation, distribution, and grouping functions.

Streaming TCM Node - Missing Value options

Missing values in the input data are replaced with an imputed value. The following replacement methods are available:

Linear interpolation

Replaces missing values by using a linear interpolation. The last valid value before the missing value and the first valid value after the missing value are used for the interpolation. If the first or last observation in the series has a missing value, then the two nearest non-missing values at the beginning or end of the series are used.

Series mean

Replaces missing values with the mean for the entire series.

Mean of nearby points

Replaces missing values with the mean of valid surrounding values. The span of nearby points is the number of valid values before and after the missing value that are used to compute the mean.

Median of nearby points

Replaces missing values with the median of valid surrounding values. The span of nearby points is the number of valid values before and after the missing value that are used to compute the median.

Linear trend

This option uses all non-missing observations in the series to fit a simple linear regression model, which is then used to impute the missing values.

Other settings:

Maximum percentage of missing values (%)

Specifies the maximum percentage of missing values that are allowed for any series. Series with more missing values than the specified maximum are excluded from the analysis.

Streaming TCM Node - General Data options

Maximum number of distinct values per dimension field

This setting applies to multidimensional data and specifies the maximum number of distinct values that are allowed for any one dimension field. By default, this limit is set to 10000 but it can be increased to an arbitrarily large number.

Streaming TCM Node - General Build options

Confidence interval width (%)

This setting controls the confidence intervals for both forecasts and model parameters. You can specify any positive value less than 100. By default, a 95% confidence interval is used.

Maximum number of inputs for each target

This setting specifies the maximum number of inputs that are allowed in the model for each target. You can specify an integer in the range 1 - 20. The model for each target always includes lagged values of itself, so setting this value to 1 specifies that the only input is the target itself.

Model tolerance

This setting controls the iterative process that is used for determining the best set of inputs for each target. You can specify any value that is greater than zero. The default is 0.001. Model tolerance is a stop criterion for predictor selection. It can affect the number of predictors that are included in the final model. But if a target can predict itself very well, other predictors may not be included in the final model.

Some trial and error may be required (for example, if you have this value set to high, you can try setting it to a smaller value to see if other predictors can be included or not).

Outlier threshold (%)

An observation is flagged as an outlier if the probability, as calculated from the model, that it is an outlier exceeds this threshold. You can specify a value in the range 50 - 100.

Number of Lags for Each Input

This setting specifies the number of lag terms for each input in the model for each target. By default, the number of lag terms is automatically determined from the time interval that is used for the analysis. For example, if the time interval is months (with an increment of one month) then the number of lags is 12. Optionally, you can explicitly specify the number of lags. The specified value must be an integer in the range 1 - 20.

Continue estimation using existing models

If you already generated a temporal causal model, select this option to reuse the criteria settings that are specified for that model, rather than building a new model. In this way, you can save time by reestimating and producing a new forecast that is based on the same model settings as before but using more recent data.

Streaming TCM Node - Estimation Period options

By default, the estimation period starts at the time of the earliest observation and ends at the time of the latest observation across all series.

By start and end times

You can specify both the start and end of the estimation period or you can specify just the start or just the end. If you omit the start or the end of the estimation period, the default value is used.

- If the observations are defined by a date/time field, then enter values for start and end in the same format that is used for the date/time field.
- For observations that are defined by cyclic periods, specify a value for each of the cyclic periods fields. Each field is displayed in a separate column.

By latest or earliest time intervals

Defines the estimation period as a specified number of time intervals that start at the earliest time interval or end at the latest time interval in the data, with an optional offset. In this context, the time interval refers to the time interval of the analysis. For example,

assume that the observations are monthly but the time interval of the analysis is quarters. Specifying Latest and a value of 24 for the Number of time intervals means the latest 24 quarters.

Optionally, you can exclude a specified number of time intervals. For example, specifying the latest 24 time intervals and 1 for the number to exclude means that the estimation period consists of the 24 intervals that precede the last one.

Streaming TCM Node - Model options

Model Name

You can specify a custom name for the model or accept the automatically generated name, which is *TCM*.

Forecast

The option to Extend records into the future sets the number of time intervals to forecast beyond the end of the estimation period. The time interval in this case is the time interval of the analysis, which is specified on the Data Specifications tab. When forecasts are requested, autoregressive models are automatically built for any input series that are not also targets. These models are then used to generate values for those input series in the forecast period. There is no maximum limit for this setting.

CPLEX Optimization node

The CPLEX Optimization node provides the ability to use complex mathematical (CPLEX) based optimization via an Optimization Programming Language (OPL) model file. This functionality was available in the IBM® Analytical Decision Management product that's no longer supported, but you can also use the CPLEX node in SPSS® Modeler without requiring IBM Analytical Decision Management.

For more information about CPLEX optimization and OPL, see the [IBM ILOG CPLEX Optimization Studio documentation](#).

The CPLEX Optimization node supports multiple data sources, or multiple dimensional incoming data. You can connect several nodes to the CPLEX Optimization node, and each prior node can be utilized to provide data to OPL model computing – set as individual tuple sets with individual field mappings.

When outputting the data generated by the CPLEX Optimization node, the original data from the data sources can be output together as single indexes, or as multiple dimensional indexes of the result.

The CPLEX Optimization node's decision variable doesn't support complex arrays.

Note:

- When running a stream containing a CPLEX Optimization node on **IBM SPSS Modeler Server**, by default the embedded Community edition CPLEX library is used. It has a limitation of 1000 variables and 1000 constraints. If you install the full edition of IBM ILOG CPLEX and want to use the full edition's CPLEX engine instead, which doesn't have such limitations, complete the following step for your platform.
 - On Windows, edit options.cfg and add the OPL library path. For example:

```
cplex_opl_lib_path="<CPLEX_path>\opl\bin\<Platform_dir>"
```

Where **<CPLEX_path>** is the CPLEX installation directory such as C:\Program Files\IBM\ILOG\CPLEX_Studio127, and **<Platform_dir>** is the platform-specific directory such as x64_win64.

- On Linux, edit modelersrv.sh and add the OPL library path. For example:

```
CPLEX_OPL_LIB_PATH=<CPLEX_path>/opl/bin/<Platform_dir>
```

Where **<CPLEX_path>** is the CPLEX installation directory such as /root/Libs_127_FullEdition/Linux_x86_64, and **<Platform_dir>** is the platform-specific directory such as x86-64_linux.

Note:

- When running a stream containing a CPLEX Optimization node in **SPSS Modeler Solution Publisher**, by default the embedded Community edition CPLEX library is used. It has a limitation of 1000 variables and 1000 constraints. If you install the full edition of IBM ILOG CPLEX and want to use the full edition's CPLEX engine instead, which doesn't have such limitations, complete the following step for your platform.
 - On Windows, add the OPL library path as a command line argument for modelerrun.exe. For example:

```
-o cplex_opl_lib_path="<CPLEX_path>\opl\bin\<Platform_dir>"
```

Where **<CPLEX_path>** is the CPLEX installation directory such as C:\Program Files\IBM\ILOG\CPLEX_Studio127, and **<Platform_dir>** is the platform-specific directory such as x64_win64.

- On Linux, edit modelerrun and add the OPL library path. For example:

```
CPLEX_OPL_LIB_PATH=<CPLEX_path>/opl/bin/<Platform_dir>
```

Where <CPLEX_path> is the CPLEX installation directory such as /root/Libs_127_FullEdition/Linux_x86_64, and <Platform_dir> is the platform-specific directory such as x86-64_linux.

- CPLEX isn't supported on macOS. You can use the node (add it to your stream, edit its properties, etc), but you can't run it.
- [Setting options for the CPLEX Optimization node](#)

Setting options for the CPLEX Optimization node

The Options tab of the CPLEX Optimization node contains the following fields.

OPL Model File. Select an Optimization Programming Language (OPL) model file.

OPL Model. After selecting an OPL model, the contents are shown here.

Input Data

On the Input Data tab, the Data Source drop-down lists all data sources (prior nodes) connected to the current CPLEX Optimization node. Selecting a data source from the drop-down refreshes the Input Mappings section below. Click Apply All Fields to generate all field mappings for the selected data source automatically. The Input Mappings table will be populated automatically.

Enter the tuple set name in the OPL model that corresponds to the incoming data. Then, if needed, verify that all tuple fields are mapped to data input fields according to their order in the tuple definition.

After setting the input mapping for a data source, you can select a different data source from the drop-down and repeat the process. The previous data source mappings will be saved automatically. Click Apply or OK when finished.

Other Data

On the Other Data tab, use the OPL Data section if you need to specify any other data for the optimization.

Output

When the output is a decision variable, it must take the prior data sources (incoming data) as indexes, and the indexes must be predefined in the Input Mappings section on the Input Data tab. No other type of decision variables are currently supported. The decision variable can have a single index or multiple indexes. SPSS® Modeler will output the CPLEX results with all or part of the original incoming data together, which is consistent with other SPSS Modeler nodes. The referred corresponding indexes must be specified in the Output Tuple field described below.

On the Output tab, choose the output mode (Raw Output or Decision Variable) and specify other options as appropriate. The Raw Output option will output the objective function value directly, regardless of name.

Objective Function Value Variable Name in OPL. This field is enabled if you selected the Decision Variable output mode. Enter the name of the objective function value variable from the OPL model.

Objective Function Value Field Name for Output. Enter the field name to use in the output. The default is _OBJECTIVE.

Output Tuple. Enter the name of the predefined tuple from the incoming data. This acts as the indexes of the decision variable and is expected to be output with the Variable Outputs. The Output Tuple should be consistent with the decision variable definition in the OPL. If there are multiple indexes, the tuple names must be joined by a comma (,).

Variable Outputs. Add one or more variables to include in the output.

Field Operations Overview

After an initial data exploration, you will probably have to select, clean, or construct data in preparation for analysis. The Field Operations palette contains many nodes useful for this transformation and preparation.

For example, using a Derive node, you might create an attribute that is not currently represented in the data. Or you might use a Binning node to recode field values automatically for targeted analysis. You will probably find yourself using a Type node frequently—it allows you to assign a measurement level, values, and a modeling role for each field in the dataset. Its operations are useful for handling missing values and downstream modeling.

The Field Operations palette contains the following nodes:

	The Automated Data Preparation (ADP) node can analyze your data and identify fixes, screen out fields that are problematic or not likely to be useful, derive new attributes when appropriate, and improve performance through intelligent screening and sampling techniques. You can use the node in fully automated fashion, allowing the node to choose and apply fixes, or you can preview the changes before they are made and accept, reject, or amend them as desired.
	The Type node specifies field metadata and properties. For example, you can specify a measurement level (continuous, nominal, ordinal, or flag) for each field, set options for handling missing values and system nulls, set the role of a field for modeling purposes, specify field and value labels, and specify values for a field.
	The Filter node filters (discards) fields, renames fields, and maps fields from one source node to another.
	The Derive node modifies data values or creates new fields from one or more existing fields. It creates fields of type formula, flag, nominal, state, count, and conditional.
	The Ensemble node combines two or more model nuggets to obtain more accurate predictions than can be gained from any one model.
	The Filler node replaces field values and changes storage. You can choose to replace values based on a CLEM condition, such as @BLANK(@FIELD). Alternatively, you can choose to replace all blanks or null values with a specific value. A Filler node is often used together with a Type node to replace missing values.
	The Anonymize node transforms the way field names and values are represented downstream, thus disguising the original data. This can be useful if you want to allow other users to build models using sensitive data, such as customer names or other details.
	The Reclassify node transforms one set of categorical values to another. Reclassification is useful for collapsing categories or regrouping data for analysis.
	The Binning node automatically creates new nominal (set) fields based on the values of one or more existing continuous (numeric range) fields. For example, you can transform a continuous income field into a new categorical field containing groups of income as deviations from the mean. Once you have created bins for the new field, you can generate a Derive node based on the cut points.
	The Recency, Frequency, Monetary (RFM) Analysis node enables you to determine quantitatively which customers are likely to be the best ones by examining how recently they last purchased from you (recency), how often they purchased (frequency), and how much they spent over all transactions (monetary).
	The Partition node generates a partition field, which splits the data into separate subsets for the training, testing, and validation stages of model building.
	The Set to Flag node derives multiple flag fields based on the categorical values defined for one or more nominal fields.
	The Restructure node converts a nominal or flag field into a group of fields that can be populated with the values of yet another field. For example, given a field named <i>payment type</i> , with values of <i>credit</i> , <i>cash</i> , and <i>debit</i> , three new fields would be created (<i>credit</i> , <i>cash</i> , <i>debit</i>), each of which might contain the value of the actual payment made.
	The Transpose node swaps the data in rows and columns so that records become fields and fields become records.

	
	Use the Time Intervals node to specify intervals and derive a new time field for estimating or forecasting. A full range of time intervals is supported, from seconds to years.
	The History node creates new fields containing data from fields in previous records. History nodes are most often used for sequential data, such as time series data. Before using a History node, you may want to sort the data using a Sort node.
	The Field Reorder node defines the natural order used to display fields downstream. This order affects the display of fields in a variety of places, such as tables, lists, and the Field Chooser. This operation is useful when working with wide datasets to make fields of interest more visible.
	Within SPSS® Modeler, items such as the Expression Builder spatial functions, the Spatio-Temporal Prediction (STP) Node, and the Map Visualization Node use the projected coordinate system. Use the Reproject node to change the coordinate system of any data that you import that uses a geographic coordinate system.

Several of these nodes can be generated directly from the audit report created by a Data Audit node. See the topic [Generating Other Nodes for Data Preparation](#) for more information.

Automated Data Preparation

Preparing data for analysis is one of the most important steps in any project—and traditionally, one of the most time consuming. Automated Data Preparation (ADP) handles the task for you, analyzing your data and identifying fixes, screening out fields that are problematic or not likely to be useful, deriving new attributes when appropriate, and improving performance through intelligent screening techniques. You can use the algorithm in fully **automatic** fashion, allowing it to choose and apply fixes, or you can use it in **interactive** fashion, previewing the changes before they are made and accept or reject them as you want.

Using ADP enables you to make your data ready for model building quickly and easily, without needing prior knowledge of the statistical concepts involved. Models will tend to build and score more quickly; in addition, using ADP improves the robustness of automated modeling processes, such as model refresh and champion / challenger.

Note: When ADP prepares a field for analysis, it creates a new field containing the adjustments or transformations, rather than replacing the existing values and properties of the old field. The old field is not used in further analysis; its role is set to None.

Example. An insurance company with limited resources to investigate homeowner's insurance claims wants to build a model for flagging suspicious, potentially fraudulent claims. Before building the model, they will ready the data for modeling using automated data preparation. Since they want to be able to review the proposed transformations before the transformations are applied, they will use automated data preparation in interactive mode.

An automotive industry group keeps track of the sales for a variety of personal motor vehicles. In an effort to be able to identify over- and underperforming models, they want to establish a relationship between vehicle sales and vehicle characteristics. They will use automated data preparation to prepare the data for analysis, and build models using the data "before" and "after" preparation to see how the results differ.

What is your objective? Automated data preparation recommends data preparation steps that will affect the speed with which other algorithms can build models and improve the predictive power of those models. This can include transforming, constructing and selecting features. The target can also be transformed. You can specify the model-building priorities that the data preparation process should concentrate on.

- Balance speed and accuracy. This option prepares the data to give equal priority to both the speed with which data are processed by model-building algorithms and the accuracy of the predictions.
- Optimize for speed. This option prepares the data to give priority to the speed with which data are processed by model-building algorithms. When you are working with very large datasets, or are looking for a quick answer, select this option.
- Optimize for accuracy. This option prepares the data to give priority to the accuracy of predictions produced by model-building algorithms.
- Custom analysis. When you want to manually change the algorithm on the Settings tab, select this option. Note that this setting is automatically selected if you subsequently make changes to options on the Settings tab that are incompatible with one of the other objectives.

Training the node

The ADP node is implemented as a process node and works in a similar way to the Type node; **training** the ADP node corresponds to instantiating the Type node. Once analysis has been performed, the specified transformations are applied to the data without further analysis as long as the upstream data model does not change. Like the Type and Filter nodes, if the ADP node is disconnected it remembers the data model and transformations so that if it is reconnected it does not need to be retrained; this enables you to train it on a subset of typical data and then copy or deploy it for use on live data as often as required.

Using the toolbar

The toolbar enables you to run and update the display of the data analysis, and generate nodes that you can use in conjunction with the original data.

- Generate From this menu you can generate either a Filter or Derive node. Note that this menu is only available when there is an analysis shown on the Analysis tab.

The Filter node removes transformed input fields. If you configure the ADP node to leave the original input fields in the dataset, this will restore the original set of inputs allowing you to interpret the score field in terms of the inputs. For example, this may be useful if you want to produce a graph of the score field against various inputs.

The Derive node can restore the original dataset and target units. You can only generate a Derive node when the ADP node contains an analysis which rescales a range target (that is, Box-Cox rescaling is selected on the Prepare Inputs & Target panel). You cannot generate a Derive node if the target is not a range, or if the Box-Cox rescaling is not selected. See the topic [Generating a Derive node](#) for more information.

- View Contains options that control what is shown on the Analysis tab. This includes the graph editing controls and the display selections for both the main panel and linked views.
- Preview Displays a sample of the transformations that will be applied to the input data.
- Analyze Data Initiates an analysis using the current settings and displays the results on the Analysis tab.
- Clear Analysis Deletes the existing analysis (only available when a current analysis exists).

Node status

The status of the ADP node on the IBM® SPSS® Modeler canvas is indicated by either an arrow or tick on the icon that shows whether or not analysis has taken place.

For more information about the calculations performed with the Automated Data Preparation node, see the *Automated Data Preparation algorithms* section of the *IBM SPSS Modeler Algorithms Guide*. The guide is available in PDF format from the \Documentation directory of the installation disk, as part of your product download, or on the Web.

- [Fields tab \(automated data preparation\)](#)
- [Settings tab \(automated data preparation\)](#)
- [Analysis tab \(automated data preparation\)](#)
- [Generating a Derive node](#)

Fields tab (automated data preparation)

Before you can build a model, you need to specify which fields you want to use as targets and as inputs. With a few exceptions, all modeling nodes will use field information from an upstream Type node. If you are using a Type node to select input and target fields, you don't need to change anything on this tab.

Use type node settings. This option tells the node to use field information from an upstream Type node. This is the default.

Use custom settings. This option tells the node to use field information specified here instead of that given in any upstream Type node(s). After selecting this option, specify the fields below as required.

Target. For models that require one or more target fields, select the target field or fields. This is similar to setting the field role to *Target* in a Type node.

Inputs. Select the input field or fields. This is similar to setting the field role to *Input* in a Type node.

Settings tab (automated data preparation)

The Settings tab comprises several different groups of settings that you can modify to fine-tune how the algorithm processes your data. If you make any changes to the default settings that are incompatible with the other objectives, the Objective tab is automatically updated to select the Customize analysis option.

- [Field settings](#)
- [Prepare dates & times \(automated data preparation\)](#)
- [Excluding fields \(automated data preparation\)](#)
- [Preparing inputs and targets](#)
- [Construction and feature selection](#)
- [Field names \(automated data preparation\)](#)

Field settings

Use frequency field. This option enables you to select a field as a frequency weight. Use this if the records in your training data represent more than one unit each; for example, if you are using aggregated data. The field values should be the number of units represented by each record.

Use weight field. This option enables you to select a field as a case weight. Case weights are used to account for differences in variance across levels of the output field.

How to handle fields that are excluded from modeling. Specify what happens to excluded fields; you can choose either to filter them out of the data or simply set their *Role* to None.

Note: This action will also be applied to the target if it is transformed. For example, if the new derived version of the target is used as the Target field, the original target is either filtered or set to None.

If the incoming fields do not match the existing analysis. Specify what happens if one or more required input fields are missing from the incoming dataset when you execute a trained ADP node.

- Stop execution and keep the existing analysis. This stops the execution process, preserves the current analysis information, and displays an error.
- Clear the existing analysis and analyze the new data. This clears the existing analysis, analyzes the incoming data, and applies the recommended transformations to that data.

Prepare dates & times (automated data preparation)

Many modeling algorithms are unable to directly handle date and time details; these settings enable you to derive new duration data that can be used as model inputs from dates and times in your existing data. The fields containing dates and times must be predefined with date or time storage types. The original date and time fields will not be recommended as model inputs following automated data preparation.

Prepare dates and times for modeling. Deselecting this option disables all other Prepare Dates & Times controls while maintaining the selections.

Compute elapsed time until reference date. This produces the number of years/months/days since a reference date for each variable containing dates.

- Reference Date. Specify the date from which the duration will be calculated with regard to the date information in the input data. Selecting Today's date means that the current system date is always used when ADP is executed. To use a specific date, select Fixed date and enter the required date. The current date is automatically entered in the Fixed date field when the node is first created.
- Units for Date Duration. Specify whether ADP should automatically decide on the date duration unit, or select from Fixed units of Years, Months, or Days.

Compute elapsed time until reference time. This produces the number of hours/minutes/seconds since a reference time for each variable containing times.

- Reference Time. Specify the time from which the duration will be calculated with regard to the time information in the input data. Selecting Current time means that the current system time is always used when ADP is executed. To use a specific time, select Fixed time and enter the required details. The current time is automatically entered in the Fixed time field when the node is first created.
- Units for Time Duration. Specify whether ADP should automatically decide on the time duration unit, or select from Fixed units of Hours, Minutes, or Seconds.

Extract Cyclical Time Elements. Use these settings to split a single date or time field into one or more fields. For example if you select all three date checkboxes, the input date field "1954-05-23" is split into three fields: 1954, 5, and 23, each using the suffix defined on the Field Names panel, and the original date field is ignored.

- Extract from dates. For any date inputs, specify if you want to extract years, months, days, or any combination.
- Extract from times. For any time inputs, specify if you want to extract hours, minutes, seconds, or any combination.

Excluding fields (automated data preparation)

Poor quality data can affect the accuracy of your predictions; therefore, you can specify the acceptable quality level for input features. All fields that are constant or have 100% missing values are automatically excluded.

Exclude low quality input fields. Deselecting this option disables all other Exclude Fields controls while maintaining the selections.

Exclude fields with too many missing values. Fields with more than the specified percentage of missing values are removed from further analysis. Specify a value greater than or equal to 0, which is equivalent to deselecting this option, and less than or equal to 100, though fields with all missing values are automatically excluded. The default is 50.

Exclude nominal fields with too many unique categories. Nominal fields with more than the specified number of categories are removed from further analysis. Specify a positive integer. The default is 100. This is useful for automatically removing fields containing record-unique information from modeling, like ID, address, or name.

Exclude categorical fields with too many values in a single category. Ordinal and nominal fields with a category that contains more than the specified percentage of the records are removed from further analysis. Specify a value greater than or equal to 0, equivalent to deselecting this option, and less than or equal to 100, though constant fields are automatically excluded. The default is 95.

Preparing inputs and targets

Because no data is ever in a perfect state for processing, you may want to adjust some of the settings before running an analysis. For example, this might include the removal of outliers, specifying how to handle missing values, or adjusting the type.

Note: If you change the values on this panel, the Objectives tab is automatically updated to select the Custom analysis option. Prepare the input and target fields for modeling. Toggles all fields on the panel either on or off.

Adjust Type and Improve Data Quality. For inputs and the target you can specify several data transformations separately; this is because you may not want to change the values of the target. For example, a prediction of income in dollars is more meaningful than a prediction measured in log(dollars). In addition, if the target has missing values there is no predictive gain to filling missing values, whereas filling missing values in inputs may enable some algorithms to process information that would otherwise be lost.

Additional settings for these transformations, such as the outlier cutoff value, are common to both the target and inputs.

You can select the following settings for either, or both, inputs and target:

- Adjust the type of numeric fields. Select this to determine if numeric fields with a measurement level of *Ordinal* can be converted to *Continuous*, or vice versa. You can specify the minimum and maximum threshold values to control the conversion.
- Reorder nominal fields. Select this to sort nominal (set) fields into order, from smallest to largest category.
- Replace outlier values in continuous fields. Specify whether to replace outliers; use this in conjunction with the Method for replacing outliers options below.
- Continuous fields: replace missing values with mean. Select this to replace missing values of continuous (range) features.
- Nominal fields: replace missing values with mode. Select this to replace missing values of nominal (set) features.
- Ordinal fields: replace missing values with median. Select this to replace missing values of ordinal (ordered set) features.

Maximum number of values for ordinal fields. Specify the threshold for redefining ordinal (ordered set) fields as continuous (range). The default is 10; therefore, if an ordinal field has more than 10 categories it is redefined as continuous (range).

Minimum number of values for continuous fields. Specify the threshold for redefining scale or continuous (range) fields as ordinal (ordered set). The default is 5; therefore, if a continuous field has fewer than 5 values it is redefined as ordinal (ordered set).

Outlier cutoff value. Specify the outlier cutoff criterion, measured in standard deviations; the default is 3.

Method for replacing outliers. Select whether outliers are to be replaced by either trimming (coerce) with the cutoff value, or to delete them and set them as missing values. Any outliers set to missing values follow the missing value handling settings selected above.

Put all continuous input fields on a common scale. To normalize continuous input fields, select this check box and choose the normalization method. The default is z-score transformation, where you can specify the Final mean, which has a default of 0, and the Final standard deviation, which has a default of 1. Alternatively, you can choose to use Min/max transformation and specify the minimum and maximum values, which have default values of 0 and 100 respectively.

This field is especially useful when you select Perform feature construction on the Construct & Select Features panel.

Rescale a continuous target with a Box-Cox transformation. To normalize a continuous (scale or range) target field, select this check box. The Box-Cox transformation has default values of 0 for the Final mean and 1 for the Final standard deviation.

Note: If you choose to normalize the target, the dimension of the target will be transformed. In this case you may need to generate a Derive node to apply an inverse transformation in order to turn the transformed units back into a recognizable format for further processing. See the topic [Generating a Derive node](#) for more information.

Construction and feature selection

To improve the predictive power of your data, you can transform the input fields, or construct new ones based on the existing fields.

Note: If you change the values on this panel, the Objectives tab is automatically updated to select the Custom analysis option. Transform, construct and select input fields to improve predictive power. Toggles all fields on the panel either on or off.

Merge sparse categories to maximize association with target. Select this to make a more parsimonious model by reducing the number of variables to be processed in association with the target. If required, change the probability value from the default of 0.05.

Note that if all categories are merged into one, the original and derived versions of the field are excluded because they have no value as a predictor.

When there is no target, merge sparse categories based on counts. If you are dealing with data that has no target, you can choose to merge sparse categories of either, or both, ordinal (ordered set) and nominal (set) features. Specify the minimum percentage of cases, or records, in the data that identifies the categories to be merged; the default is 10.

Categories are merged using the following rules:

- Merging is not performed on binary fields.
- If there are only two categories during merging, merging stops.
- If there is no original category, nor any category created during merging, with fewer than the specified minimum percent of cases, merging stops.

Bin continuous fields while preserving predictive power. Where you have data that includes a categorical target, you can bin continuous inputs with strong associations to improve processing performance. If required, change the probability value for the homogenous subsets from the default of 0.05.

If the binning operation results in a single bin for a particular field, the original and binned versions of the field are excluded because they have no value as a predictor.

Note: Binning in ADP differs from optimal binning used in other parts of IBM® SPSS® Modeler. Optimal binning uses entropy information to convert a continuous variable to a categorical variable; this needs to sort data and store it all in memory. ADP uses homogenous subsets to bin a continuous variable, this means that ADP binning does not need to sort data and does not store all data in memory. The use of the homogenous subset method to bin a continuous variable means that the number of categories after binning is always less than or equal to the number of categories of target.

Perform feature selection. Select this option to remove features with a low correlation coefficient. If required, change the probability value from the default of 0.05.

This option only applies to continuous input features where the target is continuous, and to categorical input features.

Perform feature construction. Select this option to derive new features from a combination of several existing features (which are then discarded from modeling).

This option only applies to continuous input features where the target is continuous, or where there is no target.

Field names (automated data preparation)

To easily identify new and transformed features, ADP creates and applies basic new names, prefixes, or suffixes. You can amend these names to be more relevant to your own needs and data. If you want to specify other labels, you will need to do this in a downstream Type node.

Transformed and Constructed Fields. Specify the name extensions to be applied to transformed target and input fields.

Note that in the ADP node, setting string fields to contain nothing may cause an error depending on how you chose to handle unused fields. If How to handle fields that are excluded from modeling is set to Filter out unused fields on the Field Settings panel of the Settings tab, the name extensions for inputs and the target can be set to nothing. The original fields are filtered out and the transformed fields saved over them; in this case the new transformed fields will have the same name as your original.

However if you chose Set the direction of unused fields to 'None', then empty, or null, name extensions for the target and inputs will cause an error because you will be trying to create duplicate field names.

In addition, specify the prefix name to be applied to any features that are constructed via the Select and Construct settings. The new name is created by attaching a numeric suffix to this prefix root name. The format of the number depends on how many new features are derived, for example:

- 1-9 constructed features will be named: feature1 to feature9.
- 10-99 constructed features will be named: feature01 to feature99.
- 100-999 constructed features will be named: feature001 to feature999, and so on.

This ensures that the constructed features will sort in a sensible order no matter how many there are.

Durations Computed from Dates and Times. Specify the name extensions to be applied to durations computed from both dates and times.

Cyclical Elements Extracted from Dates and Times. Specify the name extensions to be applied to cyclical elements extracted from both dates and times.

Analysis tab (automated data preparation)

1. When you are satisfied with the ADP settings, including any changes made on the Objective, Fields, and Settings tabs, click Analyze Data; the algorithm applies the settings to the data inputs and displays the results on the Analysis tab.

The Analysis tab contains both tabular and graphical output that summarizes the processing of your data and displays recommendations as to how the data may be modified or improved for scoring. You can then review and either accept or reject those recommendations.

The Analysis tab is made up of two panels, the main view on the left and the linked, or auxiliary, view on the right. There are three main views:

- Field Processing Summary (the default). See the topic [Field Processing Summary \(automated data preparation\)](#) for more information.
- Fields. See the topic [Fields \(automated data preparation\)](#) for more information.
- Action Summary. See the topic [Action Summary \(automated data preparation\)](#) for more information.

There are four linked/auxiliary views:

- Predictive Power (the default). See the topic [Predictive Power \(automated data preparation\)](#) for more information.
- Fields Table. See the topic [Fields Table \(automated data preparation\)](#) for more information.
- Field Details. See the topic [Field Details \(automated data preparation\)](#) for more information.
- Action Details. See the topic [Action Details \(automated data preparation\)](#) for more information.

Links between views

Within the main view, underlined text in the tables controls the display in the linked view. Clicking on the text allows you to get details on a particular field, set of fields, or processing step. The link that you last selected is shown in a darker color; this helps you identify the connection between the contents of the two view panels.

Resetting the views

To redisplay the original Analysis recommendations and abandon any changes you have made to the Analysis views, click Reset at the bottom of the main view panel.

- [Field Processing Summary \(automated data preparation\)](#)
- [Fields \(automated data preparation\)](#)
- [Action Summary \(automated data preparation\)](#)
- [Predictive Power \(automated data preparation\)](#)
- [Fields Table \(automated data preparation\)](#)
- [Field Details \(automated data preparation\)](#)
- [Action Details \(automated data preparation\)](#)

Field Processing Summary (automated data preparation)

The Field Processing Summary table gives a snapshot of the projected overall impact of processing, including changes to the state of the features and the number of features constructed.

Note that no model is actually built, so there isn't a measure or graph of the change in overall predictive power before and after data preparation; instead, you can display graphs of the predictive power of individual recommended predictors.

The table displays the following information:

- The number of target fields.
- The number of original (input) predictors.
- The predictors recommended for use in analysis and modeling. This includes the total number of fields recommended; the number of original, untransformed, fields recommended; the number of transformed fields recommended (excluding intermediate versions of any field, fields derived from date/time predictors, and constructed predictors); the number of fields recommended that are derived from date/time fields; and the number of constructed predictors recommended.
- The number of input predictors not recommended for use in any form, whether in their original form, as a derived field, or as input to a constructed predictor.

Where any of the Fields information is underlined, click to display more details in a linked view. Details of the Target, Input features, and Input features not used are shown in the Fields Table linked view. See the topic [Fields Table \(automated data preparation\)](#) for more information. Features recommended for use in analysis are displayed in the Predictive Power linked view. See the topic [Predictive Power \(automated data preparation\)](#) for more information.

Fields (automated data preparation)

The Fields main view displays the processed fields and whether ADP recommends using them in downstream models. You can override the recommendation for any field; for example, to exclude constructed features or include features that ADP recommends excluding. If a field has been transformed, you can decide whether to accept the suggested transformation or use the original version.

The Fields view consists of two tables, one for the target and one for predictors that were either processed or created.

Target table

The Target table is only shown if a target is defined in the data.

The table contains two columns:

- Name. This is the name or label of the target field; the original name is always used, even if the field has been transformed.
 - Measurement Level. This displays the icon representing the measurement level; hover the mouse over the icon to display a label (continuous, ordinal, nominal, and so on) that describes the data.
- If the target has been transformed the Measurement Level column reflects the final transformed version. *Note:* you cannot turn off transformations for the target.

Predictors table

The Predictors table is always shown. Each row of the table represents a field. By default the rows are sorted in descending order of predictive power.

For ordinary features, the original name is always used as the row name. Both original and derived versions of date/time fields appear in the table (in separate rows); the table also includes constructed predictors.

Note that transformed versions of fields shown in the table always represent the final versions.

By default only recommended fields are shown in the Predictors table. To display the remaining fields, select the Include nonrecommended fields in table box above the table; these fields are then displayed at the bottom of the table.

The table contains the following columns:

- Version to Use. This displays a drop-down list that controls whether a field will be used downstream and whether to use the suggested transformations. By default, the drop-down list reflects the recommendations.
- For ordinary predictors that have been transformed the drop-down list has three choices: Transformed, Original, and Do not use.

For untransformed ordinary predictors the choices are: Original and Do not use.

For derived date/time fields and constructed predictors the choices are: Transformed and Do not use.

For original date fields the drop-down list is disabled and set to Do not use.

Note: For predictors with both original and transformed versions, changing between Original and Transformed versions automatically updates the Measurement Level and Predictive Power settings for those features.

- Name. Each field's name is a link. Click a name to display more information about the field in the linked view. See the topic [Field Details \(automated data preparation\)](#) for more information.
- Measurement Level. This displays the icon representing the data type; hover the mouse over the icon to display a label (continuous, ordinal, nominal, and so on) that describes the data.

- Predictive Power. Predictive power is displayed only for fields that ADP recommends. This column is not displayed if there is no target defined. Predictive power ranges from 0 to 1, with larger values indicating "better" predictors. In general, predictive power is useful for comparing predictors within an ADP analysis, but predictive power values should not be compared across analyses.

Action Summary (automated data preparation)

For each action taken by automated data preparation, input predictors are transformed and/or filtered out; fields that survive one action are used in the next. The fields that survive through to the last step are then recommended for use in modeling, whilst inputs to transformed and constructed predictors are filtered out.

The Action Summary is a simple table that lists the processing actions taken by ADP. Where any Action is underlined, click to display more details in a linked view about the actions taken. See the topic [Action Details \(automated data preparation\)](#) for more information.

Note: Only the original and final transformed versions of each field are shown, not any intermediate versions that were used during analysis.

Predictive Power (automated data preparation)

Displayed by default when the analysis is first run, or when you select Predictors recommended for use in analysis in the Field Processing Summary main view, the chart displays the predictive power of recommended predictors. Fields are sorted by predictive power, with the field with the highest value appearing at the top.

For transformed versions of ordinary predictors, the field name reflects your choice of suffix in the Field Names panel of the Settings tab; for example: *_transformed*.

Measurement level icons are displayed after the individual field names.

The predictive power of each recommended predictor is computed from either a linear regression or naïve Bayes model, depending upon whether the target is continuous or categorical.

Fields Table (automated data preparation)

Displayed when you click Target, Predictors, or Predictors not used in the Field Processing Summary main view, the Fields Table view displays a simple table listing the relevant features.

The table contains two columns:

- Name. The predictor name.
For targets, the original name or label of the field is used, even if the target has been transformed.

For transformed versions of ordinary predictors, the name reflects your choice of suffix in the Field Names panel of the Settings tab; for example: *_transformed*.

For fields derived from dates and times, the name of the final transformed version is used; for example: *bdate_years*.

For constructed predictors, the name of the constructed predictor is used; for example: *Predictor1*.
- Measurement Level. This displays the icon representing the data type.
For the Target, the Measurement Level always reflects the transformed version (if the target has been transformed); for example, changed from ordinal (ordered set) to continuous (range, scale), or vice versa.

Field Details (automated data preparation)

Displayed when you click any Name in the Fields main view, the Field Details view contains distribution, missing values, and predictive power charts (if applicable) for the selected field. In addition, the processing history for the field and the name of the transformed field are also shown (if applicable).

For each chart set, two versions are shown side by side to compare the field with and without transformations applied; if a transformed version of the field does not exist, a chart is shown for the original version only. For derived date or time fields and constructed predictors, the charts are only shown for the new predictor.

Note: If a field is excluded due to having too many categories only the processing history is shown.

Distribution Chart

Continuous field distribution is shown as a histogram, with a normal curve overlaid, and a vertical reference line for the mean value; categorical fields are displayed as a bar chart.

Histograms are labeled to show standard deviation and skewness; however, skewness is not displayed if the number of values is 2 or fewer or the variance of the original field is less than 10-20.

Hover the mouse over the chart to display either the mean for histograms, or the count and percentage of the total number of records for categories in bar charts.

Missing Value Chart

Pie charts compare the percentage of missing values with and without transformations applied; the chart labels show the percentage.

If ADP carried out missing value handling, the post-transformation pie chart also includes the replacement value as a label -- that is, the value used in place of missing values.

Hover the mouse over the chart to display the missing value count and percentage of the total number of records.

Predictive Power Chart

For recommended fields, bar charts display the predictive power before and after transformation. If the target has been transformed, the calculated predictive power is in respect to the transformed target.

Note: Predictive power charts are not shown if no target is defined, or if the target is clicked in the main view panel.

Hover the mouse over the chart to display the predictive power value.

Processing History Table

The table shows how the transformed version of a field was derived. Actions taken by ADP are listed in the order in which they were carried out; however, for certain steps multiple actions may have been carried out for a particular field.

Note: This table is not shown for fields that have not been transformed.

The information in the table is broken down into two or three columns:

- Action. The name of the action. For example, Continuous Predictors. See the topic [Action Details \(automated data preparation\)](#) for more information.
- Details. The list of processing carried out. For example, Transform to standard units.
- Function. Only shown for constructed predictors, this displays the linear combination of input fields, for example, .06*age + 1.21*height.

Action Details (automated data preparation)

Displayed when you select any underlined Action in the Action Summary main view, the Action Details linked view displays both action-specific and common information for each processing step that was carried out; the action-specific details are displayed first.

For each action, the description is used as the title at the top of the linked view. The action-specific details are displayed below the title, and may include details of the number of derived predictors, fields recast, target transformations, categories merged or reordered, and predictors constructed or excluded.

As each action is processed, the number of predictors used in the processing may change, for example as predictors are excluded or merged.

Note: If an action was turned off, or no target was specified, an error message is displayed in place of the action details when the action is clicked in the Action Summary main view.

There are nine possible actions; however, not all are necessarily active for every analysis.

Text Fields table

The table displays the number of:

- Trailing blank values trimmed.
- Predictors excluded from analysis.

Date and Time Predictors table

The table displays the number of:

- Durations derived from date and time predictors.
- Date and time elements.
- Derived date and time predictors, in total.

The reference date or time is displayed as a footnote if any date durations were calculated.

Predictor Screening table

The table displays the number of the following predictors excluded from processing:

- Constants.
- Predictors with too many missing values.
- Predictors with too many cases in a single category.
- Nominal fields (sets) with too many categories.
- Predictors screened out, in total.

Check Measurement Level table

The table displays the numbers of fields recast, broken down into the following:

- Ordinal fields (ordered sets) recast as continuous fields.
- Continuous fields recast as ordinal fields.
- Total number recast.

If no input fields (target or predictors) were continuous or ordinal, this is shown as a footnote.

Outliers table

The table displays counts of how any outliers were handled.

- Either the number of continuous fields for which outliers were found and trimmed, or the number of continuous fields for which outliers were found and set to missing, depending on your settings in the Prepare Inputs & Target panel on the Settings tab.
- The number of continuous fields excluded because they were constant, after outlier handling.

One footnote shows the outlier cutoff value; while another footnote is shown if no input fields (target or predictors) were continuous.

Missing Values table

The table displays the numbers of fields that had missing values replaced, broken down into:

- Target. This row is not shown if no target is specified.
- Predictors. This is further broken down into the number of nominal (set), ordinal (ordered set), and continuous.
- The total number of missing values replaced.

Target table

The table displays whether the target was transformed, shown as:

- Box-Cox transformation to normality. This is further broken down into columns that show the specified criteria (mean and standard deviation) and Lambda.
- Target categories reordered to improve stability.

Categorical Predictors table

The table displays the number of categorical predictors:

- Whose categories were reordered from lowest to highest to improve stability.
- Whose categories were merged to maximize association with the target.
- Whose categories were merged to handle sparse categories.
- Excluded due to low association with the target.
- Excluded because they were constant after merging.

A footnote is shown if there were no categorical predictors.

Continuous Predictors table

There are two tables. The first displays one of the following number of transformations:

- Predictor values transformed to standard units. In addition, this shows the number of predictors transformed, the specified mean, and the standard deviation.
- Predictor values mapped to a common range. In addition, this shows the number of predictors transformed using a min-max transformation, as well as the specified minimum and maximum values.
- Predictor values binned and the number of predictors binned.

The second table displays the predictor space construction details, shown as the number of predictors:

- Constructed.
- Excluded due to a low association with the target.
- Excluded because they were constant after binning.
- Excluded because they were constant after construction.

A footnote is shown if no continuous predictors were input.

Generating a Derive node

When you generate a Derive node, it applies the inverse target transformation to the score field. By default the node enters the name of the score field that would be produced by an automodeler (such as Auto Classifier or Auto Numeric) or the Ensemble node. If a scale (range) target has been transformed the score field is shown in transformed units; for example, `log($)` instead of `$`. In order to interpret and use the results, you must convert the predicted value back to the original scale.

Note: You can only generate a Derive node when the ADP node contains an analysis which rescales a range target (that is, Box-Cox rescaling is selected on the Prepare Inputs & Target panel). You cannot generate a Derive node if the target is not a range, or if the Box-Cox rescaling is not selected.

The Derive node is created in Multiple mode and uses `@FIELD` in the expression so you can add the transformed target if required. For example using the following details:

- Target field name: `response`
- Transformed target field name: `response_transformed`
- Score field name: `$XR-response_transformed`

The Derive node would create a new field: `$XR-response_transformed_inverse`.

Note: If you are not using an automodeler or Ensemble node, you will need to edit the Derive node to transform the correct score field for your model.

Normalized continuous targets

By default, if you select the Rescale a continuous target with a Box-Cox transformation check box on the Prepare Inputs & Target panel this transforms the target and you create a new field that will be the target for your model building. For example if your original target was `response`, the new target will be `response_transformed`; models downstream of the ADP node will pick this new target up automatically.

However, this may cause issues, depending on the original target. For example, if the target was `Age`, the values of the new target will not be `Years`, but a transformed version of `Years`. This means you cannot look at the scores and interpret them since they aren't in recognizable units. In this case you can apply an inverse transformation that will turn your transformed units back into whatever they were meant to be. To do this:

1. After clicking Analyze Data to run the ADP analysis, select *Derive Node* from the *Generate* menu.
2. Place the Derive node after your nugget on the model canvas.

The Derive node will restore the score field to the original dimensions so that the prediction will be in the original `Years` values.

By default the Derive node transforms the score field generated by an auto-modeler or an ensembled model. If you are building an individual model, you need to edit the Derive node to derive from your actual score field. If you want to evaluate your model, you should add the transformed target to the Derive From field in the Derive node. This applies the same inverse transformation to the target and any downstream Evaluation or Analysis node will use the transformed data correctly as long as you switch those nodes to use field names instead of metadata.

If you also want to restore the original name, you can use a Filter node to remove the original target field if it's still there, and rename the target and score fields.

Type Node

Field properties can be specified in a source node or in a separate Type node. The functionality is similar in both nodes. The following properties are available:

- Field Double-click any field name to specify value and field labels for data in IBM® SPSS® Modeler. For example, field metadata imported from IBM SPSS Statistics can be viewed or modified here. Similarly, you can create new labels for fields and their values. The labels that you specify here are displayed throughout IBM SPSS Modeler depending on the selections you make in the stream properties dialog box.
- Measurement This is the measurement level, used to describe characteristics of the data in a given field. If all of the details of a field are known, it is called **fully instantiated**. For more information, see [Measurement levels](#).
Note: The measurement level of a field is different from its storage type, which indicates whether the data are stored as strings, integers, real numbers, dates, times, timestamps, or lists.
- Values This column enables you to specify options for reading data values from the data set, or use the Specify option to specify measurement levels and values in a separate dialog box. You can also choose to pass fields without reading their values. For more information, see [Data Values](#).
Note: You cannot amend the cell in this column if the corresponding Field entry contains a list.
- Missing Used to specify how missing values for the field will be handled. For more information, see [Defining Missing Values](#).
Note: You cannot amend the cell in this column if the corresponding Field entry contains a list.
- Check In this column, you can set options to ensure that field values conform to the specified values or ranges. For more information, see [Checking Type Values](#).
Note: You cannot amend the cell in this column if the corresponding Field entry contains a list.
- Role Used to tell modeling nodes whether fields will be Input (predictor fields) or Target (predicted fields) for a machine-learning process. Both and None are also available roles, along with Partition, which indicates a field used to partition records into separate samples for training, testing, and validation. The value Split specifies that separate models will be built for each possible value of the field. For more information, see [Setting the field role](#).

Several other options can be specified using the Type node window:

- Using the tools menu button, you can choose to Ignore Unique Fields once a Type node has been instantiated (either through your specifications, reading values, or running the stream). Ignoring unique fields will automatically ignore fields with only one value.
- Using the tools menu button, you can choose to Ignore Large Sets once a Type node has been instantiated. Ignoring large sets will automatically ignore sets with a large number of members.
- Using the tools menu button, you can choose to Convert Continuous Integers To Ordinal once a Type node has been instantiated. See the topic [Converting Continuous Data](#) for more information.
- Using the tools menu button, you can generate a Filter node to discard selected fields.
- Using the sunglasses toggle buttons, you can set the default for all fields to Read or Pass. The Types tab in the source node passes fields by default, while the Type node itself reads values by default.
- Using the Clear Values button, you can clear changes to field values made in this node (non-inherited values) and reread values from upstream operations. This option is useful for resetting changes that you may have made for specific fields upstream.
- Using the Clear All Values button, you can reset values for **all** fields read into the node. This option effectively sets the Values column to **Read** for all fields. This option is useful to reset values for all fields and reread values and types from upstream operations.
- Using the context menu, you can choose to Copy attributes from one field to another. See the topic [Copying Type Attributes](#) for more information.
- Using the View unused field settings option, you can view type settings for fields that are no longer present in the data or were once connected to this Type node. This is useful when reusing a Type node for datasets that have changed.

Viewing and setting information about types

From various source nodes as well as the Type node, you can specify field metadata and properties that are invaluable to modeling and other work in IBM® SPSS® Modeler. These properties include:

- Specifying a usage type, such as range, set, ordered set, or flag, for each field in your dataset.
- Setting options for handling missing values and system nulls.
- Setting the role of a field for modeling purposes.
- Specifying values for a field as well as options used to automatically read values from the dataset.
- Specifying field and value labels.

Select help specific to your situation from the list below.

Measurement levels

Measurement level (formerly known as "data type" or "usage type") describes the usage of the data fields in IBM® SPSS® Modeler. The measurement level can be specified on the Types tab of a source or Type node. For example, you may want to set the measurement level for an integer field with values of 1 and 0 to *Flag*. This usually indicates that 1 = *True* and 0 = *False*.

Storage versus measurement. Note that the measurement level of a field is different from its storage type, which indicates whether data are stored as a string, integer, real number, date, time, or timestamp. While data types can be modified at any point in a stream using a Type node, storage must be determined at the source when reading data into IBM SPSS Modeler (although it can subsequently be changed using a conversion function). See the topic [Setting Field Storage and Formatting](#) for more information.

Some modeling nodes indicate the permitted measurement level types for their input and target fields by means of icons on their Fields tab.

Measurement level icons

Table 1. Measurement level icons

Icon	Measurement level
	Default
	Continuous
	Categorical
	Flag
	Nominal
	Ordinal
	Typeless
	Collection
	Geospatial

The following measurement levels are available:

- Default Data whose storage type and values are unknown (for example, because they have not yet been read) are displayed as <Default>.
- Continuous Used to describe numeric values, such as a range of 0–100 or 0.75–1.25. A continuous value can be an integer, real number, or date/time.
- Categorical Used for string values when an exact number of distinct values is unknown. This is an **uninstantiated** data type, meaning that all possible information about the storage and usage of the data is not yet known. Once data have been read, the measurement level will be *Flag*, *Nominal*, or *Typeless*, depending on the maximum number of members for nominal fields specified in the Stream Properties dialog box.
- Flag Used for data with two distinct values that indicate the presence or absence of a trait, such as `true` and `false`, `Yes` and `No` or 0 and 1. The values used may vary, but one must always be designated as the "true" value, and the other as the "false" value. Data may be represented as text, integer, real number, date, time, or timestamp.
- Nominal Used to describe data with multiple distinct values, each treated as a member of a set, such as `small/medium/large`. Nominal data can have any storage—numeric, string, or date/time. Note that setting the measurement level to *Nominal* does not automatically change the values to string storage.
- Ordinal Used to describe data with multiple distinct values that have an inherent order. For example, salary categories or satisfaction rankings can be typed as ordinal data. The order is defined by the natural sort order of the data elements. For example, 1, 3, 5 is the default sort order for a set of integers, while **HIGH**, **LOW**, **NORMAL** (ascending alphabetically) is the order for a set of strings. The ordinal measurement level enables you to define a set of categorical data as ordinal data for the purposes of visualization, model building, and export to other applications (such as IBM SPSS Statistics) that recognize ordinal data as a distinct type. You can use an ordinal field anywhere that a nominal field can be used. Additionally, fields of any storage type (real, integer, string, date, time, and so on) can be defined as ordinal.
- Typeless Used for data that does not conform to any of the above types, for fields with a single value, or for nominal data where the set has more members than the defined maximum. It is also useful for cases in which the measurement level would otherwise be a set with many members (such as an account number). When you select Typeless for a field, the role is automatically set to None, with Record ID as the only alternative. The default maximum size for sets is 250 unique values. This number can be adjusted or disabled on the Options tab of the Stream Properties dialog box, which can be accessed from the Tools menu.

- Collection Used to identify non-geospatial data that is recorded in a list. A collection is effectively a list field of zero depth, where the elements in that list have one of the other measurement levels.
For more information about lists, see [List storage and associated measurement levels](#).
- Geospatial Used with the List storage type to identify geospatial data. Lists can be either List of Integer or List of Real fields with a list depth that is between zero and two, inclusive.
For more information, see [Geospatial measurement sublevels](#).

You can manually specify measurement levels, or you can allow the software to read the data and determine the measurement level based on the values that it reads.

Alternatively, where you have several continuous data fields that should be treated as categorical data, you can choose an option to convert them. See the topic [Converting Continuous Data](#) for more information.

To use auto-typing

1. In either a Type node or the Types tab of a source node, set the Values column to <Read> for the desired fields. This will make metadata available to all nodes downstream. You can quickly set all fields to <Read> or <Pass> using the sunglasses buttons on the dialog box.
2. Click Read Values to read values from the data source immediately.

To manually set the measurement level for a field

1. Select a field in the table.
 2. From the drop-down list in the Measurement column, select a measurement level for the field.
 3. Alternatively, you can use Ctrl-A or Ctrl-click to select multiple fields before using the drop-down list to select a measurement level.
- [Geospatial measurement sublevels](#)

Geospatial measurement sublevels

The Geospatial measurement level, which is used with the List storage type, has six sublevels that are used to identify different types of geospatial data.

- Point - Identifies a specific location; for example, the center of a city.
- Polygon - A series of points that identifies the single boundary of a region and its location; for example, a county.
- LineString - Also referred to as a Polyline or just a Line, a LineString is a series of points that identifies the route of a line. For example, a LineString might be a fixed item, such as road, river, or railway; or the track of something that moves, such as an aircraft's flight path or a ship's voyage.
- MultiPoint - Used when each row in your data contains multiple points per region. For example, if each row represents a city street, the multiple points for each street can be used to identify every street lamp.
- MultiPolygon - Used when each row in your data contains several polygons. For example, if each row represents the outline of a country, the US can be recorded as several polygons to identify the different areas such as the mainland, Alaska, and Hawaii.
- MultiLineString - Used when each row in your data contains several lines. Because lines cannot branch you can use a MultiLineString to identify a group of lines. For example, data such as the navigable waterways or the railway network in each country.

These measurement sublevels are used with the List storage type. For more information, see [List storage and associated measurement levels](#).

Restrictions

You must be aware of some restrictions when you use geospatial data.

- The coordinate system can affect the format of the data. For example, a Projected coordinate system uses the coordinate values x, y, and (when required) z, whereas a Geographic coordinate system uses the coordinate values longitude, latitude, and (when required) a value for either altitude or depth.
For more information about coordinate systems, see [Setting geospatial options for streams](#).
- A LineString cannot cross over itself.
- A Polygon is not self-closing; for each Polygon you must ensure that the first and last points are defined as the same.
- The direction of the data in a MultiPolygon is important; clockwise indicates a solid form and counterclockwise indicates a hole. For example, if you record an area of a country that contains lakes; the main land area border can be recorded in a clockwise direction and the shape of each lake in a counterclockwise direction.
- A Polygon cannot intersect with itself. An example of this intersection would be if you tried to plot the boundary of the polygon as a continuous line in the form of the figure 8.
- MultiPolygons cannot overlap each other.
- For Geospatial fields, the only relevant storage types are Real and Integer (the default setting is Real).

Geospatial measurement sublevel icons

Table 1. Geospatial measurement sublevel icons

Icon	Measurement level
	Point
	Polygon
	LineString
	MultiPoint
	MultiPolygon
	MultiLineString

Converting Continuous Data

Treating categorical data as continuous can have a serious effect on the quality of a model, especially if it's the target field; for example, producing a regression model rather than a binary model. To prevent this you can convert integer ranges to categorical types such as *Ordinal* or *Flag*.

1. From the Operations and Generate menu button (with the tool symbol), select Convert Continuous Integers To Ordinal. The conversion values dialog is displayed.
2. Specify the size of range that will be automatically converted; this applies to any range up to and including the size you enter.
3. Click OK. The affected ranges are converted to either *Flag* or *Ordinal* and displayed on the Types tab of the Type node.

Results of the Conversion

- Where a *Continuous* field with integer storage is changed to *Ordinal*, the lower and upper values are expanded to include all of the integer values from the lower value to the upper value. For example, if the range is 1, 5, the set of values is 1, 2, 3, 4, 5.
- If the *Continuous* field changes to *Flag*, the lower and upper values become the false and true values of the flag field.

- [Checking Type Values](#)
- [Setting the field role](#)

What is instantiation?

Instantiation is the process of reading or specifying information, such as storage type and values for a data field. To optimize system resources, instantiating is a user-directed process—you tell the software to read values by specifying options on the Types tab in a source node or by running data through a Type node.

- Data with unknown types are also referred to as *uninstantiated*. Data whose storage type and values are unknown are displayed in the *Measurement* column of the Types tab as <Default>.
- When you have some information about a field's storage, such as string or numeric, the data are called *partially instantiated*. Categorical or Continuous are partially instantiated measurement levels. For example, Categorical specifies that the field is symbolic, but you don't know whether it is nominal, ordinal, or flag.
- When all of the details about a type are known, including the values, a *fully instantiated* measurement level—nominal, ordinal, flag, or continuous—is displayed in this column. Note that the *continuous* type is used for both partially instantiated and fully instantiated data fields. Continuous data can be either integers or real numbers.

During the execution of a data stream with a Type node, uninstantiated types immediately become partially instantiated, based on the initial data values. Once all of the data have passed through the node, all data become fully instantiated unless values were set to <Pass>. If execution is interrupted, the data will remain partially instantiated. Once the Types tab has been instantiated, the values of a field are static at that point in the stream. This means that any upstream changes will not affect the values of a particular field, even if you rerun the stream. To change or update the values based on new data or added manipulations, you need to edit them in the Types tab itself or set the value for a field to <Read> or <Read +>.

When to instantiate

Generally, if your dataset is not very large and you do not plan to add fields later in the stream, instantiating at the source node is the most convenient method. However, instantiating in a separate Type node is useful when:

- The dataset is large, and the stream filters a subset prior to the Type node.
- Data have been filtered in the stream.
- Data have been merged or appended in the stream.
- New data fields are derived during processing.

Note: If you export data in a database export node, the data must be fully instantiated.

Data Values

Using the Values column of the Types tab, you can read values automatically from the data, or you can specify measurement levels and values in a separate dialog box.

The options available from the Values drop-down list provide instructions for auto-typing, as shown in the following table.

Table 1. Instructions for auto-typing

Option	Function
<Read>	Data is read when the node is executed.
<Read+>	Data is read and appended to the current data (if any exist).
<Pass>	No data is read.
<Current>	Keep current data values.
Specify...	A separate dialog box opens for you to specify values and measurement level options.

Executing a Type node or clicking Read Values auto-types and reads values from your data source based on your selection. These values can also be specified manually using the Specify option or by double-clicking a cell in the Field column.

After you make changes for fields in the Type node, you can reset value information using the following buttons on the dialog box toolbar:

- Using the Clear All Values button, you can clear changes to field values made in this node (non-inherited values) and reread values from upstream operations. This option is useful for resetting changes that you may have made for specific fields upstream.
- Using the Clear Values button, you can reset values for **all** fields read into the node. This option effectively sets the *Values* column to **Read** for all fields. This option is useful to reset values for all fields and reread values and measurement levels from upstream operations.

Grey text in the Values column

Within either a Type node, or a Source node, if the data in the Values column is shown in black text, it indicates that the values of that field have been read and are stored within that node. If no black text is present in this field, the values of that field have not been read and are determined further upstream.

There are occasions when you can see the data as gray text. This occurs when SPSS® Modeler can identify or infer the valid values of a field without actually reading and storing the data. This is likely to occur if you use one of the following nodes:

- User Input node. Because the data is defined within the node, the range of values for a field is always known, even if the values have not been stored in the node.
- Statistics File source node. If there is metadata present for the data types it enables SPSS Modeler to infer the possible range of values without reading or storing the data.

In either node, the values are shown in gray text until you click Read Values.

Warning: If you do not instantiate the data in your stream, and your data values are shown in gray, any checking of type values that you set in the Check column is not applied.

-

Using the Values Dialog Box

Clicking the Values or Missing column of the Types tab displays a drop-down list of predefined values. Choosing the Specify... option on this list opens a separate dialog box where you can set options for reading, specifying, labeling, and handling values for the selected field.

Many of the controls are common to all types of data. These common controls are discussed here.

Measurement Displays the currently selected measurement level. You can change the setting to reflect the way that you intend to use data. For instance, if a field called `day_of_week` contains numbers that represent individual days, you might want to change this to nominal data in order to create a distribution node that examines each category individually.

Storage Displays the storage type if known. Storage types are unaffected by the measurement level that you choose. To alter the storage type, you can use the Data tab in Fixed File and Variable File source nodes, or a conversion function in a Filler node.

Model Field For fields generated as a result of scoring a model nugget, model field details can also be viewed. These include the name of the target field as well as the role of the field in modeling (whether a predicted value, probability, propensity, and so on).

Values Select a method to determine values for the selected field. Selections that you make here override any selections that you made earlier from the Values column of the Type node dialog box. Choices for reading values include the following:

- Read from data Select to read values when the node is executed. This option is the same as <Read>.
- Pass Select not to read data for the current field. This option is the same as <Pass>.
- Specify values and labels Options here are used to specify values and labels for the selected field. Used with value checking, use this option to specify values that are based on your knowledge of the current field. This option activates unique controls for each type of field. Options for values and labels are covered individually in subsequent topics.
Note: You cannot specify values or labels for a field whose measurement level is Typeless or <Default>.
- Extend values from data Select to append the current data with the values that you enter here. For example, if `field_1` has a range from (0,10), and you enter a range of values from (8,16), the range is extended by adding the 16, without removing the original minimum. The new range would be (0,16). Choosing this option automatically sets the auto-typing option to <Read+>.

Max list length Only available for data with a measurement level of either Geospatial or Collection. Set the maximum length of the list by specifying the number of elements the list can contain.

Max string length Only available for typeless data; use this field when you are generating SQL to create a table. Enter the value of the largest string in your data; this generates a column in the table that is big enough for the string. If the string length value is not available, a default string size is used that may not be appropriate for the data (for example, if the value is too small, errors can occur when writing data to the table; too large a value could adversely affect performance).

Check values Select a method of coercing values to conform to the specified continuous, flag, or nominal values. This option corresponds to the Check column in the Type node dialog box, and settings made here override those in the dialog box. Used with the Specify values and labels option, value checking allows you to conform values in the data with expected values. For example, if you specify values as 1, 0 and then use the Discard option, you can discard all records with values other than 1 or 0.

Define blanks Select to activate the following controls that you use to declare missing values or blanks in your data.

- Missing values Use this table to define specific values (such as 99 or 0) as blanks. The value should be appropriate for the storage type of the field.
- Range Used to specify a range of missing values, for example, ages 1–17 or greater than 65. If a bound value is left blank, then the range is unbounded; for example, if a lower bound of 100 is specified with no upper bound, then all values greater than or equal to 100 is defined as missing. The bound values are inclusive; for example, a range with a lower bound of 5 and an upper bound of 10 includes 5 and 10 in the range definition. A missing value range can be defined for any storage type, including date/time and string (in which case the alphabetic sort order is used to determine whether a value is within the range).
- Null/White space You can also specify system nulls (displayed in the data as `$null$`) and white space (string values with no visible characters) as blanks.
Note: The Type node also treats empty strings as white space for purposes of analysis, although they are stored differently internally and may be handled differently in certain cases.

Note: To code blanks as undefined or `$null$`, use the Filler node.

Description Use this text box to specify a field label. These labels appear in various locations, such as in graphs, tables, output, and model browsers, depending on selections you make in the Stream Properties dialog box.

Related information

-

Specifying Values and Labels for Continuous Data

The *Continuous* measurement level is used for numeric fields. There are three storage types for continuous data:

- Real
- Integer
- Date/Time

The same dialog box is used to edit all continuous fields; the storage type is displayed for reference only.

Specifying Values

The following controls are unique to continuous fields and are used to specify a range of values:

Lower. Specify a lower limit for the value range.

Upper. Specify an upper limit for the value range.

Specifying Labels

You can specify labels for any value of a range field. Click the Labels button to open a separate dialog box for specifying value labels.

- [Values and Labels Subdialog Box](#)

Related information

- [Type Node](#)
 - [Using the Values Dialog Box](#)
-

Values and Labels Subdialog Box

Clicking Labels in the Values dialog box for a range field opens a new dialog box in which you can specify labels for any value in the range.

You can use the *Values* and *Labels* columns in this table to define value and label pairs. Currently defined pairs are shown here. You can add new label pairs by clicking in an empty cell and entering a value and its corresponding label. *Note:* Adding value/value-label pairs to this table will not cause any new values to be added to the field. Instead, it simply creates metadata for the field value.

The labels that you specify in the Type node are displayed in many places (as ToolTips, output labels, and so on), depending on selections that you make in the stream properties dialog box.

Specifying Values and Labels for Nominal and Ordinal Data

Nominal (set) and ordinal (ordered set) measurement levels indicate that the data values are used discretely as a member of the set. The storage types for a set can be string, integer, real number, or date/time.

The following controls are unique to nominal and ordinal fields and are used to specify values and labels:

Values. The *Values* column in the table allows you to specify values based on your knowledge of the current field. Using this table, you can enter expected values for the field and check the dataset's conformity to these values using the Check Values drop-down list. Using the arrow and delete buttons, you can modify existing values as well as reorder or delete values.

Labels. The *Labels* column enables you to specify labels for each value in the set. These labels appear in a variety of locations, such as graphs, tables, output, and model browsers, depending on selections that you make in the stream properties dialog box.

Related information

- [Type Node](#)
 - [Using the Values Dialog Box](#)
-

Specifying Values for a Flag

Flag fields are used to display data that have two distinct values. The storage types for flags can be string, integer, real number, or date/time.

True. Specify a flag value for the field when the condition is met.

False. Specify a flag value for the field when the condition is not met.

Labels. Specify labels for each value in the flag field. These labels appear in a variety of locations, such as graphs, tables, output, and model browsers, depending on selections that you make in the stream properties dialog box.

Related information

- [Type Node](#)
 - [Using the Values Dialog Box](#)
-

Specifying Values for Collection Data

Collection fields are used to display non-geospatial data that is in a list.

The only item that you can set for the Collection Measurement level is the List measure. By default this measure is set to Typeless but you can select another value from to set the measurement level of the elements within the list. You can choose one of the following options:

- Typeless
- Continuous
- Nominal
- Ordinal
- Flag

Related information

- [Type Node](#)
 - [Using the Values Dialog Box](#)
-

Specifying values for geospatial data

Geospatial fields are used to display geospatial data that is in a list.

For the Geospatial Measurement level, you can set the following options to set the measurement level of the elements within the list:

Type Select the measurement sublevel of the geospatial field. The available sublevels are determined by the depth of the list field; the defaults are: Point (zero depth), LineString (depth of one), and Polygon (depth of one).

For more information about sublevels, see [Geospatial measurement sublevels](#).

For more information about list depths, see [List storage and associated measurement levels](#).

Coordinate system This option is only available if you changed the measurement level to geospatial from a non-geospatial level. To apply a coordinate system to your geospatial data, select this check box. By default, the coordinate system set in the Tools > Stream Properties > Options > Geospatial pane is shown. To use a different coordinate system, click the Change button to display the Select Coordinate System dialog box and choose the system that you require.

For more information about coordinate systems, see [Setting geospatial options for streams](#).

Defining Missing Values

The Missing column of the Types tab indicates whether missing value handling has been defined for a field. The possible settings are:

On (*). Indicates that missing values handling is defined for this field. This could be done by means of a downstream Filler node, or through an explicit specification using the Specify option (see below).

Off. The field has no missing value handling defined.

Specify. Choose this option to display a dialog where you can declare explicit values to be considered as missing values for this field.

Checking Type Values

Turning on the Check option for each field examines all values in that field to determine whether they comply with the current type settings or the values that you have specified in the Specify Values dialog box. This is useful for cleaning up datasets and reducing the size of a dataset within a single operation.

The setting of the Check column in the Type node dialog box determines what happens when a value outside of the type limits is discovered. To change the Check settings for a field, use the drop-down list for that field in the Check column. To set the Check settings for all fields, click in the Field column and press Ctrl-A. Then use the drop-down list for any field in the Check column.

The following Check settings are available:

None. Values will be passed through without checking. This is the default setting.

Nullify. Change values outside of the limits to the system null (\$null\$).

Coerce. Fields whose measurement levels are fully instantiated will be checked for values that fall outside the specified ranges. Unspecified values will be converted to a legal value for that measurement level using the following rules:

- For flags, any value other than the true and false value is converted to the false value.
- For sets (nominal or ordinal), any unknown value is converted to the first member of the set's values.
- Numbers greater than the upper limit of a range are replaced by the upper limit.
- Numbers less than the lower limit of a range are replaced by the lower limit.
- Null values in a range are given the midpoint value for that range.

Discard. When illegal values are found, the entire record is discarded.

Warn. The number of illegal items is counted and reported in the stream properties dialog box when all of the data have been read.

Abort. The first illegal value encountered terminates the running of the stream. The error is reported in the stream properties dialog box.

- [Data Values](#)
- [Setting the field role](#)
- [Copying Type Attributes](#)

Setting the field role

The role of a field specifies how it is used in model building—for example, whether a field is an input or target (the thing being predicted).

Note: The Partition, Frequency and Record ID roles can each be applied to a single field only.

The following roles are available:

Input. The field will be used as an input to machine learning (a predictor field).

Target. The field will be used as an output or target for machine learning (one of the fields that the model will try to predict).

Both. The field will be used as both an input and an output by the Apriori node. All other modeling nodes will ignore the field.

None. The field will be ignored by machine learning. Fields whose measurement level has been set to Typeless are automatically set to None in the Role column.

Partition. Indicates a field used to partition the data into separate samples for training, testing, and (optional) validation purposes. The field must be an instantiated set type with two or three possible values (as defined in the Field Values dialog box). The first value represents the training sample, the second represents the testing sample, and the third (if present) represents the validation sample. Any additional values are ignored, and flag fields cannot be used. Note that to use the partition in an analysis, partitioning must be enabled on the Model Options tab in the appropriate model-building or analysis node. Records with null values for the partition field are excluded from the analysis when partitioning is enabled. If multiple partition fields have been defined in the stream, a single partition field must be specified on the Fields tab in each applicable modeling node. If a suitable field doesn't already exist in your data, you can create one using a Partition node or Derive node. See the topic [Partition Node](#) for more information.

Split. (Nominal, ordinal and flag fields only) Specifies that a model is to be built for each possible value of the field.

Frequency. (Numeric fields only) Setting this role enables the field value to be used as a frequency weighting factor for the record. This feature is supported by C&R Tree, CHAID, QUEST and Linear models only; all other nodes ignore this role. Frequency weighting is enabled by means of the Use frequency weight option on the Fields tab of those modeling nodes that support the feature.

Record ID. The field will be used as the unique record identifier. This feature is ignored by most nodes; however it is supported by Linear models, and is required for the IBM Netezza in-database mining nodes.

Copying Type Attributes

You can easily copy the attributes of a type, such as values, checking options, and missing values from one field to another:

1. Right-click on the field whose attributes you want to copy.
2. From the context menu, choose Copy.
3. Right-click on the field(s) whose attributes you want to change.
4. From the context menu, choose Paste Special. *Note:* You can select multiple fields using the Ctrl-click method or by using the Select Fields option from the context menu.

A new dialog box opens, from which you can select the specific attributes that you want to paste. If you are pasting into multiple fields, the options that you select here will apply to all target fields.

Paste the following attributes. Select from the list below to paste attributes from one field to another.

- **Type.** Select to paste the measurement level.
- **Values.** Select to paste the field values.
- **Missing.** Select to paste missing value settings.
- **Check.** Select to paste value checking options.
- **Role.** Select to paste the role of a field.

Related information

- [Type Node](#)

Field Format Settings Tab

The Format tab on the Table and Type nodes shows a list of current or unused fields and formatting options for each field. Following is a description of each column in the field formatting table:

Field. This shows the name of the selected field.

Format. By double-clicking a cell in this column, you can specify formatting for fields on an individual basis using the dialog box that opens. See the topic [Setting Field Format options](#) for more information. Formatting specified here overrides formatting specified in the overall stream properties.

Note: The Statistics Export and Statistics Output nodes export .sav files that include per-field formatting in their metadata. If a per-field format is specified that is not supported by the IBM® SPSS® Statistics .sav file format, then the node will use the IBM SPSS Statistics default format.

Justify. Use this column to specify how the values should be justified within the table column. The default setting is Auto, which left-justifies symbolic values and right-justifies numeric values. You can override the default by selecting Left, Right, or Center.

Column Width. By default, column widths are automatically calculated based on the values of the field. To override the automatic width calculation, click a table cell and use the drop-down list to select a new width. To enter a custom width not listed here, open the Field Formats subdialog box by double-clicking a table cell in the Field or Format column. Alternatively, you can right-click on a cell and choose Set Format.

View Current Fields. By default, the dialog box shows the list of currently active fields. To view the list of unused fields, select View unused fields settings.

Context Menu. The context menu for this tab provides various selection and setting update options. Right-click in a column to display this menu.

- **Select All.** Selects all fields.
 - **Select None.** Clears the selection.
 - **Select Fields.** Selects fields based on type or storage characteristics. Options are Select Categorical, Select Continuous (numeric), Select Typeless, Select Strings, Select Numbers, or Select Date/Time. See the topic [Measurement levels](#) for more information.
 - **Set Format.** Opens a subdialog box for specifying date, time, and decimal options on a per-field basis.
 - **Set Justify.** Sets the justification for the selected field(s). Options are Auto, Center, Left, or Right.
 - **Set Column Width.** Sets the field width for selected fields. Specify Auto to read width from the data. Or you can set field width to 5, 10, 20, 30, 50, 100, or 200.
 - [**Setting Field Format options**](#)
-

Setting Field Format options

Field formatting is specified on a subdialog box available from the Format tab on the Type and Table nodes. If you have selected more than one field before opening this dialog box, then settings from the first field in the selection are used for all. Clicking OK after making specifications here will apply these settings to all fields selected on the Format tab.

The following options are available on a per-field basis. Many of these settings can also be specified in the stream properties dialog box. Any settings made at the field level override the default specified for the stream.

Date format. Select a date format to be used for date storage fields or when strings are interpreted as dates by CLEM date functions.

Time format. Select a time format to be used for time storage fields or when strings are interpreted as times by CLEM time functions.

Number display format. You can choose from standard (####.###), scientific (#.###E+##), or currency display formats (\$###.##).

Decimal symbol. Select either a comma (,) or period (.) as a decimal separator.

Grouping symbol. For number display formats, select the symbol used to group values (For example, the comma in 3,000.00). Options include none, period, comma, space, and locale-defined (in which case the default for the current locale is used).

Decimal places (standard, scientific, currency, export). For number display formats, specifies the number of decimal places to be used when displaying real numbers. This option is specified separately for each display format. Note that the Export decimal places setting only applies to flat file exports, and it overrides the stream properties. The stream default for flat file export is whatever is specified for the Standard decimal places setting in the stream properties. The number of decimal places exported by the XML Export node is always 6.

Justify. Specifies how the values should be justified within the column. The default setting is Auto, which left-justifies symbolic values and right-justifies numeric values. You can override the default by selecting left, right, or center.

Column width. By default, column widths are automatically calculated based on the values of the field. You can specify a custom width in intervals of five using the arrows to the right of the list box.

Filtering or renaming fields

You can rename or exclude fields at any point in a stream. For example, as a medical researcher, you may not be concerned about the potassium level (field-level data) of patients (record-level data); therefore, you can filter out the K (potassium) field. This can be done using a separate Filter node or using the Filter tab on a source or output node. The functionality is the same regardless of which node it is accessed from.

- From source nodes, such as Variable File, Fixed File, Statistics File, XML, or Extension Import, you can rename or filter fields as the data are read into IBM® SPSS® Modeler.
 - Using a Filter node, you can rename or filter fields at any point in the stream.
 - From Statistics Export, Statistics Transform, Statistics Model, and Statistics Output nodes, you can filter or rename fields to conform to IBM SPSS Statistics naming standards. See the topic [Renaming or Filtering Fields for IBM SPSS Statistics](#) for more information.
 - You can use the Filter tab in any of the above nodes to define or edit multiple response sets. See the topic [Editing Multiple Response Sets](#) for more information.
 - Finally, you can use a Filter node to map fields from one source node to another.
 - [**Setting filtering options**](#)
-

Setting filtering options

The table used on the Filter tab shows the name of each field as it comes into the node as well as the name of each field as it leaves. You can use the options in this table to rename or filter out fields that are duplicates or are unnecessary for downstream operations.

- Field. Displays the input fields from currently connected data sources.
- Filter. Displays the filter status of all input fields. Filtered fields include a red X in this column, indicating that this field will not be passed downstream. Click in the *Filter* column for a selected field to turn filtering on and off. You can also select options for multiple fields simultaneously using the Shift-click method of selection.
- Field. Displays the fields as they leave the Filter node. Duplicate names are displayed in red. You can edit field names by clicking in this column and entering a new name. Or, remove fields by clicking in the *Filter* column to disable duplicate fields.

All columns in the table can be sorted by clicking on the column header.

View current fields. Select to view fields for datasets actively connected to the Filter node. This option is selected by default and is the most common method of using Filter nodes.

View unused field settings. Select to view fields for datasets that were once but are no longer connected to the Filter node. This option is useful when copying Filter nodes from one stream to another or when saving and reloading Filter nodes.

Filter Button Menu

Click the Filter button in the upper left corner of the dialog box to access a menu that provides a number of shortcuts and other options.

You can choose to:

- Remove all fields.
- Include all fields.
- Toggle all fields.
- Remove duplicates. Note that selecting this option removes all occurrences of the duplicate name, including the first one.
- Rename fields and multiple response sets to conform with other applications. See the topic [Renaming or Filtering Fields for IBM SPSS Statistics](#) for more information.
- Truncate field names.
- Anonymize field and multiple response set names.
- Use input field names.
- Edit Multiple Response Sets. See the topic [Editing Multiple Response Sets](#) for more information.
- Set the default filter state.

You can also use the arrow toggle buttons at the top of the dialog box to specify whether you want to include or discard fields by default. This is useful for large datasets where only a few fields are to be included downstream. For example, you can select only the fields you want to keep and specify that all others should be discarded (rather than individually selecting all of the fields to discard).

- [Truncating Field Names](#)
- [Anonymizing Field Names](#)
- [Editing Multiple Response Sets](#)

Truncating Field Names

From the Filter button menu (upper left corner of the Filter tab), you can choose to truncate field names.

Maximum length. Specify a number of characters to limit the length of field names.

Number of digits. If field names, when truncated, are no longer unique, they will be further truncated and differentiated by adding digits to the name. You can specify the number of digits used. Use the arrow buttons to adjust the number.

For example, the following table illustrates how field names in a medical dataset are truncated using the default settings (maximum length=8 and number of digits=2).

Table 1. Field name truncation

Field Names	Truncated Field Names
Patient Input 1	Patien01
Patient Input 2	Patien02
Heart Rate	HeartRat
BP	BP

Related information

- [Filtering or renaming fields](#)

Anonymizing Field Names

You can anonymize field names from any node that includes a Filter tab by clicking the Filter button menu in the upper left corner and choosing Anonymize Field Names. Anonymized field names consist of a string prefix plus a unique numeric-based value.

Anonymize names of. Choose Selected fields only to anonymize only the names of fields already selected on the Filter tab. The default is All fields, which anonymizes all field names.

Field names prefix. The default prefix for anonymized field names is anon_ ; choose Custom and type your own prefix if you want a different one.

Anonymize multiple response sets. Anonymizes the names of multiple response sets in the same manner as fields. See the topic [Editing Multiple Response Sets](#) for more information.

To restore the original field names, choose Use Input Field Names from the filter button menu.

Related information

- [Filtering or renaming fields](#)

Editing Multiple Response Sets

You can add or edit multiple response sets from any node that includes a Filter tab by clicking the Filter button menu in the upper left corner and choosing Edit Multiple Response Sets.

Multiple response sets are used to record data that can have more than one value for each case—for example, when asking survey respondents which museums they have visited or which magazines they read. Multiple response sets can be imported into IBM® SPSS® Modeler using a Data Collection source node or a Statistics File source node and can be defined in IBM SPSS Modeler using a Filter node.

Click New to create a new multiple response set, or click Edit to modify an existing set.

Name and label. Specifies the name and description for the set.

Type. Multiple response questions can be handled in one of two ways:

- **Multiple dichotomy set.** A separate flag field is created for each possible response; thus, if there are 10 magazines, there are 10 flag fields, each of which can have values, such as 0 or 1 for *true* or *false*. The counted value allows you to specify which value is counted as true. This method is useful when you want to allow respondents to choose all options that apply.
- **Multiple category set.** A nominal field is created for each response up to the maximum number of answers from a given respondent. Each nominal field has values representing the possible answers, such as 1 for *Time*, 2 for *Newsweek*, and 3 for *PC Week*. This method is most useful when you want to limit the number of answers—for example, when asking respondents to choose the three magazines they read most frequently.

Fields in set. Use the icons on the right to add or remove fields.

Comments

- All fields included in a multiple response set must have the same storage.
- Sets are distinct from the fields they include. For example, deleting a set will not cause the fields it includes to be deleted—merely the links between those fields. The set is still visible upstream from the point of deletion but is not visible downstream.
- If fields are renamed using a Filter node (directly on the tab or by choosing the Rename for IBM SPSS Statistics, Truncate, or Anonymize options on the Filter menu), any references to these fields used in multiple response sets will also be updated. However, any fields in a multiple response set that are dropped by the Filter node will not be removed from the multiple response set. Such fields, although no longer visible in the stream, are still referenced by the multiple response set; this could be a consideration when exporting, for example.

Derive node

One of the most powerful features in IBM® SPSS® Modeler is the ability to modify data values and derive new fields from existing data. During lengthy data mining projects, it is common to perform several derivations, such as extracting a customer ID from a string of Web log data or

creating a customer lifetime value based on transaction and demographic data. All of these transformations can be performed, using a variety of field operations nodes.

Several nodes provide the ability to derive new fields:

	The Derive node modifies data values or creates new fields from one or more existing fields. It creates fields of type formula, flag, nominal, state, count, and conditional.
	The Reclassify node transforms one set of categorical values to another. Reclassification is useful for collapsing categories or regrouping data for analysis.
	The Binning node automatically creates new nominal (set) fields based on the values of one or more existing continuous (numeric range) fields. For example, you can transform a continuous income field into a new categorical field containing groups of income as deviations from the mean. Once you have created bins for the new field, you can generate a Derive node based on the cut points.
	The Set to Flag node derives multiple flag fields based on the categorical values defined for one or more nominal fields.
	The Restructure node converts a nominal or flag field into a group of fields that can be populated with the values of yet another field. For example, given a field named <i>payment type</i> , with values of <i>credit</i> , <i>cash</i> , and <i>debit</i> , three new fields would be created (<i>credit</i> , <i>cash</i> , <i>debit</i>), each of which might contain the value of the actual payment made.
	The History node creates new fields containing data from fields in previous records. History nodes are most often used for sequential data, such as time series data. Before using a History node, you may want to sort the data using a Sort node.

Using the Derive node

Using the Derive node, you can create six types of new fields from one or more existing fields:

- Formula. The new field is the result of an arbitrary CLEM expression.
- Flag. The new field is a flag, representing a specified condition.
- Nominal. The new field is nominal, meaning that its members are a group of specified values.
- State. The new field is one of two states. Switching between these states is triggered by a specified condition.
- Count. The new field is based on the number of times that a condition has been true.
- Conditional. The new field is the value of one of two expressions, depending on the value of a condition.

Each of these nodes contains a set of special options in the Derive node dialog box. These options are discussed in subsequent topics.

Note that use of the following may change row order:

- Executing in a database via SQL pushback
 - Executing via remote IBM SPSS Analytic Server
 - Using functions that run in embedded IBM SPSS Analytic Server
 - Deriving a list (for example, see [Deriving a list or geospatial field](#))
 - Calling any of the spatial functions
- [Setting Basic Options for the Derive Node](#)
 - [Deriving Multiple Fields](#)
 - [Setting Derive Formula Options](#)
 - [Setting Derive Flag Options](#)
 - [Setting Derive Nominal Options](#)
 - [Setting Derive State Options](#)
 - [Setting Derive Count Options](#)
 - [Setting Derive Conditional Options](#)
 - [Recoding Values with the Derive Node](#)

Setting Basic Options for the Derive Node

At the top of the dialog box for Derive nodes are a number of options for selecting the type of Derive node that you need.

Mode. Select Single or Multiple, depending on whether you want to derive multiple fields. When Multiple is selected, the dialog box changes to include options for multiple Derive fields.

Derive field. For simple Derive nodes, specify the name of the field that you want to derive and add to each record. The default name is DeriveN, where N is the number of Derive nodes that you have created thus far during the current session.

Derive as. Select a type of Derive node, such as Formula or Nominal, from the drop-down list. For each type, a new field is created based on the conditions that you specify in the type-specific dialog box.

Selecting an option from the drop-down list will add a new set of controls to the main dialog box according to the properties of each Derive node type.

Field type. Select a measurement level, such as continuous, categorical, or flag, for the newly derived node. This option is common to all forms of Derive nodes.

Note: Deriving new fields often requires the use of special functions or mathematical expressions. To help you create these expressions, an Expression Builder is available from the dialog box for all types of Derive nodes and provides rule checking as well as a complete list of CLEM expressions.

- [Setting Derive Conditional Options](#)
- [Derive node](#)
- [Deriving Multiple Fields](#)
- [Recoding Values with the Derive Node](#)

Deriving Multiple Fields

Setting the mode to Multiple within a Derive node gives you the capability to derive multiple fields based on the same condition within the same node. This feature saves time when you want to make identical transformations on several fields in your dataset. For example, if you want to build a regression model predicting current salary based on beginning salary and previous experience, it might be beneficial to apply a log transformation to all three skewed variables. Rather than add a new Derive node for each transformation, you can apply the same function to all fields at once. Simply select all fields from which to derive a new field and then type the derive expression using the `@FIELD` function within the field parentheses.

Note: The `@FIELD` function is an important tool for deriving multiple fields at the same time. It allows you to refer to the contents of the current field or fields without specifying the exact field name. For instance, a CLEM expression used to apply a log transformation to multiple fields is `log(@FIELD)`.

The following options are added to the dialog box when you select Multiple mode:

Derive from. Use the Field Chooser to select fields from which to derive new fields. One output field will be generated for each selected field.
Note: Selected fields do not need to be the same storage type; however, the Derive operation will fail if the condition is not valid for *all* fields.

Field name extension. Type the extension that you would like added to the new field name(s). For example, for a new field containing the log of *Current Salary*, you could add the extension *log_* to the field name, producing *log_Current Salary*. Use the radio buttons to choose whether to add the extension as a prefix (at the beginning) or as a suffix (at the end) of the field name. The default name is *DeriveN*, where *N* is the number of Derive nodes that you have created thus far during the current session.

As in the single-mode Derive node, you now need to create an expression to use for deriving a new field. Depending on the type of Derive operation selected, there are a number of options to create a condition. These options are discussed in subsequent topics. To create an expression, you can simply type in the formula field(s) or use the Expression Builder by clicking the calculator button. Remember to use the `@FIELD` function when referring to manipulations on multiple fields.

- [Setting Basic Options for the Derive Node](#)
- [Recoding Values with the Derive Node](#)

Selecting Multiple Fields

For all nodes that perform operations on multiple input fields, such as Derive (multiple mode), Aggregate, Sort, Multiplot, and Time Plot, you can easily select multiple fields using the Select Fields dialog box.

Sort by. You can sort available fields for viewing by selecting one of the following options:

- **Natural.** View the order of fields as they have been passed down the data stream into the current node.
- **Name.** Use alphabetical order to sort fields for viewing.
- **Type.** View fields sorted by their measurement level. This option is useful when selecting fields with a particular measurement level.

Select fields from the list one at a time or use the Shift-click and Ctrl-click methods to select multiple fields. You can also use the buttons below the list to select groups of fields based on their measurement level, or to select or deselect all fields in the table.

-

Setting Derive Formula Options

Derive Formula nodes create a new field for each record in a data set based on the results of a CLEM expression. This expression cannot be conditional. To derive values that are based on a conditional expression, use the flag or conditional type of Derive node.

Formula Specify a formula by using the CLEM language to derive a value for the new field.

Note: Because SPSS® Modeler cannot know what submeasurement level is to be used for a derived list field, for the Collection and Geospatial measurement levels, you can click **Specify...** to open the Values dialog box and set the required submeasurement level. For more information, see [Setting derived list values](#).

For Geospatial fields, the only relevant storage types are Real and Integer (the default setting is Real).

- [Setting derived list values](#)
- [Deriving a list or geospatial field](#)

Related information

- [Setting Basic Options for the Derive Node](#)
 - [Setting derived list values](#)
-

Setting derived list values

The Values dialog box is displayed when you select **Specify...** from the Derive node Formula Field type drop-down list. In this dialog box, you set the submeasurement level values to be used for the Formula Field type measurement levels of either Collection or Geospatial.

Measurement Select either Collection or Geospatial. If you select any other measurement level, the dialog box displays a message that there are no editable values.

Collection

The only item that you can set for the Collection Measurement level is the List measure. By default this measure is set to Typeless but you can select another value to set the measurement level of the elements within the list. You can choose one of the following options:

- Typeless
- Categorical
- Continuous
- Nominal
- Ordinal
- Flag

Geospatial

For the Geospatial Measurement level, you can select the following options to set the measurement level of the elements within the list:

Type Select the measurement sublevel of the geospatial field. The available sublevels are determined by the depth of the list field; the defaults are as follows:

- Point (zero depth)
- LineString (depth of one)
- Polygon (depth of one)
- MultiPoint (depth of one)
- MultiLineString (depth of two)
- MultiPolygon (depth of two)

For more information about sublevels, see [Geospatial measurement sublevels](#).

For more information about list depths, see [List storage and associated measurement levels](#).

Coordinate system This option is only available if you changed the measurement level to geospatial from a non-geospatial level. To apply a coordinate system to your geospatial data, select this check box. By default, the coordinate system set in the Tools > Stream Properties > Options > Geospatial pane is shown. To use a different coordinate system, click the Change button to display the Select Coordinate System dialog box and choose the system that matches your data.

For more information about coordinate systems, see [Setting geospatial options for streams](#).

Deriving a list or geospatial field

There are occasions when data that should be recorded as a list item is imported into SPSS® Modeler with the wrong attributes. For example, as separate geospatial fields, such as an x coordinate and a y coordinate, or a longitude and latitude, as individual rows in a .csv file. In this situation, you must combine the individual fields into a single list field; one way to do this is by using the Derive node.

Note: You must know which is the x (or longitude) field and which is the y (or latitude field) field when you combine geospatial data. You must combine your data so that the resulting list field has the order of elements: [x, y] or [Longitude, Latitude], which are the standard formats for geospatial coordinates.

The following steps show a simple example of deriving a list field.

1. In your stream, attach a Derive node to your Source node.
2. On the Settings tab of the Derive node, select Formula from the Derive as list.
3. In Field Type select either Collection for a non-geospatial list, or Geospatial. By default, SPSS Modeler uses a "best guess" approach to set the correct list detail; you can select Specify... to open the Values dialog box. This dialog can be used for a collection to enter further information about the data in your list, and for geospatial it can be used to set the type of the data and specify the coordinate system of the data.
Note: For geospatial, the coordinate system you specify must exactly match the coordinate system of the data. If this is not the case, geospatial functionality will produce incorrect results.
4. In the Formula pane, enter the formula to combine your data into the correct list format. Alternatively, click the calculator button to open the Expression Builder.
A simple example of a formula to derive a list is [x, y], where x and y are separate fields in the data source. The new derived field that is created is a list where the value for each record is the concatenated x and y values for that record.

Note: Fields that are combined into a list in this way must have the same storage type.

For more information about lists, and depths of lists, see [List storage and associated measurement levels](#).

Setting Derive Flag Options

Derive Flag nodes are used to indicate a specific condition, such as high blood pressure or customer account inactivity. A flag field is created for each record, and when the true condition is met, the flag value for true is added in the field.

True value. Specify a value to include in the flag field for records that match the condition specified below. The default is T.

False value. Specify a value to include in the flag field for records that do *not* match the condition specified below. The default is F.

True when. Specify a CLEM condition to evaluate certain values of each record and give the record a true value or a false value (defined above). Note that the true value will be given to records in the case of non-false numeric values.

Note: To return an empty string, you should type opening and closing quotes with nothing between them, such as "". Empty strings are often used, for example, as the false value in order to enable true values to stand out more clearly in a table. Similarly, quotes should be used if you want a string value that would otherwise be treated as a number

Example

In releases of IBM® SPSS® Modeler prior to 12.0, multiple responses were imported into a single field, with values separated by commas. For example:

```
museum_of_design,institute_of_textiles_and_fashion  
museum_of_design  
archeological_museum  
$null$  
national_art_gallery,national_museum_of_science,other
```

To prepare this data for analysis, you could use the **hassubstring** function to generate a separate flag field for each response with an expression such as:

```
hassubstring(museums,"museum_of_design")
```

Related information

- [Setting Basic Options for the Derive Node](#)
-

Setting Derive Nominal Options

Derive Nominal nodes are used to execute a set of CLEM conditions in order to determine which condition each record satisfies. As a condition is met for each record, a value (indicating which set of conditions was met) will be added to the new, derived field.

Default value. Specify a value to be used in the new field if none of the conditions are met.

Set field to. Specify a value to enter in the new field when a particular condition is met. Each value in the list has an associated condition that you specify in the adjacent column.

If this condition is true. Specify a condition for each member in the set field to list. Use the Expression Builder to select from available functions and fields. You can use the arrow and delete buttons to reorder or remove conditions.

A condition works by testing the values of a particular field in the dataset. As each condition is tested, the values specified above will be assigned to the new field to indicate which, if any, condition was met. If none of the conditions are met, the default value is used.

Related information

- [Setting Basic Options for the Derive Node](#)
-

Setting Derive State Options

Derive State nodes are somewhat similar to Derive Flag nodes. A Flag node sets values depending on the fulfillment of a *single* condition for the current record, but a Derive State node can change the values of a field depending on how it fulfills *two independent* conditions. This means that the value will change (turn on or off) as each condition is met.

Initial state. Select whether to give each record of the new field the On or Off value initially. Note that this value can change as each condition is met.

"On" value. Specify the value for the new field when the On condition is met.

Switch "On" when. Specify a CLEM condition that will change the state to On when the condition is true. Click the calculator button to open the Expression Builder.

"Off" value. Specify the value for the new field when the Off condition is met.

Switch "Off" when. Specify a CLEM condition that will change the state to Off when the condition is false. Click the calculator button to open the Expression Builder.

Note: To specify an empty string, you should type opening and closing quotes with nothing between them, such as "". Similarly, quotes should be used if you want a string value that would otherwise be treated as a number.

Related information

- [Setting Basic Options for the Derive Node](#)
-

Setting Derive Count Options

A Derive Count node is used to apply a series of conditions to the values of a numeric field in the dataset. As each condition is met, the value of the derived count field is increased by a set increment. This type of Derive node is useful for time series data.

Initial value. Sets a value used on execution for the new field. The initial value must be a numeric constant. Use the arrow buttons to increase or decrease the value.

Increment when. Specify the CLEM condition that, when met, will change the derived value based on the number specified in Increment by. Click the calculator button to open the Expression Builder.

Increment by. Set the value used to increment the count. You can use either a numeric constant or the result of a CLEM expression.

Reset when. Specify a condition that, when met, will reset the derived value to the initial value. Click the calculator button to open the Expression Builder.

Related information

- [Setting Basic Options for the Derive Node](#)

Setting Derive Conditional Options

Derive Conditional nodes use a series of If-Then-Else statements to derive the value of the new field.

If. Specify a CLEM condition that will be evaluated for each record upon execution. If the condition is true (or non-false, in the case of numbers), the new field is given the value specified below by the Then expression. Click the calculator button to open the Expression Builder.

Then. Specify a value or CLEM expression for the new field when the If statement above is true (or non-false). Click the calculator button to open the Expression Builder.

Else. Specify a value or CLEM expression for the new field when the If statement above is false. Click the calculator button to open the Expression Builder.

Related information

- [Setting Basic Options for the Derive Node](#)

Recoding Values with the Derive Node

Derive nodes can also be used to recode values, for example by converting a string field with categorical values to a numeric nominal (set) field.

1. For Derive As, select the type of field (Nominal, Flag, etc.) as appropriate.
2. Specify the conditions for recoding values. For example, you could set the value to 1 if `Drug='drugA'`, 2 if `Drug='drugB'`, and so on.

- [Derive node](#)
- [Setting Basic Options for the Derive Node](#)
- [Deriving Multiple Fields](#)

Filler node

Filler nodes are used to replace field values and change storage. You can choose to replace values based on a specified CLEM condition, such as `@BLANK(@FIELD)`. Alternatively, you can choose to replace all blanks or null values with a specific value. Filler nodes are often used in conjunction with the Type node to replace missing values. For example, you can fill blanks with the mean value of a field by specifying an expression such as `@GLOBAL_MEAN`. This expression will fill all blanks with the mean value as calculated by a Set Globals node.

Fill in fields. Using the Field Chooser (button to the right of the text field), select fields from the dataset whose values will be examined and replaced. The default behavior is to replace values depending on the Condition and Replace with expressions specified below. You can also select an alternative method of replacement using the Replace options below.

Note: When selecting multiple fields to replace with a user-defined value, it is important that the field types are similar (all numeric or all symbolic).

Replace. Select to replace the values of the selected field(s) using one of the following methods:

- Based on condition. This option activates the Condition field and Expression Builder for you to create an expression used as a condition for replacement with the value specified.
- Always. Replaces all values of the selected field. For example, you could use this option to convert the storage of income to a string using the following CLEM expression: `(to_string(income))`.
- Blank values. Replaces all user-specified blank values in the selected field. The standard condition `@BLANK(@FIELD)` is used to select blanks. Note: You can define blanks using the Types tab of the source node or with a Type node.
- Null values. Replaces all system null values in the selected field. The standard condition `@NULL(@FIELD)` is used to select nulls.
- Blank and null values. Replaces both blank values and system nulls in the selected field. This option is useful when you are unsure whether or not nulls have been defined as missing values.

Condition. This option is available when you have selected the Based on condition option. Use this text box to specify a CLEM expression for evaluating the selected fields. Click the calculator button to open the Expression Builder.

Replace with. Specify a CLEM expression to give a new value to the selected fields. You can also replace the value with a null value by typing `undef` in the text box. Click the calculator button to open the Expression Builder.

Note: When the field(s) selected are string, you should replace them with a string value. Using the default 0 or another numeric value as the replacement value for string fields will result in an error.

Note that use of the following may change row order:

- Executing in a database via SQL pushback
 - Executing via remote IBM® SPSS® Analytic Server
 - Using functions that run in embedded IBM SPSS Analytic Server
 - Deriving a list (for example, see [Deriving a list or geospatial field](#))
 - Calling any of the spatial functions
- [Storage Conversion Using the Filler Node](#)

Storage Conversion Using the Filler Node

Using the Replace condition of a Filler node, you can easily convert the field storage for single or multiple fields. For example, using the conversion function `to_integer`, you could convert `income` from a string to an integer using the following CLEM expression: `to_integer(income)`.

You can view available conversion functions and automatically create a CLEM expression using the Expression Builder. From the Functions drop-down list, select Conversion to view a list of storage conversion functions. The following conversion functions are available:

- `to_integer(ITEM)`
- `to_real(ITEM)`
- `to_number(ITEM)`
- `to_string(ITEM)`
- `to_time(ITEM)`
- `to_timestamp(ITEM)`
- `to_date(ITEM)`
- `to_datetime(ITEM)`

Converting date and time values. Note that conversion functions (and any other functions that require a specific type of input such as a date or time value) depend on the current formats specified in the stream options dialog box. For example if you want to convert a string field with values *Jan 2003, Feb 2003*, etc. to date storage, select MON YYYY as the default date format for the stream.

Conversion functions are also available from the Derive node, for temporary conversion during a derive calculation. You can also use the Derive node to perform other manipulations such as recoding string fields with categorical values. See the topic [Recoding Values with the Derive Node](#) for more information.

Reclassify Node

The Reclassify node enables the transformation from one set of categorical values to another. Reclassification is useful for collapsing categories or regrouping data for analysis. For example, you could reclassify the values for *Product* into three groups, such as *Kitchenware*, *Bath and Linens*, and *Appliances*. Often, this operation is performed directly from a Distribution node by grouping values and generating a Reclassify node. See the topic [Using a Distribution Node](#) for more information.

Reclassification can be performed for one or more symbolic fields. You can also choose to substitute the new values for the existing field or generate a new field.

Before using a Reclassify node, consider whether another Field Operations node is more appropriate for the task at hand:

- To populate the column values in the Reclassify node, use Type node as a prefix to Reclassify node.
 - To transform numeric ranges into sets using an automatic method, such as ranks or percentiles, you should use a Binning node. See the topic [Binning Node](#) for more information.
 - To classify numeric ranges into sets manually, you should use a Derive node. For example, if you want to collapse salary values into specific salary range categories, you should use a Derive node to define each category manually.
 - To create one or more flag fields based on the values of a categorical field, such as *Mortgage_type*, you should use a Set to Flag node.
 - To convert a categorical field to numeric storage, you can use a Derive node. For example, you could convert No and Yes values to 0 and 1, respectively. See the topic [Recoding Values with the Derive Node](#) for more information.
- [Setting Options for the Reclassify Node](#)
- [Reclassifying Multiple Fields](#)
- [Storage and Measurement Level for Reclassified Fields](#)

Related information

- [Field Operations Overview](#)
- [Setting Options for the Reclassify Node](#)
- [Reclassifying Multiple Fields](#)
- [Storage and Measurement Level for Reclassified Fields](#)

Setting Options for the Reclassify Node

There are three steps to using the Reclassify node:

1. First, select whether you want to reclassify multiple fields or a single field.
2. Next, choose whether to recode into the existing field or create a new field.
3. Then, use the dynamic options in the Reclassify node dialog box to map sets as desired.

Mode. Select Single to reclassify the categories for one field. Select Multiple to activate options enabling the transformation of more than one field at a time.

Reclassify into. Select New field to keep the original nominal field and derive an additional field containing the reclassified values. Select Existing field to overwrite the values in the original field with the new classifications. This is essentially a "fill" operation.

Once you have specified mode and replacement options, you must select the transformation field and specify the new classification values using the dynamic options on the bottom half of the dialog box. These options vary depending on the mode you have selected above.

Reclassify field(s). Use the Field Chooser button on the right to select one (Single mode) or more (Multiple mode) categorical fields.

New field name. Specify a name for the new nominal field containing recoded values. This option is available only in Single mode when New field is selected above. When Existing field is selected, the original field name is retained. When working in Multiple mode, this option is replaced with controls for specifying an extension added to each new field. See the topic [Reclassifying Multiple Fields](#) for more information.

Reclassify values. This table enables a clear mapping from old set values to those you specify here.

- **Original value.** This column lists existing values for the select field(s).
 - **New value.** Use this column to type new category values or select one from the drop-down list. When you automatically generate a Reclassify node using values from a Distribution chart, these values are included in the drop-down list. This allows you to quickly map existing values to a known set of values. For example, healthcare organizations sometimes group diagnoses differently based upon network or locale. After a merger or acquisition, all parties will be required to reclassify new or even existing data in a consistent fashion. Rather than manually typing each target value from a lengthy list, you can read the master list of values in to IBM® SPSS® Modeler, run a Distribution chart for the *Diagnosis* field, and generate a Reclassify (values) node for this field directly from the chart. This process will make all of the target Diagnosis values available from the New Values drop-down list.
4. Click Get to read original values for one or more fields selected above.

5. Click Copy to paste original values over to the *New value* column for fields that have not been mapped yet. The unmapped original values are added to the drop-down list.
6. Click Clear new to erase all specifications in the *New value* column. *Note:* This option does not erase the values from the drop-down list.
7. Click Auto to automatically generate consecutive integers for each of the original values. Only integer values (no real values, such as 1.5, 2.5, and so on) can be generated.

For example, you can automatically generate consecutive product ID numbers for product names or course numbers for university class offerings. This functionality corresponds to the Automatic Recode transformation for sets in IBM SPSS Statistics.

For unspecified values use. This option is used for filling unspecified values in the new field. You can either choose to keep the original value by selecting Original value or specify a default value.

-

Reclassifying Multiple Fields

To map category values for more than one field at a time, set the mode to Multiple. This enables new settings in the Reclassify dialog box, which are described below.

Reclassify fields. Use the Field Chooser button on the right to select the fields that you want to transform. Using the Field Chooser, you can select all fields at once or fields of a similar type, such as nominal or flag.

Field name extension. When recoding multiple fields simultaneously, it is more efficient to specify a common extension added to all new fields rather than individual field names. Specify an extension such as `_recode` and select whether to append or prepend this extension to the original field names.

Related information

- [Reclassify Node](#)
 - [Setting Options for the Reclassify Node](#)

-

Storage and Measurement Level for Reclassified Fields

The Reclassify node always creates a nominal field from the recode operation. In some cases, this may change the measurement level of the field when using the Existing field reclassification mode.

The new field's storage (how data are *stored* rather than how they are *used*) is calculated based on the following Settings tab options:

- If unspecified values are set to use a default value, the storage type is determined by examining both the new values as well as the default value and determining the appropriate storage. For example, if all values can be parsed as integers, the field will have the integer storage type.
- If unspecified values are set to use the original values, the storage type is based on the storage of the original field. If all of the values can be parsed as the storage of the original field, then that storage is preserved; otherwise, the storage is determined by finding the most appropriate storage type encompassing both old and new values. For example, reclassifying an integer set { 1, 2, 3, 4, 5 } with the reclassification 4 => 0, 5 => 0 generates a new integer set { 1, 2, 3, 0 }, whereas with the reclassification 4 => "Over 3", 5 => "Over 3" will generate the string set { "1", "2", "3", "Over 3" }.

Note: If the original type was uninstantiated, the new type will be also be uninstantiated.

Anonymize Node

The Anonymize node enables you to disguise field names, field values, or both when working with data that are to be included in a model downstream of the node. In this way, the generated model can be freely distributed (for example, to Technical Support) with no danger that unauthorized users will be able to view confidential data, such as employee records or patients' medical records.

Depending on where you place the Anonymize node in the stream, you may need to make changes to other nodes. For example, if you insert an Anonymize node upstream from a Select node, the selection criteria in the Select node will need to be changed if they are acting on values that have now become anonymized.

The method to be used for anonymizing depends on various factors. For field names and all field values except Continuous measurement levels, the data are replaced by a string of the form:

`prefix_Sn`

where `prefix_` is either a user-specified string or the default string `anon_`, and `n` is an integer value that starts at 0 and is incremented for each unique value (for example, `anon_S0`, `anon_S1`, etc.).

Field values of type Continuous must be transformed because numeric ranges deal with integer or real values rather than strings. As such, they can be anonymized only by transforming the range into a different range, thus disguising the original data. Transformation of a value `x` in the range is performed in the following way:

`A*(x + B)`

where:

`A` is a scale factor, which must be greater than 0.

`B` is a translation offset to be added to the values.

Example

In the case of a field `AGE` where the scale factor `A` is set to 7 and the translation offset `B` is set to 3, the values for `AGE` are transformed into:

`7*(AGE + 3)`

- [Anonymizing Field Values](#)

Related information

- [Field Operations Overview](#)
- [Anonymizing Field Names](#)
- [Setting Options for the Anonymize Node](#)
- [Anonymizing Field Values](#)

Setting Options for the Anonymize Node

Here you can choose which fields are to have their values disguised further downstream.

Note that the data fields must be instantiated upstream from the Anonymize node before anonymize operations can be performed. You can instantiate the data by clicking the Read Values button on a Type node or on the Types tab of a source node.

Field. Lists the fields in the current dataset. If any field names have already been anonymized, the anonymized names are shown here.

Measurement. The measurement level of the field.

Anonymize Values. Select one or more fields, click this column, and choose Yes to anonymize the field value using the default prefix `anon_`; choose Specify to display a dialog box in which you can either enter your own prefix or, in the case of field values of type *Continuous*, specify whether the transformation of field values is to use random or user-specified values. Note that *Continuous* and non-*Continuous* field types cannot be specified in the same operation; you must do this separately for each type of field.

View current fields. Select to view fields for datasets actively connected to the Anonymize node. This option is selected by default.

View unused field settings. Select to view fields for datasets that were once but are no longer connected to the node. This option is useful when copying nodes from one stream to another or when saving and reloading nodes.

- [Specifying How Field Values Will Be Anonymized](#)

Specifying How Field Values Will Be Anonymized

The Replace Values dialog box lets you choose whether to use the default prefix for anonymized field values or to use a custom prefix. Clicking OK in this dialog box changes the setting of Anonymize Values on the Settings tab to Yes for the selected field or fields.

Field values prefix. The default prefix for anonymized field values is anon_ ; choose Custom and enter your own prefix if you want a different one.

The Transform Values dialog box is displayed only for fields of type Continuous and allows you to specify whether the transformation of field values is to use random or user-specified values.

Random. Choose this option to use random values for the transformation. Set random seed is selected by default; specify a value in the Seed field, or use the default value.

Fixed. Choose this option to specify your own values for the transformation.

- **Scale by.** The number by which field values will be multiplied in the transformation. Minimum value is 1; maximum is normally 10, but this may be lowered to avoid overflow.
- **Translate by.** The number that will be added to field values in the transformation. Minimum value is 0; maximum is normally 1000, but this may be lowered to avoid overflow.

Related information

- [Anonymize Node](#)

Anonymizing Field Values

Fields that have been selected for anonymization on the Settings tab have their values anonymized:

- When you run the stream containing the Anonymize node
- When you preview the values

To preview the values, click the Anonymize Values button on the Anonymized Values tab. Next, select a field name from the drop-down list.

If the measurement level is Continuous, the display shows the:

- Minimum and maximum values of the original range
- Equation used to transform the values

If the measurement level is anything other than Continuous, the screen displays the original and anonymized values for that field.

If the display appears with a yellow background, this indicates that either the setting for the selected field has changed since the last time the values were anonymized or that changes have been made to the data upstream of the Anonymize node such that the anonymized values may no longer be correct. The current set of values is displayed; click the Anonymize Values button again to generate a new set of values according to the current setting.

Anonymize Values. Creates anonymized values for the selected field and displays them in the table. If you are using random seeding for a field of type Continuous, clicking this button repeatedly creates a different set of values each time.

Clear Values. Clears the original and anonymized values from the table.

Binning Node

The Binning node enables you to automatically create new nominal fields based on the values of one or more existing continuous (numeric range) fields. For example, you can transform a continuous income field into a new categorical field containing income groups of equal width, or as deviations from the mean. Alternatively, you can select a categorical "supervisor" field in order to preserve the strength of the original association between the two fields.

Binning can be useful for a number of reasons, including:

- **Algorithm requirements.** Certain algorithms, such as Naive Bayes, Logistic Regression, require categorical inputs.
- **Performance.** Algorithms such as multinomial logistic may perform better if the number of distinct values of input fields is reduced. For example, use the median or mean value for each bin rather than using the original values.
- **Data Privacy.** Sensitive personal information, such as salaries, may be reported in ranges rather than actual salary figures in order to protect privacy.

A number of binning methods are available. Once you have created bins for the new field, you can generate a Derive node based on the cut points.

When to use a Binning node

Before using a Binning node, consider whether another technique is more appropriate for the task at hand:

- To manually specify cut points for categories, such as specific predefined salary ranges, use a Derive node. See the topic [Derive node](#) for more information.
- To create new categories for existing sets, use a Reclassify node. See the topic [Reclassify Node](#) for more information.

Missing Value Handling

The Binning node handles missing values in the following ways:

- **User-specified blanks.** Missing values specified as blanks are included during the transformation. For example, if you designated –99 to indicate a blank value using the Type node, this value will be included in the binning process. To ignore blanks during binning, you should use a Filler node to replace the blank values with the system null value.
- **System-missing values (\$null\$).** Null values are ignored during the binning transformation and remain nulls after the transformation.

The Settings tab provides options for available techniques. The View tab displays cut points established for data previously run through the node.

Setting Options for the Binning Node

Using the Binning node, you can automatically generate bins (categories) using the following techniques:

- Fixed-width binning
- Tiles (equal count or sum)
- Mean and standard deviation
- Ranks
- Optimized relative to a categorical "supervisor" field

The lower part of the dialog box changes dynamically depending on the binning method you select.

Bin fields. Continuous (numeric range) fields pending transformation are displayed here. The Binning node enables you to bin multiple fields simultaneously. Add or remove fields using the buttons on the right.

Binning method. Select the method used to determine cut points for new field bins (categories). Subsequent topics describe the options available in each case.

Bin thresholds. Specify how the bin thresholds are computed.

- **Always recompute.** Cut points and bin allocations are always recomputed when the node is run.
- **Read from Bin Values tab if available.** Cut points and bin allocations are computed only as necessary (for example, when new data has been added).

The following topics discuss options for the available methods of binning.

Related information

- [Fixed-Width Bins](#)
- [Tiles \(Equal Count or Sum\)](#)
- [Rank Cases](#)

- [Previewing the Generated Bins](#)
- [Binning Node](#)

Fixed-Width Bins

When you choose Fixed-width as the binning method, a new set of options is displayed in the dialog box.

Name extension. Specify an extension to use for the generated field(s). *_BIN* is the default extension. You may also specify whether the extension is added to the start (Prefix) or end (Suffix) of the field name. For example, you could generate a new field called *income_BIN*.

Bin width. Specify a value (integer or real) used to calculate the “width” of the bin. For example, you can use the default value, 10, to bin the field Age. Since Age has a range from 18–65, the generated bins would be as shown in the following table.

Table 1. Bins for Age with range 18–65

Bin 1	Bin 2	Bin 3	Bin 4	Bin 5	Bin 6
>=13 to <23	>=23 to <33	>=33 to <43	>=43 to <53	>=53 to <63	>=63 to <73

The start of bin intervals is calculated using the lowest scanned value minus half of the bin width (as specified). For example, in the bins shown above, 13 is used to start the intervals according to the following calculation: $18 \text{ [lowest data value]} - 5 \text{ [0.5} \times \text{ (Bin width of 10)]} = 13$.

No. of bins. Use this option to specify an integer used to determine the number of fixed-width bins (categories) for the new field(s).

Once you have executed the Binning node in a stream, you can view the bin thresholds generated by clicking the Preview tab in the Binning node dialog box. See the topic [Previewing the Generated Bins](#) for more information.

Related information

- [Setting Options for the Binning Node](#)
- [Tiles \(Equal Count or Sum\)](#)
- [Rank Cases](#)
- [Mean/Standard Deviation](#)
- [Optimal Binning](#)
- [Previewing the Generated Bins](#)

Tiles (Equal Count or Sum)

The tile binning method creates nominal fields that can be used to split scanned records into percentile groups (or quartiles, deciles, and so on) so that each group contains the same number of records, or the sum of the values in each group is equal. Records are ranked in ascending order based on the value of the specified bin field, so that records with the lowest values for the selected bin variable are assigned a rank of 1, the next set of records are ranked 2, and so on. The threshold values for each bin are generated automatically based on the data and tiling method used.

Tile name extension. Specify an extension used for field(s) generated using standard p-tiles. The default extension is *_TILE* plus *N*, where *N* is the tile number. You may also specify whether the extension is added to the start (Prefix) or end (Suffix) of the field name. For example, you could generate a new field called *income_BIN4*.

Custom tile extension. Specify an extension used for a custom tile range. The default is *_TILEN*. Note that *N* in this case will not be replaced by the custom number.

Available p-tiles are:

- **Quartile.** Generate 4 bins, each containing 25% of the cases.
- **Quintile.** Generate 5 bins, each containing 20% of the cases.
- **Decile.** Generate 10 bins, each containing 10% of the cases.
- **Vingtile.** Generate 20 bins, each containing 5% of the cases.
- **Percentile.** Generate 100 bins, each containing 1% of the cases.
- **Custom N.** Select to specify the number of bins. For example, a value of 3 would produce 3 banded categories (2 cut points), each containing 33.3% of the cases.

Note that if there are fewer discrete values in the data than the number of tiles specified, all tiles will not be used. In such cases, the new distribution is likely to reflect the original distribution of your data.

Tiling method. Specifies the method used to assign records to bins.

- **Record count.** Seeks to assign an equal number of records to each bin.
- **Sum of values.** Seeks to assign records to bins such that the sum of the values in each bin is equal. When targeting sales efforts, for example, this method can be used to assign prospects to decile groups based on value per record, with the highest value prospects in the

top bin. For example, a pharmaceutical company might rank physicians into decile groups based on the number of prescriptions they write. While each decile would contain approximately the same number of scripts, the number of individuals contributing those scripts would not be the same, with the individuals who write the most scripts concentrated in decile 10. Note that this approach assumes that all values are greater than zero, and may yield unexpected results if this is not the case.

Ties. A tie condition results when values on either side of a cut point are identical. For example, if you are assigning deciles and more than 10% of records have the same value for the bin field, then all of them cannot fit into the same bin without forcing the threshold one way or another. Ties can be moved up to the next bin or kept in the current one but must be resolved so that all records with identical values fall into the same bin, even if this causes some bins to have more records than expected. The thresholds of subsequent bins may also be adjusted as a result, causing values to be assigned differently for the same set of numbers based on the method used to resolve ties.

- **Add to next.** Select to move the tie values up to the next bin.
- **Keep in current.** Keeps tie values in the current (lower) bin. This method may result in fewer total bins being created.
- **Assign randomly.** Select to allocate the tie values randomly to a bin. This attempts to keep the number of records in each bin at an equal amount.

Example: Tiling by Record Count

The following table illustrates how simplified field values are ranked as quartiles when tiling by record count. Note the results vary depending on the selected ties option.

Table 1. Tiling by record count example

Values	Add to Next	Keep in Current
10	1	1
13	2	1
15	3	2
15	3	2
20	4	3

The number of items per bin is calculated as:

`total number of value / number of tiles`

In the simplified example above, the desired number of items per bin is 1.25 (5 values / 4 quartiles). The value 13 (being value number 2) straddles the 1.25 desired count threshold and is therefore treated differently depending on the selected ties option. In Add to Next mode, it is added into bin 2. In Keep in Current mode, it is left in bin 1, pushing the range of values for bin 4 outside that of existing data values. As a result, only three bins are created, and the thresholds for each bin are adjusted accordingly, as shown in the following table.

Table 2. Binning example result

Bin	Lower	Upper
1	≥ 10	<15
2	≥ 15	<20
3	≥ 20	≤ 20

Note: The speed of binning by tiles may benefit from enabling parallel processing.

Related information

- [Mean/Standard Deviation](#)
- [Optimal Binning](#)
- [Previewing the Generated Bins](#)

Rank Cases

When you choose Ranks as the binning method, a new set of options is displayed in the dialog box.

Ranking creates new fields containing ranks, fractional ranks, and percentile values for numeric fields depending on the options specified below.

Rank order. Select Ascending (lowest value is marked 1) or Descending (highest value is marked 1).

Rank. Select to rank cases in ascending or descending order as specified above. The range of values in the new field will be $1-N$, where N is the number of discrete values in the original field. Tied values are given the average of their rank.

Fractional rank. Select to rank cases where the value of the new field equals rank divided by the sum of the weights of the nonmissing cases. Fractional ranks fall in the range of 0–1.

Percentage fractional rank. Each rank is divided by the number of records with valid values and multiplied by 100. Percentage fractional ranks fall in the range of 1–100.

Extension. For all rank options, you can create custom extensions and specify whether the extension is added to the start (Prefix) or end (Suffix) of the field name. For example, you could generate a new field called *income_P_RANK*.

Related information

- [Setting Options for the Binning Node](#)
 - [Fixed-Width Bins](#)
 - [Tiles \(Equal Count or Sum\)](#)
 - [Mean/Standard Deviation](#)
 - [Optimal Binning](#)
 - [Previewing the Generated Bins](#)
-

Mean/Standard Deviation

When you choose Mean/standard deviation as the binning method, a new set of options is displayed in the dialog box.

This method generates one or more new fields with banded categories based on the values of the mean and standard deviation of the distribution of the specified field(s). Select the number of deviations to use below.

Name extension. Specify an extension to use for the generated field(s). *_SDBIN* is the default extension. You may also specify whether the extension is added to the start (Prefix) or end (Suffix) of the field name. For example, you could generate a new field called *income_SDBIN*.

- **+/- 1 standard deviation.** Select to generate three bins.
- **+/- 2 standard deviations.** Select to generate five bins.
- **+/- 3 standard deviations.** Select to generate seven bins.

For example, selecting +/-1 standard deviation results in the three bins as calculated and shown in the following table.

Table 1. Standard deviation bin example

Bin 1	Bin 2	Bin 3
$x < (\text{Mean} - \text{Std. Dev})$	$(\text{Mean} - \text{Std. Dev}) \leq x \leq (\text{Mean} + \text{Std. Dev})$	$x > (\text{Mean} + \text{Std. Dev})$

In a normal distribution, 68% of the cases fall within one standard deviation of the mean, 95% within two standard deviations, and 99% within three standard deviations. Note, however, that creating banded categories based on standard deviations may result in some bins being defined outside the actual data range and even outside the range of possible data values (for example, a negative salary range).

Related information

- [Setting Options for the Binning Node](#)
 - [Fixed-Width Bins](#)
 - [Tiles \(Equal Count or Sum\)](#)
 - [Rank Cases](#)
 - [Optimal Binning](#)
 - [Previewing the Generated Bins](#)
-

Optimal Binning

If the field you want to bin is strongly associated with another categorical field, you can select the categorical field as a "supervisor" field in order to create the bins in such a way as to preserve the strength of the original association between the two fields.

For example, suppose you have used cluster analysis to group states based on delinquency rates for home loans, with the highest rates in the first cluster. In this case, you might choose *Percent past due* and *Percent of foreclosures* as the Bin fields and the cluster membership field generated by the model as the supervisor field.

Name extension Specify an extension to use for the generated field(s) and whether to add it at the start (Prefix) or end (Suffix) of the field name. For example, you could generate a new field called *pastdue_OPTIMAL* and another called *inforeclosure_OPTIMAL*.

Supervisor field A categorical field used to construct the bins.

Pre-bin fields to improve performance with large datasets Indicates if preprocessing should be used to streamline optimal binning. This groups scale values into a large number of bins using a simple unsupervised binning method, represents values within each bin by the mean, and adjusts the case weight accordingly before proceeding with supervised binning. In practical terms, this method trades a degree of precision for speed.

and is recommended for large datasets. You can also specify the maximum number of bins that any variable should end up in after preprocessing when this option is used.

Merge bins that have relatively small case counts with a larger neighbor. If enabled, indicates that a bin is merged if the ratio of its size (number of cases) to that of a neighboring bin is smaller than the specified threshold; note that larger thresholds may result in more merging.

- [Cut Point Settings](#)

Related information

- [Setting Options for the Binning Node](#)
 - [Fixed-Width Bins](#)
 - [Tiles \(Equal Count or Sum\)](#)
 - [Rank Cases](#)
 - [Mean/Standard Deviation](#)
 - [Previewing the Generated Bins](#)
 - [Cut Point Settings](#)
-

Cut Point Settings

The Cut Point Settings dialog box enables you to specify advanced options for the optimal binning algorithm. These options tell the algorithm how to calculate the bins using the target field.

Bin end points. You can specify whether the lower or upper end points should be inclusive (lower $\leq x$) or exclusive (lower $< x$).

First and last bins. For both the first and last bin, you can specify whether the bins should be unbounded (extending toward positive or negative infinity) or bounded by the lowest or highest data points.

Related information

- [Optimal Binning](#)
-

Previewing the Generated Bins

The Bin Values tab in the Binning node allows you to view the thresholds for generated bins. Using the Generate menu, you can also generate a Derive node that can be used to apply these thresholds from one dataset to another.

Binned field. Use the drop-down list to select a field for viewing. Field names shown use the original field name for clarity.

Tile. Use the drop-down list to select a tile, such as 10 or 100, for viewing. This option is available only when bins have been generated using the tile method (equal count or sum).

Bin thresholds. Threshold values are shown here for each generated bin, along with the number of records that fall into each bin. For the optimal binning method only, the number of records in each bin is shown as a percentage of the whole. Note that thresholds are not applicable when the rank binning method is used.

Read Values. Reads binned values from the dataset. Note that thresholds will also be overwritten when new data are run through the stream.

Generating a Derive Node

You can use the Generate menu to create a Derive node based on the current thresholds. This is useful for applying established bin thresholds from one set of data to another. Furthermore, once these split points are known, a Derive operation is more efficient (meaning faster) than a Binning operation when working with large datasets.

RFM Analysis Node

The Recency, Frequency, Monetary (RFM) Analysis node enables you to determine quantitatively which customers are likely to be the best ones by examining how recently they last purchased from you (recency), how often they purchased (frequency), and how much they spent over all transactions (monetary).

The reasoning behind RFM analysis is that customers who purchase a product or service once are more likely to purchase again. The categorized customer data is separated into a number of bins, with the binning criteria adjusted as you require. In each of the bins, customers are assigned a score; these scores are then combined to provide an overall RFM score. This score is a representation of the customer's membership in the bins created for each of the RFM parameters. This binned data may be sufficient for your needs, for example, by identifying the most frequent, high-value customers; alternatively, it can be passed on in a stream for further modeling and analysis.

Note, however, that although the ability to analyze and rank RFM scores is a useful tool, you must be aware of certain factors when using it. There may be a temptation to target customers with the highest rankings; however, over-solicitation of these customers could lead to resentment and an actual fall in repeat business. It is also worth remembering that customers with low scores should not be neglected but instead may be cultivated to become better customers. Conversely, high scores alone do not necessarily reflect a good sales prospect, depending on the market. For example, a customer in bin 5 for recency, meaning that they have purchased very recently, may not actually be the best target customer for someone selling expensive, longer-life products such as cars or televisions.

Note: Depending on how your data are stored, you may need to precede the RFM Analysis node with an RFM Aggregate node to transform the data into a usable format. For example, input data must be in customer format, with one row per customer; if the customers' data are in transactional form, use an RFM Aggregate node upstream to derive the recency, frequency, and monetary fields. See the topic [RFM Aggregate Node](#) for more information.

The RFM Aggregate and RFM Analysis nodes in IBM® SPSS® Modeler are set up to use independent binning; that is, they rank and bin data on each measure of recency, frequency, and monetary value, without regard to their values or the other two measures.

- [RFM Analysis Node Settings](#)
- [RFM Analysis Node Binning](#)

Related information

- [Field Operations Overview](#)
- [RFM Analysis Node Settings](#)
- [RFM Analysis Node Binning](#)

RFM Analysis Node Settings

Recency. Using the Field Chooser (button to the right of the text box), select the recency field. This may be a date, timestamp, or simple number. Note that when a date or timestamp represents the date of the most recent transaction, the highest value is considered the most recent; where a number is specified, it represents the time elapsed since the most recent transaction and the lowest value is considered as the most recent.

Note: If the RFM Analysis node is preceded in the stream by an RFM Aggregate node, the Recency, Frequency, and Monetary fields generated by the RFM Aggregate node should be selected as inputs in the RFM Analysis node.

Frequency. Using the Field Chooser, select the frequency field to be used.

Monetary. Using the Field Chooser, select the monetary field to be used.

Number of bins. For each of the three output types, select the number of bins to be created. The default is 5.

Note: The minimum number of bins is 2, and the maximum is 9.

Weight. By default, the highest importance when calculating scores is given to the recency data, followed by frequency, and then monetary. If required, you can amend the weighting affecting one or several of these to change which is given the highest importance.

The RFM score is calculated as follows: (Recency score x Recency weight) + (Frequency score x Frequency weight) + (Monetary score x Monetary weight).

Ties. Specify how identical (tied) scores are to be binned. The options are:

- **Add to next.** Select to move the tie values up to the next bin.
- **Keep in current.** Keeps tie values in the current (lower) bin. This method may result in fewer total bins being created. (This is the default value.)

Bin thresholds. Specify whether the RFM scores and bin allocations are always recomputed when the node is executed or that they are computed only as necessary (for example, when new data has been added). If you select Read from Bin Values tab if available you can edit the

upper and lower cut points for the different bins on the Bin Values tab.

When executed, the RFM Analysis node bins the raw recency, frequency, and monetary fields and adds the following new fields to the dataset:

- Recency score. A rank (bin value) for Recency
- Frequency score. A rank (bin value) for Frequency
- Monetary score. A rank (bin value) for Monetary
- RFM score. The weighted sum of the recency, frequency, and monetary scores.

Add outliers to end bins. If you select this check box, records that lie below the lower bin are added to the lower bin, and records above the highest bin are added to the highest bin—otherwise, they are given a null value. This box is available only if you select Read from Bin Values tab if available.

-

RFM Analysis Node Binning

The Bin Values tab allows you to view, and in certain cases amend, the thresholds for generated bins.

Note: You can only amend values on this tab if you select Read from Bin Values tab if available on the Settings tab.

Binned field. Use the drop-down list to select a field for dividing into bins. The available values are those selected on the Settings tab.

Bin values table. Threshold values are shown here for each generated bin. If you select Read from Bin Values tab if available on the Settings tab, you can amend the upper and lower cut points for each bin by double-clicking on the relevant cell.

Read Values. Reads binned values from the dataset and populates the bin values table. Note that if you select Always recompute on the Settings tab, the bin thresholds will be overwritten when new data are run through the stream.

Ensemble Node

The Ensemble node combines two or more model nuggets to obtain more accurate predictions than can be gained from any of the individual models. By combining predictions from multiple models, limitations in individual models may be avoided, resulting in a higher overall accuracy. Models combined in this manner typically perform at least as well as the best of the individual models and often better.

This combining of nodes happens automatically in the Auto Classifier, Auto Numeric and Auto Cluster automated modeling nodes.

After using an Ensemble node, you can use an Analysis node or Evaluation node to compare the accuracy of the combined results with each of the input models. To do this, make sure the Filter out fields generated by ensembled models option is not selected on the Settings tab in the Ensemble node.

Output Fields

Each Ensemble node generates a field containing the combined scores. The name is based on the specified target field and prefixed with \$XF_, \$XS_, or \$XR_, depending on the field measurement level--flag, nominal (set), or continuous (range), respectively. For example, if the target is a flag field named *response*, the output field would be \$XF_*response*.

Confidence or propensity fields. For flag and nominal fields, additional confidence or propensity fields are created based on the ensemble method, as detailed in the following table.

Table 1. Ensemble method field creation

Ensemble method	Field name
-----------------	------------

Ensemble method	Field name
Voting	<code>\$XFC_<field></code>
Confidence-weighted voting	
Raw-propensity-weighted voting	
Adjusted-propensity-weighted voting	
Highest confidence wins	
Average raw propensity	<code>\$XFNP_<field></code>
Average adjusted raw propensity	<code>\$XFAP_<field></code>

- [Ensemble Node Settings](#)
-

Ensemble Node Settings

Target field for ensemble. Select a single field that is used as the target by two or more upstream models. The upstream models can use flag, nominal, or continuous targets, but at least two of the models must share the same target in order to combine scores.

Filter out fields generated by ensembled models. Removes from the output all of the additional fields generated by the individual models that feed into the Ensemble node. Select this check box if you are interested only in the combined score from all of the input models. Ensure that this option is deselected if, for example, you want to use an Analysis node or Evaluation node to compare the accuracy of the combined score with that of each of the individual input models.

Available settings depend on the measurement level of the field selected as the target.

Continuous Targets

For a continuous target, scores will be averaged. This is the only available method for combining scores.

When averaging scores or estimates, the Ensemble node uses a standard error calculation to work out the difference between the measured or estimated values and the true values, and to show how close those estimates matched. Standard error calculations are generated by default for new models; however, you can deselect the check box for existing models, for example, if they are to be regenerated.

Categorical Targets

For categorical targets, a number of methods are supported, including **voting**, which works by tallying the number of times each possible predicted value is chosen and selecting the value with the highest total. For example, if three out of five models predict yes and the other two predict no, then yes wins by a vote of 3 to 2. Alternatively, votes can be **weighted** based on the confidence or propensity value for each prediction. The weights are then summed, and the value with the highest total is again selected. The confidence for the final prediction is the sum of the weights for the winning value divided by the number of models included in the ensemble.

All categorical fields. For both flag and nominal fields, the following methods are supported:

- Voting
- Confidence-weighted voting
- Highest confidence wins

Flag fields only. For flag fields only, a number of methods based on propensity are also available:

- Raw propensity-weighted voting
- Adjusted propensity-weighted voting
- Average raw propensity
- Average adjusted propensity

Voting ties. For voting methods, you can specify how ties are resolved.

- **Random selection.** One of the tied values is chosen at random.
- **Highest confidence.** The tied value that was predicted with the highest confidence wins. Note that this is not necessarily the same as the highest confidence of all predicted values.
- **Raw or adjusted propensity (flag fields only).** The tied value that was predicted with the largest absolute propensity, where the absolute propensity is calculated as:

```
abs(0.5 - propensity) *
2
```

Or, in the case of adjusted propensity:

```
abs(0.5 - adjusted propensity) * 2
```

Partition Node

Partition nodes are used to generate a partition field that splits the data into separate subsets or samples for the training, testing, and validation stages of model building. By using one sample to generate the model and a separate sample to test it, you can get a good indication of how well the model will generalize to larger datasets that are similar to the current data.

The Partition node generates a nominal field with the role set to Partition. Alternatively, if an appropriate field already exists in your data, it can be designated as a partition using a Type node. In this case, no separate Partition node is required. Any instantiated nominal field with two or three values can be used as a partition, but flag fields cannot be used. See the topic [Setting the field role](#) for more information.

Multiple partition fields can be defined in a stream, but if so, a single partition field must be selected on the Fields tab in each modeling node that uses partitioning. (If only one partition is present, it is automatically used whenever partitioning is enabled.)

Enabling partitioning. To use the partition in an analysis, partitioning must be enabled on the Model Options tab in the appropriate model-building or analysis node. Deselecting this option makes it possible to disable partitioning without removing the field.

To create a partition field based on some other criterion such as a date range or location, you can also use a Derive node. See the topic [Derive node](#) for more information.

Example. When building an RFM stream to identify recent customers who have positively responded to previous marketing campaigns, the marketing department of a sales company uses a Partition node to split the data into training and test partitions.

- [Partition Node Options](#)

Related information

- [Field Operations Overview](#)
 - [Partition Node Options](#)
-

Partition Node Options

Partition field. Specifies the name of the field created by the node.

Partitions. You can partition the data into two samples (train and test) or three (train, test, and validation).

- Train and test. Partitions the data into two samples, allowing you to train the model with one sample and test with another.
- Train, test, and validation. Partitions the data into three samples, allowing you to train the model with one sample, test and refine the model using a second sample, and validate your results with a third. This reduces the size of each partition accordingly, however, and may be most suitable when working with a very large dataset.

Partition size. Specifies the relative size of each partition. If the sum of the partition sizes is less than 100%, then the records not included in a partition will be discarded. For example, if a user has 10 million records and has specified partition sizes of 5% training and 10% testing, after running the node, there should be roughly 500,000 training and one million testing records, with the remainder having been discarded.

Values. Specifies the values used to represent each partition sample in the data.

- Use system-defined values ("1," "2," and "3"). Uses an integer to represent each partition; for example, all records that fall into the training sample have a value of 1 for the partition field. This ensures the data will be portable between locales and that if the partition field is reinstated elsewhere (for example, reading the data back from a database), the sort order is preserved (so that 1 will still represent the training partition). However, the values do require some interpretation.
- Append labels to system-defined values. Combines the integer with a label; for example, training partition records have a value of **1_Training**. This makes it possible for someone looking at the data to identify which value is which, and it preserves sort order. However, values are specific to a given locale.
- Use labels as values. Uses the label with no integer; for example, Training. This allows you to specify the values by editing the labels. However, it makes the data locale-specific, and reinstatement of a partition column will put the values in their natural sort order, which may not correspond to their "semantic" order.

Seed. Only available when Repeatable partition assignment is selected. When sampling or partitioning records based on a random percentage, this option allows you to duplicate the same results in another session. By specifying the starting value used by the random number generator, you can ensure the same records are assigned each time the node is executed. Enter the desired seed value, or click the Generate button to automatically generate a random value. If this option is not selected, a different sample will be generated each time the node is executed.

Note: When using the Seed option with records read from a database, a Sort node may be required prior to sampling in order to ensure the same result each time the node is executed. This is because the random seed depends on the order of records, which is not guaranteed to stay the same in a relational database. See the topic [Sort Node](#) for more information.

Use unique field to assign partitions. Only available when Repeatable partition assignment is selected. (For Tier 1 databases only) Check this box to use SQL pushback to assign records to partitions. From the drop-down list, choose a field with unique values (such as an ID field) to ensure that records are assigned in a random but repeatable way.

Database tiers are explained in the description of the Database source node. See the topic [Database source node](#) for more information.

Generating select nodes

Using the Generate menu in the Partition node, you can automatically generate a Select node for each partition. For example, you could select all records in the training partition to obtain further evaluation or analyses using only this partition.

- [Partition Node](#)
-

Set to Flag Node

The Set to Flag node is used to derive flag fields based on the categorical values defined for one or more nominal fields. For example, your dataset might contain a nominal field, *BP* (blood pressure), with the values *High*, *Normal*, and *Low*. For easier data manipulation, you might create a flag field for high blood pressure, which indicates whether or not the patient has high blood pressure.

- [Setting Options for the Set to Flag Node](#)
-

Related information

- [Field Operations Overview](#)
 - [Setting Options for the Set to Flag Node](#)
-

Setting Options for the Set to Flag Node

Set fields. Lists all data fields with a measurement level of *Nominal* (set). Select one from the list to display the values in the set. You can choose from these values to create a flag field. Note that data must be fully instantiated using an upstream source or Type node before you can see the available nominal fields (and their values). See the topic [Type Node](#) for more information.

Field name extension. Select to enable controls for specifying an extension that will be added as a suffix or prefix to the new flag field. By default, new field names are automatically created by combining the original field name with the field value into a label, such as *Fieldname_fieldvalue*.

Available set values. Values in the set selected above are displayed here. Select one or more values for which you want to generate flags. For example, if the values in a field called *blood_pressure* are *High*, *Medium*, and *Low*, you can select *High* and add it to the list on the right. This will create a field with a flag for records with a value indicating high blood pressure.

Create flag fields. The newly created flag fields are listed here. You can specify options for naming the new field using the field name extension controls.

True value. Specify the true value used by the node when setting a flag. By default, this value is T.

False value. Specify the false value used by the node when setting a flag. By default, this value is F.

Aggregate keys. Select to group records together based on key fields specified below. When Aggregate keys is selected, all flag fields in a group will be "turned on" if *any* record was set to true. Use the Field Chooser to specify which key fields will be used to aggregate records.

Related information

- [Set to Flag Node](#)
-

Restructure Node

The Restructure node can be used to generate multiple fields based on the values of a nominal or flag field. The newly generated fields can contain values from another field or numeric flags (0 and 1). The functionality of this node is similar to that of the Set to Flag node. However, it offers more flexibility. It allows you to create fields of any type (including numeric flags), using the values from another field. You can then perform aggregation or other manipulations with other nodes downstream. (The Set to Flag node lets you aggregate fields in one step, which may be convenient if you are creating flag fields.)

For example, the following dataset contains a nominal field, *Account*, with the values *Savings* and *Draft*. The opening balance and current balance are recorded for each account, and some customers have multiple accounts of each type. Let's say you want to know whether each customer has

a particular account type, and if so, how much money is in each account type. You use the Restructure node to generate a field for each of the *Account* values, and you select *Current_Balance* as the value. Each new field is populated with the current balance for the given record.

Table 1. Sample data before restructuring

CustID	Account	Open_Bal	Current_Bal
12701	Draft	1000	1005.32
12702	Savings	100	144.51
12703	Savings	300	321.20
12703	Savings	150	204.51
12703	Draft	1200	586.32

Table 2. Sample data after restructuring

CustID	Account	Open_Bal	Current_Bal	Account_Draft_Current_Bal	Account_Savings_Current_Bal
12701	Draft	1000	1005.32	1005.32	\$null\$
12702	Savings	100	144.51	\$null\$	144.51
12703	Savings	300	321.20	\$null\$	321.20
12703	Savings	150	204.51	\$null\$	204.51
12703	Draft	1200	586.32	586.32	\$null\$

Using the Restructure Node with the Aggregate Node

In many cases, you may want to pair the Restructure node with an Aggregate node. In the previous example, one customer (with the ID 12703) has three accounts. You can use an Aggregate node to calculate the total balance for each account type. The key field is *CustID*, and the aggregate fields are the new restructured fields, *Account_Draft_Current_Bal* and *Account_Savings_Current_Bal*. The following table shows the results.

Table 3. Sample data after restructuring and aggregation

CustID	Record_Count	Account_Draft_Current_Bal_Sum	Account_Savings_Current_Bal_Sum
12701	1	1005.32	\$null\$
12702	1	\$null\$	144.51
12703	3	586.32	525.71

- [Setting Options for the Restructure Node](#)

Related information

- [Field Operations Overview](#)
- [Setting Options for the Restructure Node](#)

Setting Options for the Restructure Node

Available fields. Lists all data fields with a measurement level of *Nominal* (set) or *Flag*. Select one from the list to display the values in the set or flag, then choose from these values to create the restructured fields. Note that data must be fully instantiated using an upstream source or Type node before you can see the available fields (and their values). See the topic [Type Node](#) for more information.

Available values. Values in the set selected above are displayed here. Select one or more values for which you want to generate restructured fields. For example, if the values in a field called *Blood Pressure* are *High*, *Medium*, and *Low*, you can select *High* and add it to the list on the right. This will create a field with a specified value (see below) for records with a value of *High*.

Create restructured fields. The newly created restructured fields are listed here. By default, new field names are automatically created by combining the original field name with the field value into a label, such as *Fieldname_fieldvalue*.

Include field name. Deselect to remove the original field name as a prefix from the new field names.

Use values from other fields. Specify one or more fields whose values will be used to populate the restructured fields. Use the Field Chooser to select one or more fields. For each field chosen, one new field is created. The value field name is appended to the restructured field name—for example, *BP_High_Age* or *BP_Low_Age*. Each new field inherits the type of the original value field.

Create numeric value flags. Select to populate the new fields with numeric value flags (0 for false and 1 for true), rather than using a value from another field.

Related information

- [Restructure Node](#)
-

Transpose Node

By default, columns are fields and rows are records or observations. If necessary, you can use a Transpose node to swap the data in rows and columns so that fields become records and records become fields. For example, if you have time series data where each series is a row rather than a column, you can transpose the data prior to analysis.

- [Setting options for the Transpose node](#)
-

Setting options for the Transpose node

In the Transpose method drop-down, select the method you want the Transpose node to perform: Both fields and records, Records to fields, or Fields to records. The settings for each of the three methods are described in the following sections.

Restriction: The Records to fields and Fields to records methods are only supported on Windows 64-bit, Linux 64-bit, and Mac.

Both fields and records

New field names can be generated automatically based on a specified prefix, or read from an existing field in the data.

Use prefix. This option generates new field names automatically based on the specified prefix (**Field1**, **Field2**, and so on). You can customize the prefix as needed. With this option, you must specify the number of fields to be created, regardless of the number of rows in the original data. For example, if Number of new fields is set to 100, all data beyond the first 100 rows will be discarded. If there are fewer than 100 rows in the original data, some fields will be null. (You can increase the number of fields as needed, but the purpose of this setting is to avoid transposing a million records into a million fields, which would produce an unmanageable result.)

For example, suppose you have data with series in rows and a separate field (column) for each month. You can transpose this so that each series is in a separate field, with a row for each month.

Read from field. Reads field names from an existing field. With this option, the number of new fields is determined by the data, up to the specified maximum. Each value of the selected field becomes a new field in the output data. The selected field can have any storage type (integer, string, date, and so on), but in order to avoid duplicate field names, each value of the selected field must be unique (in other words, the number of values should match the number of rows). If duplicate field names are encountered, a warning is displayed.

- Read Values. If the selected field has not been instantiated, select this option to populate the list of new field names. If the field has already been instantiated, then this step is not necessary.
- Maximum number of values to read. When reading fields names from the data, an upper limit is specified in order to avoid creating an inordinately large number of fields. (As noted above, transposing one million records into one million fields would produce an unmanageable result.)

For example, if the first column in your data specifies the name for each series, you can use these values as fields names in the transposed data.

Transpose. By default, only continuous (numeric range) fields are transposed (either integer or real storage). Optionally, you can choose a subset of numeric fields or transpose string fields instead. However, all transposed fields must be of the same storage type—either numeric or string but not both—since mixing the input fields would generate mixed values within each output column, which violates the rule that all values of a field must have the same storage. Other storage types (date, time, timestamp) cannot be transposed.

- All numeric. Transposes all numeric fields (integer or real storage). The number of rows in the output matches the number of numeric fields in the original data.
- All string. Transposes all string fields.
- Custom. Allows you to select a subset of numeric fields. The number of rows in the output matches the number of fields selected. This option is only available for numeric fields.

Row ID name. Specifies the name of the row ID field created by the node. The values of this field are determined by the names of the fields in the original data.

Tip: When transposing time series data from rows to columns, if your original data includes a row, such as date, month, or year, that labels the period for each measurement, be sure to read these labels into IBM® SPSS® Modeler as field names (as demonstrated in the above examples, which show the month or date as field names in the original data, respectively) rather than including the label in the first row of data. This will avoid mixing labels and values in each column (which would force numbers to be read as strings, since storage types cannot be mixed within a column).

Records to fields

Fields. The Fields list contains all fields entering the Transpose node.

Index. Use the Index section to select the fields you want to use as index fields.

Fields. Use the Fields section to select the fields you want to use as fields.

Value. Use the Value section to select the fields you want to use as value fields.

Aggregate function. When there are more than one records for an index, you must aggregate the records into one. Use the Aggregate function drop-down to specify how to aggregate the records using one of the following functions. Note that aggregation impacts all fields.

- **Mean.** Returns the mean values for each key field combination. The mean is a measure of central tendency, and is the arithmetic average (the sum divided by the number of cases).
- **Sum.** Returns summed values for each key field combination. The sum is the total of the values, across all cases with nonmissing values.
- **Min.** Returns minimum values for each key field combination.
- **Max.** Returns maximum values for each key field combination.
- **Median.** Returns the median values for each key field combination. The median is a measure of central tendency that is not sensitive to outlying values (unlike the mean, which can be affected by a few extremely high or low values). Also known as the 50th percentile or 2nd quartile.
- **Count.** Returns the count of non-null values for each key field combination.

Fields to records

Fields. The Fields list contains all fields entering the Transpose node.

Index. Use the Index section to select the fields you want to use as index fields.

Value. Use the Value section to select the fields you want to use as value fields. If you don't select any value fields, then all unassigned numeric fields will be used as values. But if not numeric fields are available, then all unassigned string fields will be used.

History Node

History nodes are most often used for sequential data, such as time series data. They are used to create new fields containing data from fields in previous records. When using a History node, you may want to have data that is presorted by a particular field. You can use a Sort node to do this.

- [Setting Options for the History Node](#)

Related information

- [Field Operations Overview](#)
- [Setting Options for the History Node](#)

Setting Options for the History Node

Selected fields. Using the Field Chooser (button to the right of the text box), select the fields for which you want a history. Each selected field is used to create new fields for all records in the dataset.

Offset. Specify the latest record prior to the current record from which you want to extract historical field values. For example, if Offset is set to 3, as each record passes through this node, the field values for the third record previous will be included in the current record. Use the Span settings to specify how far back records will be extracted from. Use the arrows to adjust the offset value.

Span. Specify how many prior records from which you want to extract values. For example, if Offset is set to 3 and Span is set to 5, each record that passes through the node will have five fields added to it for each field specified in the Selected Fields list. This means that when the node is processing record 10, fields will be added from record 7 through record 3. Use the arrows to adjust the span value.

Where history is unavailable. Select one of the following options for handling records that have no history values. This usually refers to the first several records at the top of the dataset, for which there are no previous records to use as a history.

- **Discard records.** Select to discard records where no history value is available for the field selected.
- **Leave history undefined.** Select to keep records where no history value is available. The history field will be filled with an undefined value, displayed as `$null$`.
- **Fill values with.** Specify a value or string to be used for records where no history value is available. The default replacement value is `undef`, the system null. Null values are displayed using the string `$null$`.

When selecting a replacement value, keep in mind the following rules in order for proper execution to occur:

- Selected fields should be of the same storage type.

- If all of the selected fields have numeric storage, the replacement value must be parsed as an integer.
- If all of the selected fields have real storage, the replacement value must be parsed as a real.
- If all of the selected fields have symbolic storage, the replacement value must be parsed as a string.
- If all of the selected fields have date/time storage, the replacement value must be parsed as a date/time field.

If any of the above conditions are not met, you will receive an error when executing the History node.

- [History Node](#)

Field Reorder Node

The Field Reorder node enables you to define the natural order used to display fields downstream. This order affects the display of fields in a variety of places, such as tables, lists, and the Field Chooser. This operation is useful, for example, when working with wide datasets to make fields of interest more visible.

- [Setting Field Reorder Options](#)

Related information

- [Field Operations Overview](#)
- [Setting Field Reorder Options](#)

Setting Field Reorder Options

There are two ways to reorder fields: custom ordering and automatic sorting.

Custom Ordering

Select Custom Order to enable a table of field names and types where you can view all fields and use arrow buttons to create a custom order.

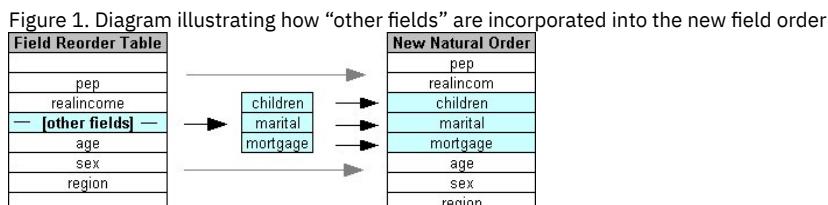

To reorder fields:

1. Select a field in the table. Use the Ctrl-click method to select multiple fields.
2. Use the simple arrow buttons to move the field(s) up or down one row.
3. Use the line-arrow buttons to move the field(s) to the bottom or top of the list.
4. Specify the order of fields not included here by moving up or down the divider row, indicated as [other fields].

More information on [other fields]

Other fields. The purpose of the [other fields] divider row is to break the table into two halves.

- Fields appearing above the divider row will be ordered (as they appear in the table) at the top of all natural orders used to display the fields downstream of this node.
- Fields appearing below the divider row will be ordered (as they appear in the table) at the bottom of all natural orders used to display the fields downstream of this node.

- All other fields not appearing in the field reorder table will appear between these “top” and “bottom” fields as indicated by the placement of the divider row.

Additional custom sorting options include:

- Sort fields in ascending or descending order by clicking on the arrows above each column header (Type, Name, and Storage). When sorting by column, fields not specified here (indicated by the [other fields] row) are sorted last in their natural order.
- Click Clear Unused to delete all unused fields from the Field Reorder node. Unused fields are displayed in the table with a red font. This indicates that the field has been deleted in upstream operations.

- Specify ordering for any new fields (displayed with a lightning icon to indicate a new or unspecified field). When you click OK or Apply, the icon disappears.

Note: If fields are added upstream after a custom order has been applied, the new fields will be appended at the bottom of the custom list.

Automatic Sorting

Select Automatic Sort to specify a parameter for sorting. The dialog box options dynamically change to provide options for automatic sorting.

Sort By. Select one of three ways to sort fields read into the Reorder node. The arrow buttons indicate whether the order will be ascending or descending. Select one to make a change.

- Name
- Type
- Storage

Fields added upstream of the Field Reorder node after auto-sort has been applied will automatically be placed in their proper position based on the sort type selected.

Related information

- [Field Reorder Node](#)
-

Time Intervals Node

The original Time Intervals node, that was available in SPSS® Modeler version 17.1 and earlier, was not compatible with Analytic Server (AS) and was deprecated in SPSS Modeler release 18.0.

The replacement Time Intervals node contains a number of changes from the original Time Intervals node. This new node can be used either with Analytic Server or in SPSS Modeler by itself.

You use the Time Intervals node to specify intervals and derive a new time field for estimating or forecasting. A full range of time intervals is supported, from seconds to years.

Use the node to derive a new time field; the new field has the same storage type as the input time field you chose. The node generates the following items:

- The field specified on the Fields tab as the Time Field, along with the chosen prefix/suffix. By default the prefix is \$TI_.
- The fields specified on the Fields tab as the Dimension fields.
- The fields specified on the Fields tab as the Fields to aggregate.

A number of extra fields can also be generated, depending on the selected interval or period (such as the minute or second within which a measurement falls).

- [Time Interval - field options](#)
 - [Time Interval - build options](#)
-

Time Interval - field options

Use the Fields tab in the Time Intervals node to select the data from which the new time interval is derived.

Fields Displays all of the input fields to the node with their measurement type icons. All time fields have the ‘continuous’ measurement type. Select the field to be used as the input.

Time Field Shows the input field from which the new time interval is derived; only a single continuous field is allowed. The field is used by the Time Intervals node as the aggregation key for converting the interval. The new field has the same storage type as the input time field chosen. If you select an integer field, it is considered to be a time index.

Dimensions fields Optionally, you can add fields here to create an individual time series that is based on the field values. As a simple example, with geospatial data, you can use a point field as a dimension. In this example, the data output from the Time Intervals node is sorted into time series for each point value in the point field.

Dimensions are ideal when you use flattened multi-dimensional data, similar to that generated by the TM1 node, or for supporting more complex data types like geospatial. Essentially, you can consider the use of the Dimensions fields as the equivalent of a **Group By** clause in a SQL query , or similar to Key fields in the Aggregate node; however, the Dimensions fields is more sophisticated in nature due to its ability to handle more complicated data structures than just traditional row and column data.

Fields to aggregate Select the fields to be aggregated as part of changing the period of the time field. Only the fields that you select here are available on the Build tab for the Custom settings for specified fields table. Any fields not included are filtered out of the data that leaves the node. This means that any fields remaining in the Fields list are filtered out of the data.

Related information

 - [Time Intervals Node](#)
 - [Time Interval - build options](#)
-

Time Interval - build options

Use the Build tab to specify options for changing the time interval and how fields in the data are aggregated, based on their measurement type.

When you aggregate data, any existing date, time, or timestamp fields are superseded by the generated fields and are dropped from the output. Other fields are aggregated based on the options you specify in this tab.

Time Interval Select the interval and periodicity for building the series.

For more information, see [Supported Intervals](#).

Default settings Select the default aggregation to be applied to data of different types. The default is applied based on the measurement level; for example, continuous fields are aggregated by the sum, while nominal fields use the mode. You can set the default for 3 different measurement levels:

- **Continuous** Available functions for continuous fields include Sum, Mean, Min, Max, Median, 1st Quartile, and 3rd Quartile.
- **Nominal** Options include Mode, Min, and Max.
- **Flag** Options are either True if any true or False if any false.

Custom settings for specified fields You can specify exceptions to the default aggregation settings for individual fields. Use the icons on the right to add or remove fields from the table, or click the cell in the appropriate column to change the aggregation function for that field. Typeless fields are excluded from the list and cannot be added to the table.

New field name extension Specify the Prefix or Suffix applied to all fields generated by the node.

Reprojection Node

With geospatial or map data, two of the most common ways that are used to identify coordinates are projected coordinate and geographic coordinate systems. Within IBM® SPSS® Modeler, items such as the Expression Builder spatial functions, the Spatio-Temporal Prediction (STP) Node, and the Map Visualization Node use the projected coordinate system and therefore any data that you import that is recorded with a geographic coordinate system must be reprojected. Where possible, geospatial fields (any fields with a geospatial measurement level) are automatically reprojected when used (not when they are imported). Where any fields cannot be reprojected automatically you use the Reproject node to change their coordinate system. Reprojecting in this way means that you can correct situations where an error occurs due to use of an incorrect coordinate system.

Example situations where you might have to reproject to change the coordinate system are shown in the following list:

- **Append** If you try to append two data sets with different coordinate systems for a geospatial field SPSS Modeler displays the following error message: Coordinate systems of <Field1> and <Field2> are not compatible. Reproject one or both fields to the same coordinate system.

<Field1> and <Field2> are the names of the geospatial fields that caused the error.
- **If/else expression** If you use an expression that contains an if/else statement with geospatial fields or return types in both parts of the expression, but with different coordinate systems, SPSS Modeler displays the following error message: The conditional expression contains incompatible coordinate systems: <arg1> and <arg2>.

<arg1> and <arg2> are the then or else arguments that return a geospatial type with different coordinate systems.

- *Constructing a list of geospatial fields* To create a list field that consists of numerous geospatial fields, all geospatial field arguments that are supplied to the list expression must be in the same coordinate system. If they are not, then the following error message is displayed: Coordinate systems of <Field1> and <Field2> are not compatible. Reproject one or both fields to the same coordinate system.

For more information about coordinate systems, see [Setting geospatial options for streams](#).

- [Setting options for the Reproject node](#)

Setting options for the Reproject node

Fields

Geo fields

By default this list is empty. You can move geospatial fields into this list from the Fields to be reprojected list to ensure that those fields are not reprojected.

Fields to be reprojected

By default this list contains all geospatial fields that are input to this node. All fields in this list are reprojected to the coordinate system that you set in the Coordinate System area.

Coordinate System

Stream default

Select this option to use the default coordinate system.

Specify

If you select this option you can use the Change button to display the Select Coordinate System dialog box and choose the coordinate system to be used for reprojection.

For more information about coordinate systems, see [Setting geospatial options for streams](#).

Common Graph Nodes Features

Several phases of the data mining process use graphs and charts to explore data brought into IBM® SPSS® Modeler. For example, you can connect a Plot or Distribution node to a data source to gain insight into data types and distributions. You can then perform record and field

manipulations to prepare the data for downstream modeling operations. Another common use of graphs is to check the distribution and relationships between newly derived fields.

The Graphs palette contains the following nodes:

	The Graphboard node offers many different types of graphs in one single node. Using this node, you can choose the data fields you want to explore and then select a graph from those available for the selected data. The node automatically filters out any graph types that would not work with the field choices.
	The Plot node shows the relationship between numeric fields. You can create a plot by using points (a scatterplot) or lines.
	The Distribution node shows the occurrence of symbolic (categorical) values, such as mortgage type or gender. Typically, you might use the Distribution node to show imbalances in the data, which you could then rectify using a Balance node before creating a model.
	The Histogram node shows the occurrence of values for numeric fields. It is often used to explore the data before manipulations and model building. Similar to the Distribution node, the Histogram node frequently reveals imbalances in the data.
	The Collection node shows the distribution of values for one numeric field relative to the values of another. (It creates graphs that are similar to histograms.) It is useful for illustrating a variable or field whose values change over time. Using 3-D graphing, you can also include a symbolic axis displaying distributions by category.
	The Multiplot node creates a plot that displays multiple Y fields over a single X field. The Y fields are plotted as colored lines; each is equivalent to a Plot node with Style set to Line and X Mode set to Sort. Multiplots are useful when you want to explore the fluctuation of several variables over time.
	The Web node illustrates the strength of the relationship between values of two or more symbolic (categorical) fields. The graph uses lines of various widths to indicate connection strength. You might use a Web node, for example, to explore the relationship between the purchase of a set of items at an e-commerce site.
	The Time Plot node displays one or more sets of time series data. Typically, you would first use a Time Intervals node to create a <i>TimeLabel</i> field, which would be used to label the x axis.
	The Evaluation node helps to evaluate and compare predictive models. The evaluation chart shows how well models predict particular outcomes. It sorts records based on the predicted value and confidence of the prediction. It splits the records into groups of equal size (quantiles) and then plots the value of the business criterion for each quantile from highest to lowest. Multiple models are shown as separate lines in the plot.
	The Map Visualization node can accept multiple input connections and display geospatial data on a map as a series of layers. Each layer is a single geospatial field; for example, the base layer might be a map of a country, then above that you might have one layer for roads, one layer for rivers, and one layer for towns.
	The E-Plot (Beta) node shows the relationship between numeric fields. It is similar to the Plot node, but its options differ and its output uses a new graphing interface specific to this node. Use the beta-level node to play around with new graphing features.
	t-Distributed Stochastic Neighbor Embedding (t-SNE) is a tool for visualizing high-dimensional data. It converts affinities of data points to probabilities. This t-SNE node in SPSS Modeler is implemented in Python and requires the scikit-learn ® Python library.

When you have added a graph node to a stream, you can double-click the node to open a dialog box for specifying options. Most graphs contain a number of unique options presented on one or more tabs. There are also several tab options common to all graphs. The following topics contain more information about these common options.

When you have configured the options for a graph node, you can run it from within the dialog box or as part of a stream. In the generated graph window, you can generate Derive (Set and Flag) and Select nodes based on a selection or region of data, effectively "subsetting" the data. For example, you might use this powerful feature to identify and exclude outliers.

- [Aesthetics, Overlays, Panels, and Animation](#)
- [Using the Output Tab](#)
- [Using the Annotations Tab](#)
- [3-D Graphs](#)

Aesthetics, Overlays, Panels, and Animation

Overlays and Aesthetics

Aesthetics (and overlays) add dimensionality to a visualization. The effect of an aesthetic (grouping, clustering, or stacking) depends on the visualization type, the type of field (variable), and the graphic element type and statistic. For example, a categorical field for color may be used to group points in a scatterplot or to create the stacks in a stacked bar chart. A continuous numeric range for color may also be used to indicate the range's values for each point in a scatterplot.

You should experiment with the aesthetics and overlays to find one that fulfills your needs. The following descriptions may help you pick the right one.

Note: Not all aesthetics or overlays are available for all visualization types.

- **Color.** When color is defined by a categorical field, it splits the visualization based on the individual categories, one color for each category. When color is a continuous numeric range, it varies the color based on the value of the range field. If the graphic element (for example, a bar or box) represents more than one record/case and a range field is used for color, the color varies based on the *mean* of the range field.
- **Shape.** Shape is defined by a categorical field that splits the visualization into elements of different shapes, one for each category.
- **Transparency.** When transparency is defined by a categorical field, it splits the visualization based on the individual categories, one transparency level for each category. When transparency is a continuous numeric range, it varies the transparency based on the value of the range field. If the graphic element (for example, a bar or box) represents more than one record/case and a range field is used for transparency, the color varies based on the *mean* of the range field. At the largest value, the graphic elements are fully transparent. At the smallest value, they are fully opaque.
- **Data Label.** Data labels are defined by any type of field whose values are used to create labels that are attached to the graphic elements.
- **Size.** When size is defined by a categorical field, it splits the visualization based on the individual categories, one size for each category. When size is a continuous numeric range, it varies the size based on the value of the range field. If the graphic element (for example, a bar or box) represents more than one record/case and a range field is used for size, the size varies based on the *mean* of the range field.

Paneling and Animation

Paneling. Paneling, also known as faceting, creates a table of graphs. One graph is generated for each category in the paneling fields, but all panels appear simultaneously. Paneling is useful for checking whether the visualization is subject to the conditions of the paneling fields. For example, you may panel a histogram by gender to determine whether the frequency distributions are equal across males and females. That is, you can check whether salary is subject to gender differences. Select a categorical field for paneling.

Animation. Animation resembles paneling in that multiple graphs are created from the values of the animation field, but these graphs are not shown together. Rather, you use the controls in Explore mode to animate the output and flip through a sequence of individual graphs. Furthermore, unlike paneling, animation does not require a categorical field. You can specify a continuous field whose values are split up into ranges automatically. You can vary the size of the range with the animation controls in explore mode. Not all visualizations offer animation.

 - [Using the Annotations Tab](#)
 - [3-D Graphs](#)
-

Using the Output Tab

For all graph types, you can specify the following options for the filename and display of generated graphs.

Note: Distribution node graphs have additional settings.

Output name. Specifies the name of the graph produced when the node is run. Auto chooses a name based on the node that generates the output. Optionally, you can select Custom to specify a different name.

Output to screen. Select to generate and display the graph in a new window.

Output to file. Select to save the output as a file.

- Output Graph. Select to produce output in a graph format. Available only in Distribution nodes.
- Output Table. Select to produce output in a table format. Available only in Distribution nodes.
- Filename. Specify a filename used for the generated graph or table. Use the ellipsis button (...) to specify a specific file and location.
- File type. Specify the file type in the drop-down list. For all graph nodes, except the Distribution node with an Output Table option, the available graph file types are as follows.
 - Bitmap (.bmp)
 - PNG (.png)
 - Output object (.cou)
 - JPEG (.jpg)
 - HTML (.html)
 - ViZml document (.xml) for use in other IBM® SPSS® Statistics applications.

For the Output Table option in the Distribution node, the available file types are as follows.

- Tab delimited data (.tab)
- Comma delimited data (.csv)
- HTML (.html)
- Output object (.cou)

Paginate output. When saving output as HTML, this option is enabled to enable you to control the size of each HTML page. (Applies only to the Distribution node.)

Lines per page. When Paginate output is selected, this option is enabled to enable you to determine the length of each HTML page. The default setting is 400 rows. (Applies only to the Distribution node.)

Using the Annotations Tab

Used for all nodes, this tab offers options to rename nodes, supply a custom ToolTip, and store a lengthy annotation.

3-D Graphs

Plots and collection graphs in IBM® SPSS® Modeler have the ability to display information on a third axis. This provides you with additional flexibility in visualizing your data to select subsets or deriving new fields for modeling.

Once you have created a 3-D graph, you can click on it and drag your mouse to rotate it and view it from any angle.

Figure 1. Collection graph with x, y, and z axes

There are two ways of creating 3-D graphs in IBM SPSS Modeler: plotting information on a third axis (true 3-D graphs) and displaying graphs with 3-D effects. Both methods are available for plots and collections.

To Plot Information on a Third Axis

1. In the graph node dialog box, click the Plot tab.
2. Click the 3-D button to enable options for the z axis.
3. Use the Field Chooser button to select a field for the z axis. In some cases, only symbolic fields are allowed here. The Field Chooser will display the appropriate fields.

To Add 3-D Effects to a Graph

1. Once you have created a graph, click the Graph tab in the output window.
2. Click the 3-D button to switch the view to a three-dimensional graph.

Graphboard node

The Graphboard node enables you to choose from many different graphs outputs (bar charts, pie charts, histograms, scatterplots, heatmaps, etc.) in one single node. You begin, in the first tab, by choosing the data fields you want to explore, and then the node presents you with a choice of graph types that work for your data. The node automatically filters out any graph types that would not work with the field choices. You can define detailed, or more advanced graph options in the Detailed tab.

Note: You must connect the Graphboard node to a stream with data in order to edit the node or select graph types.

There are two buttons that enable you to control which visualization templates (and stylesheets, and maps) are available:

Manage. Manage visualization templates, stylesheets, and maps on your computer. You can import, export, rename, and delete visualization templates, stylesheets, and maps on your local machine. See the topic [Managing Templates, Stylesheets, and Map Files](#) for more information.

Location. Change the location in which visualization templates, stylesheets, and maps are stored. The current location is listed to the right of the button. See the topic [Setting the Location of Templates, Stylesheets, and Maps](#) for more information.

 - [Graphboard Examples](#)
 - [Graphboard appearance tab](#)
 - [Setting the Location of Templates, Stylesheets, and Maps](#)
 - [Managing Templates, Stylesheets, and Map Files](#)
-

Graphboard Basic Tab

If you aren't sure which visualization type would best represent your data, use the Basic tab. When you select your data, you are then presented with a subset of visualization types that are appropriate for the data. For examples, see [Graphboard Examples](#).

1. Select one or more fields (variables) from the list. Use Ctrl+Click to select multiple fields.
Note that the measurement level of the field determines the type of visualizations that are available. You can change the measurement level by right-clicking the field in the list and choosing an option. For more information about the available measurement level types, see [Field \(Variable\) Types](#).
2. Select a visualization type. For descriptions of the available types, see [Available Built-in Graphboard Visualization Types](#).
3. For certain visualizations, you can choose a summary statistic. Different subsets of statistics are available depending on whether the statistic is count-based or calculated from a continuous field. The available statistics also depend on the template itself. A full list of statistics that may be available follows the next step.
4. If you want to define more options, such as optional aesthetics and panel fields, click Detailed. See the topic [Graphboard Detailed Tab](#) for more information.

Summary Statistics Calculated from a Continuous Field

- **Mean.** A measure of central tendency. The arithmetic average, the sum divided by the number of cases.
- **Median.** The value above and below which half of the cases fall, the 50th percentile. If there is an even number of cases, the median is the average of the two middle cases when they are sorted in ascending or descending order. The median is a measure of central tendency not sensitive to outlying values (unlike the mean, which can be affected by a few extremely high or low values).
- **Mode.** The most frequently occurring value. If several values share the greatest frequency of occurrence, each of them is a mode.
- **Minimum.** The smallest value of a numeric variable.
- **Maximum.** The largest value of a numeric variable.
- **Range.** The difference between the minimum and maximum values.
- **Mid Range.** The middle of the range, that is, the value whose difference from the minimum is equal to its difference from the maximum.

- **Sum.** The sum or total of the values, across all cases with nonmissing values.
- **Cumulative Sum.** The cumulative sum of the values. Each graphic element shows the sum for one subgroup plus the total sum of all previous groups.
- **Percent Sum.** The percentage within each subgroup based on a summed field compared to the sum across all groups.
- **Cumulative Percent Sum.** The cumulative percentage within each subgroup based on a summed field compared to the sum across all groups. Each graphic element shows the percentage for one subgroup plus the total percentage of all previous groups.
- **Variance.** A measure of dispersion around the mean, equal to the sum of squared deviations from the mean divided by one less than the number of cases. The variance is measured in units that are the square of those of the variable itself.
- **Standard Deviation.** A measure of dispersion around the mean. In a normal distribution, 68% of cases fall within one standard deviation of the mean and 95% of cases fall within two standard deviations. For example, if the mean age is 45, with a standard deviation of 10, 95% of the cases would be between 25 and 65 in a normal distribution.
- **Standard Error.** A measure of how much the value of a test statistic varies from sample to sample. It is the standard deviation of the sampling distribution for a statistic. For example, the standard error of the mean is the standard deviation of the sample means.
- **Kurtosis.** A measure of the extent to which there are outliers. For a normal distribution, the value of the kurtosis statistic is zero. Positive kurtosis indicates that the data exhibit more extreme outliers than a normal distribution. Negative kurtosis indicates that the data exhibit less extreme outliers than a normal distribution.
- **Skewness.** A measure of the asymmetry of a distribution. The normal distribution is symmetric and has a skewness value of 0. A distribution with a significant positive skewness has a long right tail. A distribution with a significant negative skewness has a long left tail. As a guideline, a skewness value more than twice its standard error is taken to indicate a departure from symmetry.

The following region statistics may result in more than one graphic element per subgroup. When using the interval, area, or edge graphic elements, a region statistic results in one graphic element showing the range. All other graphic elements result in two separate elements, one showing the start of the range and one showing the end of the range.

- **Region: Range.** The range of values between the minimum and maximum values.
- **Region: 95% Confidence Interval of Mean.** A range of values that has a 95% chance of including the population mean.
- **Region: 95% Confidence Interval of Individual.** A range of values that has a 95% chance of including the predicted value given the individual case.
- **Region: 1 Standard Deviation above/below Mean.** A range of values between 1 standard deviation above and below the mean.
- **Region: 1 Standard Error above/below Mean.** A range of values between 1 standard error above and below the mean.

Count-Based Summary Statistics

- **Count.** The number of rows/cases.
- **Cumulative Count.** The cumulative number of rows/cases. Each graphic element shows the count for one subgroup plus the total count of all previous groups.
- **Percent of Count.** The percentage of rows/cases in each subgroup compared to the total number of rows/cases.
- **Cumulative Percent of Count.** The cumulative percentage of rows/cases in each subgroup compared to the total number of rows/cases. Each graphic element shows the percentage for one subgroup plus the total percentage of all previous groups.

Field (Variable) Types

Icons appear next to fields in field lists to indicate the field type and data type. Icons also identify multiple response sets.

Table 1. Measurement level icons

Measurement Level	Numeric	String	Date	Time
Continuous		n/a		
Ordered Set				
Set				

Table 2. Multiple response set icons

Multiple response set type	Icon
Multiple response set, multiple categories	
Multiple response set, multiple dichotomies	

Measurement Level

A field's measurement level is important when you create a visualization. Following is a description of the measurement levels. You can temporarily change the measurement level by right-clicking a field in a field list and choosing an option. In most cases, you need to consider only the two broadest classifications of fields, categorical and continuous:

Categorical. Data with a limited number of distinct values or categories (for example, gender or religion). Categorical fields can be string (alphanumeric) or numeric fields that use numeric codes to represent categories (for example, 0 = *male* and 1 = *female*). Also referred to as qualitative data. Sets, ordered sets, and flags are all categorical fields.

- **Set.** A field/variable whose values represent categories with no intrinsic ranking (for example, the department of the company in which an employee works). Examples of nominal variables include region, zip code, and religious affiliation. Also known as a nominal variable.
- **Ordered Set.** A field/variable whose values represent categories with some intrinsic ranking (for example, levels of service satisfaction from highly dissatisfied to highly satisfied). Examples of ordered sets include attitude scores representing degree of satisfaction or confidence and preference rating scores. Also known as an ordinal variable.
- **Flag.** A field/variable with two distinct values, such as Yes and No or 1 and 2. Also known as a dichotomous or binary variable.

Continuous. Data measured on an interval or ratio scale, where the data values indicate both the order of values and the distance between values. For example, a salary of \$72,195 is higher than a salary of \$52,398, and the distance between the two values is \$19,797. Also referred to as quantitative, scale, or numeric range data.

Categorical fields define categories in the visualization, typically to draw separate graphic elements or to group graphic elements. Continuous fields are often summarized within categories of categorical fields. For example, a default visualization of income for gender categories would display the mean income for males and the mean income for females. The raw values for continuous fields can also be plotted, as in a scatterplot. For example, a scatterplot may show the current salary and beginning salary for each case. A categorical field could be used to group the cases by gender.

Data Types

Measurement level isn't the only property of a field that determines its type. A field is also stored as a specific data type. Possible data types are strings (non-numeric data such as letters), numeric values (real numbers), and dates. Unlike the measurement level, a field's data type cannot be changed temporarily. You must change the way the data are stored in the original data set.

Multiple Response Sets

Some data files support a special kind of "field" called a **multiple response set**. Multiple response sets aren't really "fields" in the normal sense. Multiple response sets use multiple fields to record responses to questions where the respondent can give more than one answer. Multiple response sets are treated like categorical fields, and most of the things you can do with categorical fields, you can also do with multiple response sets.

Multiple response sets can be multiple dichotomy sets or multiple category sets.

Multiple dichotomy sets. A multiple dichotomy set typically consists of multiple dichotomous fields: fields with only two possible values of a yes/no, present/absent, checked/not checked nature. Although the fields may not be strictly dichotomous, all of the fields in the set are coded the same way.

For example, a survey provides five possible responses to the question, "Which of the following sources do you rely on for news?" The respondent can indicate multiple choices by checking a box next to each choice. The five responses become five fields in the data file, coded 0 for No (not checked) and 1 for Yes (checked).

Multiple category sets. A multiple category set consists of multiple fields, all coded the same way, often with many possible response categories. For example, a survey item states, "Name up to three nationalities that best describe your ethnic heritage." There may be hundreds of possible responses, but for coding purposes the list is limited to the 40 most common nationalities, with everything else relegated to an "other" category. In the data file, the three choices become three fields, each with 41 categories (40 coded nationalities and one "other" category).

Graphboard Detailed Tab

Use the Detailed tab when you know what type of visualization you want to create or when you want to add optional aesthetics, panels, and/or animation to a visualization. For examples, see [Graphboard Examples](#).

1. If you selected a visualization type on the Basic tab, it will be displayed. Otherwise, choose one from the drop-down list. For information about the visualization types, see [Available Built-in Graphboard Visualization Types](#).
2. To the immediate right of the visualization's thumbnail image are controls for specifying the fields (variables) required for the visualization type. You must specify all of these fields.

3. For certain visualizations, you can select a summary statistic. In some cases (such as with bar charts), you can use one of these summary options for the transparency aesthetic. For descriptions of the summary statistics, see [Graphboard Basic Tab](#).
4. You can select one or more of the optional aesthetics. These can add dimensionality by allowing you to include other fields in the visualization. For example, you may use a field to vary the size of points in a scatterplot. For more information about optional aesthetics, see [Aesthetics, Overlays, Panels, and Animation](#). Please note that the transparency aesthetic is not supported through scripting.
5. If you are creating a map visualization, the Map Files group shows the map file or files that will be used. If there is a default map file, this file is displayed. To change the map file, click Select a Map File to display the Select Maps dialog box. You can also specify the default map file in this dialog box. See the topic [Selecting map files for map visualizations](#) for more information.
6. You can select one or more of the paneling or animation options. For more information about paneling and animation options, see [Aesthetics, Overlays, Panels, and Animation](#).

- [Selecting map files for map visualizations](#)

Related information

- [Graphboard node](#)

-

Selecting map files for map visualizations

If you select a map visualization template, you need a map file that defines the geographic information for drawing the map. If there is a default map file, this will be used for the map visualization. To choose a different map file, click Select a Map File on the Detailed tab to display the Select Maps dialog box.

The Select Maps dialog box allows you to choose a primary map file and a reference map file. The map files define the geographic information for drawing the map. Your application is installed with a set of standard map files. If you have other ESRI shapefiles that you want to use, you first need to convert the shapefiles to SMZ files. See the topic [Converting and Distributing Map Shapefiles](#) for more information. After converting the map, click Manage... on the Template Chooser dialog box to import the map into the Manage system so that it is available in the Select Maps dialog box.

Following are some points to consider when specifying map files:

- All map templates require at least one map file.
- The map file typically links a map key attribute to the data key.
- If the template does not require a map key that links to a data key, it requires a reference map file and fields that specify coordinates (such as longitude and latitude) for drawing elements on the reference map.
- Overlay map templates require two maps: a primary map file and a reference map file. The reference map is drawn first so that it is behind the primary map file.

For information about map terminology such as attributes and features, see [Key Concepts for Maps](#).

Map File. You can select any map file that is in the Manage system. These include pre-installed map files and map files that you imported. For more information about managing map files, see [Managing Templates, Stylesheets, and Map Files](#).

Map Key. Specify the attribute that you want to use as the key that links the map file to the data key.

Save this map file and settings as the default. Select this checkbox if you want to use the selected map file as the default. If you have specified a default map file, you don't need to specify a map file every time you create a map visualization.

Data Key. This control lists the same value as appears on the Template Chooser Detailed tab. It is provided here for convenience if you need to change the key because of the specific map file that you choose.

Display all map features in the visualization. When this option is checked, all features in the map are rendered in the visualization, even if there is no matching data key value. If you want to see only the features for which you have data, clear this option. Features identified by the map keys shown in the Unmatched Map Keys list will not be rendered in the visualization.

Compare Map and Data Values. The map key and data key link to each other to create the map visualization. The map key and the data key should draw from the same domain (for example, countries and regions). Click Compare to test whether the data key and map key values match. The displayed icon informs you of the state of the comparison. These icons are described below. If a comparison has been performed and there are data key values with no matching map key values, the data key values appear in the Unmatched Data Keys list. In the Unmatched Map Keys list, you can also see which map key values have no matching data key values. If Display all map features in the visualization is not checked, features identified by these map key values will not be rendered.

Table 1. Comparison icons

Icon	Description
	No comparison has been performed. This is the default state before you click Compare. You should proceed with caution because you don't know if the data key and map key values match.
	A comparison has been performed, and the data key and map key values match completely. For every value of the data key, there is a matching feature identified by the map key.
	A comparison has been performed, and some data key and map key values do not match. For some data key values, there is no matching feature identified by the map key. You should proceed with caution. If you proceed, the map visualization will not include all data values.
	A comparison has been performed, and no data key and map key values match. You should choose a different data key or map key because no map will be rendered if you proceed.

Available Built-in Graphboard Visualization Types

You can create several different visualization types. All of the following built-in types are available on both the Basic and Detailed tabs. Some of the descriptions for the templates (especially the map templates) identify the fields (variables) specified on the Detailed tab using special text.

Table 1. Available graph types

Chart icon	Description	Chart icon	Description
	Bar Calculates a summary statistic for a continuous numeric field and displays the results for each category of a categorical field as bars. <i>Requires:</i> A categorical field and a continuous field.		Bar of Counts Displays the proportion of rows/cases in each category of a categorical field as bars. You can also use the Distribution graph node to produce this graph. That node offers some additional options. See the topic Distribution Node for more information. <i>Requires:</i> A single categorical field.
	Pie Calculates the sum of a continuous numeric field and displays the proportion of that sum distributed in each category of a categorical field as slices of a pie. <i>Requires:</i> A categorical field and a continuous field.		Pie of Counts Displays the proportion of rows/cases in each category of a categorical field as slices of a pie. <i>Requires:</i> A single categorical field.
	3-D Bar Calculates a summary statistic for a continuous numeric field and displays the results for the crossing of categories between two categorical fields. <i>Requires:</i> A pair of categorical fields and a continuous field.		3-D Pie This is the same as Pie except with an additional 3-D effect. <i>Requires:</i> A categorical field and a continuous field.
	Line Calculates a summary statistic for a field for each value of another field and draws a line connecting the values. You can also use the Plot graph node to produce a line plot graph. That node offers some additional options. See the topic Plot Node for more information. <i>Requires:</i> A pair of fields of any type.		Area Calculates a summary statistic for a field for each value of another field and draws an area connecting the values. The difference between a line and area is minimal in that an area resembles a line with the space colored below it. However, if you use a color aesthetic, this results in a simple split of the line and a stacking of the area. <i>Requires:</i> A pair of fields of any type.
	3-D Area Displays the values of one field plotted against the values of another and split by a categorical field. An area element is drawn for each category. <i>Requires:</i> A categorical field and a pair of fields of any type.		Path Displays the values of one field plotted against the values of another, with a line connecting the values in the order they appear in the original dataset. The ordering is the primary difference between a path and a line. <i>Requires:</i> A pair of fields of any type.
	Ribbon Calculates a summary statistic for a field for each value of another field and draws a ribbon connecting the values. A ribbon is essentially a line with 3-D effects. It is not a true 3-D graph. <i>Requires:</i> A pair of fields of any type.		Surface Displays the values of three fields plotted against the values of one another, with a surface connecting the values. <i>Requires:</i> Three fields of any type.

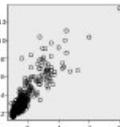

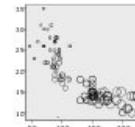

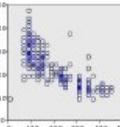

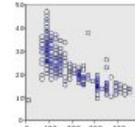

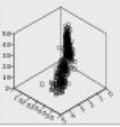

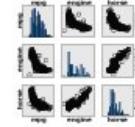

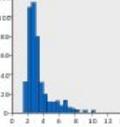

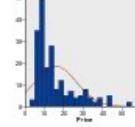

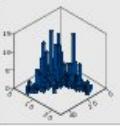

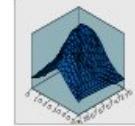

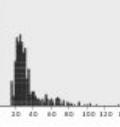

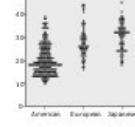

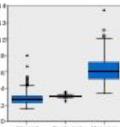

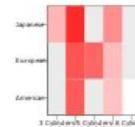

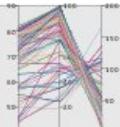

Chart icon	Description	Chart icon	Description
	<p>Scatterplot Displays the values of one field plotted against the values of another. This graph can highlight the relationship between the fields (if there is one). You can also use the Plot graph node to produce a scatterplot. That node offers some additional options. See the topic Plot Node for more information.</p> <p>Requires: A pair of fields of any type.</p>		<p>Bubble plot Like a basic scatterplot, displays the values of one field plotted against the values of another. The difference is that the values of a third field are used to vary the size of the individual points.</p> <p>Requires: Three fields of any type.</p>
	<p>Binned Scatterplot Like a basic scatterplot, displays the values of one field plotted against the values of another. The difference is that similar values are binned into groups and that the color or size aesthetic is used to indicate the number of cases in each bin.</p> <p>Requires : A pair of continuous fields.</p>		<p>Hex Binned Scatterplot See the description of Binned Scatterplot. The difference is the shape of the underlying bins, which are shaped like hexagons rather than circles. The resulting hex binned scatterplot looks similar to the binned scatterplot. However, the number of values in each bin will differ between the graphs because of the shape of the underlying bins.</p> <p>Requires: A pair of continuous fields.</p>
	<p>3-D Scatterplot Displays the values of three fields plotted against each other. This graph can highlight the relationship between the fields (if there is one). You can also use the Plot graph node to produce a 3-D scatterplot. That node offers some additional options. See the topic Plot Node for more information.</p> <p>Requires: Three fields of any type.</p>		<p>Scatterplot Matrix (SPLOM) Displays the values of one field plotted against the values of another for every field. A SPLOM is like a table of scatterplots. The SPLOM also includes a histogram of each field.</p> <p>Requires: Two or more continuous fields.</p>
	<p>Histogram Displays the frequency distribution of a field. A histogram can help you determine the distribution type and see whether the distribution is skewed. You can also use the Histogram graph node to produce this graph. That node offers some additional options. See the topic Histogram Plot Tab for more information.</p> <p>Requires: A single field of any type.</p>		<p>Histogram with Normal Distribution Displays the frequency distribution of a continuous field with a superimposed curve of the normal distribution.</p> <p>Requires: A single continuous field.</p>
	<p>3-D Histogram Displays the frequency distribution of a pair of continuous fields.</p> <p>Requires : A pair of continuous fields.</p>		<p>3-D Density Displays the frequency distribution of a pair of continuous fields. This is similar to a 3-D histogram, with the only difference being that a surface is used instead of bars to show the distribution.</p> <p>Requires: A pair of continuous fields.</p>
	<p>Dot plot Displays the individual cases/rows and stacks them at the distinct data points on the x axis. This graph is similar to a histogram in that it shows the distribution of the data, but it displays each case/row rather than an aggregated count for a specific bin (range of values).</p> <p>Requires : A single field of any type.</p>		<p>2-D Dot Plot Displays the individual cases/rows and stacks them at the distinct data points on the y axis for each category of a categorical field.</p> <p>Requires: A categorical field and a continuous field.</p>
	<p>Boxplot Calculates the five statistics (minimum, first quartile, median, third quartile, and maximum) for a continuous field for each category of a categorical field. The results are displayed as boxplot/schema elements. The boxplots can help you see how the distribution of continuous data varies among the categories.</p> <p>Requires: A categorical field and a continuous field.</p>		<p>Heat map Calculates the mean for a continuous field for the crossing of categories between two categorical fields.</p> <p>Requires : A pair of categorical fields and a continuous field.</p>
	<p>Parallel Creates parallel axes for each field and draws a line through the field value for every row/case in the data.</p> <p>Requires: Two or more continuous fields.</p>		<p>Choropleth of Counts Calculates the count for each category of a categorical field (Data Key) and draws a map that uses color saturation to represent the counts in the map features that correspond to the categories.</p> <p>Requires : A categorical field. A map file whose key matches the Data Key categories.</p>

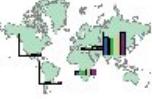

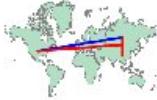

Chart icon	Description	Chart icon	Description
	Choropleth of Means/Medians/Sums Calculates the mean, median, or sum of a continuous field (Color) for each category of a categorical field (Data Key) and draws a map that uses color saturation to represent the calculated statistics in the map features that correspond to the categories. <i>Requires:</i> A categorical field and a continuous field. A map file whose key matches the Data Key categories.		Choropleth of Values Draws a map that uses color to represent values of a categorical field (Color) for the map features that correspond to values defined by another categorical field (Data Key). If there are multiple categorical values of the Color field for each feature, the modal value is used. <i>Requires:</i> A pair of categorical fields. A map file whose key matches the Data Key categories.
	Coordinates on a Choropleth of Counts This is similar to Choropleth of Counts except that there are two additional continuous fields (Longitude and Latitude) that identify coordinates for drawing points on the choropleth map. <i>Requires:</i> A categorical field and a pair of continuous fields. A map file whose key matches the Data Key categories.		Coordinates on a Choropleth of Means/Medians/Sums This is similar to Choropleth of Means/Medians/Sums except that there are two additional continuous fields (Longitude and Latitude) that identify coordinates for drawing points on the choropleth map. <i>Requires:</i> A categorical field and three continuous fields. A map file whose key matches the Data Key categories.
	Coordinates on a Choropleth of Values This is similar to Choropleth of Values except that there are two additional continuous fields (Longitude and Latitude) that identify coordinates for drawing points on the choropleth map. <i>Requires:</i> A pair of categorical fields and a pair of continuous fields. A map file whose key matches the Data Key categories.		Bars of Counts on a Map Calculates the proportion of rows/cases in each category of a categorical field (Categories) for each map feature (Data Key) and draws a map and the bar charts at the center of each map feature. <i>Requires:</i> A pair of categorical fields. A map file whose key matches the Data Key categories.
	Bars on a Map Calculates a summary statistic for a continuous field (Values) and displays the results for each category of a categorical field (Categories) for each map feature (Data Key) as bar charts positioned in the center of each map feature. <i>Requires:</i> A pair of categorical fields and a continuous field. A map file whose key matches the Data Key categories.		Pie of Counts of a Map Displays the proportion of rows/cases in each category of a categorical field (Categories) for each map feature (Data Key) and draws a map and the proportions as slices of a pie chart at the center of each map feature. <i>Requires:</i> A pair of categorical fields. A map file whose key matches the Data Key categories.
	Pie on a Map Calculates the sum of a continuous field (Values) in each category of a categorical field (Categories) for each map feature (Data Key) and draws a map and the sums as slices of a pie chart at the center of each map feature. <i>Requires:</i> A pair of categorical fields and a continuous field. A map file whose key matches the Data Key categories.		Line Chart on a Map Calculates a summary statistic for a continuous field (Y) for each value of another field (X) for each map feature (Data Key) and draws a map and line charts connecting the values at the center of each map feature. <i>Requires:</i> A categorical field and a pair of fields of any type. A map file whose key matches the Data Key categories.
	Coordinates on a Reference Map Draws a map and points using continuous fields (Longitude and Latitude) that identify coordinates for the points. <i>Requires:</i> A pair of range fields. A map file.		Arrows on a Reference Map Draws a map and arrows using continuous fields that identify the start points (Start Long and Start Lat) and end points (End Long and End Lat) for each arrow. Each record/case in the data results in an arrow in the map. <i>Requires:</i> Four continuous fields. A map file.
	Point Overlay Map Draws a reference map and superimposes another point map over it with point features colored by a categorical field (Color). <i>Requires:</i> A pair of categorical fields. A point map file whose key matches the Data Key categories. A reference map file.		Polygon Overlay Map Draws a reference map and superimposes another polygon map over it with polygon features colored by a categorical field (Color). <i>Requires:</i> A pair of categorical fields. A polygon map file whose key matches the Data Key categories. A reference map file.

Chart icon	Description	Chart icon	Description
	<p>Line Overlay Map Draws a reference map and superimposes another line map over it with line features colored by a categorical field (Color).</p> <p>Requires: A pair of categorical fields. A line map file whose key matches the Data Key categories. A reference map file.</p>

Creating Map Visualizations

For many visualizations, you have to make only two choices: fields (variables) of interest and a template to visualize those fields. No additional choices or actions are required. Map visualizations require at least one additional step: select a map file that defines the geographic information for the map visualization.

The basic steps for creating a simple map are the following:

1. Select the fields of interest on the Basic tab. For information about the type and number of fields required for different map visualizations, see [Available Built-in Graphboard Visualization Types](#).
2. Select a map template.
3. Click the Detailed tab.
4. Check that the Data Key and other required dropdown lists are set to the correct fields.
5. In the Map Files group, click Select a Map File.
6. Use the Select Maps dialog box to choose the map file and map key. The map key's values must match the values for of the field specified by Data Key. You can use the Compare button to compare these values. If you select an overlay map template, you will also need to choose a reference map. The reference map is not keyed to the data. It is used as the background for the main map. For more information about the Select Maps dialog box, see [Selecting map files for map visualizations](#).
7. Click OK to close the Select Maps dialog box.
8. In the Graphboard Template Chooser, click Run to create the map visualization.

Graphboard Examples

This section includes several different examples to demonstrate the available options. The examples also provide information for interpreting the resulting visualizations.

These examples use the stream named *graphboard.str*, which references the data files named *employee_data.sav*, *customer_subset.sav*, and *worldsales.sav*. These files are available from the *Demos* folder of any IBM® SPSS® Modeler Client installation. This can be accessed from the IBM SPSS Modeler program group on the Windows Start menu. The *graphboard.str* file is in the *streams* folder.

It is recommended that you read the examples in the order presented. Subsequent examples build on previous ones.

Example: Bar Chart with a Summary Statistic

We will create a bar chart that summarizes a continuous numeric field/variable for each category of a set/categorical variable. Specifically, we will create a bar chart that shows the mean salary for men and women.

This and several of the following examples use *Employee data*, which is a hypothetical dataset containing information about a company's employees.

1. Add a Statistics File source node that points to *employee_data.sav*.
2. Add a Graphboard node and open it for editing.
3. On the Basic tab, select *Gender* and *Current Salary*. (Use Ctrl+Click to select multiple fields/variables.)
4. Select Bar.
5. From the Summary drop-down list, select Mean.
6. Click Run.
7. On the resulting display, click the "Display field and value labels" toolbar button (the second of the group of two in the center of the toolbar).

Figure 1. Bar chart with a summary statistic

We can observe the following:

- Based on the height of the bars, it is clear that the mean salary for males is greater than the mean salary for females.

Related information

- [Example: Scatterplot Matrix \(SPLOM\)](#)
- [Example: Choropleth \(Color Map\) of Sums](#)
- [Example: Bar Charts on a Map](#)

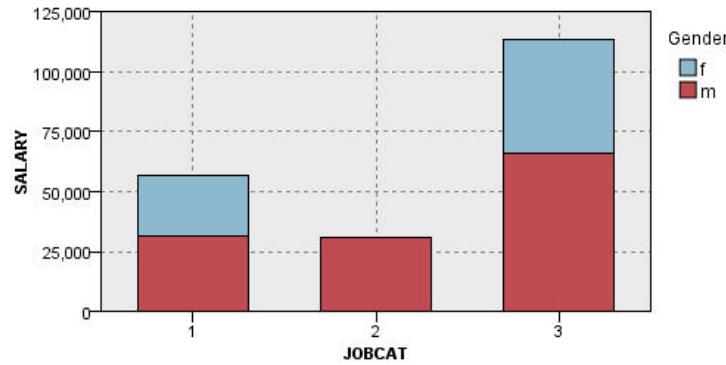

Example: Stacked Bar Chart with a Summary Statistic

We will now create a stacked bar chart to see whether the difference in mean salary between males and females is subject to job type. Perhaps females, on average, make more than males for certain job types.

Note: This example uses *Employee data*.

1. Add a Graphboard node and open it for editing.
2. On the Basic tab, select *Employment Category* and *Current Salary*. (Use Ctrl+Click to select multiple fields/variables.)
3. Select Bar.
4. From the Summary list, select Mean.
5. Click the Detailed tab. Note that your selections from the previous tab are reflected here.
6. In the Optional Aesthetics group, choose *gender* from the Color drop-down list.
7. Click Run.

Figure 1. Stacked bar chart

We can observe the following:

- The difference in mean salaries for each job type does not appear to be as great as it was in the bar chart that compared the mean salaries for all males and females. Perhaps there are varying number of males and females in each group. You could check this by creating a bar chart of counts.
- Regardless of job type, the mean salary for males is always greater than the mean salary for females.

- [Example: Heat Map](#)
- [Example: Scatterplot Matrix \(SPLOM\)](#)
- [Example: Choropleth \(Color Map\) of Sums](#)
- [Example: Bar Charts on a Map](#)

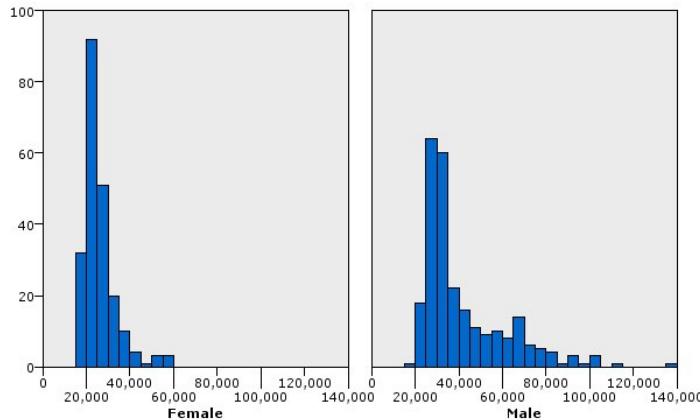

Example: Paneled Histogram

We will create a histogram that is paneled by gender so we can compare the frequency distributions of salary for men and women. The frequency distribution shows how many cases/rows lie within specific salary ranges. The paneled histogram can help us further analyze the difference in salaries between genders.

Note: This example uses *Employee data*.

1. Add a Graphboard node and open it for editing.
2. On the Basic tab, select *Current Salary*.
3. Select Histogram.
4. Click the Detailed tab.
5. In the Panels and Animation group, choose *gender* from the Panel Across drop-down list.
6. Click Run.

Figure 1. Paneled histogram

We can observe the following:

- Neither frequency distribution is a normal distribution. That is, the histograms do not resemble bell curves, as they would if the data were normally distributed.
- The taller bars are on the left side of each graph. Therefore, for both men and women, more make lower rather than higher salaries.
- The frequency distributions of salary among men and women are not equal. Notice the shape of the histograms. There are more men who make higher salaries than women who make higher salaries.

 - [Example: Heat Map](#)
 - [Example: Scatterplot Matrix \(SPLOM\)](#)
 - [Example: Choropleth \(Color Map\) of Sums](#)
 - [Example: Bar Charts on a Map](#)
-

Example: Paneled Dot Plot

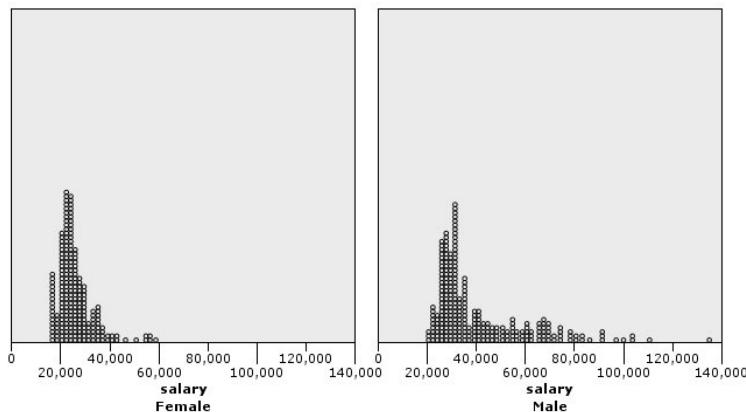

Like a histogram, a dot plot shows the distribution of a continuous numeric range. Unlike a histogram, which shows counts for binned ranges of data, a dot plot shows every row/case in the data. Therefore, a dot plot provides more granularity compared to the histogram. In fact, using a dot plot may be the preferred starting point when analyzing frequency distributions.

Note: This example uses *Employee data*.

1. Add a Graphboard node and open it for editing.
2. On the Basic tab, select *Current Salary*.
3. Select Dot Plot.
4. Click the Detailed tab.
5. In the Panels and Animation group, choose *gender* from the Panel Across drop-down list.
6. Click Run.

7. Maximize the resulting output window to view the plot more clearly.

Figure 1. Paneled dot plot

Compared to the histogram (see [Example: Paneled Histogram](#)), we can observe the following:

- The peak at 20,000 that appeared in the histogram for females is less dramatic in the dot plot. There are many cases/rows concentrated around that value, but most of those values are closer to 25,000. This level of granularity is not apparent in the histogram.
- Although the histogram for males suggests that the mean salary for males gradually declines after 40,000, the dot plot shows that the distribution is fairly uniform after that value, to 80,000. At any one salary value in that range, there are three or more males who earn that particular salary.

- [Example: Heat Map](#)
- [Example: Scatterplot Matrix \(SPLOM\)](#)
- [Example: Choropleth \(Color Map\) of Sums](#)
- [Example: Bar Charts on a Map](#)

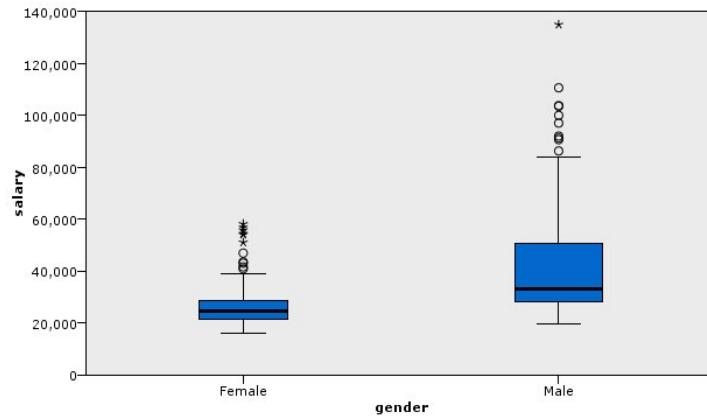

Example: Boxplot

A boxplot is another useful visualization for viewing how the data are distributed. A boxplot contains several statistical measures that we will explore after creating the visualization.

Note: This example uses *Employee data*.

1. Add a Graphboard node and open it for editing.
2. On the Basic tab, select *Gender* and *Current Salary*. (Use Ctrl+Click to select multiple fields/variables.)
3. Select Boxplot.
4. Click Run.

Figure 1. Boxplot

Let's explore the different parts of the boxplot:

- The dark line in the middle of the boxes is the median of *salary*. Half of the cases/rows have a value greater than the median, and half have a value lower. Like the mean, the median is a measure of central tendency. Unlike the mean, it is less influenced by cases/rows with extreme values. In this example, the median is lower than the mean (compare to [Example: Bar Chart with a Summary Statistic](#)). The difference between the mean and median indicates that there are a few cases/rows with extreme values that are elevating the mean. That is, there are a few employees who earn large salaries.
- The bottom of the box indicates the 25th percentile. Twenty-five percent of cases/rows have values below the 25th percentile. The top of the box represents the 75th percentile. Twenty-five percent of cases/rows have values above the 75th percentile. This means that 50% of the case/rows lie within the box. The box is much shorter for females than for males. This is one clue that *salary* varies less for females than for males. The top and bottom of the box are often called **hinges**.
- The T-bars that extend from the boxes are called **inner fences** or **whiskers**. These extend to 1.5 times the height of the box or, if no case/row has a value in that range, to the minimum or maximum values. If the data are distributed normally, approximately 95% of the data are expected to lie between the inner fences. In this example, the inner fences extend less for females compared to males, another indication that *salary* varies less for females than for males.
- The points are **outliers**. These are defined as values that do not fall in the inner fences. Outliers are extreme values. The asterisks or stars are **extreme outliers**. These represent cases/rows that have values more than three times the height of the boxes. There are several outliers for both females and males. Remember that the mean is greater than the median. The greater mean is caused by these outliers.

- [Example: Bar Charts on a Map](#)

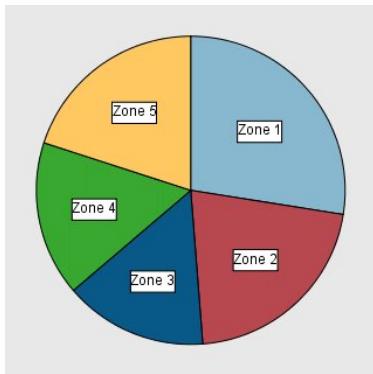

Example: Pie Chart

We will now use a different dataset to explore some other visualization types. The dataset is *customer_subset*, which is a hypothetical data file that contains information about customers.

We will first create a pie chart to check the proportion of customers in different geographic regions.

1. Add a Statistics File source node that points to *customer_subset.sav*.
2. Add a Graphboard node and open it for editing.
3. On the Basic tab, select *Geographic indicator*.
4. Select Pie of Counts.
5. Click Run.

Figure 1. Pie chart

We can observe the following:

- Zone 1 has more customers than in each of the other zones.
- Customers are equally distributed among the other zones.

 - [Example: Choropleth \(Color Map\) of Sums](#)
 - [Example: Bar Charts on a Map](#)
-

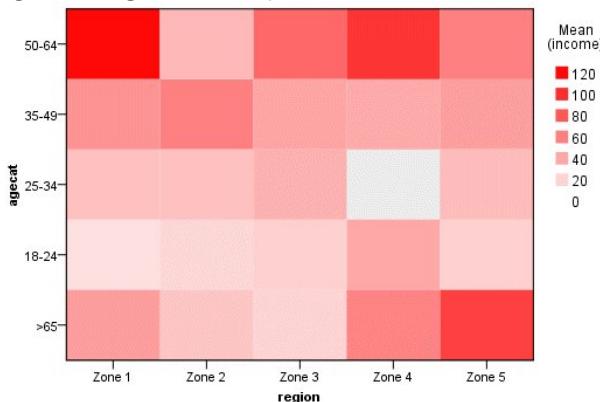

Example: Heat Map

We will now create a categorical heat map to check the mean income for customers in different geographic regions and age groups.

Note: This example uses *customer_subset*.

1. Add a Graphboard node and open it for editing.
2. On the Basic tab, select *Geographic indicator*, *Age category*, and *Household income in thousands*, in that order. (Use Ctrl+Click to select multiple fields/variables.)
3. Select Heat Map.
4. Click Run.
5. On the resulting output window, click the "Display field and value labels" toolbar button (the right-hand one of the two in the center of the toolbar).

Figure 1. Categorical heat map

We can observe the following:

- A heat map is like a table that uses colors instead of numbers to represent the values for the cells. Bright, deep red indicates the highest value, while gray indicates a low value. The value of each cell is the mean of the continuous field/variable for each pair of categories.

- Except in Zone 2 and Zone 5, the group of customers whose age is between 50 and 64 have a greater mean household income than those in other groups.
- There are no customers between the ages of 25 and 34 in Zone 4.

 - [Example: Pie Chart](#)
 - [Example: Scatterplot Matrix \(SPLOM\)](#)
 - [Example: Choropleth \(Color Map\) of Sums](#)
 - [Example: Bar Charts on a Map](#)
-

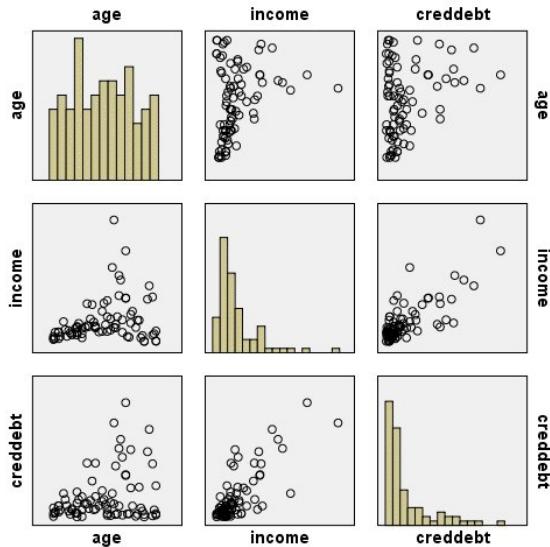

Example: Scatterplot Matrix (SPLOM)

We will create a scatterplot matrix of several different variables so that we can determine whether there are any relationships among the variables in the dataset.

Note: This example uses *customer_subset*.

1. Add a Graphboard node and open it for editing.
2. On the Basic tab, select *Age in years*, *Household income in thousands*, and *Credit card debt in thousands*. (Use Ctrl+Click to select multiple fields/variables.)
3. Select SPLOM.
4. Click Run.
5. Maximize the output window to view the matrix more clearly.

Figure 1. Scatterplot matrix (SPLOM)

We can observe the following:

- The histograms displayed on the diagonal show the distribution of each variable in the SPLOM. The histogram for *age* appears in the upper left cell, that for *income* in the center cell, and that for *creddebt* in the lower right cell. None of the variables appears normally distributed. That is, none of the histograms resembles a bell curve. Also, note that the histograms for *income* and *creddebt* are positively skewed.
- There does not seem to be any relationship between *age* and the other variables.
- There is a linear relationship between *income* and *creddebt*. That is, *creddebt* increases as *income* increases. You may want to create individual scatterplots of these variables and the other related variables to explore the relationships further.

- [Example: Pie Chart](#)
- [Example: Heat Map](#)
- [Example: Choropleth \(Color Map\) of Sums](#)
- [Example: Bar Charts on a Map](#)

Example: Choropleth (Color Map) of Sums

We will now create a map visualization. Then, in the subsequent example, we will create a variation of this visualization. The dataset is *worldsales*, which is a hypothetical data file that contains sales revenue by continent and product.

1. Add a Graphboard node and open it for editing.
2. On the Basic tab, select *Continent* and *Revenue*. (Use Ctrl+Click to select multiple fields/variables.)
3. Select Choropleth of Sums.
4. Click the Detailed tab.
5. In the Optional Aesthetics group, choose *Continent* from the Data Label drop-down list.
6. In the Map Files group, click Select a Map File.
7. In the Select Maps dialog box, check that Map is set to *Continents* and Map Key is set to *CONTINENT*.
8. In the Compare Map and Data Values groups, click Compare to ensure the map keys match the data keys. In this example, all of data key values have matching map keys and features. We can also see that there is no data for Oceania.
9. In the Select Maps dialog box, click OK.
10. Click Run.

Figure 1. Choropleth of Sums

From that map visualization, we can easily see that revenue is highest in North America and lowest in South America and Africa. Each continent is labeled because we used *Continent* for the data label aesthetic.

Example: Bar Charts on a Map

This example shows how revenue breaks down by product in each continent.

Note: This example uses *worlsales*.

1. Add a Graphboard node and open it for editing.
2. On the Basic tab, select *Continent*, *Product*, and *Revenue*. (Use Ctrl+Click to select multiple fields/variables.)
3. Select Bars on a Map.
4. Click the Detailed tab.
When using more than one field of a specific type, it is important to check that each field is assigned to the correct slot.
5. From the Categories drop-down list, choose *Product*.
6. From the Values drop-down list, choose *Revenue*.
7. From the Data Key drop-down list, choose *Continent*.
8. From the Summary drop-down list, choose *Sum*.
9. In the Map Files group, click Select a Map File.
10. In the Select Maps dialog box, check that Map is set to *Continents* and Map Key is set to *CONTINENT*.
11. In the Compare Map and Data Values groups, click Compare to ensure the map keys match the data keys. In this example, all of data key values have matching map keys and features. We can also see that there is no data for Oceania.
12. On the Select Maps dialog box, click OK.
13. Click Run.
14. Maximize the resulting output window to see the display more clearly.

Figure 1. Bar Charts on a Map

We can observe the following:

- The distribution of total revenue across products is very similar in South America and Africa.
- *Product C* generates the least revenue everywhere except in Asia.
- There is no or minimal revenue from *Product A* in Asia.

Graphboard appearance tab

You can specify appearance options before graph creation.

General appearance options

Title. Enter the text to use for the graph's title.

Subtitle. Enter the text to use for the graph's subtitle.

Caption. Enter the text to use for the graph's caption.

Sampling. Specify a method for larger datasets. You can specify a maximum dataset size or use the default number of records. Performance is enhanced for large datasets when you select the Sample option. Alternatively, you can choose to plot all data points by selecting Use all data, but you should note that this may dramatically decrease the performance of the software.

Stylesheet appearance options

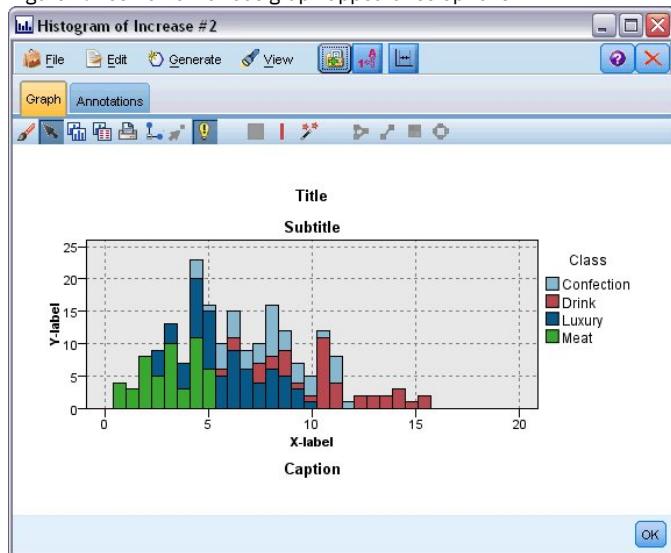

There are two buttons that enable you to control which visualization templates (and stylesheets, and maps) are available:

Manage. Manage visualization templates, stylesheets, and maps on your computer. You can import, export, rename, and delete visualization templates, stylesheets, and maps on your local machine. See the topic [Managing Templates, Stylesheets, and Map Files](#) for more information.

Location. Change the location in which visualization templates, stylesheets, and maps are stored. The current location is listed to the right of the button. See the topic [Setting the Location of Templates, Stylesheets, and Maps](#) for more information.

The following example shows where appearance options are placed on a graph. (Note that not all graphs use all these options.)

Figure 1. Position of various graph appearance options

Setting the Location of Templates, Stylesheets, and Maps

Visualization templates, visualization stylesheets, and map files are stored in a specific local folder or in the IBM® SPSS® Collaboration and Deployment Services Repository. When selecting templates, stylesheets, and maps, only the built-in ones in this location are displayed. By keeping all templates, stylesheets, and map files in one place, IBM SPSS applications can easily access them. For information about adding additional templates, stylesheets, and map files to this location, see [Managing Templates, Stylesheets, and Map Files](#).

How to Set the Location of Templates, Stylesheets, and Map Files

1. In a template or stylesheet dialog box, click Location... to display the Templates, Stylesheets, and Maps dialog box.
2. Select an option for the default location for templates, stylesheets, and map files:

Local Machine. Templates, stylesheets, and map files are located in a specific folder on your local computer. On Windows XP, this folder is C:\Documents and Settings\<user>\Application Data\SPSSInc\Graphboard. The folder cannot be changed.

IBM SPSS Collaboration and Deployment Services Repository. Templates, stylesheets, and map files are located in a user-specified folder in the IBM SPSS Collaboration and Deployment Services Repository. To identify the specific folder, click Folder. For more information, see [Using the IBM SPSS Collaboration and Deployment Services Repository as the Template, Stylesheet, and Map File Location](#).

3. Click OK.

- [Using the IBM SPSS Collaboration and Deployment Services Repository as the Template, Stylesheet, and Map File Location](#)
-

Using the IBM SPSS Collaboration and Deployment Services Repository as the Template, Stylesheet, and Map File Location

Visualization templates and stylesheets can be stored in the IBM® SPSS® Collaboration and Deployment Services Repository. This location is a specific folder in the IBM SPSS Collaboration and Deployment Services Repository. If this is set as the default location, any templates, stylesheets, and map files in this location are available for selection.

This feature requires the Statistics Adapter option.

How to Set a Folder in IBM SPSS Collaboration and Deployment Services Repository as the Location for Templates, Stylesheets, and Map Files

1. In a dialog box with a Location button, click Location....
2. Select IBM SPSS Collaboration and Deployment Services Repository.
3. Click Folder.

Note: If you are not already connected to the IBM SPSS Collaboration and Deployment Services Repository, you will be prompted for connection information.

4. In the Select Folder dialog box, select the folder in which templates, stylesheets, and map files are stored.
5. Optionally, you can select a label from Retrieve Label. Only templates, stylesheets, and map files with that label will be displayed.
6. If you are looking for a folder that contains a particular template or stylesheet, you may want to search for the template, stylesheet, or map file on the Search tab. The Select Folder dialog box automatically selects the folder in which the found template, stylesheet, or map file is located.
7. Click Select Folder.

Managing Templates, Stylesheets, and Map Files

You can manage the templates, stylesheets, and map files in the local location on your computer by using the Manage Templates, Stylesheets, and Maps dialog box. This dialog box allows you to import, export, rename, and delete visualization templates, stylesheets, and map files in the local location on your computer.

Click Manage... in one of the dialog boxes where you select templates, stylesheets, or maps.

Manage Templates, Stylesheets, and Maps Dialog Box

The Template tab lists all the local templates. The Stylesheet tab lists all the local stylesheets, as well as displaying example visualizations with sample data. You can select one of the stylesheets to apply its styles to the example visualizations. See the topic [Applying stylesheets](#) for more information. The Map tab lists all the local map files. This tab also displays the map keys including sample values, a comment if one was provided when creating the map, and a preview of the map.

The following buttons operate on whichever tab is currently activated.

Import. Import a visualization template, stylesheet, or map file from the file system. Importing a template, stylesheet, or map file makes it available to the IBM® SPSS® application. If another user sent you a template, stylesheet, or map file, you import the file before using it in your application.

Export. Export a visualization template, stylesheet, or map file to the file system. Export a template, stylesheet, or map file when you want to send it to another user.

Rename. Rename the selected visualization template, stylesheet, or map file. You cannot change a name to one that's already used.

Export Map Key. Export the map keys as a comma-separated values (CSV) file. This button is enabled only on the Map tab.

Delete. Delete the selected visualization template(s), stylesheet(s), or map file(s). You can select multiple templates, stylesheets, or map files with Ctrl-click. There is no undo action for deleting so proceed with caution.

Converting and Distributing Map Shapefiles

The Graphboard Template Chooser allows you to create map visualizations from the combination of a visualization template and an SMZ file. SMZ files are similar to ESRI shapefiles (SHP file format) in that they contain the geographic information for drawing a map (for example, country borders), but they are optimized for map visualizations. The Graphboard Template Chooser is pre-installed with a select number of SMZ files. If you have an existing ESRI shapefile that you want to use for map visualizations, you first need to convert the shapefile to an SMZ file using the Map Conversion Utility. The Map Conversion Utility supports point, polyline, or polygon (shape types 1, 3, and 5) ESRI shapefiles containing a single layer.

In addition to converting ESRI shapefiles, the Map Conversion Utility allows you to modify the map's level of detail, change feature labels, merge features, and move features, among many other optional changes. You can also use the Map Conversion Utility to modify an existing SMZ file (including the pre-installed ones).

Editing pre-installed SMZ files

1. Export the SMZ file from the Manage system. See the topic [Managing Templates, Stylesheets, and Map Files](#) for more information.
2. Use the Map Conversion Utility to open and edit the exported SMZ file. It is recommended that you save the file with a different name. See the topic [Using the Map Conversion Utility](#) for more information.
3. Import the modified SMZ file into the Manage system. See the topic [Managing Templates, Stylesheets, and Map Files](#) for more information.

Additional Resources for Map Files

Geospatial data in the SHP file format, which could be used to support your mapping needs, is available from many private and public sources. Check with local government web sites if you seek free data. Many of the templates in this product are based on publicly available data obtained from GeoCommons (<http://www.geocommons.com>) and the U.S. Census Bureau (<http://www.census.gov>).

IMPORTANT NOTICE: Information concerning non-IBM products was obtained from the suppliers of those products, their published announcements or other publicly available sources. IBM has not tested those products and cannot confirm the accuracy of performance, compatibility or any other claims related to non-IBM products. Questions on the capabilities of non-IBM products should be addressed to the suppliers of those products. Any references in this information to non-IBM Web sites are provided for convenience only and do not in any manner serve as an endorsement of those Web sites. The materials at those Web sites are not part of the materials for this IBM program, unless indicated in a Notices file accompanying this IBM program, and use of the materials sites is at your own risk.

- [Key Concepts for Maps](#)
- [Using the Map Conversion Utility](#)
- [Distributing map files](#)

Key Concepts for Maps

Understanding some key concepts related to shapefiles will help you use the Map Conversion Utility effectively.

A **shapefile** provides the geographic information for drawing a map. There are three types of shapefiles that the Map Conversion Utility supports:

- **Point.** The shapefile identifies the locations of points, such as cities.
- **Polyline.** The shapefile identifies paths and their locations, such as rivers.
- **Polygon.** The shapefile identifies bounded regions and their locations, such as countries.

Most commonly, you will use a polygon shapefile. Choropleth maps are created from polygon shapefiles. Choropleth maps use color to represent a value within individual polygons (regions). Point and polyline shapefiles are typically overlaid on a polygon shapefile. An example is a point shapefile of U.S. cities overlaid on a polygon shapefile of U.S. states.

A shapefile is comprised of **features**. Features are the individual geographical entities. For example, features may be countries, states, cities, and so on. The shapefile also contains data about the features. These data are stored in **attributes**. Attributes are similar to fields or variables in a data file. There is at least one attribute that is the **map key** for the feature. The map key may be a label, such as country or state name. The map key is what you will link to a variable/field in a data file to create a map visualization.

Note that you will be able to retain only the key attribute or attributes in the SMZ file. The Map Conversion Utility does not support saving additional attributes. This means that you will need to create multiple SMZ files if you want to aggregate at different levels. For example, if you want to aggregate U.S. states and regions, you will need separate SMZ files: one that has a key identifying states and one that has a key identifying regions.

Using the Map Conversion Utility

How to start the Map Conversion Utility

From the menus choose:

Tools > Map Conversion Utility

There are four major screens (steps) in the Map Conversion Utility. One of the steps also involves sub-steps for more detailed control over editing the map file.

- [Step 1 - Choose Destination and Source Files](#)
- [Step 2 - Choose Map Key](#)
- [Step 3 - Edit the Map](#)
- [Step 4 - Finish](#)

Related information

- [Converting and Distributing Map Shapefiles](#)
- [Key Concepts for Maps](#)
- [Distributing map files](#)

Step 1 - Choose Destination and Source Files

You first have to select a source map file and a destination for the converted map file. You will need both the .shp and .dbf files for the shapefile.

Select a .shp (ESRI) or .smz file for conversion. Browse to an existing map file on your computer. This is the file that you will convert to and save as an SMZ file. The .dbf file for the shapefile *must* be stored in the same location with a base file name that matches the .shp file. The .dbf file is required because it contains the attribute information for the .shp file.

Set a destination and file name for the converted map file. Enter a path and file name for the SMZ file that will be created from the original map source.

- **Import to the Template Chooser.** In addition to saving a file on the file system, you can optionally add the map to the Manage list of the Template Chooser. If you choose this option, the map will automatically be available in the Template Chooser for IBM® SPSS® products installed on your computer. If you don't import to the Template Chooser now, you will need to import it manually at a later time. For more information about importing maps into the Template Chooser Manage system, see [Managing Templates, Stylesheets, and Map Files](#).

Related information

- [Using the Map Conversion Utility](#)
- [Step 2 - Choose Map Key](#)
- [Step 3 - Edit the Map](#)
- [Step 4 - Finish](#)

Step 2 - Choose Map Key

Now you will choose which map keys to include in the SMZ file. You can then change some options that will affect rendering of the map. The subsequent steps in the Map Conversion Utility include a preview of the map. The rendering options that you choose will be used to generate the map preview.

Choose primary map key. Select the attribute that is the primary key for identifying and labeling features in the map. For example, a world map's primary key may be the attribute identifying country names. The primary key will also link your data to the map features, so be sure that the values (labels) of the attribute you choose will match the values in your data. Example labels are displayed when you choose an attribute. If you need to change these labels, you will be able to do so in a later step.

Choose additional keys to include. In addition to the primary map key, check any other key attributes that you want to include in the generated SMZ file. For example, some attributes may contain translated labels. If you expect data coded in other languages, you may want to preserve these attributes. Note that you can choose only those additional keys that represent the same features as the primary key. For example if the primary key were the full names of U.S. states, you can select only those alternate keys that represent U.S. States, such as state abbreviations.

Automatically smooth the map. Shapefiles with polygons typically contain too many data points and too much detail for statistical map visualizations. The excess details can be distracting and negatively impact performance. You can reduce the level of detail and generalize the map with smoothing. The map will look crisper and render more quickly as a result. When the map is automatically smoothed, the maximum angle is 15 degrees and the percentage to keep is 99. For information about these settings, see [Smooth the map](#). Note that you have the opportunity to apply additional smoothing later in another step.

Remove boundaries between touching polygons in the same feature. Some features may include sub-features that have boundaries internal to the main features of interest. For example, a world map of continents may contain internal boundaries for the countries contained within each continent. If you choose this option, the internal boundaries will not appear in the map. In the world map of continents example, choosing this option would remove the country borders, while retaining the continent borders.

Related information

- [Using the Map Conversion Utility](#)
 - [Step 1 - Choose Destination and Source Files](#)
 - [Step 3 - Edit the Map](#)
 - [Step 4 - Finish](#)
-

Step 3 - Edit the Map

Now that you have specified basic options for the map, you can edit more specific ones. These modifications are optional. This step of the Map Conversion Utility guides you through the associated tasks and displays a preview of the map so you can verify your changes. Some tasks may not be available depending on shapefile type (point, polyline, or polygon) and coordinate system.

Every task has the following common controls on the left side of the Map Conversion Utility.

Show the labels on the map. By default, feature labels are not shown in the preview. You can choose to display the labels. Although the labels can help identify features, they may interfere with direct selection on the preview map. Turn on this option when you need it, for example when you are editing the feature labels.

Color the map preview. By default, the preview map displays areas with a solid color. All features are the same color. You can choose to have an assortment of colors assigned to the individual map features. This option may help distinguish different features in the map. It will be especially helpful when you merge features and want to see how the new features are represented in the preview.

Every task also has the following common control on the right side of the Map Conversion Utility.

Undo. Click Undo to revert to the last state. You can undo a maximum of 100 changes.

- [Smooth the map](#)
- [Edit the feature labels](#)
- [Merge features](#)
- [Move features](#)
- [Delete features](#)
- [Delete individual elements](#)
- [Set the projection](#)

Related information

- [Using the Map Conversion Utility](#)
 - [Step 1 - Choose Destination and Source Files](#)
 - [Step 2 - Choose Map Key](#)
 - [Step 4 - Finish](#)
-

Smooth the map

Shapefiles with polygons typically contain too many data points and too much detail for statistical map visualizations. The excess details can be distracting and negatively impact performance. You can reduce the level of detail and generalize the map with smoothing. The map will look crisper and render more quickly as a result. This option is not available for point and polyline maps.

Max. angle. The maximum angle, which must be a value between 1 and 20, specifies the tolerance for smoothing sets of points that are almost linear. A larger value allows more tolerance for the linear smoothing and will subsequently drop more points, resulting in a more generalized map. To apply linear smoothing, the Map Conversion Utility checks the inner angle formed by every set of three points in the map. If 180 minus the angle is less than the specified value, the Map Conversion Utility will drop the middle point. In other words, the Map Conversion Utility is checking

whether the line formed by the three points is almost straight. If it is, the Map Conversion Utility treats the line as a straight line between the endpoints and drops the middle point.

Percent to keep. The percentage to keep, which must be a value between 90 and 100, determines the amount of land area to keep when the map is smoothed. This option affects only those features that have multiple polygons, as would be the case if a feature included islands. If the total area of a feature minus a polygon is greater than the specified percentage of the original area, the Map Conversion Utility will drop the polygon from the map. The Map Conversion Utility will never remove all polygons for the feature. That is, there will always be at least one polygon for the feature, regardless of the amount of smoothing applied.

After you choose a maximum angle and percentage to keep, click Apply. The preview will update with the smoothing changes. If you need to smooth the map again, repeat until you obtain the level of smoothness you want. Note that there is a limit to the smoothing. If you repeatedly smooth, you will reach a point when no additional smoothing can be applied to the map.

Related information

- [Step 3 - Edit the Map](#)
 - [Edit the feature labels](#)
 - [Merge features](#)
 - [Move features](#)
 - [Delete features](#)
 - [Delete individual elements](#)
 - [Set the projection](#)
-

Edit the feature labels

You can edit the feature labels as needed (perhaps to match your expected data) and also re-position the labels in the map. Even if you don't think you need to change the labels, you should review them before creating visualizations from the map. Because labels are not shown by default in the preview, you may also want to select Show the labels on the map to display them.

Keys. Select the key containing the feature labels that you want to review and/or edit.

Features. This list displays the feature labels contained in the selected key. To edit the label, double-click it in the list. If labels are shown on the map, you can also double-click the feature labels directly in the map preview. If you want to compare the labels to an actual data file, click Compare.

X/Y. These text boxes list the current center point of the selected feature's label on the map. The units are displayed in the map's coordinates. These may be local, Cartesian coordinates (for example, the State Plane Coordinate System) or geographic coordinates (where X is longitude and Y is latitude). Enter coordinates for the new position of the label. If labels are shown, you can also click and drag a label on the map to move it. The text boxes will update with the new position.

Compare. If you have a data file that contains data values that are intended to match the features labels for a particular key, click Compare to display the Compare to an External Data Source dialog box. In this dialog box you will be able to open the data file and compare its values directly with those in the map key's feature labels.

- [Compare to an External Data Source dialog box](#)

Related information

- [Step 3 - Edit the Map](#)
 - [Smooth the map](#)
 - [Merge features](#)
 - [Move features](#)
 - [Delete features](#)
 - [Delete individual elements](#)
 - [Set the projection](#)
 - [Compare to an External Data Source dialog box](#)
-

Compare to an External Data Source dialog box

The Compare to an External Data Source dialog box allows you to open a tab-separated values file (with a .txt extension), a comma-separated values file (with a .csv extension), or a data file formatted for IBM® SPSS® Statistics (with a .sav extension). When the file is open, you can select a field in the data file to compare to the feature labels in a specific map key. You can then correct any discrepancies in the map file.

Fields in the data file. Choose the field whose values you want to compare to the feature labels. If the first row in the .txt or .csv file contains descriptive labels for each field, check Use first row as column labels. Otherwise, each field will be identified by its position in the data file (for example, "Column 1", "Column 2", and so on).

Key to compare. Choose the map key whose feature labels you want to compare to the data file field values.

Compare. Click when you are ready to compare the values.

Comparison Results. By default, the Comparison Results table lists only the unmatched field values in the data file. The application tries to find a related feature label, usually by checking for inserted or missing spaces. Click the dropdown list in the *Map Label* column to match the feature label in the map file to the displayed field value. If there is no corresponding feature label in your map file, choose *Leave Unmatched*. If you want to see all field values, even those that already match a feature label, clear Display only unmatched cases. You may do this if you want to override one or more matches.

You can use each feature only once to match it to a field value. If you want to match multiple features to a single field value, you can merge the features and then match the new, merged feature to the field value. For more information about merging features, see [Merge features](#).

Related information

- [Edit the feature labels](#)

Merge features

Merging features is useful for creating larger regions in a map. For example, if you were converting a map of states, you could merge the states (the features in this example) into larger North, South, East, and West regions.

Keys. Select the map key containing the feature labels that will help you identify the features you want to merge.

Features. Click the first feature that you want to merge. Ctrl-click the other features that you want to merge. Note that the features will also be selected in the map preview. You can click and Ctrl-click the features directly in the map preview in addition to selecting them from the list.

After selecting the features that you want to merge, click Merge to display the Name the Merged Feature dialog box, where you will be able to apply a label to the new feature. You may want to check Color the map preview after merging features to ensure that the results are what you expect.

After merging features, you may also want to move the label for the new feature. You can do that in the *Edit the feature labels* task. See the topic [Edit the feature labels](#) for more information.

- [Name the Merged Feature dialog box](#)

Related information

- [Edit the feature labels](#)
- [Move features](#)
- [Delete features](#)
- [Delete individual elements](#)
- [Set the projection](#)
- [Name the Merged Feature dialog box](#)

Name the Merged Feature dialog box

The Name the Merged Feature dialog box allows you to assign labels to the new merged feature.

The Labels table displays information for each key in the map file and allows you to assign a label for each key.

New Label. Enter a new label for the merged feature to assign to the specific map key.

Key. The map key to which you are assigning the new label.

Old Labels. The labels for the features that will be merged into the new feature.

Remove boundaries between touching polygons. Check this option to remove the boundaries from the features that were merged together. For example, if you merged states into geographic regions, this option would remove the boundaries around the individual states.

Related information

- [Merge features](#)
-

Move features

You can move features in the map. This can be useful when you want to put features together, like a mainland and outlying islands.

Keys. Select the map key containing the feature labels that will help you identify the features you want to move.

Features. Click the feature that you want to move. Note that the feature will be selected in the map preview. You can also click the feature directly in the map preview.

X/Y. These text boxes list the current center point of the feature on the map. The units are displayed in the map's coordinates. These may be local, Cartesian coordinates (for example, the State Plane Coordinate System) or geographic coordinates (where X is longitude and Y is latitude). Enter coordinates for the new position of the feature. You can also click and drag a feature on the map to move it. The text boxes will update with the new position.

Related information

 - [Smooth the map](#)
 - [Edit the feature labels](#)
 - [Merge features](#)
 - [Delete features](#)
 - [Delete individual elements](#)
 - [Set the projection](#)
-

Delete features

You can delete unwanted features from the map. This can be useful when you want to remove some clutter by deleting features that won't be of interest in the map visualization.

Keys. Select the map key containing the feature labels that will help you identify the features you want to delete.

Features. Click the feature that you want to delete. If you want to delete multiple features simultaneously, Ctrl-click the additional features. Note that the features will also be selected in the map preview. You can click and Ctrl-click the features directly in the map preview in addition to selecting them from the list.

Related information

- [Step 3 - Edit the Map](#)
 - [Smooth the map](#)
 - [Edit the feature labels](#)
 - [Merge features](#)
 - [Move features](#)
 - [Delete individual elements](#)
 - [Set the projection](#)
-

Delete individual elements

In addition to deleting whole features, you can delete some of the individual elements that compose the features, such as lakes and small islands. This option is not available for point maps.

Elements. Click the elements that you want to delete. If you want to delete multiple elements simultaneously, Ctrl-click the additional elements. Note that the elements will also be selected in the map preview. You can click and Ctrl-click the elements directly in the map preview in addition to selecting them from the list. Because the list of element names is not descriptive (each element is assigned a number within the feature), you should check the selection in the map preview to ensure you have selected the elements you want.

Related information

- [Step 3 - Edit the Map](#)
 - [Smooth the map](#)
 - [Edit the feature labels](#)
 - [Merge features](#)
 - [Move features](#)
 - [Delete features](#)
 - [Set the projection](#)
-

Set the projection

The map projection specifies the way in which the three-dimensional Earth is represented in two dimensions. All projections cause distortions. However, some projections are more suitable depending on whether you are viewing a global map or a more local one. Also some projections preserve the shape of the original features. Projections that preserve shape are conformal projections. This option is available only for maps with geographic coordinates (longitude and latitude).

Unlike other options in the Map Conversion Utility, the projection can be changed after a map visualization is created.

Projection. Select a map projection. If you are creating a global or hemispherical map, use the *Local*, *Mercator*, or *Winkel Tripel* projections. For smaller areas, use the *Local*, *Lambert Conformal Conic*, or *Transverse Mercator* projections. All projections use the WGS83 ellipsoid for the datum.

- The **Local** projection is always used when the map was created with a local coordinate system, such as the State Plane Coordinate System. These coordinate systems are defined by Cartesian coordinates rather than geographic coordinates (longitude and latitude). In the Local projection, horizontal and vertical lines are equally spaced in a Cartesian coordinate system. The Local projection is not conformal.
- The **Mercator** projection is a conformal projection for global maps. Horizontal and vertical lines are straight and always perpendicular to each other. Note that the Mercator projection extends to infinity as it approaches the North and South Poles, so it cannot be used if your map includes the North or South Pole. Distortion is greatest when the map approaches these limits.
- The **Winkel Tripel** projection is a non-conformal projection for global maps. Although it is not conformal, it provides a good balance between shape and size. Except for the Equator and Prime Meridian, all lines are curved. If your global map includes the North or South Pole, this is a good projection choice.
- As its name suggests, the **Lambert Conformal Conic** projection is a conformal projection and is used for maps of continental or smaller land masses that are longer East and West compared to North and South.
- The **Transverse Mercator** is another conformal projection for maps of continental or smaller land masses. Use this projection for land masses that are longer North and South compared to East and West.

 - [Smooth the map](#)
 - [Edit the feature labels](#)
 - [Merge features](#)
 - [Move features](#)
 - [Delete features](#)
 - [Delete individual elements](#)
-

Step 4 - Finish

At this point you can add a comment to describe the map file and also create a sample data file from the map keys.

Map keys. If there are multiple keys in the map file, select a map key whose feature labels you want to display in the preview. If you create a data file from the map, these labels will be used for the data values.

Comment. Enter a comment that describes the map or provides additional information that may be relevant to your users, such as the sources for the original shapefiles. The comment will appear in the Graphboard Template Chooser's Manage system.

Create a data set from the feature labels. Check this option if you want to create a data file from the displayed feature labels. When you click Browse..., you will be able to specify a location and file name. If you add a .txt extension, the file will be saved as a tab-separate values file. If you add a .csv extension, the file will be saved as a comma-separated values file. If you add a .sav extension, the file will be saved in IBM® SPSS® Statistics format. SAV is the default when no extension is specified.

Related information

- [Using the Map Conversion Utility](#)
 - [Step 1 - Choose Destination and Source Files](#)
 - [Step 2 - Choose Map Key](#)
 - [Step 3 - Edit the Map](#)
-

Distributing map files

In the first step of the Map Conversion Utility, you chose a location where to save the converted SMZ file. You may have also chosen to add the map to the Manage system for the Graphboard Template Chooser. If you chose to save to the Manage system, the map will be available to you in any IBM® SPSS® product that you run on the same computer.

To distribute the map to other users, you will need to send the SMZ to them. Those users can then use the Manage system to import the map. You can simply send the file whose location you specified in step 1. If you want to send a file that's in the Manage system, you first need to export it:

1. In the Template Chooser, click Manage...
2. Click the Map tab.
3. Select the map you want to distribute.
4. Click Export... and choose a location where you want to save the file.

Now you can send the physical map file to other users. Users will need to reverse this process and import the map into the Manage system.

Plot Node

Plot nodes show the relationship between numeric fields. You can create a plot using points (also known as a scatterplot), or you can use lines. You can create three types of line plots by specifying an X Mode in the dialog box.

X Mode = Sort

Setting X Mode to Sort causes data to be sorted by values for the field plotted on the x axis. This produces a single line running from left to right on the graph. Using a nominal field as an overlay produces multiple lines of different hues running from left to right on the graph.

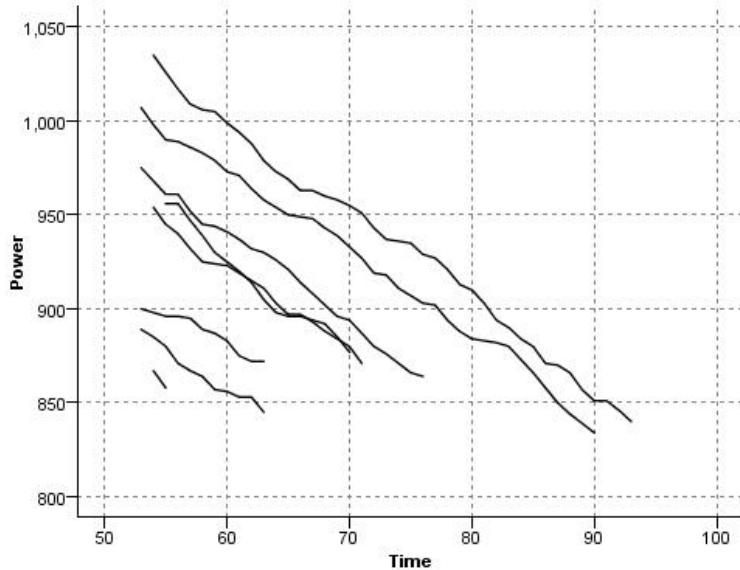

Figure 1. Line plot with X Mode set to Sort

X Mode = Overlay

Setting X Mode to Overlay creates multiple line plots on the same graph. Data are not sorted for an overlay plot; as long as the values on the x axis increase, data will be plotted on a single line. If the values decrease, a new line begins. For example, as x moves from 0 to 100, the y values will be plotted on a single line. When x falls below 100, a new line will be plotted in addition to the first one. The finished plot might have numerous plots useful for comparing several series of y values. This type of plot is useful for data with a periodic time component, such as electricity demand over successive 24-hour periods.

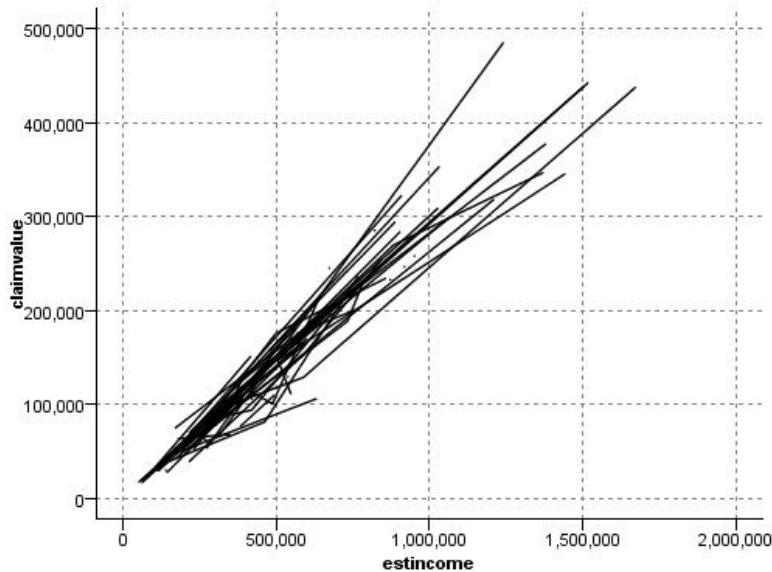

Figure 2. Line plot with X Mode set to Overlay

X Mode = As Read

Setting X Mode to As Read plots x and y values as they are read from the data source. This option is useful for data with a time series component where you are interested in trends or patterns that depend on the order of the data. You may need to sort the data before creating this type of plot. It may also be useful to compare two similar plots with X Mode set to Sort and As Read in order to determine how much of a pattern depends on the sorting.

Figure 3. Line plot shown earlier as Sort, executed again with X Mode set to As Read

You can also use the Graphboard node to produce scatterplots and line plots. However, you have more options to choose from in this node. See the topic [Available Built-in Graphboard Visualization Types](#) for more information.

Plot Node Tab

Plots show values of a *Y* field against values of an *X* field. Often, these fields correspond to a dependent variable and an independent variable, respectively.

X field. From the list, select the field to display on the horizontal *x* axis.

Y field. From the list, select the field to display on the vertical *y* axis.

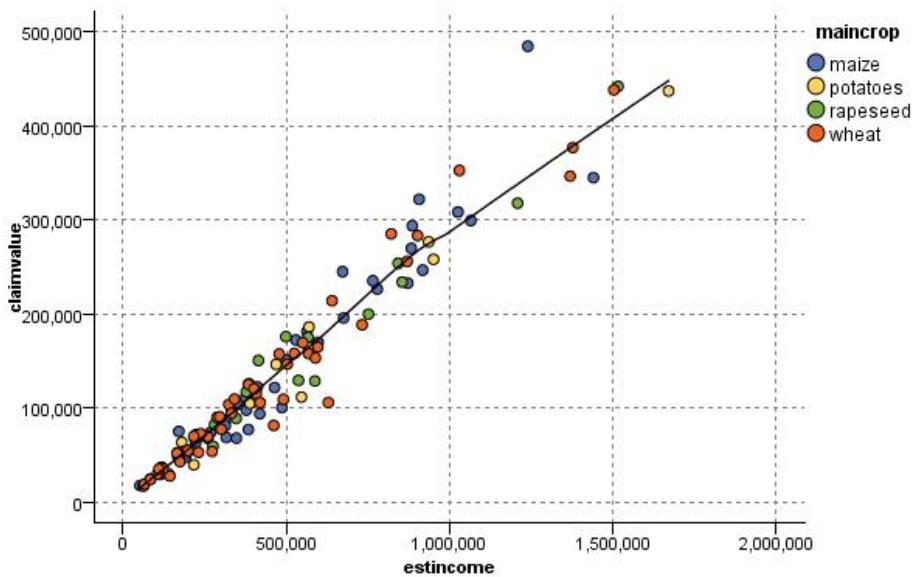

Z field. When you click the 3-D chart button, you can then choose a field from the list to display on the *z* axis.

Overlay. There are several ways to illustrate categories for data values. For example, you can use *maincrop* as a color overlay to indicate the *estincome* and *claimvalue* values for the main crop grown by claim applicants. See the topic [Aesthetics, Overlays, Panels, and Animation](#) for more information.

Overlay type. Specifies whether an overlay function or smoother is displayed. The smoother and overlay functions are always calculated as a function of *y*.

- **None.** No overlay is displayed.
- **Smoother.** Displays a smoothed fit line computed using locally weighted iterative robust least squares regression (LOESS). This method effectively computes a series of regressions, each focused on a small area within the plot. This produces a series of "local" regression lines that are then joined to create a smooth curve.

Figure 1. Plot with a LOESS smoother overlay

- **Function.** Select to specify a known function to compare to actual values. For example, to compare actual versus predicted values, you can plot the function $y = x$ as an overlay. Specify a function for $y =$ in the text box. The default function is $y = x$, but you can specify any sort of function, such as a quadratic function or an arbitrary expression, in terms of x .
- Note:* Overlay functions are not available for a panel or animation graph.

Once you have set options for a plot, you can run the plot directly from the dialog box by clicking Run. You may, however, want to use the Options tab for additional specifications, such as binning, X Mode, and style.

Related information

- [Plot Node](#)
 - [Plot Options Tab](#)
 - [Plot Appearance Tab](#)
 - [Using a Plot Graph](#)
-

Plot Options Tab

Style. Select either Point or Line for the plot style. Selecting Line activates the X Mode control. Selecting Point will use a plus symbol (+) as the default point shape. Once the graph is created, you can change the point shape and alter its size.

X Mode. For line plots, you must choose an X Mode to define the style of the line plot. Select Sort, Overlay, or As Read. See the topic [Plot Node](#) for more information. For Overlay or As Read, you should specify a maximum dataset size used to sample the first n records. Otherwise, the default 2,000 records will be used.

Automatic X range. Select to use the entire range of values in the data along this axis. Deselect to use an explicit subset of values based on your specified Min and Max values. Either enter values or use the arrows. Automatic ranges are selected by default to enable rapid graph building.

Automatic Y range. Select to use the entire range of values in the data along this axis. Deselect to use an explicit subset of values based on your specified Min and Max values. Either enter values or use the arrows. Automatic ranges are selected by default to enable rapid graph building.

Automatic Z range. Only when a 3-D graph is specified on the Plot tab. Select to use the entire range of values in the data along this axis. Deselect to use an explicit subset of values based on your specified Min and Max values. Either enter values or use the arrows. Automatic ranges are selected by default to enable rapid graph building.

Jitter. Also known as **agitation**, jitter is useful for point plots of a dataset in which many values are repeated. In order to see a clearer distribution of values, you can use jitter to distribute the points randomly around the actual value.

Note to users of earlier versions of IBM® SPSS® Modeler : The jitter value used in a plot uses a different metric in this release of IBM SPSS Modeler. In earlier versions, the value was an actual number, but it is now a proportion of the frame size. This means that agitation values in old streams are likely to be too large. For this release, any nonzero agitation values will be converted to the value 0.2.

Maximum number of records to plot. Specify a method for plotting large datasets. You can specify a maximum dataset size or use the default 2,000 records. Performance is enhanced for large datasets when you select the Bin or Sample options. Alternatively, you can choose to plot all

data points by selecting Use all data, but you should note that this may dramatically decrease the performance of the software.

Note: When X Mode is set to Overlay or As Read, these options are disabled and only the first *n* records are used.

- **Bin.** Select to enable binning when the dataset contains more than the specified number of records. Binning divides the graph into fine grids before actually plotting and counts the number of points that would appear in each of the grid cells. In the final graph, one point is plotted per cell at the bin centroid (average of all point locations in the bin). The size of the plotted symbols indicates the number of points in that region (unless you have used size as an overlay). Using the centroid and size to represent the number of points makes the binned plot a superior way to represent large datasets, because it prevents overplotting in dense regions (undifferentiated masses of color) and reduces symbol artifacts (artificial patterns of density). Symbol artifacts occur when certain symbols (particularly the plus symbol [+]) collide in a way that produces dense areas not present in the raw data.
- **Sample.** Select to randomly sample the data to the number of records entered in the text field. The default is 2,000.

Using a Plot Graph

Plots and multiplots are essentially plots of X against Y . For example, if you are exploring potential fraud in agricultural grant applications, you might want to plot the income claimed on the application versus the income estimated by a neural net. Using an overlay, such as crop type, will illustrate whether there is a relationship between claims (value or number) and type of crop.

Figure 1. Plot of the relationship between estimated income and claim value with main crop type as an overlay

Since plots, multiplots, and evaluation charts are two-dimensional displays of Y against X , it is easy to interact with them by defining regions, marking elements, or even drawing bands. You can also generate nodes for the data represented by those regions, bands, or elements. See the topic [Exploring Graphs](#) for more information.

Related information

- [Plot Node](#)
- [Plot Node Tab](#)

Multiplot Plot Tab

A multiplot is a special type of plot that displays multiple Y fields over a single X field.

X field. From the list, select the field to display on the horizontal x axis.

Y fields. Select one or more fields from the list to display over the range of X field values. Use the Field Chooser button to select multiple fields. Click the delete button to remove fields from the list.

Overlay. There are several ways to illustrate categories for data values. For example, you might use an animation overlay to display multiple plots for each value in the data. This is useful for sets containing upwards of 10 categories. When used for sets with more than 15 categories, you may notice a decrease in performance. See the topic [Aesthetics, Overlays, Panels, and Animation](#) for more information.

Normalize. Select to scale all Y values to the range 0–1 for display on the graph. Normalizing helps you explore the relationship between lines that might otherwise be obscured due to differences in the range of values for each series and is recommended when plotting multiple lines on the same graph, or when comparing plots in side-by-side panels. (Normalizing is not necessary when all data values fall within a similar range.)

Figure 1. Standard multiplot showing power-plant fluctuation over time (note that without normalizing, the plot for Pressure is impossible to see)

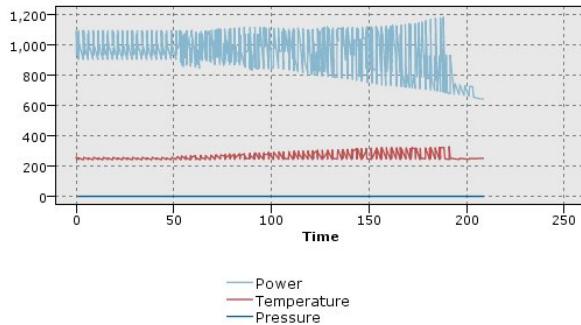

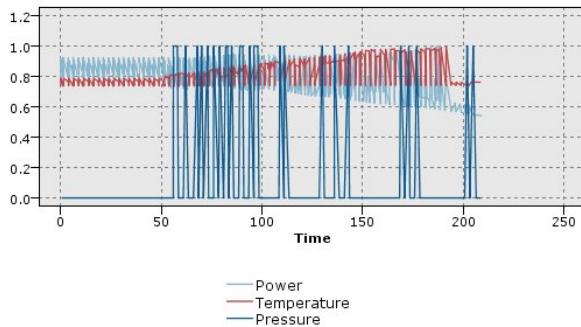

Figure 2. Normalized multiplot showing a plot for Pressure

Overlay function. Select to specify a known function to compare to actual values. For example, to compare actual versus predicted values, you can plot the function $y = x$ as an overlay. Specify a function for $y =$ in the text box. The default function is $y = x$, but you can specify any sort of function, such as a quadratic function or an arbitrary expression, in terms of x .

Note: Overlay functions are not available for a panel or animation graph.

When number of records greater than. Specify a method for plotting large datasets. You can specify a maximum dataset size or use the default 2,000 points. Performance is enhanced for large datasets when you select the Bin or Sample options. Alternatively, you can choose to plot all data points by selecting Use all data, but you should note that this may dramatically decrease the performance of the software.

Note: When X Mode is set to Overlay or As Read, these options are disabled and only the first n records are used.

- **Bin.** Select to enable binning when the dataset contains more than the specified number of records. Binning divides the graph into fine grids before actually plotting and counts the number of connections that would appear in each of the grid cells. In the final graph, one connection is used per cell at the bin centroid (average of all connection points in the bin).
- **Sample.** Select to randomly sample the data to the specified number of records.

Time Plot Node

Time Plot nodes enable you to view one or more time series plotted over time. The series you plot must contain numeric values and are assumed to occur over a range of time in which the periods are uniform.

In SPSS® Modeler versions 17.1 and earlier, you usually use a Time Intervals node before a Time Plot node to create a *TimeLabel* field, which is used by default to label the x axis in the graphs.

For more information, see [Time Intervals Node \(deprecated\)](#).

Figure 1. Plotting sales of men's and women's clothing and jewelry over time

Creating Interventions and Events

You can create Event and Intervention fields from the time plot by generating a derive (flag or nominal) node from the context menus. For example, you could create an event field in the case of a rail strike, where the drive state is True if the event happened and False otherwise. For an Intervention field, for a price rise for example, you could use a derive count to identify the date of the rise, with 0 for the old price and 1 for the new price. See the topic [Derive node](#) for more information.

Time Plot Tab

Plot. Provides a choice of how to plot time series data.

- **Selected series.** Plots values for selected time series. If you select this option when plotting confidence intervals, deselect the Normalize check box.
- **Selected Time Series models.** Used in conjunction with a Time Series model, this option plots all the related fields (actual and predicted values, as well as confidence intervals) for one or more selected time series. This option disables some other options in the dialog box. This is the preferred option if plotting confidence intervals.

Series. Select one or more fields with time series data you want to plot. The data must be numeric.

X axis label. Choose either the default label or a single field to use as the label for the x axis in plots. If you choose Default, the system uses the TimeLabel field created from a Time Intervals node upstream (for streams created in SPSS® Modeler versions 17.1 and earlier), or sequential integers if there is no upstream Time Intervals node.

For more information, see [Time Intervals Node \(deprecated\)](#).

Display series in separate panels. Specifies whether each series is displayed in a separate panel. Alternatively, if you do not choose to panel, all time series are plotted on the same graph, and smoothers will not be available. When plotting all time series on the same graph, each series will

be represented by a different color.

Normalize. Select to scale all Y values to the range 0–1 for display on the graph. Normalizing helps you explore the relationship between lines that might otherwise be obscured due to differences in the range of values for each series and is recommended when plotting multiple lines on the same graph, or when comparing plots in side-by-side panels. (Normalizing is not necessary when all data values fall within a similar range.)

Display. Select one or more elements to display in your plot. You can choose from lines, points, and (LOESS) smoothers. Smoothers are available only if you display the series in separate panels. By default, the line element is selected. Make sure you select at least one plot element before you run the graph node; otherwise, the system will return an error stating that you have selected nothing to plot.

Limit records. Select this option if you want to limit the number of records plotted. Specify the number of records, read from the beginning of your data file, that will be plotted in the Maximum number of records to plot option. By default this number is set to 2,000. If you want to plot the last *n* records in your data file, you can use a Sort node prior to this node to arrange the records in descending order by time.

Distribution Node

A distribution graph or table shows the occurrence of symbolic (non-numeric) values, such as mortgage type or gender, in a dataset. A typical use of the Distribution node is to show imbalances in the data that can be rectified by using a Balance node before creating a model. You can automatically generate a Balance node using the Generate menu in the distribution graph or table window.

You can also use the Graphboard node to produce bar of counts graphs. However, you have more options to choose from in this node. See the topic [Available Built-in Graphboard Visualization Types](#) for more information.

Note: To show the occurrence of numeric values, you should use a Histogram node.

Distribution Plot Tab

Plot. Select the type of distribution. Select Selected fields to show the distribution of the selected field. Select All flags (true values) to show the distribution of true values for flag fields in the dataset.

Field. Select a nominal or flag field for which to show the distribution of values. Only fields that have not been explicitly set as numeric appear on the list.

Overlay. Select a nominal or flag field to use as a color overlay, illustrating the distribution of its values within each value of the specified field. For example, you can use marketing campaign response (*pep*) as an overlay for number of children (*children*) to illustrate responsiveness by family size. See the topic [Aesthetics, Overlays, Panels, and Animation](#) for more information.

Normalize by color. Select to scale bars so that all bars take up the full width of the graph. The overlay values equal a proportion of each bar, making comparisons across categories easier.

Sort. Select the method used to display values in the distribution graph. Select Alphabetic to use alphabetical order or By count to list values in decreasing order of occurrence.

Proportional scale. Select to scale the distribution of values so that the value with the largest count fills the full width of the plot. All other bars are scaled against this value. Deselecting this option scales bars according to the total counts of each value.

Related information

- [Distribution Node](#)
- [Distribution Plot Tab](#)
- [Using a Distribution Node](#)

Using a Distribution Node

Distribution nodes are used to show the distribution of symbolic values in a dataset. They are frequently used before manipulation nodes to explore the data and correct any imbalances. For example, if instances of respondents without children occur much more frequently than other types of respondents, you might want to reduce these instances so that a more useful rule can be generated in later data mining operations. A Distribution node will help you to examine and make decisions about such imbalances.

The Distribution node is unusual in that it produces both a graph and a table to analyze your data.

Figure 1. Distribution graph showing the number of people with or without children who responded to a marketing campaign

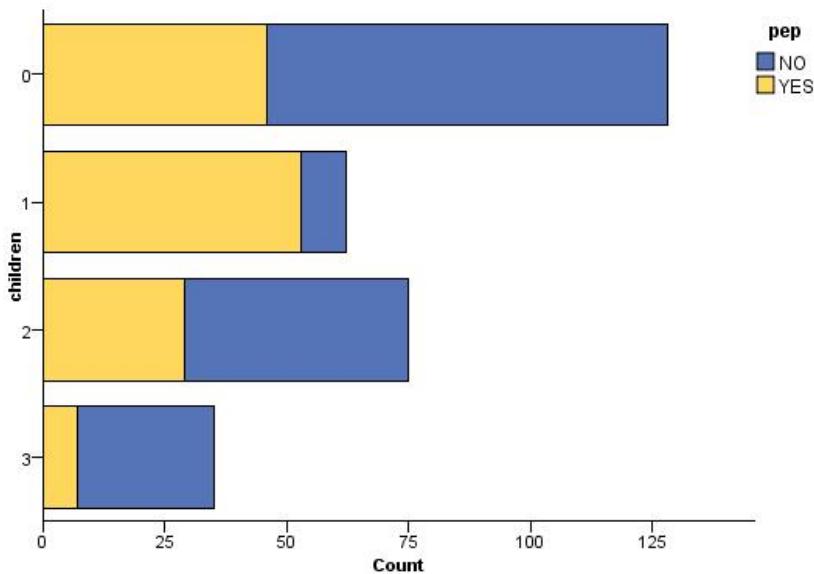

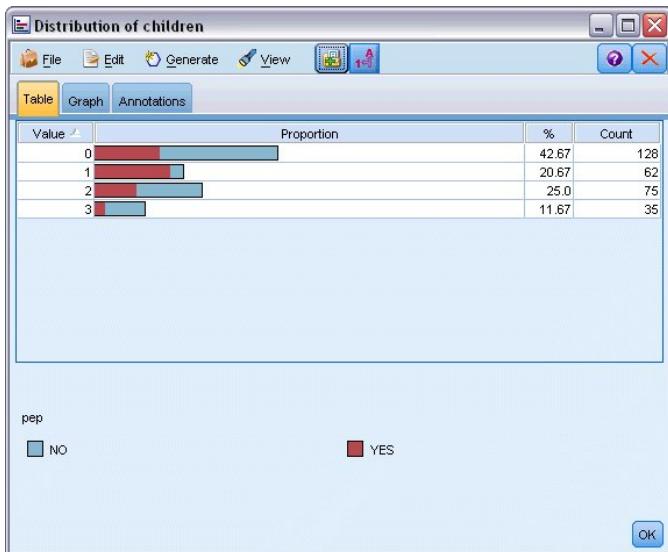

Figure 2. Distribution table showing the proportion of people with or without children who responded to a marketing campaign

Once you have created a distribution table and graph and examined the results, you can use options from the menus to group values, copy values, and generate a number of nodes for data preparation. In addition, you can copy or export the graph and table information for use in other applications, such as MS Word or MS PowerPoint. See the topic [Printing, saving, copying, and exporting graphs](#) for more information.

To Select and Copy Values from a Distribution Table

1. Click and hold the mouse button while dragging it over the rows to select a set of values. You can also use the Edit menu to Select All values.
 2. From the Edit menu, choose Copy Table or Copy Table (inc. field names).
 3. Paste to the clipboard or into the desired application.
- Note:* The bars do not get copied directly. Instead, the table values are copied. This means that overlaid values will not be displayed in the copied table.

To Group Values from a Distribution Table

1. Select values for grouping using the Ctrl+click method.
2. From the Edit menu, choose Group.

Note: When you group and ungroup values, the graph on the Graph tab is automatically redrawn to show the changes.

You can also:

- Ungroup values by selecting the group name in the distribution list and choosing Ungroup from the Edit menu.
- Edit groups by selecting the group name in the distribution list and choosing Edit group from the Edit menu. This opens a dialog box where values can be shifted to and from the group.

Generate Menu Options

You can use options on the Generate menu to select a subset of data, derive a flag field, regroup values, reclassify values, or balance the data from either a graph or table. These operations generate a data preparation node and place it on the stream canvas. To use the generated node, connect it to an existing stream. See the topic [Generating Nodes from Graphs](#) for more information.

Histogram Plot Tab

Field. Select a numeric field for which to show the distribution of values. Only fields that have not been explicitly defined as symbolic (categorical) will be listed.

Overlay. Select a symbolic field to show categories of values for the specified field. Selecting an overlay field converts the histogram to a stacked chart with colors used to represent different categories of the overlay field. Using the Histogram node, there are three types of overlays: color, panel, and animation. See the topic [Aesthetics, Overlays, Panels, and Animation](#) for more information.

Histogram Options Tab

Automatic X range. Select to use the entire range of values in the data along this axis. Deselect to use an explicit subset of values based on your specified Min and Max values. Either enter values or use the arrows. Automatic ranges are selected by default to enable rapid graph building.

Bins. Select either By number or By width.

- Select By number to display a fixed number of bars whose width depends on the range and the number of bins specified. Indicate the number of bins to be used in the graph in the No. of bins option. Use the arrows to adjust the number.
- Select By width to create a graph with bars of a fixed width. The number of bins depends on the specified width and the range of values. Indicate the width of the bars in the Bin width option.

Normalize by color. Select to adjust all bars to the same height, displaying overlaid values as a percentage of the total cases in each bar.

Show normal curve. Select to add a normal curve to the graph showing the mean and variance of the data.

Separate bands for each color. Select to display each overlaid value as a separate band on the graph.

Using Histograms

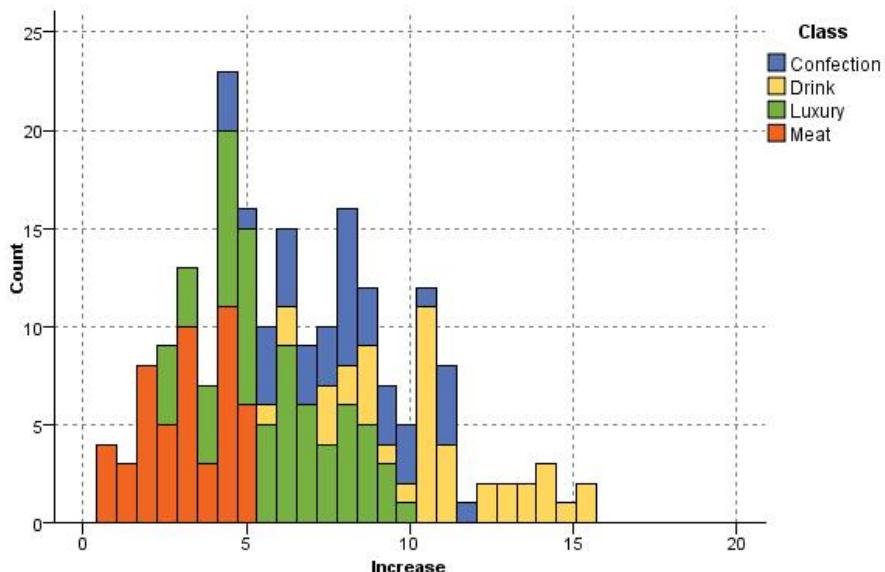

Histograms show the distribution of values in a numeric field whose values range along the x axis. Histograms operate similarly to collections graphs. Collections show the distribution of values for one numeric field *relative to the values of another*, rather than the occurrence of values for a single field.

Once you have created a graph, you can examine the results and define bands to split values along the x axis or define regions. You can also mark elements within the graph. See the topic [Exploring Graphs](#) for more information.

You can use options on the Generate menu to create Balance, Select, or Derive nodes using the data in the graph or more specifically within bands, regions, or marked elements. This type of graph is frequently used before manipulation nodes to explore the data and correct any imbalances by generating a Balance node from the graph to use in the stream. You can also generate a Derive Flag node to add a field showing

which band each record falls into or a Select node to select all records within a particular set or range of values. Such operations help you to focus on a particular subset of data for further exploration. See the topic [Generating Nodes from Graphs](#) for more information.

Collection Node

Collections are similar to histograms except that collections show the distribution of values for one numeric field relative to the values of another, rather than the occurrence of values for a single field. A collection is useful for illustrating a variable or field whose values change over time. Using 3-D graphing, you can also include a symbolic axis displaying distributions by category. Two dimensional Collections are shown as stacked bar charts, with overlays where used. See the topic [Aesthetics, Overlays, Panels, and Animation](#) for more information.

Web Node

Web nodes show the strength of relationships between values of two or more symbolic fields. The graph displays connections using varying types of lines to indicate connection strength. You can use a Web node, for example, to explore the relationship between the purchase of various items at an e-commerce site or a traditional retail outlet.

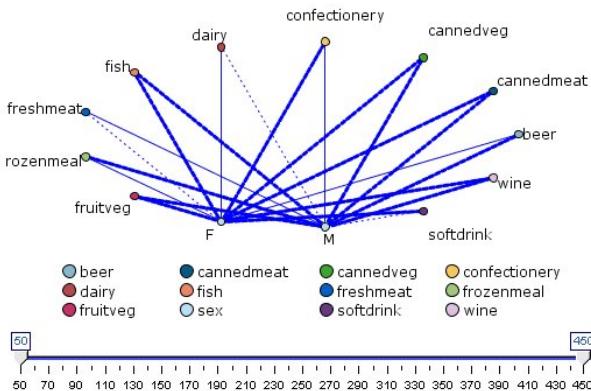

Figure 1. Web graph showing relationships between the purchase of grocery items

Directed Webs

Directed Web nodes are similar to Web nodes in that they show the strength of relationships between symbolic fields. However, directed web graphs show connections only from one or more From fields to a single To field. The connections are unidirectional in the sense that they are one-way connections.

Figure 2. Directed web graph showing the relationship between the purchase of grocery items and gender

Like Web nodes, the graph displays connections using varying types of lines to indicate connection strength. You can use a Directed Web node, for example, to explore the relationship between gender and a proclivity for certain purchase items.

Web Plot Tab

Web. Select to create a web graph illustrating the strength of relationships between all specified fields.

Directed web. Select to create a directional web graph illustrating the strength of relationships between multiple fields and the values of one field, such as gender or religion. When this option is selected, a To Field is activated and the Fields control below is renamed From Fields for additional clarity.

To Field (directed web only). Select a flag or nominal field used for a directed web. Only fields that have not been explicitly set as numeric are listed.

Fields/From Fields. Select fields to create a web graph. Only fields that have not been explicitly set as numeric are listed. Use the Field Chooser button to select multiple fields or select fields by type.

Note: For a directed web, this control is used to select From fields.

Show true flags only. Select to display only true flags for a flag field. This option simplifies the web display and is often used for data where the occurrence of positive values is of special importance.

Line values are. Select a threshold type from the drop-down list.

- Absolute sets thresholds based on the number of records having each pair of values.
- Overall percentages shows the absolute number of cases represented by the link as a proportion of all of the occurrences of each pair of values represented in the web graph.
- Percentages of smaller field/value and Percentages of larger field/value indicate which field/value to use for evaluating percentages. For example, suppose 100 records have the value *drugY* for the field *Drug* and only 10 have the value *LOW* for the field *BP*. If seven records have both values *drugY* and *LOW*, this percentage is either 70% or 7%, depending on which field you are referencing, smaller (*BP*) or larger (*Drug*).

Note: For directed web graphs, the third and fourth options above are not available. Instead, you can select Percentage of "To" field/value and Percentage of "From" field/value.

Strong links are heavier. Selected by default, this is the standard way of viewing links between fields.

Weak links are heavier. Select to reverse the meaning of links displayed in bold lines. This option is frequently used for fraud detection or examination of outliers.

Web Options Tab

The Options tab for Web nodes contains a number of additional options to customize the output graph.

Number of Links. The following options are used to control the number of links displayed in the output graph. Some of these options, such as Weak links above and Strong links above, are also available in the output graph window. You can also use a slider control in the final graph to adjust the number of links displayed.

- Maximum number of links to display. Specify a number indicating the maximum number of links to show on the output graph. Use the arrows to adjust the value.
- Show only links above. Specify a number indicating the minimum value for which to show a connection in the web. Use the arrows to adjust the value.
- Show all links. Specify to display all links regardless of minimum or maximum values. Selecting this option may increase processing time if there are a large number of fields.

Discard if very few records. Select to ignore connections that are supported by too few records. Set the threshold for this option by entering a number in Min. records/line.

Discard if very many records. Select to ignore strongly supported connections. Enter a number in Max. records/line.

Weak links below. Specify a number indicating the threshold for weak connections (dotted lines) and regular connections (normal lines). All connections below this value are considered weak.

Strong links above. Specify a threshold for strong connections (heavy lines) and regular connections (normal lines). All connections above this value are considered strong.

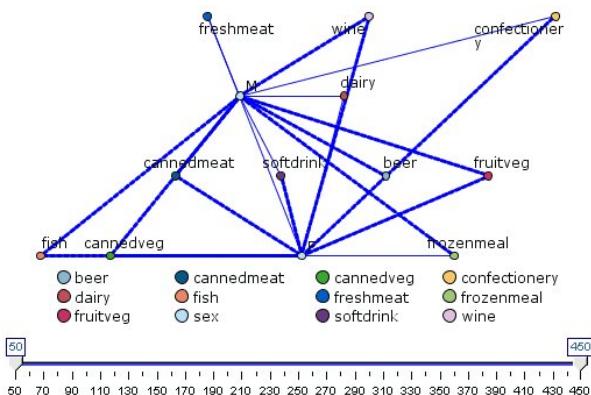

Link Size. Specify options for controlling the size of links:

- Link size varies continuously. Select to display a range of link sizes reflecting the variation in connection strengths based on actual data values.
- Link size shows strong/normal/weak categories. Select to display three strengths of connections--strong, normal, and weak. The cutoff points for these categories can be specified above as well as in the final graph.

Web Display. Select a type of web display:

- Circle layout. Select to use the standard web display.
- Network layout. Select to use an algorithm to group together the strongest links. This is intended to highlight strong links using spatial differentiation as well as weighted lines.
- Directed Layout. Select to create a directed web display that uses the To Field selection from the Plot tab as the focus for the direction.
- Grid Layout. Select to create a web display that is laid out in a regularly spaced grid pattern.

Figure 1. Web graph showing strong connections from frozenmeal and cannedveg to other grocery items

Note: When filtering the displayed links (using either the slider in the web graph or the Show only links above control on the Web node's Options tab), you may end up in a situation where all the links that remain to be displayed are of a single value (in other words, they're either all weak links, all medium links, or all strong links, as defined by the Weak links below and Strong links above controls on the Web node's Options tab). If this happens, all the links are all displayed with the medium width line in the web graph output.

Web Appearance Tab

You can specify appearance options before graph creation.

Title. Enter the text to use for the graph's title.

Subtitle. Enter the text to use for the graph's subtitle.

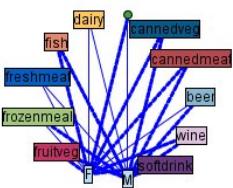

Caption. Enter the text to use for the graph's caption.

Show legend. You can specify whether the legend is displayed. For plots with a large number of fields, hiding the legend may improve the appearance of the plot.

Use labels as nodes. You can include the label text within each node rather than displaying adjacent labels. For plots with a small number of fields, this may result in a more readable chart.

Figure 1. Web graph showing labels as nodes

Relationship between gender and grocery purchases

- [Web Plot Tab](#)
- [Web Options Tab](#)
- [Using a Web Graph](#)
- [Adjusting Web Thresholds](#)
- [Creating a web summary](#).

Using a Web Graph

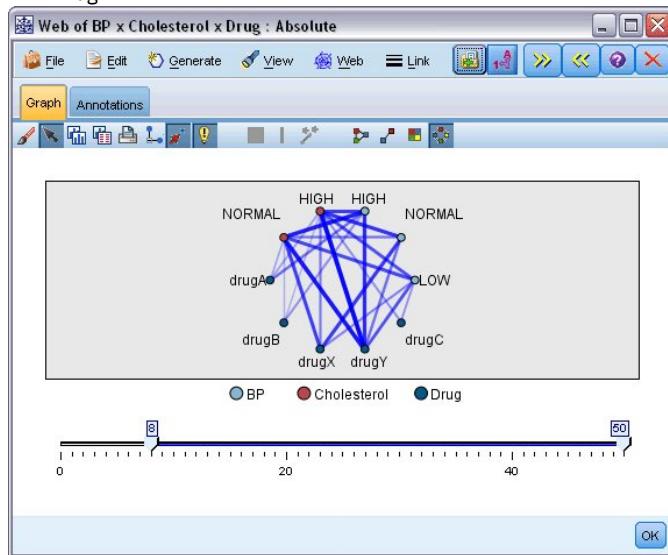

Web nodes are used to show the strength of relationships between values of two or more symbolic fields. Connections are displayed in a graph with varying types of lines to indicate connections of increasing strength. You can use a Web node, for example, to explore the relationship between cholesterol levels, blood pressure, and the drug that was effective in treating the patient's illness.

- Strong connections are shown with a heavy line. This indicates that the two values are strongly related and should be further explored.

- Medium connections are shown with a line of normal weight.
- Weak connections are shown with a dotted line.
- If no line is shown between two values, this means either that the two values never occur in the same record or that this combination occurs in a number of records below the threshold specified in the Web node dialog box.

Once you have created a Web node, there are several options for adjusting the graph display and generating nodes for further analysis.

Figure 1. Web graph indicating a number of strong relationships, such as normal blood pressure with DrugX and high cholesterol with DrugY

For both Web nodes and Directed Web nodes, you can:

- Change the layout of the web display.
- Hide points to simplify the display.
- Change the thresholds controlling line styles.
- Highlight lines between values to indicate a "selected" relationship.
- Generate a Select node for one or more "selected" records or a Derive Flag node associated with one or more relationships in the web.

To adjust points

- **Move** points by clicking the mouse on a point and dragging it to the new location. The web will be redrawn to reflect the new location.
- **Hide** points by right-clicking on a point in the web and choosing Hide or Hide and Replan from the context menu. Hide simply hides the selected point and any lines associated with it. Hide and Replan redraws the web, adjusting for any changes you have made. Any manual moves are undone.
- **Show** all hidden points by choosing Reveal All or Reveal All and Replan from the Web menu in the graph window. Selecting Reveal All and Replan redraws the web, adjusting to include all previously hidden points and their connections.

To select, or "highlight," lines

Selected lines are highlighted in red.

1. To select a single line, left-click the line.
2. To select multiple lines, do one of the following:
 - Using the cursor, draw a circle around the points whose lines you want to select.
 - Hold down the Ctrl key and left-click the individual lines you want to select.

You can deselect all selected lines by clicking the graph background, or by choosing Clear Selection from the Web menu in the graph window.

To view the web using a different layout

From the Web menu, choose Circle Layout, Network Layout, Directed Layout, or Grid Layout to change the layout of the graph.

To turn the links slider on or off

From the View menu, choose Links Slider.

To select or flag records for a single relationship

1. Right-click on the line representing the relationship of interest.
2. From the context menu, choose Generate Select Node For Link or Generate Derive Node For Link.

A Select node or Derive node is automatically added to the stream canvas with the appropriate options and conditions specified:

- The Select node selects all records in the given relationship.
- The Derive node generates a flag indicating whether the selected relationship holds true for records in the entire dataset. The flag field is named by joining the two values in the relationship with an underscore, such as `LOW_drugC` or `drugC_LOW`.

To select or flag records for a group of relationships

1. Select the line(s) in the web display representing relationships of interest.
 2. From the Generate menu in the graph window, choose Select Node ("And"), Select Node ("Or"), Derive Node ("And"), or Derive Node ("Or").
- The "Or" nodes give the disjunction of conditions. This means that the node will apply to records for which any of the selected relationships hold.
 - The "And" nodes give the conjunction of conditions. This means that the node will apply only to records for which all selected relationships hold. An error occurs if any of the selected relationships are mutually exclusive.

After you have completed your selection, a Select node or Derive node is automatically added to the stream canvas with the appropriate options and conditions specified.

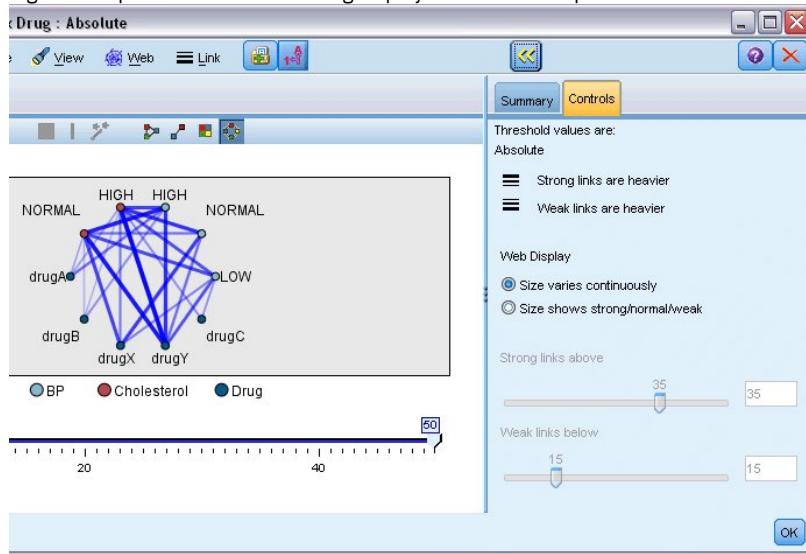

Note: When filtering the displayed links (using either the slider in the web graph or the Show only links above control on the Web node's Options tab), you may end up in a situation where all the links that remain to be displayed are of a single value (in other words, they're either all weak links, all medium links, or all strong links, as defined by the Weak links below and Strong links above controls on the Web node's Options tab). If this happens, all the links are all displayed with the medium width line in the web graph output.

- [Adjusting Web Thresholds](#)
- [Creating a web summary](#)

Adjusting Web Thresholds

After you have created a web graph, you can adjust the thresholds controlling line styles using the toolbar slider to change the minimum visible line. You can also view additional threshold options by clicking the yellow double-arrow button on the toolbar to expand the web graph window. Then click the Controls tab to view additional options.

Figure 1. Expanded window featuring display and threshold options

Threshold values are. Shows the type of threshold selected during creation in the Web node dialog box.

Strong links are heavier. Selected by default, this is the standard way of viewing links between fields.

Weak links are heavier. Select to reverse the meaning of links displayed in bold lines. This option is frequently used for fraud detection or examination of outliers.

Web Display. Specify options for controlling the size of links in the output graph:

- **Size varies continuously.** Select to display a range of link sizes reflecting the variation in connection strengths based on actual data values.
- **Size shows strong/normal/weak.** Select to display three strengths of connections--strong, normal, and weak. The cutoff points for these categories can be specified above as well as in the final graph.

Strong links above. Specify a threshold for strong connections (heavy lines) and regular connections (normal lines). All connections above this value are considered strong. Use the slider to adjust the value or enter a number in the field.

Weak links below. Specify a number indicating the threshold for weak connections (dotted lines) and regular connections (normal lines). All connections below this value are considered weak. Use the slider to adjust the value or enter a number in the field.

After you have adjusted the thresholds for a web, you can replan, or redraw, the web display with the new threshold values through the web menu located on the web graph toolbar. Once you have found settings that reveal the most meaningful patterns, you can update the original settings in the Web node (also called the Parent Web node) by choosing Update Parent Node from the Web menu in the graph window.

Evaluation node

The Evaluation node offers an easy way to evaluate and compare predictive models to choose the best model for your application. Evaluation charts show how models perform in predicting particular outcomes. They work by sorting records based on the predicted value and confidence of the prediction, splitting the records into groups of equal size (**quantiles**), and then plotting the value of the business criterion for each quantile, from highest to lowest. Multiple models are shown as separate lines in the plot.

Outcomes are handled by defining a specific value or range of values as a **hit**. Hits usually indicate success of some sort (such as a sale to a customer) or an event of interest (such as a specific medical diagnosis). You can define hit criteria on the Options tab of the dialog box, or you can use the default hit criteria as follows:

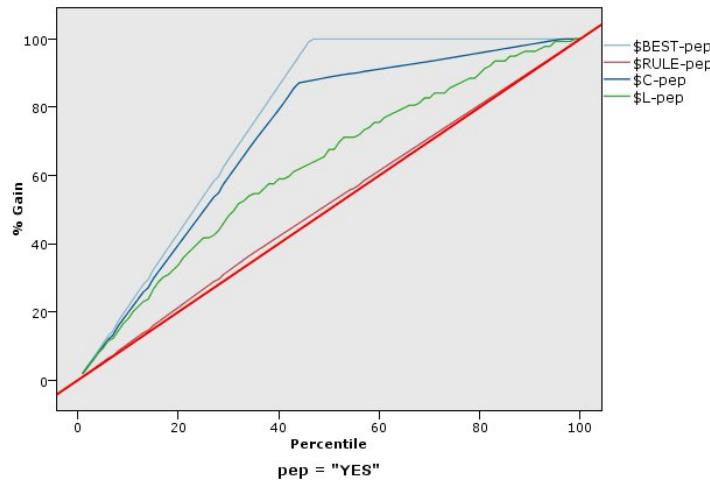

- Flag output fields are straightforward; hits correspond to *true* values.
- For Nominal output fields, the first value in the set defines a hit.
- For Continuous output fields, hits equal values greater than the midpoint of the field's range.

There are six types of evaluation charts, each of which emphasizes a different evaluation criterion.

Gains Charts

Gains are defined as the proportion of total hits that occurs in each quantile. Gains are computed as $(\text{number of hits in quantile} / \text{total number of hits}) \times 100\%$.

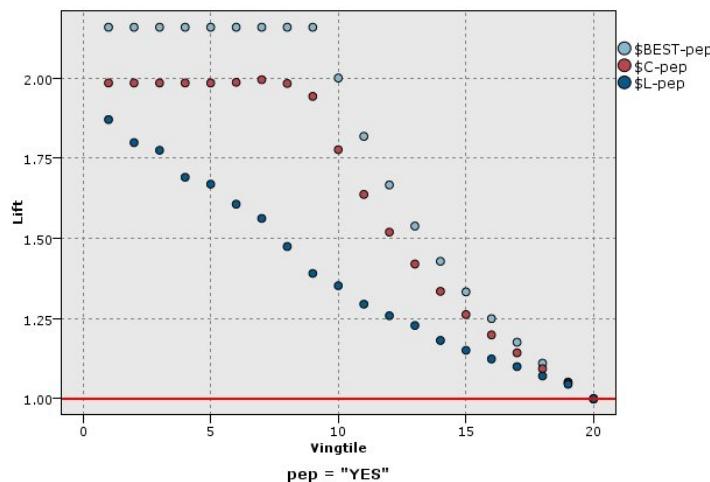

Figure 1. Gains chart (cumulative) with baseline, best line, and business rule displayed

Lift Charts

Lift compares the percentage of records in each quantile that are hits with the overall percentage of hits in the training data. It is computed as $(\text{hits in quantile} / \text{records in quantile}) / (\text{total hits} / \text{total records})$.

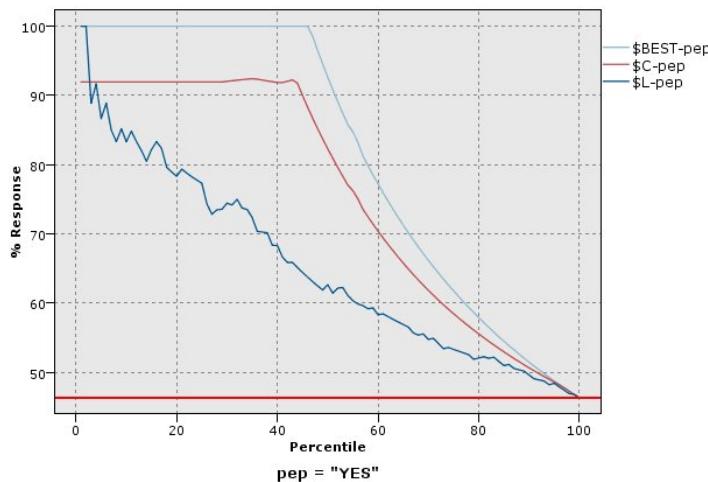

Figure 2. Lift chart (cumulative) using points and best line

Response Charts

Response is simply the percentage of records in the quantile that are hits. Response is computed as $(\text{hits in quantile} / \text{records in quantile}) \times 100\%$.

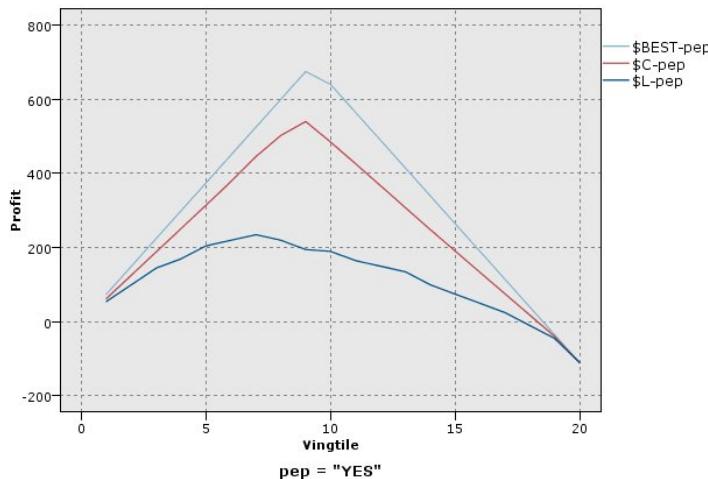

Figure 3. Response chart (cumulative) with best line

Profit Charts

Profit equals the revenue for each record minus the cost for the record. Profits for a quantile are simply the sum of profits for all records in the quantile. Revenues are assumed to apply only to hits, but costs apply to all records. Profits and costs can be fixed or can be defined by fields in the data. Profits are computed as (sum of revenue for records in quantile – sum of costs for records in quantile).

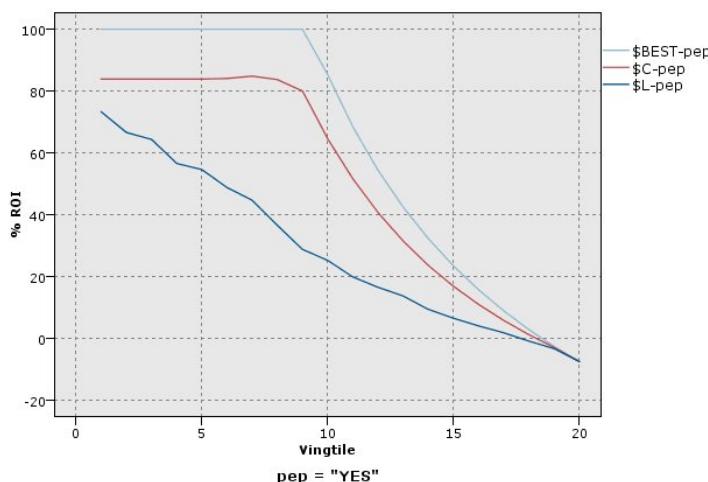

Figure 4. Profit chart (cumulative) with best line

ROI Charts

ROI (return on investment) is similar to profit in that it involves defining revenues and costs. ROI compares profits to costs for the quantile. ROI is computed as (profits for quantile / costs for quantile) × 100%.

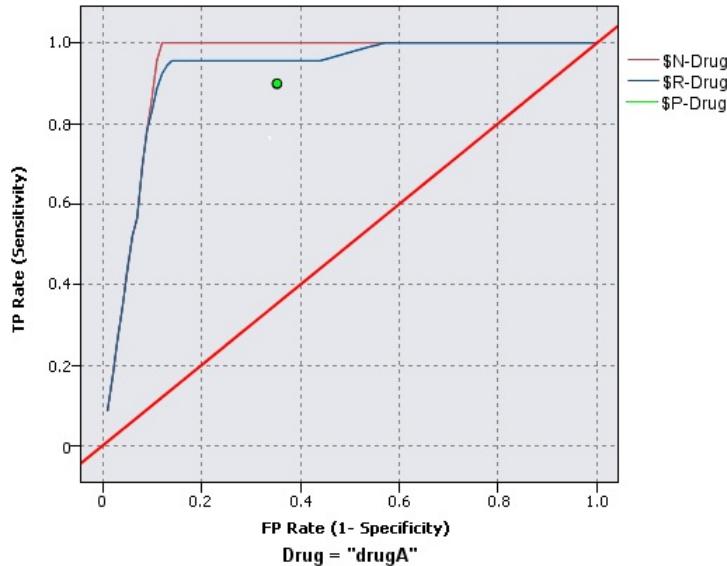

Figure 5. ROI chart (cumulative) with best line

ROC Charts

ROC (receiver operator characteristic) can only be used with binary classifiers. ROC can be used to visualize, organize and select classifiers based on their performance. A ROC chart plots the true positive rate (or sensitivity) against the false positive rate of the classifier. A ROC chart depicts the relative trade-offs between benefits (true positives) and costs (false positives). A true positive is an instance that is a hit and is classified as a hit. Therefore the true positive rate is calculated as the number of true positives / number of instances that are actually hits. A false positive is an instance that is a miss and is classified as a hit. Therefore the false positive rate is calculated as the number of false positives / number of instances that are actually misses.

Figure 6. ROC chart with best line

Evaluation charts can also be cumulative, so that each point equals the value for the corresponding quantile plus all higher quantiles. Cumulative charts usually convey the overall performance of models better, whereas noncumulative charts often excel at indicating particular problem areas for models.

Note: The Evaluation node doesn't support the use of commas in field names. If you have field names containing commas, you must either remove the commas or surround the field name in quotes.

- [Evaluation Plot Tab](#)
- [Evaluation Options tab](#)
- [Evaluation Appearance Tab](#)
- [Reading the Results of a Model Evaluation](#)
- [Using an Evaluation Chart](#)

Evaluation Plot Tab

Chart type. Select one of the following types: Gains, Response, Lift, Profit, ROI (return on investment), or ROC (receiver operator characteristic).

Cumulative plot. Select to create a cumulative chart. Values in cumulative charts are plotted for each quantile plus all higher quantiles. (Cumulative plot is not available for ROC charts.)

Include baseline. Select to include a baseline in the plot, indicating a perfectly random distribution of hits where confidence becomes irrelevant. (Include baseline is not available for Profit and ROI charts.)

Include best line. Select to include a best line in the plot, indicating perfect confidence (where hits = 100% of cases). (Include best line) is not available for ROC charts.)

Use profit criteria for all chart types. Select to use the profit criteria (cost, revenue, and weight) when calculating the evaluation measures, instead of the normal count of hits. For models with certain numeric targets, such as a model that predicts the revenue obtained from a customer in response to an offer, the value of the target field gives a better measure of the performance of the model than the count of hits. Selecting this option enables the Costs, Revenue, and Weight fields for Gains, Response, and Lift charts. To use the profit criteria for these three chart types, it is recommended that you set Revenue to be the target field, Cost to be 0.0 so that profit is equal to revenue, and that you specify a user defined hit condition of "true" so that all records are counted as hits. (Use profit criteria for all chart types is not available for ROC charts.)

Find predicted/predictor fields using. Select either Model output field metadata to search for the predicted fields in the graph using their metadata, or select Field name format to search for them by name.

Plot score fields. Select this check box to enable the score fields chooser. Then select one or more range, or continuous, score fields; that is, fields which are not strictly predictive models but which might be useful to rank records in terms of propensity to be a hit. The Evaluation node can compare any combination of one or more score fields with one or more predictive models. A typical example might be to compare several RFM fields with your best predictive model.

Target. Select the target field using the field chooser. Choose any instantiated flag or nominal field with two or more values.

Note: This target field is only applicable to score fields (predictive models define their own targets), and is ignored if a custom hit criterion is set on the Options tab.

Split by partition. If a partition field is used to split records into training, test, and validation samples, select this option to display a separate evaluation chart for each partition. See the topic [Partition Node](#) for more information.

Note: When splitting by partition, records with null values in the partition field are excluded from the evaluation. This will never be an issue if a Partition node is used, since Partition nodes do not generate null values.

Plot. Select the size of quantiles to plot in the chart from the drop-down list. Options include Quartiles, Quintiles, Deciles, Vingtiles, Percentiles, and 1000-tiles. (Plot is not available for ROC charts.)

Style. Select Line or Point.

For all chart types except ROC charts, additional controls enable you to specify costs, revenue, and weights.

- Costs. Specify the cost associated with each record. You can select Fixed or Variable costs. For fixed costs, specify the cost value. For variable costs, click the Field Chooser button to select a field as the cost field. (Costs is not available for ROC charts.)
- Revenue. Specify the revenue associated with each record that represents a hit. You can select Fixed or Variable costs. For fixed revenue, specify the revenue value. For variable revenue, click the Field Chooser button to select a field as the revenue field. (Revenue is not available for ROC charts.)
- Weight. If the records in your data represent more than one unit, you can use frequency weights to adjust the results. Specify the weight associated with each record, using Fixed or Variable weights. For fixed weights, specify the weight value (the number of units per record). For variable weights, click the Field Chooser button to select a field as the weight field. (Weight is not available for ROC charts.)

Evaluation Options tab

The Options tab for evaluation charts provides flexibility in defining hits, scoring criteria, and business rules displayed in the chart. You can also set options for exporting the results of the model evaluation.

User defined hit. Select to specify a custom condition used to indicate a hit. This option is useful for defining the outcome of interest rather than deducing it from the type of target field and the order of values.

- Condition. When User defined hit is selected above, you must specify a CLEM expression for a hit condition. For example, `@TARGET = "YES"` is a valid condition indicating that a value of Yes for the target field will be counted as a hit in the evaluation. The specified condition will be used for all target fields. To create a condition, type in the field or use the Expression Builder to generate a condition expression. If the data are instantiated, you can insert values directly from the Expression Builder.

User defined score. Select to specify a condition used for scoring cases before assigning them to quantiles. The default score is calculated from the predicted value and the confidence. Use the Expression field to create a custom scoring expression.

- Expression. Specify a CLEM expression used for scoring. For example, if a numeric output in the range 0–1 is ordered so that lower values are better than higher, you might define a hit as `@TARGET < 0.5` and the associated score as `1 - @PREDICTED`. The score expression must result in a numeric value. To create a condition, type in the field or use the Expression Builder to generate a condition expression.

Include business rule. Select to specify a rule condition reflecting criteria of interest. For example, you may want to display a rule for all cases where `mortgage = "Y" and income >= 33000`. Business rules are drawn on the chart and labeled in the key as *Rule*. (Include business rule is not supported for ROC charts.)

- Condition. Specify a CLEM expression used to define a business rule in the output chart. Simply type in the field or use the Expression Builder to generate a condition expression. If the data are instantiated, you can insert values directly from the Expression Builder.

Export results to file. Select to export the results of the model evaluation to a delimited text file. You can read this file to perform specialized analyses on the calculated values. Set the following options for export:

- **Filename.** Enter the filename for the output file. Use the ellipsis button (...) to browse to the desired folder.
- **Delimiter.** Enter a character, such as a comma or space, to use as the field delimiter.

Include field names. Select this option to include field names as the first line of the output file.

New line after each record. Select this option to begin each record on a new line.

Evaluation Appearance Tab

You can specify appearance options before graph creation.

Title. Enter the text to use for the graph's title.

Subtitle. Enter the text to use for the graph's subtitle.

Text. Either accept the automatically generated text label, or select Custom to specify a label.

X label. Either accept the automatically generated x-axis (horizontal) label or select Custom to specify a label.

Y label. Either accept the automatically generated y-axis (vertical) label or select Custom to specify a label.

Display gridline. Selected by default, this option displays a gridline behind the plot or graph that enables you to more easily determine region and band cutoff points. Gridlines are always displayed in white unless the graph background is white; in this case, they are displayed in gray.

Reading the Results of a Model Evaluation

The interpretation of an evaluation chart depends to a certain extent on the type of chart, but there are some characteristics common to all evaluation charts. For cumulative charts, higher lines indicate better models, especially on the left side of the chart. In many cases, when comparing multiple models the lines will cross, so that one model will be higher in one part of the chart and another will be higher in a different part of the chart. In this case, you need to consider what portion of the sample you want (which defines a point on the x axis) when deciding which model to choose.

Most of the noncumulative charts will be very similar. For good models, noncumulative charts should be high toward the left side of the chart and low toward the right side of the chart. (If a noncumulative chart shows a sawtooth pattern, you can smooth it out by reducing the number of quantiles to plot and re-executing the graph.) Dips on the left side of the chart or spikes on the right side can indicate areas where the model is predicting poorly. A flat line across the whole graph indicates a model that essentially provides no information.

Gains charts. Cumulative gains charts always start at 0% and end at 100% as you go from left to right. For a good model, the gains chart will rise steeply toward 100% and then level off. A model that provides no information will follow the diagonal from lower left to upper right (shown in the chart if Include baseline is selected).

Lift charts. Cumulative lift charts tend to start above 1.0 and gradually descend until they reach 1.0 as you go from left to right. The right edge of the chart represents the entire dataset, so the ratio of hits in cumulative quantiles to hits in data is 1.0. For a good model, lift should start well above 1.0 on the left, remain on a high plateau as you move to the right, and then trail off sharply toward 1.0 on the right side of the chart. For a model that provides no information, the line will hover around 1.0 for the entire graph. (If Include baseline is selected, a horizontal line at 1.0 is shown in the chart for reference.)

Response charts. Cumulative response charts tend to be very similar to lift charts except for the scaling. Response charts usually start near 100% and gradually descend until they reach the overall response rate (total hits / total records) on the right edge of the chart. For a good model, the line will start near or at 100% on the left, remain on a high plateau as you move to the right, and then trail off sharply toward the overall response rate on the right side of the chart. For a model that provides no information, the line will hover around the overall response rate for the entire graph. (If Include baseline is selected, a horizontal line at the overall response rate is shown in the chart for reference.)

Profit charts. Cumulative profit charts show the sum of profits as you increase the size of the selected sample, moving from left to right. Profit charts usually start near 0, increase steadily as you move to the right until they reach a peak or plateau in the middle, and then decrease toward

the right edge of the chart. For a good model, profits will show a well-defined peak somewhere in the middle of the chart. For a model that provides no information, the line will be relatively straight and may be increasing, decreasing, or level depending on the cost/revenue structure that applies.

ROI charts. Cumulative ROI (return on investment) charts tend to be similar to response charts and lift charts except for the scaling. ROI charts usually start above 0% and gradually descend until they reach the overall ROI for the entire dataset (which can be negative). For a good model, the line should start well above 0%, remain on a high plateau as you move to the right, and then trail off rather sharply toward the overall ROI on the right side of the chart. For a model that provides no information, the line should hover around the overall ROI value.

ROC charts. ROC curves generally have the shape of a cumulative gains chart. The curve starts at the (0,0) coordinate and ends at the (1,1) coordinate as you go from left to right. A chart that rises steeply toward the (0,1) coordinate then levels off indicates a good classifier. A model that classifies instances at random as hits or misses will follow the diagonal from lower left to upper right (shown in the chart if Include baseline is selected). If no confidence field is provided for a model, the model is plotted as a single point. The classifier with the optimum threshold of classification is located closest to the (0,1) coordinate, or upper left corner, of the chart. This location represents a high number of instances that are correctly classified as hits, and a low number of instances that are incorrectly classified as hits. Points above the diagonal line represent good classification results. Points below the diagonal line represent poor classification results that are worse than if the instances were classified at random.

Using an Evaluation Chart

Using the mouse to explore an evaluation chart is similar to using a histogram or collection graph. The x axis represents model scores across the specified quantiles, such as vingtiles or deciles.

Figure 1. Working with an evaluation chart

You can partition the x axis into bands just as you would for a histogram by using the splitter icon to display options for automatically splitting the axis into equal bands. See the topic [Exploring Graphs](#) for more information. You can manually edit the boundaries of bands by selecting Graph Bands from the Edit menu.

Once you have created an evaluation chart, defined bands, and examined the results, you can use options on the Generate menu and the context menu to automatically create nodes based upon selections in the graph. See the topic [Generating Nodes from Graphs](#) for more information.

When generating nodes from an evaluation chart, you will be prompted to select a single model from all available models in the chart.

Select a model and click OK to generate the new node onto the stream canvas.

Map Visualization Node

The Map Visualization node can accept multiple input connections and display geospatial data on a map as a series of layers. Each layer is a single geospatial field; for example, the base layer might be a map of a country, then above that you might have one layer for roads, one layer for rivers, and one layer for towns.

Although most geospatial datasets ordinarily contain a single geospatial field, when there are multiple geospatial fields in a single input you can choose which fields to display. Two fields from the same input connection cannot be displayed at the same time; however, you can copy and paste the incoming connection and display a different field from each.

Map Visualization Plot Tab

Layers

This table displays information about the inputs to the map node. The order of the layers dictates the order in which the layers are displayed in both the map preview and the visual output when the node is executed. The top row in the table is the 'top' layer and the bottom row is the 'base' layer; in other words, each layer is shown on the map in front of the layer directly below it in the table.

Note: Where a layer in the table contains a three-dimensional geospatial field only the x and y axes are plotted. The z axis is ignored.

Name

Names are automatically created for each layer and are made up using the following format: `tag[source_node:connected_node]`. By default, the tag is shown as a number, with 1 representing the first input that is connected, 2 for the second input, and so on. If required, press the Edit Layer button to change the tag in the Change Map Layer Options dialog box. For example, you might change the tag to be "roads" or "cities" to reflect the data input.

Type

Shows the measurement type icon of the geospatial field that is selected as the layer. If the input data contains multiple fields with a geospatial measurement type the default selection uses the following sort order:

1. Point
2. Linestring
3. Polygon
4. MultiPoint
5. MultiLinestring
6. MultiPolygon

Note: If there are two fields with the same measurement type, the first field (alphabetically by name) is selected by default.

Symbol

Note: This column is only completed for Point and MultiPoint fields.

Shows the symbol that is used for Point or MultiPoint fields. If required, press the Edit Layer button to change the symbol in the Change Map Layer Options dialog box.

Color

Shows the color that is selected to represent layer on the map. If required, press the Edit Layer button to change the color in the Change Map Layer Options dialog box. The color is applied to different items depending on the measurement type.

- For Points or MultiPoints, the color is applied to the symbol for the layer.
- For Linestrings and Polygons, the color is applied to the entire shape. Polygons always have a black outline; the color that is shown in the column is the color that is used to fill the shape.

Preview

This pane shows a preview of the current selection of inputs in the Layers table. The preview takes into account the order of layers, symbol, color, and any other display settings that are associated with the layers and, when possible, updates the display whenever the settings change. If you change details elsewhere in your stream, such as the geospatial fields to use as layers, or if you amend details such as associated aggregation functions, you might need to click the Refresh Data button to update the preview.

Use the Preview to set your display settings before you run your stream. To protect against time delays that could be caused by using a large dataset, the preview samples each layer and creates a display from the first 100 records.

- [Change map layers](#)

Related information

- [Map Visualization Node](#)
 - [Map Visualization Appearance Tab](#)
 - [Change map layers](#)
-

Change map layers

You can use the Change Map Layer Options dialog box to amend various details of any layer that is shown on the Plot tab of the Map Visualization node.

Input details

Tag

By default, the tag is a number; you can replace this number with a more meaningful tag to help identify the layer on the map. For example, the tag might be the name of the data input, such as "Cities".

Layer field

If you have more than one geospatial field in your input data, use this option to select the field that you want to display as a layer on the map.

By default, the layers you can choose from are in the following sort order.

- Point
- LineString
- Polygon
- MultiPoint
- MultiLineString
- MultiPolygon

Display settings

Use hex binning

Note: This option affects only point and multipoint fields.

Hex (hexagonal) binning combines proximate points (based on their x and y coordinates) into a single point to display on the map. The single point is shown as a hexagon, but is effectively rendered as a polygon.

Because the hexagon is rendered as a polygon, any point fields with hex binning turned on are treated as polygons. This means that if you choose to Order by type on the map node dialog box, any point layers that have hex binning applied are rendered above polygon layers but below linestring and point layers.

If you use hex binning for a multipoint field, the field is first converted into a point field by binning the multipoint values to calculate the central point. Central points are used to calculate the hex bins.

Aggregation

Note: This column is only available when you select the Use hex binning check box and also select an Overlay.

If you select an Overlay field for a points layer that uses hex binning, all of the values in that field must be aggregated for all points within the hexagon. Specify an aggregation function for any overlay fields you want to apply to the map. The available aggregation functions depend on the measurement type.

- Aggregation functions for a Continuous measurement type, with Real or Integer storage:
 - Sum
 - Mean
 - Min
 - Max
 - Median
 - First Quartile
 - Third Quartile
- Aggregation functions for a Continuous measurement type, with Time, Date, or Timestamp storage:
 - Mean
 - Min
 - Max
- Aggregation functions for Nominal or Categorical measurement types:
 - Mode
 - Min
 - Max
- Aggregation functions for a Flag measurement type:
 - True, if any are true
 - False, if any are false

Color

Use this option to choose either a standard color to apply to all features of the geospatial field, or an overlay field, which colors the features based on the values from another field in the data.

If you select Standard, you can choose a color from the palette of colors that are shown in the Chart Category Color Order pane in the Display tab of the User Options dialog box.

For more information, see [Setting display options](#).

If you select Overlay, you can choose any field from the data source that contains the geospatial field that was selected as the Layer field.

- For nominal or categorical overlay fields, the color palette that you can choose from is the same as that shown for the Standard color options.
- For continuous and ordinal overlay fields a second drop-down list is displayed, from which you select a color. When you select a color, the overlay is applied by varying the saturation of that color according to the values in the continuous or ordinal field. The highest value uses the color chosen from the drop-down list and lower values are shown by correspondingly lower saturations.

Symbol

Note: Only enabled for point and multipoint measurement types.

Use this option to choose whether to have a Standard symbol, which is applied to all records of your geospatial field, or an Overlay symbol, which changes the symbol icon for the points based on the values of another field in your data.

If you select Standard, you can choose one of the default symbols from a drop-down list to represent the point data on the map.

If you select Overlay, you can choose any nominal, ordinal, or categorical field from the data source that contains the geospatial field that was selected as the Layer field. For each value in the overlay field, a different symbol is displayed on the map.

For example, your data might contain a point field that represents the locations of shops and the overlay might be a shop type field. In this example, all food shops might be identified on the map by a cross symbol and all electronics shops by a square symbol.

Size

Note: Only enabled for point, multipoint, linestring and multilinestring measurement types.

Use this option to choose whether to have a Standard size, which is applied to all records of your geospatial field, or an Overlay size, which changes the size of the symbol icon or line thickness based on the values of another field in your data.

If you select Standard, you can choose a pixel width value. Options available are 1, 2, 3, 4, 5, 10, 20, or 30.

If you select Overlay, you can choose any field from the data source that contains the geospatial field that was selected as the Layer field. The thickness of the line or point varies depending on the value of the chosen field.

Transparency

Use this option to choose whether to have a Standard transparency, which is applied to all records of your geospatial field, or an Overlay transparency, which changes the transparency of the symbol, line, or polygon based on the values of another field in your data.

If you select Standard, you can choose from a selection of transparency levels that start from 0% (opaque) and increase in 10% increments to 100% (transparent).

If you select Overlay, you can choose any field from the data source that contains the geospatial field that was selected as the Layer field. A different level of transparency is displayed on the map for each value in the overlay field. The transparency is applied to the color chosen from the color drop-down list for the point, line, or polygon.

Data Label

Note: This option is not available if you select the Use hex binning check box.

Use this option to select a field to use as data labels on the map. For example, if applied to a polygon layer, the data label might be the name field, containing the name of each polygon. If you select the name field, those names are displayed on the map.

t-SNE node

t-Distributed Stochastic Neighbor Embedding (t-SNE)© is a tool for visualizing high-dimensional data. It converts affinities of data points to probabilities. The affinities in the original space are represented by Gaussian joint probabilities and the affinities in the embedded space are represented by Student's t-distributions. This allows t-SNE to be particularly sensitive to local structure and has a few other advantages over existing techniques:¹

- Revealing the structure at many scales on a single map
- Revealing data that lie in multiple, different, manifolds, or clusters
- Reducing the tendency to crowd points together at the center

The t-SNE node in SPSS® Modeler is implemented in Python and requires the scikit-learn© Python library. For details about t-SNE and the scikit-learn library, see:

- <https://scikit-learn.org/stable/modules/generated/sklearn.manifold.TSNE.html#sklearn.manifold.TSNE>
- <https://scikit-learn.org/stable/modules/manifold.html#t-sne>

The Python tab on the Nodes Palette contains this node and other Python nodes. The t-SNE node is also available on the Graphs tab.

t-SNE node Expert options

Choose Simple mode or Expert mode depending on which options you want to set for the t-SNE node.

Visualization type. Select 2D or 3D to specify whether to draw the graph as two-dimensional or three-dimensional.

Method. Select Barnes Hut or Exact. By default, the gradient calculation algorithm uses Barnes-Hut approximation which runs much faster than the Exact method. Barnes-Hut approximation allows the t-SNE technique to be applied to large, real-world datasets. The Exact algorithm will do a better job of avoiding nearest-neighbor errors.

Init. Select Random or PCA for the initialization of embedding.

Target Field. Select the target field to show as a colormap on the output graph. The graph will use one color if no target field is specified here.

Optimization

Perplexity. The perplexity is related to the number of nearest neighbors that are used in other manifold learning algorithms. Larger datasets usually require a larger perplexity. Consider selecting a value between 5 and 50. Default is 30, and the range is 2 - 9999999.

Early exaggeration. This setting controls how tight natural clusters in the original space will be in the embedded space, and how much space will be between them. Default is 12, and the range is 2 - 9999999.

Learning rate. If the learning rate is too high, the data might look like a "ball" with any point approximately equidistant from its nearest neighbors. If the learning rate is too low, most points may look compressed in a dense cloud with few outliers. If the cost function gets stuck in a bad local minimum, increasing the learning rate may help. Default is 200, and the range is 0 - 9999999.

Max iterations. The maximum number of iterations for the optimization. Default is 1000, and the range is 250 - 9999999.

Angular size. The angular size of a distant node as measured from a point. Enter a value between 0 and 1. Default is 0.5.

Random seed

Set random seed. Select this option and click Generate to generate the seed used by the random number generator.

Optimization stop condition

Max iterations without progress. The maximum number of iterations without progress to perform before stopping the optimization, used after 250 initial iterations with early exaggeration. Note that progress is only checked every 50 iterations, so this value is rounded to the next multiple of 50. Default is 300, and the range is 0 - 9999999.

Min gradient norm. If the gradient norm is below this minimum threshold, the optimization will stop. Default is 1.0E-7.

Metric. The metric to use when calculating distance between instances in a feature array. If the metric is a string, it must be one of the options allowed by `scipy.spatial.distance.pdist` for its metric parameter, or a metric listed in `pairwise.PAIRWISE_DISTANCE_FUNCTIONS`. Select one of the available metric types. Default is euclidean.

When number of records greater than. Specify a method for plotting large datasets. You can specify a maximum dataset size or use the default 2,000 points. Performance is enhanced for large datasets when you select the Bin or Sample options. Alternatively, you can choose to plot all data points by selecting Use all data, but you should note that this may dramatically decrease the performance of the software.

- Bin. Select to enable binning when the dataset contains more than the specified number of records. Binning divides the graph into fine grids before actually plotting and counts the number of connections that would appear in each of the grid cells. In the final graph, one connection is used per cell at the bin centroid (average of all connection points in the bin).
- Sample. Select to randomly sample the data to the specified number of records.

The following table shows the relationship between the settings on the Expert tab of the SPSS® Modeler t-SNE node dialog and the Python t-SNE library parameters.

Table 1. Node properties mapped to Python library parameters

SPSS Modeler setting	Script name (property name)	Python t-SNE parameter
Mode	<code>mode_type</code>	
Visualization type	<code>n_components</code>	<code>n_components</code>
Method	<code>method</code>	<code>method</code>
Initialization of embedding	<code>init</code>	<code>init</code>
Target	<code>target_field</code>	<code>target_field</code>
Perplexity	<code>perplexity</code>	<code>perplexity</code>
Early exaggeration	<code>early_exaggeration</code>	<code>early_exaggeration</code>

SPSS Modeler setting	Script name (property name)	Python t-SNE parameter
Learning rate	learning_rate	learning_rate

Random seed	random_seed	random_state
Max iterations without progress	n_iter_without_progress	n_iter_without_progress
Min gradient norm	min_grad_norm	min_grad_norm
Perform t-SNE with multiple perplexities	isGridSearch	

t-SNE node Output options

Specify options for the t-SNE node output on the Output tab.

Output name. Specify the name of the output that is produced when the node runs. If you select Auto, the name of the output is automatically set.

Output to screen. Select this option to generate and display the output in a new window. The output is also added to the Output manager.

Output to file. Select this option to save the output to a file. Doing so enables the File name and File type fields. The t-SNE node requires access to this output file if you want to create plots using other fields for comparison purposes – or to use its output as predictors in classification or regression models. The t-SNE model creates a result file of x, y (and z) coordinate fields that is most easily accessed using a Fixed File source node.

Accessing and plotting t-SNE data

If you use the Output to file option to save t-SNE output to files, you can then create plots using other fields for comparison purposes – or use the output as predictors in classification or regression models. The t-SNE model creates a result file of x, y (and z) coordinate fields that is most easily accessed using a Fixed File source node. This section provides example information.

1. In the t-SNE node dialog, open the Output tab.
 2. Select Output to file and type a file name. Use the default HTML file type. When you run the model, this will generate three output files in your output location:
 - A text file (result_xxxxxx.txt)
 - An HTML file (the file name you specified)
 - A PNG file (tsne_chart_yyyyyy.png)
- The text file will contain the data you need, but for technical reasons it may be in standard or scientific format. If it's in scientific format (1.1111111e+01), then you need to create a new stream that recognizes the format:

Accessing t-SNE plot data when the text file is in scientific numeric format

1. Create a new stream (File > New Stream).
2. Go to Tools > Stream Properties > Options, select Number formats, and select Scientific (#.###E+##) for the number display format.
3. Add a Fixed File source node to your canvas, and use the following settings on the File tab:
 - Skip header lines: 1
 - Record length: 54
 - tSNE_x Start: 3, Length: 16
 - tSNE_y Start: 20, Length: 16
 - tSNE_z Start: 36, Length: 16
4. On the Type tab, the numbers should be recognized as Real. Click Read Values and you should see field values similar to:

Table 1. Example field values

Field	Measurement	Values
tSNE_x	Continuous	[-7.07176703, 7.14338837]
tSNE_y	Continuous	[-9.2188112, 8.89647667]
tSNE_x	Continuous	[-9.95892882, 9.95742482]

5. Add a Select node to the stream so you can delete the following bottom two rows of text in the file which are read as nulls:

```
*****
Perform t-SNE (total time 9.5s)
```

On the Settings tab of the Select node, select Discard for the mode and use the condition @NULL(tSNE_x) to delete the rows.

6. Add a Type node and a Flat File export node to the stream to create a Var. File source node that will copy and paste back into your original stream.

Accessing t-SNE plot data when the text file is in standard numeric format

1. Create a new stream (File > New Stream).
2. Add a Fixed File source node to your canvas. The following three nodes are all that's required to access the t-SNE data.

Figure 1. Stream for accessing t-SNE plot data in standard numeric format

3. Use the following settings on the File tab of the Fixed File source node:
 - Skip header lines: 1
 - Record length: 29
 - tSNE_x Start: 3, Length: 12
 - tSNE_y Start: 16, Length: 12
4. On the Filter tab, you can rename **field1** and **field2** to **tsneX** and **tsneY**.
5. Add a Merge node to connect it to your stream by using the Order merge method.
6. You can now use a Plot node to plot **tsneX** versus **tsneY** and color it with your field under investigation.

t-SNE model nuggets

t-SNE model nuggets contain all of the information captured by the t-SNE model. The following tabs are available.

Graph

The Graph tab displays chart output for the t-SNE node. A pyplot scatter chart shows the low dimensions result. If you didn't select the Perform t-SNE with multiple perplexities option on the [Expert](#) tab of the t-SNE node, only one graph is included rather than six graphs with different perplexities.

Text output

The Text output tab displays the results of the t-SNE algorithm. If you chose the 2D visualization type on the [Expert](#) tab of the t-SNE node, the result here is the point value in two dimensions. If you chose 3D, the result is the point value in three dimensions.

E-Plot (Beta) node

E-Plot (Beta) nodes show the relationship between numeric fields. The E-Plot (Beta) node is similar to the [Plot](#) node, but its options differ and it uses new graphing capabilities. Use the node to play around with new graphing features in SPSS® Modeler.

The E-Plot (Beta) node provides scatterplots, line charts, and bar charts to illustrate the relationship between numeric fields. The new graphing interface in this node is intuitive and modern, very customizable, and the data charts are interactive. For more information, see [Using an e-plot graph](#).

- [E-Plot \(Beta\) node Plot tab](#)
- [E-Plot \(Beta\) node Options tab](#)
- [E-Plot \(Beta\) Appearance tab](#)
- [Using an e-plot graph](#)

E-Plot (Beta) node Plot tab

Plots show values of a Y field against values of an X field. Often, these fields correspond to a dependent variable and an independent variable, respectively.

X field. From the list, select the field to display on the horizontal x axis.

Y field. From the list, select the field to display on the vertical y axis.

Overlay. There are different ways to illustrate categories for data values. For example, you might use a *maincrop* field as a color overlay to indicate the *estincome* and *claimvalue* values for the main crop grown by claim applicants. Select fields for color mapping, size mapping, and shape mapping in the output. Also select any other interested fields to include in the interactive output. See the topic [Aesthetics, Overlays, Panels, and Animation](#) for more information.

Once you have set options for an e-plot, you can run the plot directly from the dialog box by clicking Run. You may, however, want to use the Options tab for additional specifications.

E-Plot (Beta) node Options tab

Maximum number of records to plot. Specify a method for plotting large datasets. You can specify a maximum dataset size or use the default 2,000 records. Performance is enhanced for large datasets when you select the Sample option. The Sample option randomly samples the data to the number of records entered in the text field. Alternatively, you can choose to plot all data points by selecting Use all data, but you should note that this may dramatically decrease the performance of the software.

E-Plot (Beta) Appearance tab

You can specify a title and subtitle before graph creation, if desired. These options can also be specified or changed after graph creation.

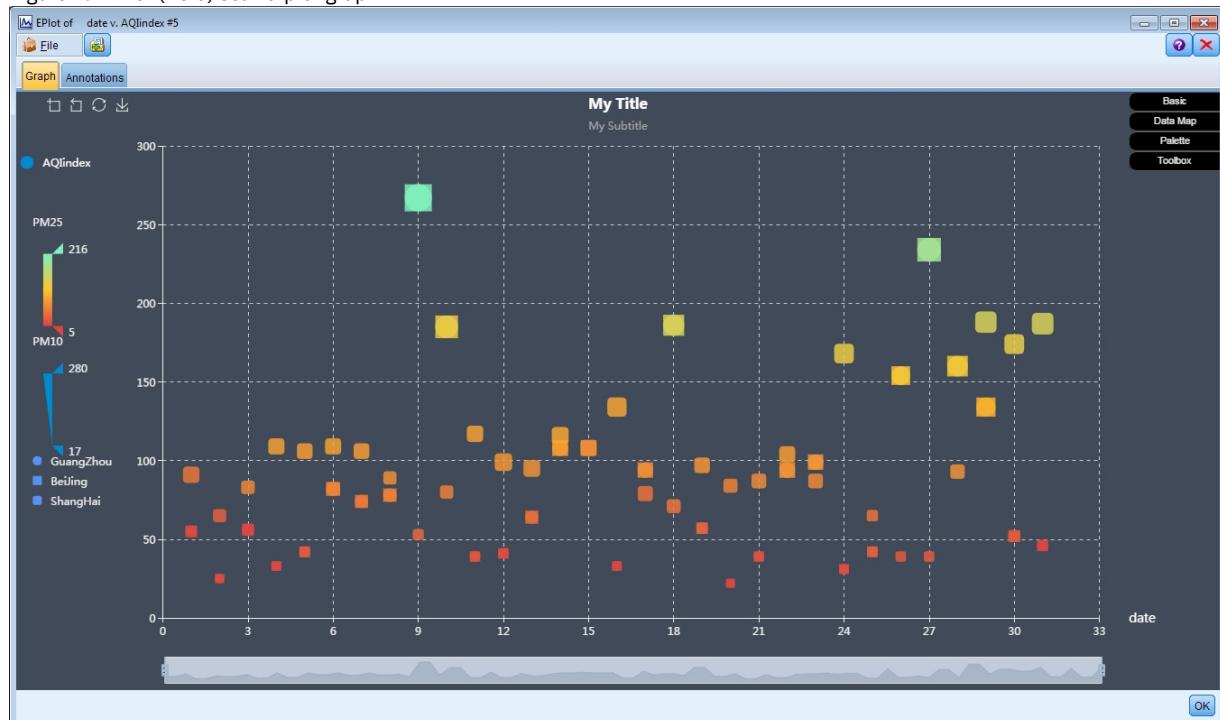

Title. Enter the text to use for the graph's title.

Subtitle. Enter the text to use for the graph's subtitle.

Using an e-plot graph

The E-Plot (Beta) node provides scatterplots, line charts, and bar charts to illustrate the relationship between numeric fields. The new graphing interface introduced in this beta node includes many new and improved capabilities.

Figure 1. E-Plot (Beta) scatterplot graph

On the Graph tab, the upper left corner provides a toolbar for zooming in on a specific section of the chart, zooming back out, returning to the initial full view, or saving the chart for external use:

Figure 2. Toolbar

At the bottom of the window, you can use the slider to zoom in on a specific section of the chart. Move the small rectangular controls on the right and the left to zoom. To use this slider, you must first turn it on in the Toolbox options area.

Figure 3. Zoom slider

The left side of the window provides controls for changing the range of values shown. To use these controls, you must first specify options in the Data Map options area. In the example below, a field named **PM25** is selected for the color map, a field named **PM10** is selected for the size map, and a field called **City** is selected for the shape map. You can hover over the vertical color bars to highlight the corresponding areas of the graph, or slide the upper and lower triangles.

Figure 4. Range controls

On the right side of the window, a set of expandable options is available that you can use to interact with the data and change the chart's appearance in real time:

Figure 5. Expandable options

Basic options

Figure 6. Basic options	Select the dark or light theme, specify a title and a subtitle, select a chart type (scatter, line, or bar), and select the series shown on the Y axis. If you select Line chart, only the fields on the Y axis will be displayed and only the fields on the Y axis will be available in the Data Map options for color map and size map. If you select Bar chart, only color map options will be available in the Data Map options. For the series, all Interested fields you selected on the Plot tab of the E-Plot node will be available here.
-------------------------	--

Data Map options

Figure 7. Data map options 	<p>Select a continuous field or a categorical field for the Color Map. If a continuous field is selected, colors from green to red will be shown. The lower the value is, the closer to red its color will be – and the higher the value is, the closer to green its color will be. If a categorical field is selected, the field color will be displayed according to the defined color palette.</p> <p>Size Map only supports continuous fields. The lower the value is on the chart, the smaller its plot size will be.</p> <p>Shape Map only supports categorical fields. The shape displayed on the map is defined by a categorical field that splits the visualization into elements of different shapes – one for each category.</p>
--	---

Palette options

Figure 8. Palette options 	<p>Use the Palette if you want to customize the colors used for the title and the series. Select the title or the series from the drop-down, click Edit Predefined Colors, and then click More to select a color. Or you can use the RGB or Hex fields to specify an exact color.</p>
---	---

Toolbox options

Figure 9. Toolbox options 	<p>Use the Toolbox options to turn on or off the zoom slider, set gridline properties, and turn on or off mouse tracking. Mouse tracking shows your exact coordinate position when hovering over the chart.</p>
---	---

Working with Graph Output

When you run a stream and obtain a graph, you can interact and edit this graph directly in the output window. For example, you can:

- [Explore the graph](#) by analyzing the data and identifying values. You can draw bands and regions or mark elements to generate Select, Derive, or Balance nodes
- [Edit the graph](#) to change the graph's layout and look.
- [Apply title, footnote, or axis labels](#).
- [Update or change the stylesheet](#).
- [Print, save, copy, or export the graph](#).

- [Adding Titles and Footnotes](#)
- [Using Graph Stylesheets](#)
- [Printing, saving, copying, and exporting graphs](#)

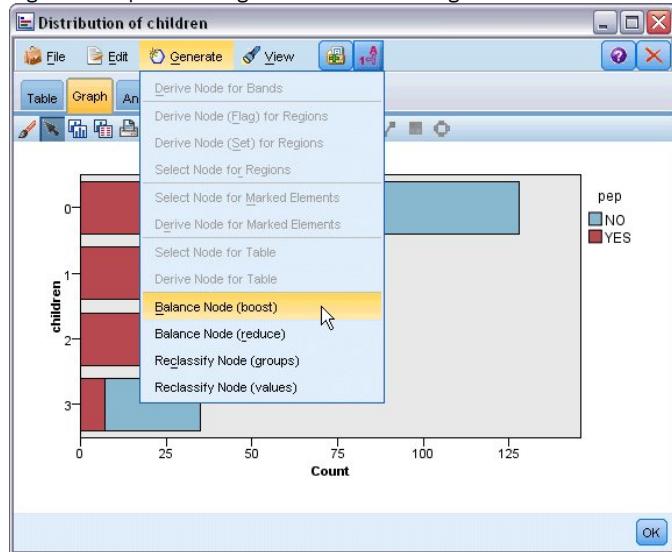

Exploring Graphs

While Edit mode allows you to edit the graph's layout and look, Explore mode allows you to analytically explore the data and values represented by the graph. The main goal of exploration is to analyze the data and then identify values using bands, regions, and marking to generate Select, Derive, or Balance nodes. To select this mode, choose View > Explore Mode from the menus (or click the toolbar icon).

While some graphs can use all of the exploration tools, others accept only one. Explore mode includes:

- Defining and editing bands, which are used to split the values along a scale x axis. See the topic [Using Bands](#) for more information.
- Defining and editing regions, which are used to identify a group of values within the rectangular area. See the topic [Using Regions](#) for more information.
- Marking and unmarking elements to hand select the values that could be used to generate a Select or Derive node. See the topic [Using Marked Elements](#) for more information.
- Generating nodes using the values identified by bands, regions, marked elements, and web links to use in your stream. See the topic [Generating Nodes from Graphs](#) for more information.

Using Bands

In any graph with a scale field on the x axis, you can draw vertical band lines to split the range of values on the x axis. If a graph has multiple panels, a band line drawn in one panel is also represented in the other panels as well.

Not all graphs accept bands. Some of those graphs which can have bands include: histograms, bar charts and distributions, plots (line, scatter, time, etc.), collections, and evaluation charts. In graphs with paneling, bands appear in all panels. And in some cases in a SPLOM, you will see a horizontal band line since the axis on which the field/variable band was drawn has been flipped.

Figure 1. Graph with three bands

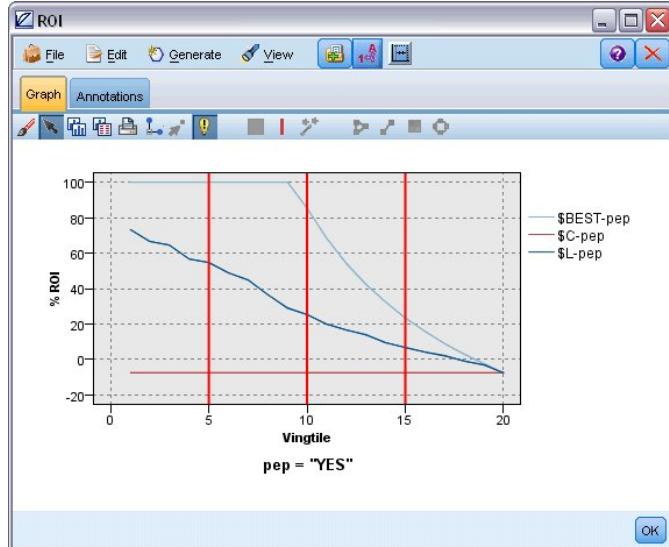

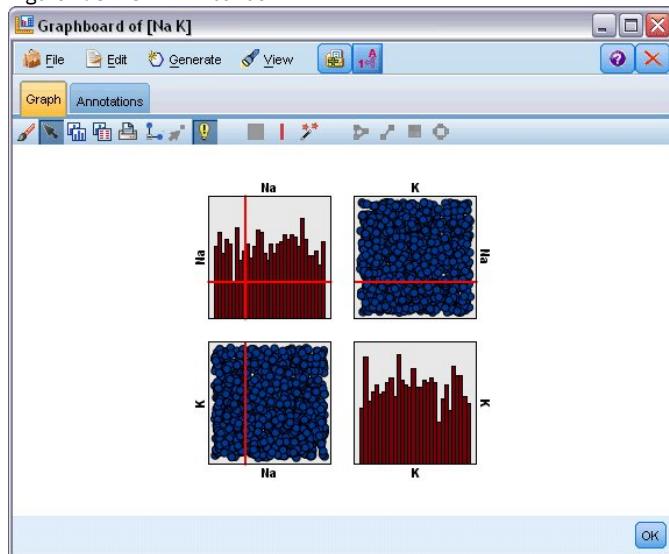

Figure 2. SPLOM with bands

Defining Bands

In a graph without bands, adding a band line splits the graph into two bands. The band line value represents the starting point, also referred to as the lower bound, of the second band when reading the graph from left to right. Likewise, in a graph with two bands, adding a band line splits one of those bands into two, which results in three bands. By default, bands are named *bandN*, where *N* equals the number of bands from left to right on the x axis.

Once you have defined a band, you can drag-and-drop the band to reposition it on the x axis. You can see more shortcuts by right-clicking within a band for tasks such as renaming, deleting, or generating nodes for that specific band.

To define bands:

1. Verify that you are in Explore mode. From the menus, choose View > Explore Mode.
2. In the Explore mode toolbar, click the Draw Band button.

Figure 3. Draw Bands toolbar button

3. In a graph that accepts bands, click the x-axis value point at which you want to define a band line.

Note: Alternatively, click the Split Graph into Bands toolbar icon and enter the number of equal bands you want and click Split.

Figure 4. Splitter icon used to expand the toolbar with options for splitting into bands

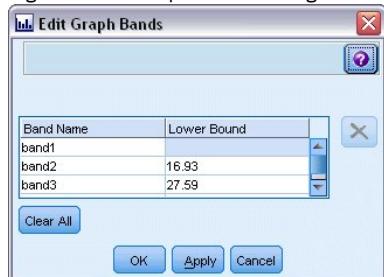

Figure 5. Creating equal bands toolbar with bands enabled

Editing, Renaming, and Deleting Bands

You can edit the properties of existing bands in the Edit Graph Bands dialog box or through context menus in the graph itself.

Figure 6. Edit Graph Bands dialog box

To edit bands:

1. Verify that you are in Explore mode. From the menus, choose View > Explore Mode.
2. In the Explore mode toolbar, click the Draw Band button.
3. From the menus, choose Edit > Graph Bands. The Edit Graph Bands dialog box opens.
4. If you have multiple fields in your graph (such as with SPLOM graphs), you can select the field you want in the drop-down list.
5. Add a new band by typing a name and lower bound. Press the Enter key to begin a new row.
6. Edit a band's boundary by adjusting the Lower Bound value.
7. Rename a band by entering a new band name.
8. Delete a band by selecting the line in the table and clicking the delete button.
9. Click OK to apply your changes and close the dialog box.

Note: Alternatively, you can delete and rename bands directly in the graph by right-clicking the band's line and choosing the option you want from the context menus.

Related information

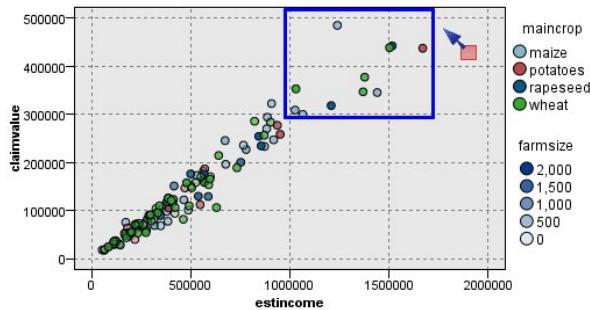

- [Exploring Graphs](#)
- [Using Regions](#)
- [Using Marked Elements](#)
- [Generating Nodes from Graphs](#)

Using Regions

In any graph with two scale (or range) axes, you can draw regions to group values within a rectangular area you draw, called a region. A **region** is an area of the graph described by its minimum and maximum X and Y values. If a graph has multiple panels, a region drawn in one panel is also represented in the other panels as well.

Not all graphs accept regions. Some of those graphs that accept regions include: plots (line, scatter, bubble, time, etc.), SPLOM, and collections. These regions are drawn in X,Y space and cannot, therefore, be defined in 1-D, 3-D, or animated plots. In graphs with paneling, regions appear in all panels. With a scatterplot matrix (SPLOM), a corresponding region will appear in the corresponding upper plots but not on the diagonal plots since they show only one scale field.

Figure 1. Defining a region of high claim values

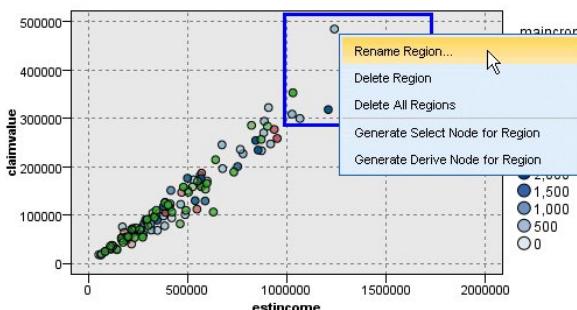

Defining Regions

Wherever you define a region, you are creating a grouping of values. By default, each new region is called *Region<N>*, where *N* corresponds to the number of regions already created.

Once you have a defined a region, you can right-click the region line to get some basic shortcuts. However, you can see many other shortcuts by right-clicking inside the region (not on the line) for tasks such as renaming, deleting, or generating Select and Derive nodes for that specific region.

You can select subsets of records on the basis of their inclusion in a particular region or in one of several regions. You can also incorporate region information for a record by producing a Derive node to flag records based on their inclusion in a region. See the topic [Generating Nodes from Graphs](#) for more information.

Figure 2. Exploring the region of high claim values

To define regions:

1. Verify that you are in Explore mode. From the menus, choose View > Explore Mode.
2. In the Explore mode toolbar, click the Draw Region button.

Figure 3. Draw Region toolbar button

3. In a graph that accepts regions, click and drag your mouse to draw the rectangular region.

Editing, Renaming and Deleting Regions

You can edit the properties of existing regions in the Edit Graph Regions dialog box or through context menus in the graph itself.

Figure 4. Specifying properties for the defined regions

To edit regions:

1. Verify that you are in Explore mode. From the menus, choose View > Explore Mode.
2. In the Explore mode toolbar, click the Draw Region button.
3. From the menus, choose Edit > Graph Regions. The Edit Graph Regions dialog box opens.
4. If you have multiple fields in your graph (for example, SPLOM graphs), you must define the field for the region in the *Field A* and *Field B* columns.
5. Add a new region on a new line by typing a name, selecting field names (if applicable) and defining the maximum and minimum boundaries for each field. Press the Enter key to begin a new row.
6. Edit existing region boundaries by adjusting the Min and Max values for *A* and *B*.
7. Rename a region by changing the region's name in the table.
8. Delete a region by selecting the line in the table and clicking the delete button.
9. Click OK to apply your changes and close the dialog box.

Note: Alternatively, you can delete and rename regions directly in the graph by right-clicking the region's line and choosing the option you want from the context menus.

Using Marked Elements

You can mark elements, such as bars, slices, and points, in any graph. Lines, areas, and surfaces cannot be marked in graphs other than time plot, multiplot, and evaluation graphs since lines refers to fields in those cases. Whenever you mark an element, you are essentially highlighting all of the data represented by that element. In any graph where the same case is represented in more than one place (such as SPLOM), marking is synonymous with brushing. You can mark elements in graphs and even within bands and regions. Whenever you mark an element and then go back into Edit mode, the marking still remains visible.

Figure 1. Marking elements in a SPLOM

You can mark and unmark elements by clicking on elements in the graph. When you first click an element to mark it, the element appears with a thick border color to indicate that it has been marked. If you click the element again, the border disappears and the element is no longer marked.

To mark multiple elements, you can either hold down the Ctrl key while clicking elements, or you can drag the mouse around each of the elements you want marked using the "magic wand". Remember that if you click another area or element without holding down the Ctrl key, all previously marked elements are cleared.

You can generate Select and Derive nodes from the marked elements in your graph. See the topic [Generating Nodes from Graphs](#) for more information.

To mark elements:

1. Verify that you are in Explore mode. From the menus, choose View > Explore Mode.
2. In the Explore mode toolbar, click the Mark Elements button.

Figure 2. Mark Elements toolbar button

3. Either click on the element you require, or click and drag your mouse to draw a line around the region containing multiple elements.

- [Generating Nodes from Graphs](#)

Generating Nodes from Graphs

One of the most powerful features offered by IBM® SPSS® Modeler graphs is the ability to generate nodes from a graph or a selection within the graph. For example, from a time plot graph, you can generate Derive and Select nodes based on a selection or region of data, effectively "subsetting" the data. For example, you might use this powerful feature to identify and exclude outliers.

Whenever you can draw a band, you can also generate a Derive node. In graphs with two scale axes, you can generate Derive or Select nodes from the regions drawn in your graph. In graphs with marked elements, you can generate Derive nodes, Select nodes, and in some cases Filter nodes from these elements. Balance node generation is enabled for any graph showing a distribution of counts.

Figure 1. Graph with the generate menu showing

Whenever you generate a node, it is placed on the stream canvas directly so that you can connect it to an existing stream. The following nodes can be generated from graphs: Select, Derive, Balance, Filter, and Reclassify.

Select Nodes

Select nodes can be generated to test for inclusion of the records within a region and exclusion of all records falling outside the region or the reverse for downstream processing.

- **For bands.** You can generate a Select node that includes or excludes the records within that band. Select node for Bands only is only available through contextual menus since you need to select which band to use in the Select node.
- **For regions.** You can generate a Select node that includes or excludes the records within a region.

- **For marked elements.** You can generate Select nodes to capture the records corresponding to the marked elements or web graph links.

Derive Nodes

Derive nodes can be generated from regions, bands, and marked elements. All graphs can produce Derive nodes. In the case of evaluation charts, a dialog box for selecting the model appears. In the case of web graphs, Derive Node ("And") and Derive Node ("Or") are possible.

- **For bands.** You can generate a Derive node that produces a category for each interval marked on the axis, using the band names listed in the Edit Bands dialog box as category names.
- **For regions.** You can generate a Derive node (Derive as flag) that creates a flag field called *in_region* with the flags set to *T* for records inside any region and *F* for records outside all regions. You can also generate a Derive node (Derive as set) that produces a set with a value for each region with a new field called *region* for each record, which takes as its value the name of the region into which the records fall. Records falling outside all regions receive the name of the default region. Value names become the region names listed in the Edit regions dialog box.
- **For marked elements.** You can generate a Derive node that calculates a flag that is *True* for all marked elements and *False* for all other records.

Balance Nodes

Balance nodes can be generated to correct imbalances in the data, such as reducing the frequency of common values (use Balance Node (reduce) menu option) or boosting the occurrence of infrequent values (use Balance Node (boost) menu option). Balance node generation is enabled for any graph showing a distribution of counts, such as Histogram, Dot, Collection, Bar of Counts, Pie of Counts, and Multiplot.

Filter Nodes

Filter nodes can be generated to rename or filter fields based on the lines or nodes marked in the graph. In the case of evaluation charts, the best fit line does not generate a filter node.

Reclassify Nodes

Reclassify nodes can be generated to recode values. This option is used for distribution graphs. You can generate a Reclassify node for **groups** to recode specific values of a displayed field depending upon their inclusion in a group (select groups using Ctrl+click on the **Tables** tab). You can also generate a reclassify node for **values** to recode data into an existing set of numerous values, such as reclassifying data into a standard set of values in order to merge financial data from various companies for analysis.

Note: If the values are predefined, you can read them into IBM SPSS Modeler as a flat file and use a distribution to display all values. Then generate a Reclassify (values) node for this field directly from the chart. Doing so will put all the target values in the Reclassify node's *New values* column (drop-down list).

When setting options for the Reclassify node, the table enables a clear mapping from old set values to new values you specify:

- **Original value.** This column lists existing values for the select field(s).
- **New value.** Use this column to type new category values or select one from the drop-down list. When you automatically generate a Reclassify node using values from a Distribution chart, these values are included in the drop-down list. This allows you to quickly map existing values to a known set of values. For example, healthcare organizations sometimes group diagnoses differently based upon network or locale. After a merger or acquisition, all parties will be required to reclassify new or even existing data in a consistent fashion. Rather than manually typing each target value from a lengthy list, you can read the master list of values in to IBM SPSS Modeler, run a Distribution chart for the *Diagnosis* field, and generate a Reclassify (values) node for this field directly from the chart. This process will make all of the target Diagnosis values available from the New Values drop-down list.

For more information about the Reclassify Node, see [Setting Options for the Reclassify Node](#).

Generating Nodes from Graphs

You can use the Generate menu in the graph output window to generate nodes. The generated node will be placed on the stream canvas. To use the node, connect it to an existing stream.

To generate a node from a graph:

1. Verify that you are in Explore mode. From the menus, choose View > Explore Mode.
2. In the Explore mode toolbar, click the Region button.
3. Define bands, regions, or any marked elements needed to generate your node.
4. From the Generate menu, choose the kind of node you want to produce. Only those which are possible are enabled.

Note: Alternatively, you can also generate nodes directly from the graph by right-clicking and choosing the generate option you want from the context menus.

Editing Visualizations

While Explore mode allows you to analytically explore the data and values represented by the visualization, Edit mode allows you to change the visualization's layout and look. For example, you can change the fonts and colors to match your organization's style guide. To select this mode, choose View > Edit Mode from the menus (or click the toolbar icon).

In Edit mode, there are several toolbars that affect different aspects of the visualization's layout. If you find that there are any you don't use, you can hide them to increase the amount of space in the dialog box in which the graph is displayed. To select or deselect toolbars, click the relevant toolbar name on the View menu.

Note: To add further detail to your visualizations, you can apply title, footnote, and axis labels. See the topic [Adding Titles and Footnotes](#) for more information.

You have several options for editing a visualization in **Edit mode**. You can:

- Edit text and format it.
- Change the fill color, transparency, and pattern of frames and graphic elements.
- Change the color and dashing of borders and lines.
- Rotate and change the shape and aspect ratio of point elements.
- Change the size of graphic elements (such as bars and points).
- Adjust the space around items by using margins and padding.
- Specify formatting for numbers.
- Change the axis and scale settings.
- Sort, exclude, and collapse categories on a categorical axis.
- Set the orientation of panels.
- Apply transformations to a coordinate system.
- Change statistics, graphic element types, and collision modifiers.
- Change the position of the legend.
- Apply visualization stylesheets.

The following topics describe how to perform these various tasks. It is also recommended that you read the general rules for editing graphs.

How to Switch to Edit Mode

From the menus choose:

General Rules for Editing Visualizations

Edit Mode

All edits are done in Edit mode. To enable Edit mode, from the menus choose:

View > Edit Mode

Selection

The options available for editing depend on selection. Different toolbar and properties palette options are enabled depending on what is selected. Only the enabled items apply to the current selection. For example, if an axis is selected, the Scale, Major Ticks, and Minor Ticks tabs are available in the properties palette.

Here are some tips for selecting items in the visualization:

- Click an item to select it.
- Select a graphic element (such as points in a scatterplot or bars in a bar chart) with a single click. After initial selection, click again to narrow the selection to groups of graphic elements or a single graphic element.
- Press Esc to deselect everything.

Palettes

When an item is selected in the visualization, the various palettes are updated to reflect the selection. The palettes contain controls for making edits to the selection. Palettes may be toolbars or a panel with multiple controls and tabs. Palettes can be hidden, so ensure the necessary palette is displayed for making edits. Check the View menu for palettes that are currently displayed.

You can reposition the palettes by clicking and dragging the empty space in a toolbar palette or the left side of other palettes. Visual feedback lets you know where you can dock the palette. For non-toolbar palettes, you can also click the close button to hide the palette and the undock button to display the palette in a separate window. Click the help button to display help for the specific palette.

Automatic Settings

Some settings provide an -auto- option. This indicates that automatic values are applied. Which automatic settings are used depends on the specific visualization and data values. You can enter a value to override the automatic setting. If you want to restore the automatic setting, delete the current value and press Enter. The setting will display -auto- again.

Removing/Hiding Items

You can remove/hide various items in the visualization. For example, you can hide the legend or axis label. To delete an item, select it and press Delete. If the item does not allow deletion, nothing will happen. If you accidentally delete an item, press Ctrl+Z to undo the deletion.

State

Some toolbars reflect the state of the current selection, others don't. The properties palette always reflects state. If a toolbar does not reflect state, this is mentioned in the topic that describes the toolbar.

Related information

- [Editing Visualizations](#)
-

Editing and Formatting Text

You can edit text in place and change the formatting of an entire text block. Note that you can't edit text that is linked directly to data values. For example, you can't edit a tick label because the content of the label is derived from the underlying data. However, you can format any text in the visualization.

How to Edit Text in Place

1. Double-click the text block. This action selects all the text. All toolbars are disabled at this time, because you cannot change any other part of the visualization while editing text.
2. Type to replace the existing text. You can also click the text again to display a cursor. Position the cursor where you want and enter the additional text.

How to Format Text

1. Select the frame containing the text. Do not double-click the text.
2. Format text using the font toolbar. If the toolbar is not enabled, make sure only the *frame* containing the text is selected. If the text itself is selected, the toolbar will be disabled.

You can change the font:

- Color
- Family (for example, Arial or Verdana)
- Size (the unit is pt unless you indicate a different unit, such as pc)
- Weight
- Alignment relative to the text frame

Formatting applies to all the text in a frame. You can't change the formatting of individual letters or words in any particular block of text.

Related information

 - [General Rules for Editing Visualizations](#)
-

Changing Colors, Patterns, Dashings, and Transparency

Many different items in a visualization have a fill and border. The most obvious example is a bar in a bar chart. The color of the bars is the fill color. They may also have a solid, black border around them.

There are other less obvious items in the visualization that have fill colors. If the fill color is transparent, you may not know there is a fill. For example, consider the text in an axis label. It appears as if this text is "floating" text, but it actually appears in a frame that has a transparent fill color. You can see the frame by selecting the axis label.

Any frame in the visualization can have a fill and border style, including the frame around the whole visualization. Also, any fill has an associated opacity/transparency level that can be adjusted.

How to Change the Colors, Patterns, Dashing, and Transparency

1. Select the item you want to format. For example, select the bars in a bar chart or a frame containing text. If the visualization is split by a categorical variable or field, you can also select the group that corresponds to an individual category. This allows you to change the default aesthetic assigned to that group. For example, you can change the color of one of the stacking groups in a stacked bar chart.
2. To change the fill color, the border color, or the fill pattern, use the color toolbar.

Note: This toolbar does not reflect the state of the current selection.

To change a color or fill, you can click the button to select the displayed option or click the drop-down arrow to choose another option. For colors, notice there is one color that looks like white with a red, diagonal line through it. This is the transparent color. You could use this, for example, to hide the borders on bars in a histogram.

- The first button controls the fill color. If the color is associated with a continuous or ordinal field, this button changes the fill color for the color associated with the highest value in the data. You can use the Color tab on the properties palette to change the color associated with the lowest value and missing data. The color of the elements will change incrementally from the Low color to the High color as the values of the underlying data increase.
- The second button controls the border color.

- The third button controls the fill pattern. The fill pattern uses the border color. Therefore, the fill pattern is visible only if there is a visible border color.
 - The fourth control is a slider and text box that control the opacity of the fill color and pattern. A lower percentage means less opacity and more transparency. 100% is fully opaque (no transparency).
3. To change the dashing of a border or line, use the line toolbar.
Note: This toolbar does not reflect the state of the current selection.

As with the other toolbar, you can click the button to select the displayed option or click the drop-down arrow to choose another option.

- [General Rules for Editing Visualizations](#)

Rotating and Changing the Shape and Aspect Ratio of Point Elements

You can rotate point elements, assign a different predefined shape, or change the aspect ratio (the ratio of width to height).

How to Modify Point Elements

1. Select the point elements. You cannot rotate or change the shape and aspect ratio of individual point elements.
2. Use the symbol toolbar to modify the points.
 - The first button allows you to change the shape of the points. Click the drop-down arrow and select a predefined shape.
 - The second button allows you to rotate the points to a specific compass position. Click the drop-down arrow and then drag the needle to the position you want.
 - The third button allows you to change the aspect ratio. Click the drop-down arrow and then click and drag the rectangle that appears. The shape of the rectangle represents the aspect ratio.

Changing the size of graphic elements

You can change the size of the graphic elements in the visualization. These include bars, lines, and points among others. If the graphic element is sized by a variable or field, the specified size is the *minimum* size.

How to change the size of the graphic elements

1. Select the graphic elements you want to resize.
2. Use the slider to change the size.

Specifying Margins and Padding

If there is too much or too little spacing around or inside a frame in the visualization, you can change its margin and padding settings. The **margin** is the amount of space between the frame and other items around it. The **padding** is the amount of space between the border of the frame and the *contents* of the frame.

How to Specify Margins and Padding

1. Select the frame for which you want to specify margins and padding. This can be a text frame, the frame around the legend, or even the data frame displaying the graphic elements (such as bars and points).
2. Use the Margins tab on the properties palette to specify the settings. All sizes are in pixels unless you indicate a different unit (such as cm or in).

Formatting Numbers

You can specify the format for numbers in tick labels on a continuous axis or data value labels displaying a number. For example, you can specify that numbers displayed in the tick labels are shown in thousands.

How to Specify Number Formats

1. Select the continuous axis tick labels or the data value labels if they contain numbers.
2. Click the Format tab on the properties palette.
3. Select the number formatting options you want:

Prefix. A character to display at the beginning of the number. For example, enter a dollar sign (\$) if the numbers are salaries in U.S. dollars.

Suffix. A character to display at the end of the number. For example, enter a percentage sign (%) if the numbers are percentages.

Min. Integer Digits. Minimum number of digits to display in the integer part of a decimal representation. If the actual value does not contain the minimum number of digits, the integer part of the value will be padded with zeros.

Max. Integer Digits. Maximum number of digits to display in the integer part of a decimal representation. If the actual value exceeds the maximum number of digits, the integer part of the value will be replaced with asterisks.

Min. Decimal Digits. Minimum number of digits to display in the decimal part of a decimal or scientific representation. If the actual value does not contain the minimum number of digits, the decimal part of the value will be padded with zeros.

Max. Decimal Digits. Maximum number of digits to display in the decimal part of a decimal or scientific representation. If the actual value exceeds the maximum number of digits, the decimal is rounded to the appropriate number of digits.

Scientific. Whether to display numbers in scientific notation. Scientific notation is useful for very large or very small numbers. -auto- lets the application determine when scientific notation is appropriate.

Scaling. A scale factor, which is a number by which the original value is divided. Use a scale factor when the numbers are large, but you don't want the label to extend too much to accommodate the number. If you change the number format of the tick labels, be sure to edit the axis title to indicate how the number should be interpreted. For example, assume your scale axis displays salaries and the labels are 30,000, 50,000, and 70,000. You might enter a scale factor of 1000 to display 30, 50, and 70. You should then edit the scale axis title to include the text in thousands.

Parentheses for -ve. Whether parentheses should be displayed around negative values.

Grouping. Whether to display a character between groups of digits. Your computer's current locale determines which character is used for digit grouping.

Changing the Axis and Scale Settings

There are several options for modifying axes and scales.

How to change axis and scale settings

1. Select any part of the axis (for example, the axis label or tick labels).
2. Use the Scale, Major Ticks, and Minor Ticks tabs on the properties palette to change the axis and scale settings.

Scale tab

Note: The Scale tab does not appear for graphs where the data is pre-aggregated (for example, histograms).

Type. Specifies whether the scale is linear or transformed. Scale transformations help you understand the data or make assumptions necessary for statistical inference. On scatterplots, you might use a transformed scale if the relationship between the independent and dependent variables or fields is nonlinear. Scale transformations can also be used to make a skewed histogram more symmetric so that it resembles a normal distribution. Note that you are transforming only the scale on which the data are displayed; you are not transforming the actual data.

- **linear.** Specifies a linear, untransformed scale.

- **log.** Specifies a base-10 log transformed scale. To accommodate zero and negative values, this transformation uses a modified version of the log function. This "safe log" function is defined as `sign(x)`
`* log(1 + abs(x))`. So `safeLog(-99)` equals:
`sign(-99)`
`* log(1 + abs(-99)) = -1 * log(1 + 99) = -1 * 2 = -2`
- **power.** Specifies a power transformed scale, using an exponent of 0.5. To accommodate negative values, this transformation uses a modified version of the power function. This "safe power" function is defined as `sign(x) * pow(abs(x), 0.5)`. So `safePower(-100)` equals:
`sign(-100)`
`* pow(abs(-100), 0.5) = -1 * pow(100, 0.5) = -1 * 10 = -10`

Min/Max/Nice Low/Nice High. Specifies the range for the scale. Selecting Nice Low and Nice High allows the application to select an appropriate scale based on the data. The minimum and maximum are "nice" because they are typically whole values greater or less than the maximum and minimum data values. For example, if the data range from 4 to 92, a nice low and high for scale may be 0 and 100 rather than the actual data minimum and maximum. Be careful that you don't set a range that is too small and hides important items. Also note that you cannot set an explicit minimum and maximum if the Include zero option is selected.

Low Margin/High Margin. Create margins at the low and/or high end of the axis. The margin appears perpendicular to the selected axis. The unit is pixels unless you indicate a different unit (such as cm or in). For example, if you set the High Margin to 5 for the vertical axis, a horizontal margin of 5 px runs along the top of the data frame.

Reverse. Specifies whether the scale is reversed.

Include zero. Indicates that the scale should include 0. This option is commonly used for bar charts to ensure the bars begin at 0, rather than a value near the height of the smallest bar. If this option is selected, Min and Max are disabled because you cannot set a custom minimum and maximum for the scale range.

Major Ticks/Minor Ticks Tabs

Ticks or tick marks are the lines that appear on an axis. These indicate values at specific intervals or categories. **Major ticks** are the tick marks with labels. These are also longer than other tick marks. **Minor ticks** are tick marks that appear between the major tick marks. Some options are specific to the tick type, but most options are available for major and minor ticks.

Show ticks. Specifies whether major or minor ticks are displayed on a graph.

Show gridlines. Specifies whether gridlines are displayed at the major or minor ticks. **Gridlines** are lines that cross a whole graph from axis to axis.

Position. Specifies the position of the tick marks relative to the axis.

Length. Specifies the length of the tick marks. The unit is pixels unless you indicate a different unit (such as cm or in).

Base. Applies only to major ticks. Specifies the value at which the first major tick appears.

Delta. Applies only to major ticks. Specifies the difference between major ticks. That is, major ticks will appear at every n th value, where n is the delta value.

Divisions. Applies only to minor ticks. Specifies the number of minor tick divisions between major ticks. The number of minor ticks is one less than the number of divisions. For example, assume that there are major ticks at 0 and 100. If you enter 2 as the number of minor tick divisions, there will be one minor tick at 50, dividing the 0–100 range and creating two divisions.

Editing Categories

You can edit the categories on a categorical axis in several ways:

- Change the sort order for displaying the categories.
- Exclude specific categories.
- Add a category that does not appear in the data set.
- Collapse/combine small categories into one category.

How to Change the Sort Order of Categories

1. Select a categorical axis. The Categories palette displays the categories on the axis.

Note: If the palette is not visible, make sure that you have it enabled. From the View menu in IBM® SPSS® Modeler, choose Categories.

2. In the Categories palette, select a sorting option from the drop-down list:

Custom. Sort categories based on the order in which they appear in the palette. Use the arrow buttons to move categories to the top of the list, up, down, and to the bottom of the list.

Data. Sort categories based on the order in which they occur in the dataset.

Name. Sort categories alphabetically, using the names as displayed in the palette. This may be either the value or label, depending on whether the toolbar button to display values and labels is selected.

Value. Sort categories by the underlying data value, using the values displayed in parentheses in the palette. Only data sources with metadata (such as IBM SPSS Statistics data files) support this option.

Statistic. Sort categories based on the calculated statistic for each category. Examples of statistics include counts, percentages, and means. This option is available only if a statistic is used in the graph.

How to Add a Category

By default, only categories that appear in the data set are available. You can add a category to the visualization if needed.

1. Select a categorical axis. The Categories palette displays the categories on the axis.

Note: If the palette is not visible, make sure that you have it enabled. From the View menu in IBM SPSS Modeler, choose Categories.

2. In the Categories palette, click the add category button:

Figure 1. Add category button

3. In the Add a new category dialog box, enter a name for the category.

4. Click OK.

How to Exclude Specific Categories

1. Select a categorical axis. The Categories palette displays the categories on the axis.

Note: If the palette is not visible, make sure that you have it enabled. From the View menu in IBM SPSS Modeler, choose Categories.

2. In the Categories palette, select a category name in the Include list, and then click the X button. To move the category back, select its name in the Excluded list, and then click the arrow to the right of the list.

How to Collapse/Combine Small Categories

You can combine categories that are so small you don't need to display them separately. For example, if you have a pie chart with many categories, consider collapsing categories with a percentage less than 10. Collapsing is available only for statistics that are additive. For example, you can't add means together because means are not additive. Therefore, combining/collapsing categories using a mean is not available.

1. Select a categorical axis. The Categories palette displays the categories on the axis.

Note: If the palette is not visible, make sure that you have it enabled. From the View menu in IBM SPSS Modeler, choose Categories.

2. In the Categories palette, select Collapse and specify a percentage. Any categories whose percentage of the total is less than the specified number are combined into one category. The percentage is based on the statistic shown in the chart. Collapsing is available only for count-based and summation (sum) statistics.

Changing the Orientation Panels

If you are using panels in your visualization, you can change their orientation.

How to Change the Orientation of the Panels

1. Select any part of the visualization.
2. Click the Panels tab on the properties palette.
3. Select an option from Layout:

Table. Lays out panels like a table, in that there is a row or column assigned to every individual value.

Transposed. Lays out panels like a table, but also swaps the original rows and columns. This option is not the same as transposing the graph itself. Note that the x axis and the y axis are unchanged when you select this option.

List. Lays out panels like a list, in that each cell represents a combination of values. Columns and rows are no longer assigned to individual values. This option allows the panels to wrap if needed.

Transforming the Coordinate System

Many visualizations are displayed in a flat, rectangular coordinate system. You can transform the coordinate system as needed. For example, you can apply a polar transformation to the coordinate system, add oblique drop shadow effects, and transpose the axes. You can also undo any of these transformations if they are already applied to the current visualization. For example, a pie chart is drawn in a polar coordinate system. You can undo the polar transformation and display the pie chart as a single stacked bar in a rectangular coordinate system.

How to Transform the Coordinate System

1. Select the coordinate system that you want to transform. You select the coordinate system by selecting the frame around the individual graph.
2. Click the Coordinates tab on the properties palette.
3. Select the transformations that you want to apply to the coordinate system. You can also deselect a transformation to undo it.
Transposed. Changing the orientation of the axes is called **transposing**. It is similar to swapping the vertical and horizontal axes in a 2-D visualization.

Polar. A polar transformation draws the graphic elements at a specific angle and distance from the center of the graph. A pie chart is a 1-D visualization with a polar transformation that draws the individual bars at specific angles. A radar chart is a 2-D visualization with a polar transformation that draws graphic elements at specific angles and distances from the center of the graph. A 3-D visualization would also include an additional depth dimension.

Oblique. An oblique transformation adds a 3-D effect to the graphic elements. This transformation adds depth to the graphic elements, but the depth is purely decorative. It is not influenced by particular data values.

Same Ratio. Applying the same ratio specifies that the same distance on each scale represents the same difference in data values. For example, 2cm on both scales represent a difference of 1000.

Pre-transform inset %. If axes are clipped after the transformation, you may want to add insets to the graph before applying the transformation. The insets shrink the dimensions by a certain percentage before any transformations are applied to the coordinate system. You have control over the lower x, upper x, lower y, and upper y dimensions, in that order.

Post-transform inset %. If you want to change the aspect ratio of the graph, you can add insets to the graph after applying the transformation. The insets shrink the dimensions by a certain percentage after any transformations are applied to the coordinate system. These insets can also be applied even if no transformation is applied to the graph. You have control over the lower x, upper x, lower y, and upper y dimensions, in that order.

Changing Statistics and Graphic Elements

You can convert a graphic element to another type, change the statistic used to draw the graphic element, or specify the collision modifier that determines what happens when graphic elements overlap.

How to Convert a Graphic Element

1. Select the graphic element that you want to convert.
2. Click the Element tab on the properties palette.
3. Select a new graphic element type from the Type list.

Table 1. Graphic element types

Graphic Element Type	Description
Point	A marker identifying a specific data point. A point element is used in scatterplots and other related visualizations.
Interval	A rectangular shape drawn at a specific data value and filling the space between an origin and another data value. An interval element is used in bar charts and histograms.
Line	A line that connects data values.
Path	A line that connects data values in the order they appear in the dataset.
Area	A line that connects data elements with the area between the line and an origin filled in.
Polygon	A multi-sided shape enclosing a data region. A polygon element could be used in a binned scatterplot or a map.
Schema	An element consisting of a box with whiskers and markers indicating outliers. A schema element is used for boxplots.

How to Change the Statistic

1. Select the graphic element whose statistic you want to change.
2. Click the Element tab on the properties palette.

How to Specify the Collision Modifier

The collision modifier determines what happens when graphic elements overlap.

1. Select the graphic element for which you want to specify the collision modifier.
2. Click the Element tab on the properties palette.
3. From the Modifier drop-down list, select a collision modifier. -auto- lets the application determine which collision modifier is appropriate for the graphic element type and statistic.

Overlay. Draw graphic elements on top of each other when they have the same value.

Stack. Stack graphic elements that would normally be superimposed when they have the same data values.

Dodge. Move graphic elements next to other graphic elements that appear at the same value, rather than superimposing them. The graphic elements are arranged symmetrically. That is, the graphic elements are moved to opposite sides of a central position. Dodging is very similar to clustering.

Pile. Move graphic elements next to other graphic elements that appear at the same value, rather than superimposing them. The graphic elements are arranged asymmetrically. That is, the graphic elements are piled on top of one another, with the graphic element on the bottom positioned at a specific value on the scale.

Jitter (normal). Randomly reposition graphic elements at the same data value using a normal distribution.

Jitter (uniform). Randomly reposition graphic elements at the same data value using a uniform distribution.

Adding Titles and Footnotes

For all graph types you can add unique title, footnote, or axis labels to help identify what is shown in the graph.

Adding Titles to Graphs

1. From the menus, choose Edit > Add Graph Title. A text box containing <TITLE> is displayed above the graph.
2. Verify that you are in Edit mode. From the menus, choose View > Edit Mode.
3. Double-click the <TITLE> text.
4. Type the required title and press Return.

Adding Footnotes to Graphs

1. From the menus, choose Edit > Add Graph Footnote. A text box containing <FOOTNOTE> is displayed below the graph.
2. Verify that you are in Edit mode. From the menus, choose View > Edit Mode.
3. Double-click the <FOOTNOTE> text.
4. Type the required title and press Return.

Using Graph Stylesheets

Basic graph display information, such as colors, fonts, symbols, and line thickness, are controlled by a stylesheet. There is a default stylesheet supplied with IBM® SPSS® Modeler; however, you can make changes to it if you need. For example, you may have a corporate color scheme for presentations that you want used in your graphs. See the topic [Editing Visualizations](#) for more information.

In the graph nodes, you can use the Edit mode to make style changes to the look of a graph. You can then use the Edit > Styles menu to save the changes as a stylesheet to apply to all graphs that you subsequently generate from the current graph node or as a new default stylesheet for all graphs that you produce using IBM SPSS Modeler.

There are five stylesheet options available from the Styles option on the Edit menu:

- **Switch Stylesheet.** This displays a list of different, stored, stylesheets that you can select to change the look of your graphs. See the topic [Applying stylesheets](#) for more information.
- **Store Styles in Node.** This stores modifications to the selected graph's styles so that they are applied to any future graphs created from the same graph node in the current stream.
- **Store Styles as Default.** This stores modifications to the selected graph's styles so that they are applied to all future graphs created from any graph node in any stream. After selecting this option, you can use Apply Default Styles to change any other existing graphs to use the same styles.
- **Apply Default Styles.** This changes the selected graph's styles to those that are currently saved as the default styles.
- **Apply Original Styles.** This changes a graph's styles back to the ones supplied as the original default.
- [Applying stylesheets](#)

Applying stylesheets

You can apply a visualization stylesheet that specifies stylistic properties of the visualization. For example, the stylesheet can define fonts, dashings, and colors, among other options. To a certain extent, stylesheets provide a shortcut for edits that you would have to perform manually. Note, however, that a stylesheet is limited to *style* changes. Other changes such as the position of the legend or the scale range are not stored in the stylesheet.

How to Apply a Stylesheet

1. From the menus choose:
Edit > Styles > Switch Stylesheet

2. Use the Switch Stylesheet dialog box to select a stylesheet.
3. Click Apply to apply the stylesheet to the visualization without closing the dialog. Click OK to apply the stylesheet and close the dialog box.

Switch>Select Stylesheet Dialog Box

The table at the top of the dialog box lists all of the visualization stylesheets that are currently available. Some stylesheets are pre-installed, while others may have been created in the IBM® SPSS® Visualization Designer (a separate product).

The bottom of the dialog box shows example visualizations with sample data. Select one of the stylesheets to apply its styles to the example visualizations. These examples can help you determine how the stylesheet will affect your actual visualization.

The dialog box also offers the following options.

Existing styles. By default, a stylesheet can overwrite all the styles in the visualization. You can change this behavior.

- **Overwrite all styles.** When applying the stylesheet, overwrite all styles in the visualization, including those styles modified in the visualization during the current editing session.
- **Preserve modified styles.** When applying the stylesheet, overwrite only those styles that were *not* modified in the visualization during the current editing session. Styles that were modified during the current editing session are preserved.

Manage. Manage visualization templates, stylesheets, and maps on your computer. You can import, export, rename, and delete visualization templates, stylesheets, and maps on your local machine. See the topic [Managing Templates, Stylesheets, and Map Files](#) for more information.

Location. Change the location in which visualization templates, stylesheets, and maps are stored. The current location is listed to the right of the button. See the topic [Setting the Location of Templates, Stylesheets, and Maps](#) for more information.

Printing, saving, copying, and exporting graphs

Each graph has a number of options that enable you to save or print the graph or export it to another format. Most of these options are available from the File menu. In addition, from the Edit menu, you can choose to copy the graph, the data within it, or the Microsoft Office Drawing Object for use in another application.

Printing

To print the graph, use the Print menu item or button. Before you print, you can use Page Setup and Print Preview to set print options and preview the output. For more information about configuring page headers and footers, see [Setting Header and Footer Preferences](#).

Saving graphs

To save the graph to an IBM® SPSS® Modeler output file (*.cou), choose File > Save or File > Save As from the menus.

or

To save the graph in the repository, choose File > Store Output from the menus.

Copying graphs

To copy the graph for use in another application, such as MS Word or MS PowerPoint, choose Edit > Copy Graph from the menus.

Copying data

To copy the data for use in another application, such as MS Excel or MS Word, choose Edit > Copy Data from the menus. By default, the data will be formatted as HTML. Use Paste Special in the other application to view other formatting options when pasting.

Copying Microsoft Office Graphic Object

You can copy a graph as a Microsoft Office Graphic Object and use it in Microsoft Office applications such as Excel or PowerPoint. To copy a graph, choose Edit > Copy Microsoft Office Graphic Object from the menus. The content will be copied to your clipboard, and will be in binary format by default. Use Paste Special in the Microsoft Office application to specify other formatting options when pasting.

Note that some content may not support this feature, in which case the Copy Microsoft Office Graphic Object menu option will be disabled. Also note that the appearance of the graph may be different after pasting into an Office application, but the graph data is the same.

There are six types of graph output that can be copied and pasted into Excel: Simple Bar, Stacked Bar, Simple Boxplot, Clustered Boxplot, Simple Scatter, and Grouped Scatter. If using Panel and Animation options for any of these graph types, the Copy Microsoft Office Graphic Object option

will be disabled in SPSS Modeler. And for other settings such as Optional Aesthetics or Overlay, the option is partially supported. See the following table for details:

Table 1. Copy Microsoft Graphic Object support

Graph Output Template	Modeler Graph Node	Modeler Graph Type	Basic Setting	Optional Aesthetics	Overlay	Microsoft Graphic Object Copy Support	Comments
Simple Bar	Graphboard	Bar	Yes	No	N/A	Yes	
		Bar of Counts	Yes	No	N/A	Yes	
		Distribution	Bar	N/A	No	Yes	
Stacked Bar	Graphboard	Bar	Yes	Yes	N/A	Yes with limitation	Only Yes for the categorical variable in Optional Aesthetics.
		Bar of Counts	Yes	Yes	N/A	Yes with limitation	Only Yes for the categorical variable in Optional Aesthetics.
		Distribution	Bar	N/A	Yes	Yes	
Boxplot	Graphboard	Boxplot	Yes	No	N/A	Yes with limitation	Only Yes on Windows.
		Boxplot	Yes	Yes	N/A	No	
Clustered Boxplot	Graphboard	Clustered Boxplot	Yes	No	N/A	Yes with limitation	Only Yes on Windows.
		Clustered Boxplot	Yes	Yes	N/A	No	
Simple Scatter	Graphboard	Bubble Plot	Yes	No	N/A	Yes with limitation	Only Yes for the continuous variables in both X and Y fields, and the categorical variable in Sizes.
		Scatterplot	Yes	No	N/A	Yes with limitation	Only Yes for the continuous variables in both X and Y fields.
		Plot	Point	N/A	No	Yes with limitation	Only Yes for the continuous variables in both X and Y fields.
Grouped Scatter	Graphboard	Bubble Plot	Yes	Yes	N/A	No	
		Scatterplot	Yes	Yes	N/A	Yes with limitation	Only Yes for the continuous variables in both X and Y fields, and the categorical variable in Optional Aesthetics.
		Plot	Point	N/A	Yes	Yes with limitation	Only Yes for the continuous variables in both X and Y fields, and the categorical variable in the Overlay option.

Exporting graphs

The Export Graph option enables you to export the graph in one of the following formats: Bitmap (.bmp), JPEG (.jpg), PNG (.png), HTML (.html), PDF (.pdf), or ViZml document (.xml) for use in other applications.

Note: When the PDF option is selected, the graphs are exported as high resolution PDF files that are cropped to the size of the graphic. To export graphs, choose File > Export Graph from the menus and then choose the format.

Exporting tables

The Export Table option enables you to export the table in one of the following formats: tab delimited (.tab), comma delimited (.csv), or HTML (.html).

To export tables, choose File > Export Table from the menus and then choose the format.

The remainder of this section focuses on the specific options for creating graphs and using them in their output windows.

- [Setting Header and Footer Preferences](#)
-

Setting Header and Footer Preferences

For graphs and other types of output, you can specify options for headers and footers when the page is printed.

Page Header. Select the type and position of page headers for printing and exporting.

Page Footer. Select the type and position of page footers for printing and exporting.

Font options. Select a font and its point size from the drop-down lists. Click the bold or italic buttons to add these effects.

Draw border around header and footer. Select to enclose the header and footer in a thin rectangular border.

Overview of Output Nodes

Output nodes provide the means to obtain information about your data and models. They also provide a mechanism for exporting data in various formats to interface with your other software tools.

The following output nodes are available:

	The Table node displays the data in table format, which can also be written to a file. This is useful anytime that you need to inspect your data values or export them in an easily readable form.
	The Matrix node creates a table that shows relationships between fields. It is most commonly used to show the relationship between two symbolic fields, but it can also show relationships between flag fields or numeric fields.

	The Analysis node evaluates predictive models' ability to generate accurate predictions. Analysis nodes perform various comparisons between predicted values and actual values for one or more model nuggets. They can also compare predictive models to each other.
	The Data Audit node provides a comprehensive first look at the data, including summary statistics, histograms and distribution for each field, as well as information on outliers, missing values, and extremes. Results are displayed in an easy-to-read matrix that can be sorted and used to generate full-size graphs and data preparation nodes.
	The Transform node allows you to select and visually preview the results of transformations before applying them to selected fields.
	The Statistics node provides basic summary information about numeric fields. It calculates summary statistics for individual fields and correlations between fields.
	The Means node compares the means between independent groups or between pairs of related fields to test whether a significant difference exists. For example, you could compare mean revenues before and after running a promotion or compare revenues from customers who did not receive the promotion with those who did.
	The Report node creates formatted reports containing fixed text as well as data and other expressions derived from the data. You specify the format of the report using text templates to define the fixed text and data output constructions. You can provide custom text formatting by using HTML tags in the template and by setting options on the Output tab. You can include data values and other conditional output by using CLEM expressions in the template.
	The Set Globals node scans the data and computes summary values that can be used in CLEM expressions. For example, you can use this node to compute statistics for a field called <i>age</i> and then use the overall mean of <i>age</i> in CLEM expressions by inserting the function <code>@GLOBAL_MEAN(age)</code> .
	The Simulation Fitting node examines the statistical distribution of the data in each field and generates (or updates) a Simulation Generate node, with the best fitting distribution assigned to each field. The Simulation Generate node can then be used to generate simulated data.
	The Simulation Evaluation node evaluates a specified predicted target field, and presents distribution and correlation information about the target field.

Managing output

The Output manager shows the charts, graphs, and tables generated during an IBM® SPSS® Modeler session. You can always reopen an output by double-clicking it in the manager—you do not have to rerun the corresponding stream or node.

To view the Output manager

Open the View menu and choose Managers. Click the Outputs tab.

From the Output manager, you can:

- Display existing output objects, such as histograms, evaluation charts, and tables.
- Rename output objects.
- Save output objects to disk or to the IBM SPSS Collaboration and Deployment Services Repository (if available).
- Add output files to the current project.
- Delete unsaved output objects from the current session.
- Open saved output objects or retrieve them from the IBM SPSS Collaboration and Deployment Services Repository (if available).

To access these options, right-click anywhere on the Outputs tab.

Related information

- [Viewing output](#)

Viewing output

On-screen output is displayed in an output browser window. The output browser window has its own set of menus that allow you to print or save the output, or export it to another format. Note that specific options may vary depending on the type of output.

Printing, saving, and exporting data. More information is available as follows:

- To print the output, use the Print menu option or button. Before you print, you can use Page Setup and Print Preview to set print options and preview the output.
For more information about configuring page headers and footers, see [Setting Header and Footer Preferences](#).
- To save the output to an IBM® SPSS® Modeler output file (.cou), choose Save or Save As from the File menu.
- To save the output in another format, such as text or HTML, choose Export from the File menu. See the topic [Exporting Output](#) for more information.
Note that you can only select these formats if the output contains data that can be sensibly exported in that way. For example, the contents of a decision tree could be exported as text, but the contents of a K-means model would not make sense as text.
- To save the output in a shared repository so that other users can view it using the IBM SPSS Collaboration and Deployment Services Deployment Portal, choose Publish to Web from the File menu. Note that this option requires a separate license for IBM SPSS Collaboration and Deployment Services.

Selecting cells and columns. The Edit menu contains various options for selecting, deselecting, and copying cells and columns, as appropriate for the current output type. See [Selecting cells and columns](#) for more information.

Generating new nodes. The Generate menu enables you to generate new nodes based on the contents of the output browser. The options vary depending on the type of output and the items in the output that are currently selected. For details about the node-generation options for a particular type of output, see the documentation for that output.

- [Publish to Web](#)
- [Viewing Output in an HTML Browser](#)
- [Exporting Output](#)
- [Selecting cells and columns](#)

Publish to Web

The Publish to Web feature enables you to publish certain types of stream output to a central shared IBM® SPSS® Collaboration and Deployment Services Repository that forms the basis of IBM SPSS Collaboration and Deployment Services. If you use this option, other users who need to view this output can do so by using Internet access and an IBM SPSS Collaboration and Deployment Services account--they do not need to have IBM SPSS Modeler installed.

The following table lists the IBM SPSS Modeler nodes that support the Publish to Web feature. Output from these nodes is stored in the IBM SPSS Collaboration and Deployment Services Repository in output object (.cou) format, and can be viewed directly in the IBM SPSS Collaboration and Deployment Services Deployment Portal.

Other types of output can be viewed only if the relevant application (e.g. IBM SPSS Modeler, for stream objects) is installed on the user's machine.

Table 1. Nodes supporting Publish to Web

Node Type	Node
Graphs	all
Output	Table
	Matrix
	Data Audit
	Transform
	Means
	Analysis
	Statistics
	Report (HTML)
IBM SPSS Statistics	Statistics Output

- [Publishing Output to the Web](#)
- [Viewing Published Output Over the Web](#)

Publishing Output to the Web

To publish output to the Web:

1. In an IBM® SPSS® Modeler stream, execute one of the nodes listed in the table. Doing so creates an output object (for example, a table, matrix or report object) in a new window.

2. From the output object window, choose:

File > Publish to Web

Note: If you just want to export simple HTML files for use with a standard Web browser, choose Export from the File menu and select HTML.

3. Connect to the IBM SPSS Collaboration and Deployment Services Repository.

When you have connected successfully, the Repository: Store dialog is displayed, offering a number of storage options.

4. When you have chosen the storage options you want, click Store.

Viewing Published Output Over the Web

You must have an IBM® SPSS® Collaboration and Deployment Services account set up in order to use this feature. If you have the relevant application installed for the object type you want to view (for example, IBM SPSS Modeler or IBM SPSS Statistics), the output is displayed in the application itself rather than in the browser.

To view published output over the Web:

1. Point your browser to `http://<repos_host>:<repos_port>/peb`
where `repos_host` and `repos_port` are the hostname and port number for the IBM SPSS Collaboration and Deployment Services host.
2. Enter the login details for your IBM SPSS Collaboration and Deployment Services account.
3. Click on Content Repository.
4. Navigate to, or search for, the object you want to view.
5. Click on the object name. For some object types, such as graphs, there may be a delay while the object is rendered in the browser.

Viewing Output in an HTML Browser

From the Advanced tab on the Linear, Logistic, and PCA/Factor model nuggets, you can view the displayed information in a separate browser, such as Internet Explorer. The information is output as HTML, enabling you to save it and reuse it elsewhere, such as on a corporate intranet, or Internet site.

To display the information in a browser, click the launch button, situated below the model icon in the top left of the Advanced tab of the model nugget.

Related information

- [Viewing output](#)
- [Exporting Output](#)
- [Selecting cells and columns](#)

Exporting Output

In the output browser window, you may choose to export the output to another format, such as text or HTML. The export formats vary depending on the type of output, but in general are similar to the file type options available if you select Save to file in the node used to generate the output.

Note: You can only select these formats if the output contains data that can be sensibly exported in that way. For example, the contents of a decision tree could be exported as text, but the contents of a K-means model would not make sense as text.

To Export Output

1. In the output browser, open the File menu and choose Export. Then choose the file type that you want to create:

- **Tab Delimited (*.tab).** This option generates a formatted text file containing the data values. This style is often useful for generating a plain-text representation of the information that can be imported into other applications. This option is available for the Table, Matrix, and Means nodes.
- **Comma Delimited (*.dat).** This option generates a comma-delimited text file containing the data values. This style is often useful as a quick way to generate a data file that can be imported into spreadsheets or other data analysis applications. This option is available for the Table, Matrix, and Means nodes.
- **Transposed Tab Delimited (*.tab).** This option is identical to the Tab Delimited option, but the data is transposed so that rows represent fields and the columns represent records.
- **Transposed Comma Delimited (*.dat).** This option is identical to the Comma Delimited option, but the data is transposed so that rows represent fields and the columns represent records.

- **HTML (*.html).** This option writes HTML-formatted output to a file or files.

Related information

Selecting cells and columns

A number of nodes, including the Table node, Matrix node, and Means node, generate tabular output. These output tables can be viewed and manipulated in similar ways, including selecting cells, copying all or part of the table to the Clipboard, generating new nodes based on the current selection, and saving and printing the table.

Selecting cells. To select a cell, click it. To select a rectangular range of cells, click one corner of the desired range, drag the mouse to the other corner of the range, and release the mouse button. To select an entire column, click the column heading. To select multiple columns, use Shift-click or Ctrl-click on column headings.

When you make a new selection, the old selection is cleared. By holding down the Ctrl key while selecting, you can add the new selection to any existing selection instead of clearing the old selection. You can use this method to select multiple, noncontiguous regions of the table. The Edit menu also contains the Select All and Clear Selection options.

Reordering columns. The Table node and Means node output browsers allow you to move columns in the table by clicking a column heading and dragging it to the desired location. You can move only one column at a time.

Related information

-

Table node

The Table node creates a table that lists the values in your data. All fields and all values in the stream are included, making this an easy way to inspect your data values or export them in an easily readable form. Optionally, you can highlight records that meet a certain condition.

Note: Unless you are working with small datasets, it is recommended that you select a subset of the data to pass into the Table node. The Table node cannot display properly when the number of records surpasses a size that can be contained in the display structure (for example, 100 million rows).

- [Table Node Settings Tab](#)
 - [Output Node Output Tab](#)
 - [Table Browser](#)
-

Table Node Settings Tab

Highlight records where. You can highlight records in the table by entering a CLEM expression that is true for the records to be highlighted. This option is enabled only when Output to screen is selected.

Related information

- [Table node](#)
 - [Table Browser](#)
 - [Output Node Output Tab](#)
-

Output Node Output Tab

For nodes that generate table-style output, the Output tab enables you to specify the format and location of the results.

Output name. Specifies the name of the output produced when the node is executed. Auto chooses a name based on the node that generates the output. Optionally, you can select Custom to specify a different name.

Output to screen (the default). Creates an output object to view online. The output object will appear on the Outputs tab of the manager window when the output node is executed.

Output to file. Saves the output to a file when the node is executed. If you choose this option, enter a filename (or navigate to a directory and specify a filename using the File Chooser button) and select a file type. Note that some file types may be unavailable for certain types of output.

Note:

Output data from output nodes is encoded according to the following rules:

- When executing an output node, the stream encoding value (which is set on the Stream Options tab) will be set to the output.
- After the output is generated, its encoding will not be changed even when the stream encoding is changed.
- When exporting output node output, the output file is exported with the currently defined stream encoding. After the output is created, even if you change the stream encoding, it will not impact the generated output.

Note the following exceptions to these rules:

- All HTML exports are encoded in UTF-8 format.
- Output from the Extension output node is generated by a custom user script. So the encoding is controlled by the script.

The following options are available for saving the output to a file:

- Data (tab delimited) (*.tab). This option generates a formatted text file containing the data values. This style is often useful for generating a plain-text representation of the information that can be imported into other applications. This option is available for the Table, Matrix, and Means nodes.
- Data (comma delimited) (*.dat). This option generates a comma-delimited text file containing the data values. This style is often useful as a quick way to generate a data file that can be imported into spreadsheets or other data analysis applications. This option is available for the Table, Matrix, and Means nodes.
- HTML (*.html). This option writes HTML-formatted output to a file or files. For tabular output (from the Table, Matrix, or Means nodes), a set of HTML files contains a contents panel listing field names and the data in an HTML table. The table may be split over multiple HTML files if the number of rows in the table exceeds the Lines per page specification. In this case, the contents panel contains links to all table pages and provides a means of navigating the table. For non-tabular output, a single HTML file is created containing the results of the node.
Note: If the HTML output contains only formatting for the first page, select Paginate output and adjust the Lines per page specification to include all output on a single page. Or if the output template for nodes such as the Report node contains custom HTML tags, be sure you have specified Custom as the format type.
- Text File (*.txt). This option generates a text file containing the output. This style is often useful for generating output that can be imported into other applications, such as word processors or presentation software. This option is not available for some nodes.
- Output object (*.cou). Output objects saved in this format can be opened and viewed in IBM® SPSS® Modeler, added to projects, and published and tracked using the IBM SPSS Collaboration and Deployment Services Repository.

Output view. For the Means node, you can specify whether simple or advanced output is displayed by default. Note you can also toggle between these views when browsing the generated output. See the topic [Means Node Output Browser](#) for more information.

Format. For the Report node, you can choose whether output is automatically formatted or formatted using HTML included in the template. Select Custom to allow HTML formatting in the template.

Title. For the Report node, you can specify optional title text that will appear at the top of the report output.

Highlight inserted text. For the Report node, select this option to highlight text generated by CLEM expressions in the Report template. See the topic [Report Node Template Tab](#) for more information. This option is not recommended when using Custom formatting.

Lines per page. For the Report node, specify a number of lines to include on each page during Auto formatting of the output report.

Transpose data. This option transposes the data before export, so that rows represent fields and the columns represent records.

Note: For large tables, the above options can be somewhat inefficient, especially when working with a remote server. In such cases, using a File output node provides much better performance. See the topic [Flat File Export Node](#) for more information.

Table Browser

The table browser displays tabular data and enables you to perform standard operations including selecting and copying cells, reordering columns, and saving and printing the table. See the topic [Selecting cells and columns](#) for more information. These are the same operations that you can carry out when previewing the data in a node.

Exporting table data. You can export data from the table browser by choosing:

File...>Export

See the topic [Exporting Output](#) for more information.

Data is exported in the system default encoding format, which is specified in the Windows Control Panel or, if running in distributed mode, on the server computer.

Searching the table. The search button (with the binoculars icon) on the main toolbar activates the search toolbar, enabling you to search the table for specific values. You can search forward or backward in the table, you can specify a case-sensitive search (the Aa button), and you can interrupt a search-in-progress with the interrupt search button.

Generating new nodes. The Generate menu contains node generation operations.

- **Select Node ("Records").** Generates a Select node that selects the records for which any cell in the table is selected.
- **Select ("And").** Generates a Select node that selects records containing *all* of the values selected in the table.
- **Select ("Or").** Generates a Select node that selects records containing *any* of the values selected in the table.
- **Derive ("Records").** Generates a Derive node to create a new flag field. The flag field contains *T* for records for which any cell in the table is selected and *F* for the remaining records.
- **Derive ("And").** Generates a Derive node to create a new flag field. The flag field contains *T* for records containing *all* of the values selected in the table and *F* for the remaining records.
- **Derive ("Or").** Generates a Derive node to create a new flag field. The flag field contains *T* for records containing *any* of the values selected in the table and *F* for the remaining records.

-

Matrix node

The Matrix node enables you to create a table that shows relationships between fields. It is most commonly used to show the relationship between two categorical fields (flag, nominal, or ordinal), but it can also be used to show relationships between continuous (numeric range) fields.

- [Matrix Node Settings Tab](#)
 - [Matrix Node Appearance Tab](#)
 - [Matrix node output browser](#)
-

Matrix Node Settings Tab

The Settings tab enables you to specify options for the structure of the matrix.

Fields. Select a field selection type from the following options:

- **Selected.** This option enables you to select a categorical field for the rows and one for the columns of the matrix. The rows and columns of the matrix are defined by the list of values for the selected categorical field. The cells of the matrix contain the summary statistics selected below.
- **All flags (true values).** This option requests a matrix with one row and one column for each flag field in the data. The cells of the matrix contain the counts of double positives for each flag combination. In other words, for a row corresponding to *bought bread* and a column corresponding to *bought cheese*, the cell at the intersection of that row and column contains the number of records for which both *bought bread* and *bought cheese* are true.
- **All numerics.** This option requests a matrix with one row and one column for each numeric field. The cells of the matrix represent the sum of the cross-products for the corresponding pair of fields. In other words, for each cell in the matrix, the values for the row field and the column field are multiplied for each record and then summed across records.

Include missing values. Includes user-missing (blank) and system missing (\$null\$) values in the row and column output. For example, if the value *N/A* has been defined as user-missing for the selected column field, a separate column labeled *N/A* will be included in the table (assuming this value actually occurs in the data) just like any other category. If this option is deselected, the *N/A* column is excluded regardless of how often it occurs.

Note: The option to include missing values applies only when selected fields are cross-tabulated. Blank values are mapped to \$null\$ and are excluded from aggregation for the function field when the mode is Selected and the content is set to Function and for all numeric fields when the mode is set to All Numerics.

Cell contents. If you have chosen Selected fields above, you can specify the statistic to be used in the cells of the matrix. Select a count-based statistic, or select an overlay field to summarize values of a numeric field based on the values of the row and column fields.

- **Cross-tabulations.** Cell values are counts and/or percentages of how many records have the corresponding combination of values. You can specify which cross-tabulation summaries you want using the options on the Appearance tab. The global chi-square value is also displayed along with the significance. See the topic [Matrix node output browser](#) for more information.
- **Function.** If you select a summary function, cell values are a function of the selected overlay field values for cases having the appropriate row and column values. For example, if the row field is *Region*, the column field is *Product*, and the overlay field is *Revenue*, then the cell in the *Northeast* row and the *Widget* column will contain the sum (or average, minimum, or maximum) of revenue for widgets sold in the northeast region. The default summary function is Mean. You can select another function for summarizing the function field. Options include Mean, Sum, SDev (standard deviation), Max (maximum), and Min (minimum).

Related information

 - [Matrix Node Appearance Tab](#)
 - [Matrix node output browser](#)
-

Matrix Node Appearance Tab

The Appearance tab enables you to control sorting and highlighting options for the matrix, as well as statistics presented for cross-tabulation matrices.

Rows and columns. Controls the sorting of row and column headings in the matrix. The default is Unsorted. Select Ascending or Descending to sort row and column headings in the specified direction.

Overlay. Enables you to highlight extreme values in the matrix. Values are highlighted based on cell counts (for cross-tabulation matrices) or calculated values (for function matrices).

- **Highlight top.** You can request the highest values in the matrix to be highlighted (in red). Specify the number of values to highlight.
- **Highlight bottom.** You can also request the lowest values in the matrix to be highlighted (in green). Specify the number of values to highlight.

Note: For the two highlighting options, ties can cause more values than requested to be highlighted. For example, if you have a matrix with six zeros among the cells and you request Highlight bottom 5, all six zeros will be highlighted.

Cross-tabulation cell contents. For cross-tabulations, you can specify the summary statistics contained in the matrix for cross-tabulation matrices. These options are not available when either the All Numerics or Function option is selected on the Settings tab.

- **Counts.** Cells include the number of records with the row value that have the corresponding column value. This is the only default cell content.
- **Expected values.** The expected value for number of records in the cell, assuming that there is no relationship between the rows and columns. Expected values are based on the following formula:
$$p(\text{row value}) * p(\text{column value}) * \text{total number of records}$$
- **Residuals.** The difference between observed and expected values.
- **Percentage of row.** The percentage of all records with the row value that have the corresponding column value. Percentages sum to 100 within rows.
- **Percentage of column.** The percentage of all records with the column value that have the corresponding row value. Percentages sum to 100 within columns.
- **Percentage of total.** The percentage of all records having the combination of column value and row value. Percentages sum to 100 over the whole matrix.
- **Include row and column totals.** Adds a row and a column to the matrix for column and row totals.
- **Apply Settings.** (Output Browser only) Enables you to make changes to the appearance of the Matrix node output without having to close and reopen the Output Browser. Make the changes on this tab of the Output Browser, click this button and then select the Matrix tab to see the effect of the changes.

Related information

- [Matrix node](#)
 - [Matrix Node Settings Tab](#)
 - [Matrix node output browser](#)
 - [Output Node Output Tab](#)
-

Matrix node output browser

The matrix browser displays cross-tabulated data and enables you to perform operations on the matrix, including selecting cells, copying the matrix to the Clipboard in whole or in part, generating new nodes based on the matrix selection, and saving and printing the matrix. The matrix browser may also be used to display output from certain models, such as Naive Bayes models from Oracle.

The File and Edit menus provide the usual options for printing, saving, exporting output, and for selecting and copying data. See the topic [Viewing output](#) for more information.

Chi-square. For a cross-tabulation of two categorical fields, the global Pearson chi-square is also displayed below the table. This test indicates the probability that the two fields are unrelated, based on the difference between observed counts and the counts you would expect if no relationship exists. For example, if there were no relationship between customer satisfaction and store location, you would expect similar satisfaction rates across all stores. But if customers at certain stores consistently report higher rates than others, you might suspect it wasn't a coincidence. The greater the difference, the smaller the probability that it was the result of chance sampling error alone.

- The chi-square test indicates the probability that the two fields are unrelated, in which case any differences between observed and expected frequencies are the result of chance alone. If this probability is very small—typically less than 5%—then the relationship between the two fields is said to be significant.
- If there is only one column or one row (a one-way chi-square test), the degrees of freedom is the number of cells minus one. For a two-way chi-square, the degrees of freedom is the number of rows minus one times the number of columns minus one.
- Use caution when interpreting the chi-square statistic if any of the expected cell frequencies are less than five.
- The chi-square test is available only for a cross-tabulation of two fields. (When All flags or All numerics is selected on the Settings tab, this test is not displayed.)

Generate menu. The Generate menu contains node generation operations. These operations are available only for cross-tabulated matrices, and you must have at least one cell selected in the matrix.

- Select Node. Generates a Select node that selects the records that match any selected cell in the matrix.
- Derive Node (Flag). Generates a Derive node to create a new flag field. The flag field contains *T* for records that match any selected cell in the matrix and *F* for the remaining records.
- Derive Node (Set). Generates a Derive node to create a new nominal field. The nominal field contains one category for each contiguous set of selected cells in the matrix.

- [Matrix Node Settings Tab](#)
- [Matrix Node Appearance Tab](#)

Analysis Node

The Analysis node enables you to evaluate the ability of a model to generate accurate predictions. Analysis nodes perform various comparisons between predicted values and actual values (your target field) for one or more model nuggets. Analysis nodes can also be used to compare predictive models to other predictive models.

When you execute an Analysis node, a summary of the analysis results is automatically added to the Analysis section on the Summary tab for each model nugget in the executed stream. The detailed analysis results appear on the Outputs tab of the manager window or can be written directly to a file.

Note: Because Analysis nodes compare predicted values to actual values, they are only useful with supervised models (those that require a target field). For unsupervised models such as clustering algorithms, there are no actual results available to use as a basis for comparison.

- [Analysis Node Analysis Tab](#)
- [Analysis Output Browser](#)

Analysis Node Analysis Tab

The Analysis tab enables you to specify the details of the analysis.

Coincidence matrices (for symbolic or categorical targets). Shows the pattern of matches between each generated (predicted) field and its target field for categorical targets (either flag, nominal, or ordinal). A table is displayed with rows defined by actual values and columns defined by predicted values, with the number of records having that pattern in each cell. This is useful for identifying systematic errors in prediction. If there is more than one generated field related to the same output field but produced by different models, the cases where these fields agree and disagree are counted and the totals are displayed. For the cases where they agree, another set of correct/wrong statistics is displayed.

Performance evaluation. Shows performance evaluation statistics for models with categorical outputs. This statistic, reported for each category of the output field(s), is a measure of the average information content (in bits) of the model for predicting records belonging to that category. It takes the difficulty of the classification problem into account, so accurate predictions for rare categories will earn a higher performance evaluation index than accurate predictions for common categories. If the model does no better than guessing for a category, the performance evaluation index for that category will be 0.

Evaluation metrics (AUC & Gini, binary classifiers only). For binary classifiers, this option reports the AUC (area under curve) and Gini coefficient evaluation metrics. Both of these evaluation metrics are calculated together for each binary model. The values of the metrics are reported in a table in the analysis output browser.

The AUC evaluation metric is calculated as the area under an ROC (receiver operator characteristic) curve, and is a scalar representation of the expected performance of a classifier. The AUC is always between 0 and 1, with a higher number representing a better classifier. A diagonal ROC curve between the coordinates (0,0) and (1,1) represents a random classifier, and has an AUC of 0.5. Therefore, a realistic classifier will not have an AUC of less than 0.5.

The Gini coefficient evaluation metric is sometimes used as an alternative evaluation metric to the AUC, and the two measures are closely related. The Gini coefficient is calculated as twice the area between the ROC curve and the diagonal, or as $\text{Gini} = 2\text{AUC} - 1$. The Gini coefficient is always between 0 and 1, with a higher number representing a better classifier. The Gini coefficient is negative in the unlikely event that the ROC curve is below the diagonal.

Confidence figures (if available). For models that generate a confidence field, this option reports statistics on the confidence values and their relationship to predictions. There are two settings for this option:

- **Threshold for.** Reports the confidence level above which the accuracy will be the specified percentage.
- **Improve accuracy.** Reports the confidence level above which the accuracy is improved by the specified factor. For example, if the overall accuracy is 90% and this option is set to 2.0, the reported value will be the confidence required for 95% accuracy.

Find predicted/predictor fields using. Determines how predicted fields are matched to the original target field.

- **Model output field metadata.** Matches predicted fields to the target based on model field information, allowing a match even if a predicted field has been renamed. Model field information can also be accessed for any predicted field from the Values dialog box using a Type node. See the topic [Using the Values Dialog Box](#) for more information.
- **Field name format.** Matches fields based on the naming convention. For example predicted values generated by a C5.0 model nugget for a target named *response* must be in a field named *\$C-response*.

Separate by partition. If a partition field is used to split records into training, test, and validation samples, select this option to display results separately for each partition. See the topic [Partition Node](#) for more information.

Note: When separating by partition, records with null values in the partition field are excluded from the analysis. This will never be an issue if a Partition node is used, since Partition nodes do not generate null values.

User defined analysis. You can specify your own analysis calculation to be used in evaluating your model(s). Use CLEM expressions to specify what should be computed for each record and how to combine the record-level scores into an overall score. Use the functions @TARGET and @PREDICTED to refer to the target (actual output) value and the predicted value, respectively.

- **If.** Specify a conditional expression if you need to use different calculations depending on some condition.
- **Then.** Specify the calculation if the If condition is true.
- **Else.** Specify the calculation if the If condition is false.
- **Use.** Select a statistic to compute an overall score from the individual scores.

Break down analysis by fields. Shows the categorical fields available for breaking down the analysis. In addition to the overall analysis, a separate analysis will be reported for each category of each breakdown field.

Related information

- [Analysis Node](#)
- [Analysis Output Browser](#)
- [Output Node Output Tab](#)

Analysis Output Browser

The analysis output browser displays the results of executing the Analysis node. The usual saving, exporting, and printing options are available from the File menu. See the topic [Viewing output](#) for more information.

When you first browse Analysis output, the results are expanded. To hide results after viewing them, use the expander control to the left of the item to collapse the specific results you want to hide or click the Collapse All button to collapse all results. To see results again after collapsing them, use the expander control to the left of the item to show the results or click the Expand All button to show all results.

Results for output field. The Analysis output contains a section for each output field for which there is a corresponding prediction field created by a generated model.

Comparing. Within the output field section is a subsection for each prediction field associated with that output field. For categorical output fields, the top level of this section contains a table showing the number and percentage of correct and incorrect predictions and the total number of records in the stream. For numeric output fields, this section shows the following information:

- **Minimum Error.** Shows the minimum error (difference between observed and predicted values).
- **Maximum Error.** Shows the maximum error.
- **Mean Error.** Shows the average (mean) of errors across all records. This indicates whether there is a systematic **bias** (a stronger tendency to overestimate than to underestimate, or vice versa) in the model.
- **Mean Absolute Error.** Shows the average of the absolute values of the errors across all records. Indicates the average magnitude of error, independent of the direction.
- **Standard Deviation.** Shows the standard deviation of the errors.
- **Linear Correlation.** Shows the linear correlation between the predicted and actual values. This statistic varies between -1.0 and 1.0. Values close to +1.0 indicate a strong positive association, so that high predicted values are associated with high actual values and low predicted values are associated with low actual values. Values close to -1.0 indicate a strong negative association, so that high predicted values are associated with low actual values, and vice versa. Values close to 0.0 indicate a weak association, so that predicted values are more or less independent of actual values. Note: A blank entry here indicates that linear correlation cannot be computed in this case, because either the actual or predicted values are constant.
- **Occurrences.** Shows the number of records used in the analysis.

Coincidence Matrix. For categorical output fields, if you requested a coincidence matrix in the analysis options, a subsection appears here containing the matrix. The rows represent actual observed values, and the columns represent predicted values. The cell in the table indicates the number of records for each combination of predicted and actual values.

Performance Evaluation. For categorical output fields, if you requested performance evaluation statistics in the analysis options, the performance evaluation results appear here. Each output category is listed with its performance evaluation statistic.

Confidence Values Report. For categorical output fields, if you requested confidence values in the analysis options, the values appear here. The following statistics are reported for model confidence values:

- **Range.** Shows the range (smallest and largest values) of confidence values for records in the stream data.
- **Mean Correct.** Shows the average confidence for records that are classified correctly.
- **Mean Incorrect.** Shows the average confidence for records that are classified incorrectly.
- **Always Correct Above.** Shows the confidence threshold above which predictions are always correct and shows the percentage of cases meeting this criterion.
- **Always Incorrect Below.** Shows the confidence threshold below which predictions are always incorrect and shows the percentage of cases meeting this criterion.
- **X% Accuracy Above.** Shows the confidence level at which accuracy is X%. X is approximately the value specified for Threshold for in the Analysis options. For some models and datasets, it is not possible to choose a confidence value that gives the exact threshold specified in the options (usually due to clusters of similar cases with the same confidence value near the threshold). The threshold reported is the closest value to the specified accuracy criterion that can be obtained with a single confidence value threshold.
- **X Fold Correct Above.** Shows the confidence value at which accuracy is X times better than it is for the overall dataset. X is the value specified for Improve accuracy in the Analysis options.

Agreement between. If two or more generated models that predict the same output field are included in the stream, you will also see statistics on the **agreement** between predictions generated by the models. This includes the number and percentage of records for which the predictions agree (for categorical output fields) or error summary statistics (for continuous output fields). For categorical fields, it includes an analysis of predictions compared to actual values for the subset of records on which the models agree (generate the same predicted value).

Evaluation Metrics. For binary classifiers, if you requested evaluation metrics in the analysis options, the values of the AUC and Gini coefficient evaluation metrics are shown in a table in this section. The table has one row for each binary classifier model. The evaluation metrics table is shown for each output field, rather than for each model.

Data Audit node

The Data Audit node provides a comprehensive first look at the data you bring into IBM® SPSS® Modeler, presented in an easy-to-read matrix that can be sorted and used to generate full-size graphs and a variety of data preparation nodes.

- The Audit tab displays a report that provides summary statistics, histograms, and distribution graphs that may be useful in gaining a preliminary understanding of the data. The report also displays the storage icon before the field name.
- The Quality tab in the audit report displays information about outliers, extremes, and missing values, and offers tools for handling these values.

Using the Data Audit node

The Data Audit node can be attached directly to a source node or downstream from an instantiated Type node. You can also generate a number of data preparation nodes based on the results. For example, you can generate a Filter node that excludes fields with too many missing values to be useful in modeling, and generate a SuperNode that imputes missing values for any or all of the fields that remain. This is where the real power of the audit comes in, enabling you not only to assess the current state of your data, but to take action based on the assessment.

Screening or sampling the data. Because an initial audit is particularly effective when dealing with big data, a Sample node may be used to reduce processing time during the initial exploration by selecting only a subset of records. The Data Audit node can also be used in combination with nodes such as Feature Selection and Anomaly Detection in the exploratory stages of analysis.

- [Data Audit Node Settings Tab](#)
- [Data Audit Quality Tab](#)
- [Data Audit Output Browser](#)

Data Audit Node Settings Tab

The Settings tab enables you to specify basic parameters for the audit.

Default. You can simply attach the node to your stream and click Run to generate an audit report for all fields based on default settings, as follows:

- If there are no Type node settings, all fields are included in the report.
- If there are Type settings (regardless of whether or not they are instantiated), all *Input*, *Target*, and *Both* fields are included in the display. If there is a single *Target* field, use it as the Overlay field. If there is more than one *Target* field specified, no default overlay is specified.

Use custom fields. Select this option to manually select fields. Use the field chooser button on the right to select fields individually or by type.

Overlay field. The overlay field is used in drawing the thumbnail graphs shown in the audit report. In the case of a continuous (numeric range) field, bivariate statistics (covariance and correlation) are also calculated. If a single *Target* field is present based on Type node settings, it is used as the default overlay field as described above. Alternatively, you can select Use custom fields in order to specify an overlay.

Display. Enables you to specify whether graphs are available in the output, and to choose the statistics displayed by default.

- Graphs. Displays a graph for each selected field; either a distribution (bar) graph, histogram, or scatterplot as appropriate for the data. Graphs are displayed as thumbnails in the initial report, but full-sized graphs and graph nodes can also be generated. See the topic [Data Audit Output Browser](#) for more information.
- Basic/Advanced statistics. Specifies the level of statistics displayed in the output by default. While this setting determines the initial display, all statistics are available in the output regardless of this setting. See the topic [Display Statistics](#) for more information.

Median and mode. Calculates the median and mode for all fields in the report. Note that with large datasets, these statistics may increase processing time, since they take longer than others to compute. In the case of the median only, the reported value may be based on a sample of 2000 records (rather than the full dataset) in some cases. This sampling is done on a per-field basis in cases where memory limits would otherwise be exceeded. When sampling is in effect, the results will be labeled as such in the output (*Sample Median* rather than just *Median*). All statistics other than the median are always computed using the full dataset.

Empty or typeless fields. When used with instantiated data, typeless fields are not included in the audit report. To include typeless fields (including empty fields), select Clear All Values in any upstream Type nodes. This ensures that data are not instantiated, causing all fields to be included in the report. For example, this may be useful if you want to obtain a complete list of all fields or generate a Filter node that will exclude those that are empty. See the topic [Filtering Fields with Missing Data](#) for more information.

Data Audit Quality Tab

The Quality tab in the Data Audit node provides options for handling missing values, outliers, and extreme values.

Missing Values

- Count of records with valid values. Select this option to show the number of records with valid values for each evaluated field. Note that null (undefined) values, blank values, white spaces and empty strings are always treated as invalid values.
- Breakdown counts of records with invalid values. Select this option to show the number of records with each type of invalid value for each field.

Outliers and Extreme Values

Detection method for outliers and extreme values. Two methods are supported:

Standard deviation from the mean. Detects outliers and extremes based on the number of standard deviations from the mean. For example, if you have a field with a mean of 100 and a standard deviation of 10, you could specify 3.0 to indicate that any value below 70 or above 130 should be treated as an outlier.

Interquartile range. Detects outliers and extremes based on the interquartile range, which is the range within which the two central quartiles fall (between the 25th and 75th percentiles). For example, based on the default setting of 1.5, the lower threshold for outliers would be $Q1 - 1.5 * IQR$ and the upper threshold would be $Q3 + 1.5 * IQR$. Note that using this option may slow performance on large datasets.

Data Audit Output Browser

The Data Audit browser is a powerful tool for gaining overview of your data. The Audit tab displays thumbnail graphs, storage icons, and statistics for all fields, while the Quality tab displays information about outliers, extremes, and missing values. Based on the initial graphs and summary statistics, you might decide to recode a numeric field, derive a new field, or reclassify the values of a nominal field. Or you may want to explore further using more sophisticated visualization. You can do this right from the audit report browser using the Generate menu to create any number of nodes that can be used to transform or visualize the data.

- Sort columns by clicking on the column header, or reorder columns using drag and drop. Most standard output operations are also supported. See the topic [Viewing output](#) for more information.
- View values and ranges for fields by double-clicking a field in the Measurement or Unique columns.
- Use the toolbar or Edit menu to show or hide value labels, or to choose the statistics you want to display. See the topic [Display Statistics](#) for more information.
- Verify the storage icons to the left of the field names. Storage describes the way data are stored in a field. For example, a field with values of 1 and 0 stores integer data. This is distinct from the measurement level, which describes the usage of the data, and does not affect storage. See the topic [Setting Field Storage and Formatting](#) for more information.

-

Viewing and Generating Graphs

If no overlay is selected, the Audit tab displays either bar charts (for nominal or flag fields) or histograms (continuous fields).

For a nominal or flag field overlay, the graphs are colored by the values of the overlay.

For a continuous field overlay, two-dimensional scatterplots are generated rather than one-dimensional bars and histograms. In this case, the x axis maps to the overlay field, enabling you to see the same scale on all x axes as you read down the table.

- For Flag or Nominal fields, hold the mouse cursor over a bar to display the underlying value or label in a ToolTip.
 - For Flag or Nominal fields, use the toolbar to toggle the orientation of thumbnail graphs from horizontal to vertical.
 - To generate a full-sized graph from any thumbnail, double-click on the thumbnail, or select a thumbnail and choose Graph Output from the Generate menu. *Note:* If a thumbnail graph was based on sampled data, the generated graph will contain all cases if the original data stream is still open.
- You can only generate a graph if the Data Audit node that created the output is connected to the stream.
- To generate a matching graph node, select one or more fields on the Audit tab and choose Graph Node from the Generate menu. The resulting node is added to the stream canvas and can be used to re-create the graph each time the stream is run.
 - If an overlay set has more than 100 values, a warning is raised and the overlay is not included.

Display Statistics

The Display Statistics dialog box enables you to choose the statistics displayed on the Audit tab. The initial settings are specified in the Data Audit node. See the topic [Data Audit Node Settings Tab](#) for more information.

Minimum. The smallest value of a numeric variable.

Maximum. The largest value of a numeric variable.

Sum. The sum or total of the values, across all cases with nonmissing values.

Range. The difference between the largest and smallest values of a numeric variable, the maximum minus the minimum.

Mean. A measure of central tendency. The arithmetic average, the sum divided by the number of cases.

Standard Error of Mean. A measure of how much the value of the mean may vary from sample to sample taken from the same distribution. It can be used to roughly compare the observed mean to a hypothesized value (that is, you can conclude the two values are different if the ratio of the difference to the standard error is less than -2 or greater than +2).

standard deviation. A measure of dispersion around the mean, equal to the square root of the variance. The standard deviation is measured in the same units as the original variable.

Variance. A measure of dispersion around the mean, equal to the sum of squared deviations from the mean divided by one less than the number of cases. The variance is measured in units that are the square of those of the variable itself.

Skewness. A measure of the asymmetry of a distribution. The normal distribution is symmetric and has a skewness value of 0. A distribution with a significant positive skewness has a long right tail. A distribution with a significant negative skewness has a long left tail. As a guideline, a skewness value more than twice its standard error is taken to indicate a departure from symmetry.

Standard Error of Skewness. The ratio of skewness to its standard error can be used as a test of normality (that is, you can reject normality if the ratio is less than -2 or greater than +2). A large positive value for skewness indicates a long right tail; an extreme negative value indicates a long left tail.

Kurtosis. A measure of the extent to which there are outliers. For a normal distribution, the value of the kurtosis statistic is zero. Positive kurtosis indicates that the data exhibit more extreme outliers than a normal distribution. Negative kurtosis indicates that the data exhibit less extreme outliers than a normal distribution.

Standard Error of Kurtosis. The ratio of kurtosis to its standard error can be used as a test of normality (that is, you can reject normality if the ratio is less than -2 or greater than +2). A large positive value for kurtosis indicates that the tails of the distribution are longer than those of a normal distribution; a negative value for kurtosis indicates shorter tails (becoming like those of a box-shaped uniform distribution).

Unique. Evaluates all effects simultaneously, adjusting each effect for all other effects of any type.

Valid. Valid cases having neither the system-missing value, nor a value defined as user-missing. Note that null (undefined) values, blank values, white spaces and empty strings are always treated as invalid values.

Median. The value above and below which half of the cases fall, the 50th percentile. If there is an even number of cases, the median is the average of the two middle cases when they are sorted in ascending or descending order. The median is a measure of central tendency not sensitive to outlying values (unlike the mean, which can be affected by a few extremely high or low values).

Mode. The most frequently occurring value. If several values share the greatest frequency of occurrence, each of them is a mode.

Note that median and mode are suppressed by default in order to improve performance but can be selected on the Settings tab in the Data Audit node. See the topic [Data Audit Node Settings Tab](#) for more information.

Statistics for Overlays

If a continuous (numeric range) overlay field is in use, the following statistics are also available:

Covariance. An unstandardized measure of association between two variables, equal to the cross-product deviation divided by N-1.

Imputing Missing Values

The audit report lists the percentage of complete records for each field, along with the number of valid, null, and blank values. You can choose to impute missing values for specific fields as appropriate, and then generate a SuperNode to apply these transformations.

1. In the Impute Missing column, specify the type of values you want to impute, if any. You can choose to impute blanks, nulls, both, or specify a custom condition or expression that selects the values to impute.

There are several types of missing values recognized by IBM® SPSS® Modeler:

- Null or system-missing values. These are nonstring values that have been left blank in the database or source file and have not been specifically defined as "missing" in a source or Type node. System-missing values are displayed as \$null\$. Note that empty strings are not considered nulls in IBM SPSS Modeler, although they may be treated as nulls by certain databases.
- Empty strings and white space. Empty string values and white space (strings with no visible characters) are treated as distinct from null values. Empty strings are treated as equivalent to white space for most purposes. For example, if you select the option to treat white space as blanks in a source or Type node, this setting applies to empty strings as well.
- Blank or user-defined missing values. These are values such as `unknown`, `99`, or `-1` that are explicitly defined in a source node or Type node as missing. Optionally, you can also choose to treat nulls and white space as blanks, which allows them to be flagged for special treatment and to be excluded from most calculations. For example, you can use the `@BLANK` function to treat these values, along with other types of missing values, as blanks.

2. In the Method column, specify the method you want to use.

The following methods are available for imputing missing values:

Fixed. Substitutes a fixed value (either the field mean, midpoint of the range, or a constant that you specify).

Random. Substitutes a random value based on a normal or uniform distribution.

Expression. Allows you to specify a custom expression. For example, you could replace values with a global variable created by the Set Globals node.

Algorithm. Substitutes a value predicted by a model based on the C&RT algorithm. For each field imputed using this method, there will be a separate C&RT model, along with a Filler node that replaces blanks and nulls with the value predicted by the model. A Filter node is then used to remove the prediction fields generated by the model.

3. To generate a Missing Values SuperNode, from the menus choose:

Generate > Missing Values SuperNode

The Missing Values SuperNode dialog box is displayed.

4. Select All fields or Selected fields only, and specify a sample size if desired. (The specified sample is a percentage; by default, 10% of all records are sampled.)
5. Click OK to add the generated SuperNode to the stream canvas.
6. Attach the SuperNode to the stream to apply the transformations.

Within the SuperNode, a combination of model nugget, Filler, and Filter nodes is used as appropriate. To understand how it works, you can edit the SuperNode and click Zoom In, and you can add, edit, or remove specific nodes within the SuperNode to fine-tune the behavior.

-

Handling Outliers and Extreme Values

The audit report lists number of outliers and extremes is listed for each field based on the detection options specified in the Data Audit node. See the topic [Data Audit Quality Tab](#) for more information. You can choose to coerce, discard, or nullify these values for specific fields as appropriate, and then generate a SuperNode to apply the transformations.

1. In the Action column, specify handling for outliers and extremes for specific fields as desired.

The following actions are available for handling outliers and extremes:

- **Coerce.** Replaces outliers and extreme values with the nearest value that would not be considered extreme. For example if an outlier is defined to be anything above or below three standard deviations, then all outliers would be replaced with the highest or lowest value within this range.
 - **Discard.** Discards records with outlying or extreme values for the specified field.
 - **Nullify.** Replaces outliers and extremes with the null or system-missing value.
 - **Coerce outliers / discard extremes.** Discards extreme values only.
 - **Coerce outliers / nullify extremes.** Nullifies extreme values only.
2. To generate the SuperNode, from the menus choose:
Generate > Outlier & Extreme SuperNode

The Outlier SuperNode dialog box is displayed.

3. Select All fields or Selected fields only, and then click OK to add the generated SuperNode to the stream canvas.
4. Attach the SuperNode to the stream to apply the transformations.

Optionally, you can edit the SuperNode and zoom in to browse or make changes. Within the SuperNode, values are discarded, coerced, or nullified using a series of Select and/or Filler nodes as appropriate.

Filtering Fields with Missing Data

From the Data Audit browser, you can create a new Filter node based on the results of the Quality analysis by using the Generate Filter from Quality dialog box.

Mode. Select the desired operation for specified fields, either Include or Exclude.

- **Selected fields.** The Filter node will include/exclude the fields selected on the Quality tab. For example you could sort the table on the % Complete column, use Shift-click to select the least complete fields, and then generate a Filter node that excludes these fields.
- **Fields with quality percentage higher than.** The Filter node will include/exclude fields where the percentage of complete records is greater than the specified threshold. The default threshold is 50%.

Filtering Empty or Typeless Fields

Note that after data values have been instantiated, typeless or empty fields are excluded from the audit results and from most other output in IBM® SPSS® Modeler. These fields are ignored for purposes of modeling, but may bloat or clutter the data. If so, you can use the Data Audit browser to generate a Filter node from that removes these fields from the stream.

1. To make sure that all fields are included in the audit, including empty or typeless fields, click Clear All Values in the upstream source or Type node, or set Values to <Pass> for all fields.
2. In the Data Audit browser, sort on the % Complete column, select the fields that have zero valid values (or some other threshold) and use the Generate menu to produce a Filter node which can be added to the stream.

-

Selecting Records with Missing Data

From the Data Audit browser, you can create a new Select node based on the results of the quality analysis.

1. In the Data Audit browser, choose the Quality tab.
2. From the menu, choose:
Generate...>Missing Values Select Node

The Generate Select Node dialog box is displayed.

Select when record is. Specify whether records should be kept when they are Valid or Invalid.

Look for invalid values in. Specify where to check for invalid values.

- **All fields.** The Select node will check all fields for invalid values.
- **Fields selected in table.** The Select node will check only the fields currently selected in the Quality output table.
- **Fields with quality percentage higher than.** The Select node will check fields where the percentage of complete records is greater than the specified threshold. The default threshold is 50%.

Consider a record invalid if an invalid value is found in. Specify the condition for identifying a record as invalid.

- **Any of the above fields.** The Select node will consider a record invalid if *any* of the fields specified above contains an invalid value for that record.
- **All of the above fields.** The Select node will consider a record invalid only if *all* of the fields specified above contain invalid values for that record.

Generating Other Nodes for Data Preparation

A variety of nodes used in data preparation can be generated directly from the Data Audit browser, including Reclassify, Binning, and Derive nodes. For example:

- You can derive a new field based on the values of *claimvalue* and *farmincome* by selecting both in the audit report and choosing Derive from the Generate menu. The new node is added to the stream canvas.
- Similarly, you may determine, based on audit results, that recoding *farmincome* into percentile-based bins provides a more focused analysis. To generate a Binning node, select the field row in the display and choose Binning from the Generate menu.

Once a node is generated and added to the stream canvas, you must attach it to the stream and open the node to specify options for the selected field(s).

Transform Node

Normalizing input fields is an important step before using traditional scoring techniques, such as regression, logistic regression, and discriminant analysis. These techniques carry assumptions about normal distributions of data that may not be true for many raw data files. One approach to dealing with real-world data is to apply transformations that move a raw data element toward a more normal distribution. In addition, normalized fields can easily be compared with each other—for example, income and age are on totally different scales in a raw data file but when normalized, the relative impact of each can be easily interpreted.

The Transform Node provides an output viewer that enables you to perform a rapid visual assessment of the best transformation to use. You can see at a glance whether variables are normally distributed and, if necessary, choose the transformation you want and apply it. You can pick multiple fields and perform one transformation per field.

After selecting the preferred transformations for the fields, you can generate Derive or Filler nodes that perform the transformations and attach these nodes to the stream. The Derive node creates new fields, while the Filler node transforms the existing ones. See the topic [Generating Graphs](#) for more information.

Transform node Fields tab

On the Fields tab, you can specify which fields of the data you want to use for viewing possible transformations and applying them. Only numeric fields can be transformed. Click the field selector button and select one or more numeric fields from the list displayed.

- [Transform Node Options Tab](#)
 - [Transform Node Output Tab](#)
 - [Transform Node Output Viewer](#)
-

Transform Node Options Tab

The Options tab enables you to specify the type of transformations you want to include. You can choose to include all available transformations or select transformations individually.

In the latter case, you can also enter a number to offset the data for the inverse and log transformations. Doing so is useful in situations where a large proportion of zeros in the data would bias the mean and standard deviation results.

For example, assume that you have a field named *BALANCE* that has some zero values in it, and you want to use the inverse transformation on it. To avoid undesired bias, you would select Inverse (1/x) and enter 1 in the Use a data offset field. (Note that this offset is not related to that performed by the @OFFSET sequence function in IBM® SPSS® Modeler.)

All formulas. Indicates that all available transformations should be calculated and shown in the output.

Select formulas. Enables you to select the different transformations to be calculated and shown in the output.

- **Inverse (1/x).** Indicates that the inverse transformation should be displayed in the output.

- **Log (log n).** Indicates that the \log_n transformation should be displayed in the output.
- **Log (log 10).** Indicates that the \log_{10} transformation should be displayed in the output.
- **Exponential.** Indicates that the exponential transformation (e^x) should be displayed in the output.
- **Square Root.** Indicates that the square root transformation should be displayed in the output.

Transform Node Output Tab

The Output tab lets you specify the output format and location of the output. You can also choose to display the results on the screen, or send them to one of the standard file types. See the topic [Output Node Output Tab](#) for more information.

Transform Node Output Viewer

The output viewer enables you to see the results of executing the Transform Node. The viewer is a powerful tool that displays multiple transformations per field in thumbnail views of the transformation, enabling you to compare fields quickly. You can use options on its File menu to save, export, or print the output. See the topic [Viewing output](#) for more information.

For each transformation (other than Selected Transform), a legend is displayed underneath in the format:

Mean (Standard deviation)

- [Generating Nodes for the Transformations](#)

Generating Nodes for the Transformations

The output viewer provides a useful starting point for your data preparation. For example, you might want to normalize the field *AGE* so that you can use a scoring technique (such as logistic regression or discriminant analysis) that assumes a normal distribution. Based upon the initial graphs and summary statistics, you might decide to transform the *AGE* field according to a particular distribution (for example, log). After selecting the preferred distribution, you can then generate a derive node with a standardized transformation to use for scoring.

You can generate the following field operations nodes from the output viewer:

- Derive
- Filler

A Derive node creates new fields with the desired transformations, while the Filler node transforms existing fields. The nodes are placed on the canvas in the form of a SuperNode.

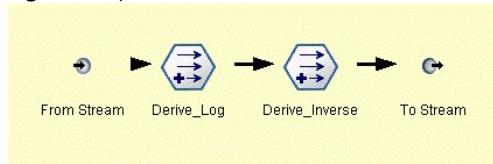

If you select the same transformation for different fields, a Derive or Filler node contains the formulas for that transformation type for all the fields to which that transformation applies. For example, assume that you have selected the fields and transformations, shown in the following table, to generate a Derive node.

Table 1. Example of Derive node generation

Field	Transformation
<i>AGE</i>	Current Distribution
<i>INCOME</i>	Log
<i>OPEN_BAL</i>	Inverse
<i>BALANCE</i>	Inverse

The following nodes are contained in the SuperNode:

Figure 1. SuperNode on canvas

In this example, the Derive_Log node has the log formula for the *INCOME* field, and the Derive_Inverse node has the inverse formulas for the *OPEN_BAL* and *BALANCE* fields.

To Generate a Node

1. For each field in the output viewer, select the desired transformation.
2. From the Generate menu, choose Derive Node or Filler Node as desired.
Doing so displays the Generate Derive Node or Generate Filler Node dialog box, as appropriate.

Choose Non-standardized transformation or Standardized transformation (z-score) as desired. The second option applies a z score to the transformation; z scores represent values as a function of distance from the mean of the variable in standard deviations. For example, if you apply the log transformation to the AGE field and choose a standardized transformation, the final equation for the generated node will be:

$(\log(\text{AGE}) - \text{Mean}) / \text{SD}$

Once a node is generated and appears on the stream canvas:

1. Attach it to the stream.
2. For a SuperNode, optionally double-click the node to view its contents.
3. Optionally double-click a Derive or Filler node to modify options for the selected field(s).

- [Generating Graphs](#)
-

Generating Graphs

You can generate full-size histogram output from a thumbnail histogram in the output viewer.

To Generate a Graph

1. Double-click a thumbnail graph in the output viewer.
or
2. Select a thumbnail graph in the output viewer.

2. From the Generate menu, choose Graph output.

Doing so displays the histogram with a normal distribution curve overlaid. This enables you to compare how closely each available transformation matches a normal distribution.

Note: You can only generate a graph if the Transform node that created the output is connected to the stream.

- [Other Operations](#)
-

Other Operations

From the output viewer, you can also:

- Sort the output grid by the Field column.
 - Export the output to an HTML file. See the topic [Exporting Output](#) for more information.
-

Statistics Node

The Statistics node gives you basic summary information about numeric fields. You can get summary statistics for individual fields and correlations between fields.

- [Statistics Node Settings Tab](#)
 - [Statistics Output Browser](#)
-

Statistics Node Settings Tab

Examine. Select the field or fields for which you want individual summary statistics. You can select multiple fields.

Statistics. Select the statistics to report. Available options include Count, Mean, Sum, Min, Max, Range, Variance, Std Dev, Std Error of Mean, Median, and Mode.

Correlate. Select the field or fields that you want to correlate. You can select multiple fields. When correlation fields are selected, the correlation between each Examine field and the correlation field(s) will be listed in the output.

Correlation Settings. You can specify options for displaying the strength of correlations in the output. See the topic [Correlation Settings](#) for more information.

- [Correlation Settings](#)

Correlation Settings

IBM® SPSS® Modeler can characterize correlations with descriptive labels to help highlight important relationships. The **correlation** measures the strength of relationship between two continuous (numeric range) fields. It takes values between -1.0 and 1.0. Values close to +1.0 indicate a strong positive association so that high values on one field are associated with high values on the other and low values are associated with low values. Values close to -1.0 indicate a strong negative association so that high values for one field are associated with low values for the other, and vice versa. Values close to 0.0 indicate a weak association, so that values for the two fields are more or less independent.

Using the Correlation Settings dialog box you can control display of correlation labels, change the thresholds that define the categories, and change the labels used for each range. Because the way you characterize correlation values depends greatly on the problem domain, you may want to customize the ranges and labels to fit your specific situation.

Show correlation strength labels in output. This option is selected by default. Deselect this option to omit the descriptive labels from the output.

Correlation Strength. There are two options for defining and labeling the strength of correlations:

- **Define correlation strength by importance (1-p).** Labels correlations based on importance, defined as 1 minus the significance, or 1 minus the probability that the difference in means could be explained by chance alone. The closer this value comes to 1, the greater the chance that the two fields are *not* independent—in other words, that some relationship exists between them. Labeling correlations based on importance is generally recommended over absolute value because it accounts for variability in the data—for example, a coefficient of 0.6 may be highly significant in one dataset and not significant at all in another. By default, importance values between 0.0 and 0.9 are labeled as *Weak*, those between 0.9 and 0.95 are labeled as *Medium*, and those between 0.95 and 1.0 are labeled as *Strong*.
- **Define correlation strength by absolute value.** Labels correlations based on the absolute value of the Pearson's correlation coefficient, which ranges between -1 and 1, as described above. The closer the absolute value of this measure comes to 1, the stronger the correlation. By default, correlations between 0.0 and 0.3333 (in absolute value) are labeled as *Weak*, those between 0.3333 and 0.6666 are labeled as *Medium*, and those between 0.6666 and 1.0 are labeled as *Strong*. Note, however, that the significance of any given value is difficult to generalize from one dataset to another; for this reason, defining correlations based on probability rather than absolute value is recommended in most cases.

Statistics Output Browser

The Statistics node output browser displays the results of the statistical analysis and enables you to perform operations, including selecting fields, and generating new nodes based on the selection, and saving and printing the results. The usual saving, exporting, and printing options are available from the File menu, and the usual editing options are available from the Edit menu. See the topic [Viewing output](#) for more information.

When you first browse Statistics output, the results are expanded. To hide results after viewing them, use the expander control to the left of the item to collapse the specific results you want to hide or click the Collapse All button to collapse all results. To see results again after collapsing them, use the expander control to the left of the item to show the results or click the Expand All button to show all results.

The output contains a section for each *Examine* field, containing a table of the requested statistics.

- **Count.** The number of records with valid values for the field.
- **Mean.** The average (mean) value for the field across all records.
- **Sum.** The sum of values for the field across all records.
- **Min.** The minimum value for the field.
- **Max.** The maximum value for the field.
- **Range.** The difference between the minimum and maximum values.
- **Variance.** A measure of the variability in the values of a field. It is calculated by taking the difference between each value and the overall mean, squaring it, summing across all of the values, and dividing by the number of records.
- **Standard Deviation.** Another measure of variability in the values of a field, calculated as the square root of the variance.
- **Standard Error of Mean.** A measure of the uncertainty in the estimate of the field's mean if the mean is assumed to apply to new data.
- **Median.** The "middle" value for the field; that is, the value that divides the upper half of the data from the lower half of the data (based on values of the field).
- **Mode.** The most common single value in the data.

Correlations. If you specified correlate fields, the output also contains a section listing the Pearson correlation between the Examine field and each correlate field, and optional descriptive labels for the correlation values. See the topic [Correlation Settings](#) for more information.

Generate menu. The Generate menu contains node generation operations.

- **Filter.** Generates a Filter node to filter out fields that are uncorrelated or weakly correlated with other fields. See the topic [Generating a Filter Node from Statistics](#) for more information.
- [Generating a Filter Node from Statistics](#)

- [Correlation Settings](#)
- [Generating a Filter Node from Statistics](#)

Generating a Filter Node from Statistics

The Filter node generated from a Statistics output browser will filter fields based on their correlations with other fields. It works by sorting the correlations in order of absolute value, taking the largest correlations (according to the criterion set in the Generate Filter from Statistics dialog box), and creating a filter that passes all fields that appear in any of those large correlations.

Mode. Decide how to select correlations. Include causes fields appearing in the specified correlations to be retained. Exclude causes the fields to be filtered.

Include/Exclude fields appearing in. Define the criterion for selecting correlations.

- **Top number of correlations.** Selects the specified number of correlations and includes/excludes fields that appear in any of those correlations.
- **Top percentage of correlations (%).** Selects the specified percentage ($n\%$) of correlations and includes/excludes fields that appear in any of those correlations.
- **Correlations greater than.** Selects correlations greater in absolute value than the specified threshold.

Means Node

The Means node compares the means between independent groups or between pairs of related fields to test whether a significant difference exists. For example, you can compare mean revenues before and after running a promotion or compare revenues from customers who didn't receive the promotion with those who did.

You can compare means in two different ways, depending on your data:

- **Between groups within a field.** To compare independent groups, select a test field and a grouping field. For example, you could exclude a sample of "holdout" customers when sending a promotion and compare mean revenues for the holdout group with all of the others. In this case, you would specify a single test field that indicates the revenue for each customer, with a flag or nominal field that indicates whether they received the offer. The samples are independent in the sense that each record is assigned to one group or another, and there is no way to link a specific member of one group to a specific member of another. You can also specify a nominal field with more than two values to compare the means for multiple groups. When executed, the node calculates a one-way ANOVA test on the selected fields. In cases where there are only two field groups, the one-way ANOVA results are essentially the same as an independent-samples *t* test. See the topic [Comparing Means for Independent Groups](#) for more information.
 - **Between pairs of fields.** When comparing means for two related fields, the groups must be paired in some way for the results to be meaningful. For example, you could compare the mean revenues from the same group of customers before and after running a promotion or compare usage rates for a service between husband-wife pairs to see if they are different. Each record contains two separate but related measures that can be compared meaningfully. When executed, the node calculates a paired-samples *t* test on each field pair selected. See the topic [Comparing Means Between Paired Fields](#) for more information.
- [Comparing Means for Independent Groups](#)
 - [Comparing Means Between Paired Fields](#)
 - [Means Node Options](#)
 - [Means Node Output Browser](#)

Comparing Means for Independent Groups

Select Between groups within a field in the Means node to compare the mean for two or more independent groups.

Grouping field. Select a numeric flag or nominal field with two or more distinct values that divides records into the groups you want to compare, such as those who received an offer versus those who did not. Regardless of the number of test fields, only one grouping field can be selected.

Test fields. Select one or more numeric fields that contain the measures you want to test. A separate test will be conducted for each field you select. For example, you could test the impact of a given promotion on usage, revenue, and churn.

- [Means Node](#)
- [Comparing Means Between Paired Fields](#)
- [Means Node Options](#)
- [Means Node Output Browser](#)
- [Means Output Comparing Groups within a Field](#)
- [Means Output Comparing Pairs of Fields](#)

Comparing Means Between Paired Fields

Select Between pairs of fields in the Means node to compare means between separate fields. The fields must be related in some way for the results to be meaningful, such as revenues before and after a promotion. Multiple field pairs can also be selected.

Field one. Select a numeric field that contains the first of the measures you want to compare. In a before-and-after study, this would be the "before" field.

Field two. Select the second field you want to compare.

Add. Adds the selected pair to the Test field pair(s) list.

Repeat field selections as needed to add multiple pairs to the list.

Correlation settings. Enables you to specify options for labeling the strength of correlations. See the topic [Correlation Settings](#) for more information.

Means Node Options

The Options tab enables you to set the threshold p values used to label results as important, marginal, or unimportant. You can also edit the label for each ranking. Importance is measured on a percentage scale and can be broadly defined as 1 minus the probability of obtaining a result (such as the difference in means between two fields) as extreme as or more extreme than the observed result by chance alone. For example, a p value greater than 0.95 indicates less than a 5% chance that the result could be explained by chance alone.

Importance labels. You can edit the labels used to label each field pair or group in the output. The default labels are *important*, *marginal*, and *unimportant*.

Cutoff values. Specifies the threshold for each rank. Typically p values greater than 0.95 would rank as important, while those lower than 0.9 would be unimportant, but these thresholds can be adjusted as needed.

Note: Importance measures are available in a number of nodes. The specific computations depend on the node and on the type of target and input fields used, but the values can still be compared, since all are measured on a percentage scale.

Means Output Comparing Groups within a Field

When comparing groups within a field, the name of the grouping field is displayed above the output table, and means and related statistics are reported separately for each group. The table includes a separate row for each test field.

The following columns are displayed:

- **Field.** Lists the names of the selected test fields.
- **Means by group.** Displays the mean for each category of the grouping field. For example, you might compare those who received a special offer (*New Promotion*) with those who didn't (*Standard*). In the advanced view, the standard deviation, standard error, and count are also displayed.
- **Importance.** Displays the importance value and label. See the topic [Means Node Options](#) for more information.

Advanced Output

In the advanced view, the following additional columns are displayed.

- **F-Test.** This test is based on the ratio of the variance between the groups and the variance within each group. If the means are the same for all groups, you would expect the *F* ratio to be close to 1 since both are estimates of the same population variance. The larger this ratio, the greater the variation between groups and the greater the chance that a significant difference exists.
- **df.** Displays the degrees of freedom.

Means Output Comparing Pairs of Fields

When comparing separate fields, the output table includes a row for each selected field pair.

- **Field One/Two.** Displays the name of the first and second field in each pair. In the advanced view, the standard deviation, standard error, and count are also displayed.
- **Mean One/Two.** Displays the mean for each field, respectively.
- **Correlation.** Measures the strength of relationship between two continuous (numeric range) fields. Values close to +1.0 indicate a strong positive association, and values close to -1.0 indicate a strong negative association. See the topic [Correlation Settings](#) for more information.
- **Mean Difference.** Displays the difference between the two field means.
- **Importance.** Displays the importance value and label. See the topic [Means Node Options](#) for more information.

Advanced Output

Advanced output adds the following columns:

95% Confidence Interval. Lower and upper boundaries of the range within which the true mean is likely to fall in 95% of all possible samples of this size from this population.

T-Test. The *t* statistic is obtained by dividing the mean difference by its standard error. The greater the absolute value of this statistic, the greater the probability that the means are not the same.

df. Displays the degrees of freedom for the statistic.

Report Node

The Report node enables you to create formatted reports containing fixed text, as well as data and other expressions derived from the data. You specify the format of the report by using text templates to define the fixed text and the data output constructions. You can provide custom text formatting using HTML tags in the template and by setting options on the Output tab. Data values and other conditional output are included in the report using CLEM expressions in the template.

Alternatives to the Report Node

The Report node is most typically used to list records or cases output from a stream, such as all records meeting a certain condition. In this regard, it can be thought of as a less-structured alternative to the Table node.

- If you want a report that lists field information or anything else that is defined in the stream rather than the data itself (such as field definitions specified in a Type node), then a script can be used instead.
- To generate a report that includes multiple output objects (such as a collection of models, tables, and graphs generated by one or more streams) and that can be output in multiple formats (including text, HTML, and Microsoft Word/Office), an IBM® SPSS® Modeler project can be used.
- To produce a list of field names without using scripting, you can use a Table node preceded by a Sample node that discards all records. This produces a table with no rows, which can be transposed on export to produce a list of field names in a single column. (Select Transpose data on the Output tab in the Table node to do this.)

 - [Report Node Template Tab](#)
 - [Report Node Output Browser](#)
 - [Output Node Output Tab](#)
-

Report Node Template Tab

Creating a template. To define the contents of the report, you create a template on the Report node Template tab. The template consists of lines of text, each of which specifies something about the contents of the report, and some special tag lines used to indicate the scope of the content lines. Within each content line, CLEM expressions enclosed in square brackets ([]]) are evaluated before the line is sent to the report. There are three possible scopes for a line in the template:

Fixed. Lines that are not marked otherwise are considered fixed. Fixed lines are copied into the report only once, after any expressions that they contain are evaluated. For example, the line

```
This is my report, printed on [@TODAY]
```

would copy a single line to the report, containing the text and the current date.

Global (iterate ALL). Lines contained between the special tags #**ALL** and # are copied to the report once for each record of input data. CLEM expressions (enclosed in brackets) are evaluated based on the current record for each output line. For example, the lines

```
#ALL
For record [@INDEX], the value of AGE is [AGE]
#
```

would include one line for each record indicating the record number and age.

To generate a list of all records:

```
#ALL
[Age] [Sex] [Cholesterol] [BP]
#
```

Conditional (iterate WHERE). Lines contained between the special tags #**WHERE** <condition> and # are copied to the report once for each record where the specified condition is true. The condition is a CLEM expression. (In the **WHERE** condition, the brackets are optional.) For example, the lines

```
#WHERE [SEX = 'M']
Male at record no. [@INDEX] has age [AGE].
#
```

will write one line to the file for each record with a value of M for sex. The complete report will contain the fixed, global, and conditional lines defined by applying the template to the input data.

You can specify options for displaying or saving results using the Output tab, common to various types of output nodes. See the topic [Output Node Output Tab](#) for more information.

Outputting Data in HTML or XML Format

You can include HTML or XML tags directly in the template in order to write reports in either of these formats. For example, the following template produces an HTML table.

```
This report is written in HTML.
Only records where Age is above 60 are included.

<HTML>
<TABLE border="2">
```

```

<TR>
  <TD>Age</TD>
  <TD>BP</TD>
  <TD>Cholesterol</TD>
  <TD>Drug</TD>
</TR>

#WHERE Age > 60
<TR>
  <TD>[Age]</TD>
  <TD>[BP]</TD>
  <TD>[Cholesterol]</TD>
  <TD>[Drug]</TD>
</TR>
#
</TABLE>
</HTML>

```

Set Globals Node

The Set Globals node scans the data and computes summary values that can be used in CLEM expressions. For example, you can use a Set Globals node to compute statistics for a field called *age* and then use the overall mean of *age* in CLEM expressions by inserting the function `@GLOBAL_MEAN(age)`.

- [Set Globals Node Settings Tab](#)

Related information

- [Overview of Output Nodes](#)
 - [Set Globals Node Settings Tab](#)
-

Set Globals Node Settings Tab

Globals to be created. Select the field or fields for which you want globals to be available. You can select multiple fields. For each field, specify the statistics to compute by making sure that the statistics you want are selected in the columns next to the field name.

- **MEAN.** The average (mean) value for the field across all records.
- **SUM.** The sum of values for the field across all records.
- **MIN.** The minimum value for the field.
- **MAX.** The maximum value for the field.
- **SDEV.** The standard deviation, which is a measure of variability in the values of a field and is calculated as the square root of the variance.

Default operation(s). The options selected here will be used when new fields are added to the Globals list above. To change the default set of statistics, select or deselect statistics as appropriate. You can also use the Apply button to apply the default operations to all fields in the list.

Note: Some operations are not applicable to non-numeric fields (for example, Sum for a date/time field). Operations that cannot be used with a selected field are disabled.

Clear all globals before executing. Select this option to remove all global values before calculating new values. If this option is not selected, newly calculated values replace older values, but globals that are not recalculated remain available, as well.

Display preview of globals created after execution. If you select this option, the Globals tab of the stream properties dialog box will appear after execution to display the calculated global values.

- [Set Globals Node](#)

Simulation Fitting Node

The Simulation Fitting node fits a set of candidate statistical distributions to each field in the data. The fit of each distribution to a field is assessed using a goodness of fit criterion. When a Simulation Fitting node is executed, a Simulation Generate node is built (or an existing node is updated). Each field is assigned its best fitting distribution. The Simulation Generate node can then be used to generate simulated data for each field.

Although the Simulation Fitting node is a terminal node, it does not add a model to the generated models palette, add an output or chart to the outputs tab, or export data.

Note: If the historical data is sparse (that is, there are lots of missing values), it may difficult for the fitting component to find enough valid values to fit distributions to the data. In cases where the data is sparse, before fitting you should either remove the sparse fields if they are not required, or impute the missing values. Using the options on the Quality tab of the Data Audit node you can view the number of complete records, identify which fields are sparse, and select an imputation method. If there are an insufficient number of records for distribution fitting, you can use a Balance node to increase the number of records.

Using a Simulation Fitting node to automatically create a Simulation Generate node

The first time the Simulation Fitting node is executed, a Simulation Generate node is created with an update link to the Simulation Fitting node. If the Simulation Fitting node is executed again, a new Simulation Generate node will be created only if the update link has been removed. A Simulation Fitting node can also be used to update a connected Simulation Generate node. The result depends on whether the same fields are present in both nodes, and if the fields are unlocked in the Simulation Generate node. See the topic [Simulation Generate Node](#) for more information.

A Simulation Fitting node can only have an update link to a Simulation Generate node. To define an update link to a Simulation Generate node, follow these steps:

1. Right-click the Simulation Fitting node.
2. From the menu, select Define Update Link.
3. Click the Simulation Generate node to which you want to define an update link.

To remove an update link between a Simulation Fitting node and a Simulation Generate node, right-click on the update link, and select Remove Link.

- [Distribution Fitting](#)
- [Simulation Fitting Node Settings Tab](#)

Related information

- [Overview of Output Nodes](#)
- [Distribution Fitting](#)
- [Simulation Fitting Node Settings Tab](#)

Distribution Fitting

A statistical distribution is the theoretical frequency of the occurrence of values that a variable can take. In the Simulation Fitting node, a set of theoretical statistical distributions is compared to each field of data. The distributions that are available for fitting are described in the topic [Distributions](#). The parameters of the theoretical distribution are adjusted to give the best fit to the data according to a measurement of the goodness of fit; either the Anderson-Darling criterion or the Kolmogorov-Smirnov criterion. The results of the distribution fitting by the Simulation Fitting node show which distributions were fitted, the best estimates of the parameters for each distribution, and how well each distribution fits the data. During distribution fitting, correlations between fields with numeric storage types, and contingencies between fields with a categorical distribution, are also calculated. The results of the distribution fitting are used to create a Simulation Generate node.

Before any distributions are fitted to your data, the first 1000 records are examined for missing values. If there are too many missing values, distribution fitting is not possible. If so, you must decide whether either of the following options are appropriate:

- Use an upstream node to remove records with missing values.
- Use an upstream node to impute values for missing values.

Distribution fitting does not exclude user-missing values. If your data have user-missing values and you want those values to be excluded from distribution fitting then you should set those values to system missing.

The role of a field is not taken into account when the distributions are fitted. For example, fields with the role Target are treated the same as fields with roles of Input, None, Both, Partition, Split, Frequency, and ID.

Fields are treated differently during distribution fitting according to their storage type and measurement level. The treatment of fields during distribution fitting is described in the following table.

Table 1. Distribution fitting according to storage type and measurement level of fields

Storage type			Measurement Level			
	Continuous	Categorical	Flag	Nominal	Ordinal	Typeless
String	Impossible		Categorical, dice and fixed distributions are fitted			
Integer						
Real						
Time	All distributions are fitted. Correlations and contingencies are calculated.		The categorical distribution is fitted. Correlations are not calculated.		Binomial, negative binomial and Poisson distributions are fitted, and correlations are calculated.	Field is ignored and not passed to the Simulation Generate node.
Date						
Timestamp						
Unknown			Appropriate storage type is determined from the data.			

Fields with the measurement level ordinal are treated like continuous fields and are included in the correlations table in the Simulation Generate node. If you want a distribution other than binomial, negative binomial or Poisson to be fitted to an ordinal field, you must change the measurement level of the field to continuous. If you have previously defined a label for each value of an ordinal field, and then change the measurement level to continuous, the labels will be lost.

Fields that have single values are not treated differently during distribution fitting to fields with multiple values. Fields with the storage type time, date, or timestamp are treated as numeric.

Fitting Distributions to Split Fields

If your data contains a split field, and you want distribution fitting to be carried out separately for each split, you must transform the data by using an upstream Restructure node. Using the Restructure node, generate a new field for each value of the split field. This restructured data can then be used for distribution fitting in the Simulation Fitting node.

 - [Simulation Fitting Node Settings Tab](#)
 - [Distributions](#)
-

Simulation Fitting Node Settings Tab

Source node name. You can generate the name of the generated (or updated) Simulation Generate node automatically by selecting Auto. The automatically generated name is the name specified in the Simulation Fitting node if a custom name has been specified (or Sim Gen if no custom name has been specified in the Simulation Fitting node). Select Custom to specify a custom name in the adjoining text field. Unless the text field is edited, the default custom name is Sim Gen.

Fitting Options With these options you can specify how the distributions are fitted to the fields and how the fit of the distributions is assessed.

- **Number of cases to sample.** This specifies the number of cases to use when fitting distributions to the fields in the data set. Select All cases to fit distributions to all of the records in the data. If your data set is very large, you might want to consider limiting the number of

cases that are used for distribution fitting. Select Limit to first N cases to use only the first N cases. Click the arrows to specify the number of cases to use. Alternatively, you can use an upstream node to take a random sample of records for distribution fitting.

- **Goodness of fit criteria (continuous fields only).** For continuous fields, select either the Anderson-Darling test or the Kolmogorov-Smirnov test of goodness of fit to rank distributions when fitting distributions to the fields. The Anderson-Darling test is selected by default and is especially recommended when you want to ensure the best possible fit in the tail regions. Both statistics are calculated for every candidate distribution, but only the selected statistic is used to order the distributions and determine the best fitting distribution.
- **Bins (empirical distribution only).** For continuous fields, the Empirical distribution is the cumulative distribution function of the historical data. It is the probability of each value, or range of values, and is derived directly from the data. You can specify the number of bins that are used for calculating the Empirical distribution for continuous fields by clicking the arrows. The default is 100 and the maximum is 1000.
- **Weight field (optional).** If your data set contains a weight field, click the field picker icon and select the weight field from the list. The weight field is then excluded from the distribution fitting process. The list shows all fields in the data set that have the measurement level continuous. You can select only one weight field.

Simulation Evaluation Node

The Simulation Evaluation node is a terminal node that evaluates a specified field, provides a distribution of the field, and produces charts of distributions and correlations. This node is primarily used to evaluate continuous fields. It therefore complements the evaluation chart, which is generated by an Evaluation node and is useful for evaluating discrete fields. Another difference is that the Simulation Evaluation node evaluates a single prediction across several iterations, whereas the Evaluation node evaluates multiple predictions each with a single iteration. Iterations are generated when more than one value is specified for a distribution parameter in the Simulation Generate node. See the topic [Iterations](#) for more information.

The Simulation Evaluation node is designed to be used with data that was obtained from the Simulation Fitting and Simulation Generate nodes. The node can, however, be used with any other node. Any number of processing steps can be placed between the Simulation Generate node and the Simulation Evaluation node.

Important: The Simulation Evaluation node requires a minimum of 1000 records with valid values for the target field.

-

Simulation Evaluation Node Settings Tab

On the Settings tab of the Simulation Evaluation node, you can specify the role of each field in your data set, and customize the output that is generated by the simulation.

Select an item. Enables you to switch between the three views of the Simulation Evaluation node: Fields, Density Functions, and Outputs.

Fields view

Target field. This is a required field. Click the arrow to select the target field of your data set from the drop-down list. The selected field can have either continuous, ordinal or nominal measurement level, but cannot have date or an unspecified measurement level.

Iteration field (optional). If your data has an iteration field that indicates to which iteration each record in your data belongs, you must select it here. This means that each iteration will be evaluated separately. Only fields with continuous, ordinal or nominal measurement levels can be selected.

Input data is already sorted by iteration. Only enabled if an iteration field is specified in the Iteration field (optional) field. Only select this option if you are sure that your input data is already sorted by the iteration field specified in Iteration field (optional).

Maximum number of iterations to plot. Only enabled if an iteration field is specified in the Iteration field (optional) field. Click the arrows to specify the number of iterations to plot. Specifying this number avoids trying to plot too many iterations on a single chart, which would make the plot difficult to interpret. The lowest level that the maximum number of iterations can be set to is 2; the highest level is 50. The maximum number of iterations to plot is initially set to 10.

Input fields for correlation tornado. The correlation tornado chart is a bar chart that displays the correlation coefficients between the specified target and each of the specified inputs. Click the field picker icon to select the input fields to be included in the tornado chart, from a list of available simulated inputs. Only input fields with continuous and ordinal measurement levels can be selected. Nominal, typeless, and date input fields are not available in the list and cannot be selected.

Density Functions view

With the options in this view, you can customize the output for probability density functions and cumulative distribution functions for continuous targets, as well as bar charts of predicted values for categorical targets.

Density functions. Density functions are the primary means of probing the set of outcomes from your simulation.

- **Probability density function (PDF).** Select this option to produce a probability density function for the target field. The probability density function displays the distribution of the target values. You can use the probability density function to determine the probability that the target is within a particular region. For categorical targets (targets with a measurement level of nominal or ordinal) a bar chart is generated that displays the percentage of cases that fall in each category of the target.
- **Cumulative distribution function (CDF).** Select this option to produce a cumulative distribution function for the target field. The cumulative distribution function displays the probability that the value of the target is less than or equal to a specified value. It is only available for continuous targets.

Reference lines (continuous). These options are enabled if Probability density function (PDF), Cumulative distribution function (CDF), or both, are selected. With these options, you can add various fixed vertical reference lines to probability density functions and cumulative distribution functions.

- **Mean.** Select this option to add a reference line at the mean value of the target field.
- **Median.** Select this option to add a reference line at the median value of the target field.
- **Standard Deviations.** Select this option to add reference lines at plus and minus a specified number of standard deviations from the mean of the target field. Selecting this option enables the adjoining Number field. Click the arrows to specify the number of standard deviations. The minimum number of standard deviations is 1 and the maximum is 10. The number of standard deviations is initially set to 3.
- **Percentiles.** Select this option to add reference lines at two percentile values of the distribution of the target field. Selecting this option enables the adjoining Bottom and Top text fields. For example, entering a value of 90 in the Top text field would add a reference line at the 90th percentile of the target, which is the value below which 90% of the observations fall. Likewise, a value of 10 in the Bottom text field represents the tenth percentile of the target, which is the value below which 10% of the observations fall.
- **Custom reference lines.** Select this option to add reference lines at specified values along the horizontal axis. Selecting this option enables the adjoining Values table. Every time that you enter a valid number into the Values table, a new empty row is appended to the bottom of the table. A *valid* number is a number within the range of values of the target field

Note: When multiple density functions or distribution functions (from multiple iterations) are displayed on a single chart, reference lines (other than custom lines) are separately applied to each function.

Categorical target (PDF only). These options are only enabled if Probability density function (PDF) is selected.

- **Category values to report.** For models with categorical target fields, the result of the model is a set of predicted probabilities, one for each category, that the target value falls in each category. The category with the highest probability is taken to be the predicted category and used in generating the bar chart for the probability density function. Select Predicted category to generate the bar chart. Select Predicted probabilities to generate histograms of the distribution of predicted probabilities for each of the categories of the target field. You can also select Both to generate both types of chart.
- **Grouping for sensitivity analysis.** Simulations that include sensitivity analysis iterations generate an independent target field (or predicted target field from a model) for each iteration that is defined by the analysis. There is one iteration for each value of the distribution parameter that is being varied. When iterations are present, the bar chart of the predicted category for a categorical target field is displayed as a clustered bar chart that includes the results for all iterations. Select either Group categories together or Group iterations together.

Outputs view

Percentile values of target distributions. With these options, you can choose to create a table of percentile values of the target distributions, and specify the percentiles to display.

Create a table of percentile values. For continuous target fields, select this option to obtain a table of specified percentiles of the target distributions. Choose one of the following options to specify the percentiles:

- **Quartiles.** Quartiles are the 25th, 50th, and 75th percentiles of the target field distribution. The observations are divided into four groups of equal size.
- **Intervals.** If you want an equal number of groups other than four, select Intervals. Selecting this option enables the adjoining Number field. Click the arrows to specify the number of intervals. The minimum number of intervals is 2 and the maximum is 100. The number of intervals is initially set to 10.
- **Custom percentiles.** Select Custom percentiles to specify individual percentiles, for example, the 99th percentile. Selecting this option enables the adjoining Values table. Every time that you enter a valid number, between 1 and 100, into the Values table, a new empty row is

appended to the bottom of the table.

Simulation Evaluation node output

When the Simulation Evaluation node is executed, the output is added to the Output manager. The Simulation Evaluation output browser displays the results of executing the Simulation Evaluation node. The usual saving, exporting, and printing options are available from the File menu, and the usual editing options are available from the Edit menu. See the topic [Viewing output](#) for more information. The View menu is only enabled if one of the charts is selected. It is not enabled for the distribution table or information outputs. From the View menu you can select Edit Mode to change the layout and look of the chart, or Explore Mode to explore the data and values represented by the chart. The Static mode fixes the chart reference lines (and sliders) in their current positions so they cannot be moved. The Static mode is the only mode where you can copy, print, or export the chart with its reference lines. To select this mode, click Static Mode on the View menu.

The Simulation Evaluation output browser window consists of two panels. On the left of the window, there is a navigation panel that displays thumbnail representations of the charts that were generated when the Simulation Evaluation node was executed. When a thumbnail is selected, the chart output is displayed on the panel on the right of the window.

Navigation Panel

The navigation panel of the output browser contains thumbnails of the charts that are generated from a simulation. The thumbnails that are shown on the navigation panel depend on the measurement level of the target field, and on the options that are selected in the Simulation Evaluation node dialog box. Descriptions of the thumbnails are given in the following table.

Table 1. Navigation panel thumbnails

Thumbnail	Description	Comments
	Probability density function	This thumbnail is shown only if the measurement level of the target field is continuous, and Probability Density Function (PDF) is selected on the Density Functions view of the Simulation Evaluation node dialog box. If the measurement level of the target field is categorical, this thumbnail is not shown.
	Cumulative distribution function	This thumbnail is shown only if the measurement level of the target field is continuous, and Cumulative Distribution Function (CDF) is selected on the Density Functions view of the Simulation Evaluation node dialog box. If the measurement level of the target field is categorical, this thumbnail is not shown.
	Predicted category values	This thumbnail is shown only if the measurement level of the target field is categorical, Probability Density Function (PDF) is selected on the Density Functions view of the Simulation Evaluation node dialog box, and either Predicted category or Both is selected in the Category values to report area. If the measurement level of the target field is continuous, this thumbnail is not shown.

Thumbnail	Description	Comments
	Predicted category probabilities	This thumbnail is shown only if the measurement level of the target field is categorical, Probability Density Function (PDF) is selected on the Density Functions view of the Simulation Evaluation node dialog box, and either Predicted probabilities or Both is selected in the Category values to report area. If the measurement level of the target field is continuous, this thumbnail is not shown.
	Tornado charts	This thumbnail is shown only if one or more input fields are selected in the Input fields for correlation tornado field on the Fields view of the Simulation Evaluation node dialog box.
	Distribution table	This thumbnail is shown only if the measurement level of the target field is continuous, and Create a table of percentile values is selected on the Outputs view of the Simulation Evaluation node dialog box. The View menu is disabled for this chart. If the measurement level of the target field is categorical, this thumbnail is not shown.
	Information	This thumbnail is always shown. The View menu is disabled for this output.

Chart output

The types of output charts that are available depend on the measurement level of the target field, whether an iteration field is used, and the options that are selected in the Simulation Evaluation node dialog box. A number of the charts that are generated from a simulation have interactive features that you can use to customize the display. Interactive features are available by clicking Chart Options. All simulation charts are graphboard visualizations.

Probability density function charts for continuous targets. This chart shows both probability and frequency, with the probability scale on the left vertical axis and the frequency scale on the right vertical axis. The chart has two sliding vertical reference lines that divide the chart into separate regions. The table below the chart displays the percent of the distribution that is in each of the regions. If multiple density functions are displayed on the same chart (because of iterations), the table has a separate row for the probabilities that are associated with each density function, and an extra column that contains the iteration name and a color that is associated with each density function. The iterations are listed in the table in alphabetical order, according to the iteration label. If no iteration label is available, the iteration value is used instead. The table cannot be edited.

Each of the reference lines has a slider (inverted triangle) that you can use to easily move the line. Each slider has a label that indicates its current position. By default, the sliders are positioned at the 5th and 95th percentiles of the distribution. If there are multiple iterations, the sliders are positioned at the 5th and 95th percentiles of the first iteration that is listed in the table. You cannot move the lines to cross through each other.

A number of additional features are available by clicking Chart Options. In particular, you can explicitly set the positions of the sliders, add fixed reference lines, and change the chart view from a continuous curve to a histogram. See the topic [Chart Options](#) for more information. Right-click the chart to copy or export the chart.

Cumulative distribution function charts for continuous targets. This chart has the same two movable vertical reference lines and associated table that are described for the probability density function chart. The slider controls and table behave the same as the probability density function when there are multiple iterations. The same colors that are used to identify which density function belongs to each iteration are used for the distribution functions.

This chart also provides access to the Chart Options dialog box, which enables you to explicitly set the positions of the sliders, add fixed reference lines, and specify whether the cumulative distribution function is displayed as an increasing function (the default) or a decreasing function. See the topic [Chart Options](#) for more information. Right-click the chart to copy, export, or edit the chart. Selecting Edit opens the chart in a floating graphboard editor window.

Predicted category values chart for categorical targets. For categorical target fields, a bar chart displays the predicted values. The predicted values are displayed as the percent of the target field that is predicted to fall in each category. For categorical target fields with sensitivity analysis iterations, results for the predicted target category are displayed as a clustered bar chart that includes the results for all iterations. The chart is clustered by category or by iteration, depending on which option was selected in the Grouping for sensitivity analysis area in the Density Functions view of the Simulation Evaluation node dialog box. Right-click the chart to copy, export, or edit the chart. Selecting Edit opens the chart in a floating graphboard editor window.

Predicted category probabilities chart for categorical targets. For categorical target fields, a histogram displays the distribution of predicted probabilities for each of the categories of the target. For categorical target fields with sensitivity analysis iterations, the histograms are displayed by category or by iteration, depending on which option was selected in the Grouping for sensitivity analysis area in the Density Functions view of the Simulation Evaluation node dialog box. If the histograms are grouped by category, a drop-down list containing the iteration labels enables you to choose which iteration to display. You can also select the iteration to display by right-clicking the chart and selecting the iteration from the Iteration submenu. If the histograms are grouped by iteration, a drop-down list containing the category names enables you to choose which category to display. You can also select which category to display by right-clicking the chart and selecting the category from the Category submenu.

This chart is only available for a subset of models, and on the model nugget the option to generate all group probabilities must be selected. For example, on the Logistic model nugget, you must select Append all probabilities. The following model nuggets support this option:

- Logistic, SVM, Bayes, Neural Net and KNN
- Db2/ISW in-database mining models for logistic regression, decision trees and naïve Bayes

By default, the option to generate all group probabilities is not selected on these model nuggets.

Tornado charts. The tornado chart is a bar chart that shows the sensitivity of the target field to each of the specified inputs. The sensitivity is measured by the correlation of the target with each input. The title of the chart contains the name of the target field. Each bar on the chart represents the correlation between the target field and an input field. The simulated inputs that are included on the chart are the inputs that are selected in the Input fields for correlation tornado field on the Fields view of the Simulation Evaluation node dialog box. Each bar is labeled with the correlation value. Bars are ordered by the absolute value of the correlations, from largest value to smallest. If there are iterations, a separate chart is generated for each iteration. Each chart has a subtitle, which contains the name of the iteration.

Distribution table. This table contains the value of the target field, below which the specified percent of the observations fall. The table contains a row for each percentile value that is specified on the Outputs view of the Simulation Evaluation node dialog box. The percentile values can be quartiles, a different number of equally spaced percentiles, or individually specified percentiles. The distribution table contains a column for each iteration.

Information. This section gives an overall summary of the fields and records that are used in the evaluation. It also shows the input fields and record counts, which are broken down for each iteration.

Chart Options

In the Chart Options dialog box you can customize the display of activated charts of probability density functions and cumulative distribution functions that are generated from a simulation.

View. The View drop-down list only applies to the probability density function chart. You can use it to toggle the chart view from a continuous curve to a histogram. This feature is disabled when multiple density functions (from multiple iterations) are displayed on the same chart. When there are multiple density functions, the density functions can only be viewed as continuous curves.

Order. The Order drop-down list only applies to the cumulative distribution function chart. It specifies whether the cumulative distribution function is displayed as an ascending function (the default) or a descending function. When displayed as a descending function, the value of the function at a given point on the horizontal axis is the probability that the target field lies to the right of that point.

Slider positions. The Upper text field contains the current position of the right sliding reference line. The Lower text field contains the current position of the left sliding reference line. You can explicitly set the positions of the sliders by entering values in the Upper and Lower text fields. The value in the Lower text field must be strictly less than the value in the Upper text field. You can remove the left reference line by selecting -Infinity, effectively setting the position to negative infinity. This action disables the Lower text field. You can remove the right reference line by selecting Infinity, effectively setting its position to infinity. This action disables the Upper text field. You cannot remove both reference lines; selecting -Infinity disables the Infinity check box, and vice versa.

Reference lines. You can add various fixed vertical reference lines to probability density functions and cumulative distribution functions.

- **Mean.** You can add a reference line at the mean of the target field.
- **Median.** You can add a reference line at the median of the target field.
- **Standard Deviations.** You can add reference lines at plus and minus a specified number of standard deviations from the mean of the target field. You can enter the number of standard deviations to be used in the adjoining text field. The minimum number of standard deviations is 1, and the maximum is 10. The number of standard deviations is initially set to 3.
- **Percentiles.** You can add reference lines at one or two percentile values of the distribution for the target field by entering values into the Bottom and Top text fields. For example, a value of 95 in the Top text field represents the 95th percentile, which is the value below which 95% of the observations fall. Likewise, a value of 5 in the Bottom text field represents the fifth percentile, which is the value below which

5% of the observations fall. For the Bottom text field, the minimum percentile value is 0, and the maximum is 49. For the Top text field, the minimum percentile value is 50, and the maximum is 100.

- **Custom positions.** You can add reference lines at specified values along the horizontal axis. You can remove custom reference lines by deleting the entry from the grid.

When you click OK, the sliders, labels above the sliders, reference lines, and the table below the chart are updated to reflect the options that are selected in the Chart Options dialog box. Click Cancel to close the dialog box without making any changes. Reference lines can be removed by deselecting the associated choice in the Chart Options dialog and clicking OK.

Note: When multiple density functions or distribution functions are displayed on a single chart (because of results from sensitivity analysis iterations), reference lines (other than custom lines) are separately applied to each function. Only the reference lines for the first iteration are shown. The reference line labels include the iteration label. The iteration label is derived from upstream, typically from a Simulation Generate node. If no iteration label is available, the iteration value is used instead. The Mean, Median, Standard Deviations, and Percentiles options are disabled for cumulative distribution functions with multiple iterations.

Extension Output node

If Output to screen is selected on the Output tab of the Extension Output node dialog, on-screen output is displayed in an output browser window. The output is also added to the Output manager. The output browser window has its own set of menus that allow you to print or save the output, or export it to another format. The Edit menu only contains the Copy option. The Extension Output node's output browser has two tabs; the Text Output tab that displays text output, and the Graph Output tab that displays graphs and charts.

If Output to file is selected on the Output tab of the Extension Output node dialog, the output browser window is not displayed upon successful execution of the Extension Output node.

- [Extension Output node - Syntax tab](#)
 - [Extension Output node - Console Output tab](#)
 - [Extension Output node - Output tab](#)
 - [Extension Output Browser](#)
-

Extension Output node - Syntax tab

Select your type of syntax – R or Python for Spark. See the following sections for more information. When your syntax is ready, you can click Run to execute the Extension Output node. The output objects are added to the Output manager, or optionally to the file specified in the Filename field on the Output tab.

R Syntax

R Syntax. You can enter, or paste, custom R scripting syntax for data analysis into this field.

Convert flag fields. Specifies how flag fields are treated. There are two options: Strings to factor, Integers and Reals to double, and Logical values (True, False). If you select Logical values (True, False) the original values of the flag fields are lost. For example, if a field has values Male and Female, these are changed to True and False.

Convert missing values to the R 'not available' value (NA). When selected, any missing values are converted to the R NA value. The value NA is used by R to identify missing values. Some R functions that you use might have an argument that can be used to control how the function behaves when the data contain NA. For example, the function might allow you to choose to automatically exclude records that contain NA. If this option is not selected, any missing values are passed to R unchanged, and might cause errors when your R script is executed.

Convert date/time fields to R classes with special control for time zones. When selected, variables with date or datetime formats are converted to R date/time objects. You must select one of the following options:

- **R POSIXct.** Variables with date or datetime formats are converted to R POSIXct objects.
- **R POSIXlt (list).** Variables with date or datetime formats are converted to R POSIXlt objects.

Note: The POSIX formats are advanced options. Use these options only if your R script specifies that datetime fields are treated in ways that require these formats. The POSIX formats do not apply to variables with time formats.

Python Syntax

Python Syntax. You can enter, or paste, custom Python scripting syntax for data analysis into this field. For more information about Python for Spark, see [Python for Spark](#) and [Scripting with Python for Spark](#).

Extension Output node - Console Output tab

The Console Output tab contains any output that is received when the R script or Python for Spark script on the Syntax tab runs (for example, if using an R script, it shows output received from the R console when the R script in the R Syntax field on the Syntax tab is executed). This output might include R or Python error messages or warnings that are produced when the R or Python script is executed. The output can be used, primarily, to debug the script. The Console Output tab also contains the script from the R Syntax or Python Syntax field.

Every time the Extension Output script is executed, the content of the Console Output tab is overwritten with the output received from the R console or Python for Spark. The output cannot be edited.

Extension Output node - Output tab

Output name. Specifies the name of the output that is produced when the node is executed. When Auto is selected, the name of the output is automatically set to "R Output" or "Python Output" depending on the script type. Optionally, you can select Custom to specify a different name.

Output to screen. Select this option to generate and display the output in a new window. The output is also added to the Output manager.

Output to file. Select this option to save the output to a file. Doing so enables the Output Graph and Output File radio buttons.

Output Graph. Only enabled if Output to file is selected. Select this option to save any graphs that result from executing the Extension Output node to a file. Specify a filename to use for the generated output in the Filename field. Click the ellipses button (...) to choose a specific file and location. Specify the file type in the File type drop-down list. The following file types are available:

- Output object (.cou)
- HTML (.html)

Output Text. Only enabled if Output to file is selected. Select this option to save any text output that results from executing the Extension Output node to a file. Specify a filename to use for the generated output in the Filename field. Click the ellipses button (...) to choose a specific file and location. Specify the file type in the File type drop-down list. The following file types are available:

- HTML (.html)
- Output object (.cou)
- Text document (.txt)

Extension Output Browser

If Output to screen is selected on the Output tab of the Extension Output node dialog box, on-screen output is displayed in an output browser window. The output is also added to the Output manager. The output browser window has its own set of menus that allow you to print or save the output, or export it to another format. The Edit menu only contains the Copy option. The output browser of the Extension Output node has two tabs:

- The Text Output tab displays text output
- The Graph Output tab displays graphs and charts

If Output to file is selected on the Output tab of the Extension Output node dialog box instead of Output to screen, the output browser window is not displayed upon successful execution of the Extension Output node.

- [Extension Output Browser - Text Output tab](#)
- [Extension Output Browser - Graph Output tab](#)

Extension Output Browser - Text Output tab

The Text Output tab displays any text output that is generated when the R script or Python for Spark script on the Syntax tab of the Extension Output node is executed.

Note: R or Python for Spark error messages or warnings that result from executing your Extension Output script are always displayed on the Console Output tab of the Extension Output node.

Extension Output Browser - Graph Output tab

The Graph Output tab displays any graphs or charts that are generated when the R script or Python for Spark script on the Syntax tab of the Extension Output node is executed. For example, if your R script contains a call to the `R plot` function, the resulting graph is displayed on this tab.

KDE nodes

Kernel Density Estimation (KDE)© uses the Ball Tree or KD Tree algorithms for efficient queries, and walks the line between unsupervised learning, feature engineering, and data modeling. Neighbor-based approaches such as KDE are some of the most popular and useful density estimation techniques. KDE can be performed in any number of dimensions, though in practice high dimensionality can cause a degradation of performance. The KDE Modeling and KDE Simulation nodes in SPSS® Modeler expose the core features and commonly used parameters of the KDE library. The nodes are implemented in Python.¹

To use a KDE node, you must set up an upstream Type node. The KDE node will read input values from the Type node (or the Types tab of an upstream source node).

The KDE Modeling node is available on SPSS Modeler's Modeling tab and Python tab. The KDE Modeling node generates a model nugget, and the nugget's scored values are kernel density values from the input data.

The KDE Simulation node is available on the Output tab and the Python tab. The KDE Simulation node generates a KDE Gen source node that can create some records that have the same distribution as the input data. The KDE Gen node includes a Settings tab where you can specify how many records the node will create (default is 1) and generate a random seed.

For more information about KDE, including examples, see the KDE documentation available at <http://scikit-learn.org/stable/modules/density.html#kernel-density-estimation>.¹

¹ "User Guide." *Kernel Density Estimation*. Web. © 2007-2018, scikit-learn developers.

- [KDE Modeling node and KDE Simulation node Fields](#)
- [KDE nodes Build Options](#)
- [KDE Modeling node and KDE Simulation node Model Options](#)

KDE Modeling node and KDE Simulation node Fields

The Fields tab specifies which fields are used in the analysis.

Use predefined roles. This option uses the input settings from an upstream Type node (or the Types tab of an upstream source node).

Use custom field assignments. To manually assign inputs, select this option.

Fields. Use the arrow buttons to assign items manually from this list to the Inputs list on the right of the screen. The icons indicate the valid measurement levels for each field. To select all the fields in the list, click the All button, or click an individual measurement level button to select all fields with that measurement level.

Inputs. Select one or more fields as inputs for clustering. KDE can only deal with continuous fields.

KDE nodes Build Options

Use the Build Options tab to specify build options for the KDE nodes, including basic options for kernel density parameters and cluster labels, and advanced options such as tolerance, leaf size, and whether to use a breadth-first approach. For additional information about these options,

see the following online resources:

- [Kernel Density Estimation Python API Parameter Reference](#)¹
- [Kernel Density Estimation User Guide](#)²

Basic

Bandwidth. Specify the bandwidth of the kernel.

Kernel. Select the kernel to use. Available kernels for the KDE Modeling node are Gaussian, Tophat, Epanechnikov, Exponential, Linear, or Cosine. Available kernels for the KDE Simulation node are Gaussian or Tophat. For details about these available kernels, see the [Kernel Density Estimation User Guide](#).²

Algorithm. Select Auto, Ball Tree or KD Tree for the tree algorithm to use. For more information, see [Ball Tree](#)³ and [KD Tree](#).⁴

Metric. Select a distance metric. Available metrics are Euclidean, Braycurtis, Chebyshev, Canberra, Cityblock, Dice, Hamming, Infinity, Jaccard, L1, L2, Matching, Manhattan, P, Rogerstanimoto, Russellrao, Sokalmichener, Sokalsneath, Kulsinski, or Minkowski. If you select Minkowski, set the P Value as desired.

The metrics available in this drop-down will vary depending on which algorithm you choose. Also note that the normalization of the density output is correct only for the Euclidean distance metric.

Advanced

Absolute Tolerance. Specify the desired absolute tolerance of the result. A larger tolerance will generally result in faster run time. Default is 0.0.

Relative Tolerance. Specify the desired relative tolerance of the result. A larger tolerance will generally result in faster run time. Default is 1E-8.

Leaf Size. Specify the leaf size of the underlying tree. Default is 40. Changing the leaf size may significantly impact performance and required memory. For more information about the Ball Tree and KD Tree algorithms, see [Ball Tree](#)³ and [KD Tree](#).⁴

Breadth first. Select True if you want to use a breadth-first approach or False to use a depth-first approach.

The following table shows the relationship between the settings in the SPSS® Modeler KDE node dialogs and the Python KDE library parameters.

Table 1. Node properties mapped to Python library parameters

SPSS Modeler setting	Script name (property name)	KDE parameter
Inputs	inputs	
Bandwidth	bandwidth	bandwidth
Kernel	kernel	kernel
Algorithm	algorithm	algorithm
Metric	metric	metric
P Value	pValue	pValue
Absolute Tolerance	atol	atol
Relative Tolerance	rtol	Rtol
Leaf Size	leafSize	leafSize
Breadth first	breadthFirst	breadthFirst

KDE Modeling node and KDE Simulation node Model Options

Model name. You can generate the model name automatically based on the target or ID field (or model type in cases where no such field is specified) or specify a custom name.

IBM SPSS Statistics Helper Applications

If a compatible version of IBM® SPSS® Statistics is installed and licensed on your computer, you can configure IBM SPSS Modeler to process data with IBM SPSS Statistics functionality using the Statistics Transform, Statistics Model, Statistics Output, or Statistics Export nodes.

For information on product compatibility with the current version of IBM SPSS Modeler, see the corporate Support site at <http://www.ibm.com/support>.

To configure IBM SPSS Modeler to work with IBM SPSS Statistics and other applications, choose:

Tools > Options > Helper Applications

IBM SPSS Statistics Interactive. Enter the full path and name of the command (for example, C:\Program Files\IBM\SPSS\Statistics\<nn>\stats.exe) to be used when launching IBM SPSS Statistics directly on a data file produced by the Statistics Export node. See [Statistics Export Node](#) for more information.

Connection. If IBM SPSS Statistics Server is located on the same host as IBM SPSS Modeler Server, you can enable a connection between the two applications, which increases efficiency by leaving data on the server during analysis. Select Server to enable the Port option below. The default setting is Local.

Port. Specify the server port for IBM SPSS Statistics Server.

IBM SPSS Statistics Location Utility. To enable IBM SPSS Modeler to use the Statistics Transform, Statistics Model, and Statistics Output nodes, you must have a copy of IBM SPSS Statistics installed and licensed on the computer where the stream is run.

- If running IBM SPSS Modeler in local (stand-alone) mode, the licensed copy of IBM SPSS Statistics must be on the local computer. Click this button to specify the location of the local IBM SPSS Statistics installation you want to use for the licensing.
- In addition, if running in distributed mode against a remote IBM SPSS Modeler Server, you also need to run a utility at the IBM SPSS Modeler Server host to create the *statistics.ini* file, which indicates to IBM SPSS Statistics the installation path for IBM SPSS Modeler Server. To do this, from the command prompt, change to the IBM SPSS Modeler Server *bin* directory and, for Windows, run:

```
statisticsutility -location=<IBM SPSS Statistics installation path>/
```

Alternatively, for UNIX, run:

```
./statisticsutility -location=<IBM SPSS Statistics installation path>/bin
```

If you do not have a licensed copy of IBM SPSS Statistics on your local machine, you can still run the Statistics File node against a IBM SPSS Statistics server, but attempts to run other IBM SPSS Statistics nodes will display an error message.

Comments

If you have trouble running the IBM SPSS Statistics procedure nodes, consider the following tips:

- If field names used in IBM SPSS Modeler are longer than eight characters (for versions prior to IBM SPSS Statistics 12.0), longer than 64 characters (for IBM SPSS Statistics 12.0 and subsequent versions), or contain invalid characters, it is necessary to rename or truncate them before reading them into IBM SPSS Statistics. See [Renaming or Filtering Fields for IBM SPSS Statistics](#) for more information.
- If IBM SPSS Statistics was installed after IBM SPSS Modeler, you may need to specify the IBM SPSS Statistics location, as explained previously.

Export Nodes

Overview of Export Nodes

Export nodes provide a mechanism for exporting data in various formats to interface with your other software tools.

The following export nodes are available:

	The Database export node writes data to an ODBC-compliant relational data source. In order to write to an ODBC data source, the data source must exist and you must have write permission for it.
	The Flat File export node outputs data to a delimited text file. It is useful for exporting data that can be read by other analysis or spreadsheet software.
	The Statistics Export node outputs data in IBM® SPSS® Statistics .sav or .zsav format. The .sav or .zsav files can be read by IBM SPSS Statistics Base and other products. This is also the format used for cache files in IBM SPSS Modeler.
	The Data Collection export node outputs data in the format used by Data Collection market research software. A Data Collection Data Library must be installed to use this node.
	The IBM Cognos Export node exports data in a format that can be read by Cognos databases.
	The IBM Cognos TM1 Export node exports data in a format that can be read by Cognos TM1 databases.
	The SAS export node outputs data in SAS format, to be read into SAS or a SAS-compatible software package. Three SAS file formats are available: SAS for Windows/OS2, SAS for UNIX, or SAS Version 7/8.
	The Excel export node outputs data in the Microsoft Excel .xlsx file format. Optionally, you can choose to launch Excel automatically and open the exported file when the node is executed.
	The XML export node outputs data to a file in XML format. You can optionally create an XML source node to read the exported data back into the stream.
	The JSON export node outputs data in JSON format. See JSON Export node for more information.

Database Export Node

You can use Database nodes to write data to ODBC-compliant relational data sources, which are explained in the description of the Database source node. See the topic [Database source node](#) for more information.

Use the following general steps to write data to a database:

1. Install an ODBC driver and configure a data source to the database you want to use.
2. On the Database node Export tab, specify the data source and table you want to write to. You can create a new table or insert data into an existing one.
3. Specify additional options as needed.

These steps are described in more detail in the next several topics.

Database Node Export Tab

Note: Some of the databases to which you can export might not support column names in tables that are more than 30 characters long. If an error message is displayed that mentions that your table has an incorrect column name, reduce the size of the name to fewer than 30 characters.

Data source. Shows the selected data source. Enter the name or select it from the drop-down list. If you don't see the desired database in the list, select Add new database connection and locate your database from the Database Connections dialog box. See [Adding a database connection](#) for more information.

Table name. Enter the name of the table to which you want to send the data. If you select the Insert into table option,

- You can select an existing table in the database by clicking the Select button.
- If you provide a table name that does not currently exist, a new table will be created with the specified name, and data will be inserted into it.

Create table. Select this option to create a new database table or to overwrite an existing database table.

Insert into table. Select this option to:

- Insert the data into new rows in an existing database table, or
- Insert the data into a table that doesn't exist. In this case, a new table will be created and data will be inserted as new rows in the newly created table.

Merge table. (Where available) Select this option to update selected database columns with values from corresponding source data fields. Selecting this option enables the Merge button, which displays a dialog from where you can map source data fields to database columns.

Drop existing table. Select this option to delete any existing table with the same name when creating a new table.

Delete existing rows. Select this option to delete existing rows from the table before exporting, when inserting into a table.

Note: If either of the two options above are selected, you will receive an Overwrite warning message when you execute the node. To suppress the warnings, deselect Warn when a node overwrites a database table on the Notifications tab of the User Options dialog box.

Default string size. Fields you have marked as typeless in an upstream Type node are written to the database as string fields. Specify the size of strings to be used for typeless fields.

Click Schema to open a dialog box where you can set various export options (for databases that support this feature), set SQL data types for your fields, and specify the primary key for purposes of database indexing. See [Database export schema options](#) for more information.

Click Indexes to specify options for indexing the exported table in order to improve database performance. See [Database Export Index Options](#) for more information.

Click Advanced to specify bulk loading and database commit options. See [Database export advanced options](#) for more information.

Quote table and column names. Select options used when sending a `CREATE TABLE` statement to the database. Tables or columns with spaces or nonstandard characters must be quoted.

- As needed. Select to allow IBM® SPSS® Modeler to automatically determine when quoting is needed on an individual basis.
- Always. Select to always enclose table and column names in quotes.
- Never. Select to disable the use of quotes.

Generate an import node for this data. Select to generate a Database source node for the data as exported to the specified data source and table. Upon execution, this node is added to the stream canvas.

Database Export Merge Options

This dialog enables you to map fields from the source data onto columns in the target database table. Where a source data field is mapped to a database column, the column value is replaced with the source data value when the stream is run. Unmapped source fields are left unchanged in the database.

Map Fields. This is where you specify the mapping between source data fields and database columns. Source data fields with the same name as columns in the database are mapped automatically.
